Adaptations of the DNA replication licensing process in mouse embryonic stem cells

A. Kanellou[1], T. Giavridis[1], S. Taraviras[2], Z. Lygerou[1]
[1]Medical School, Laboratory of General Biology, [2]Medical School, Laboratory of Physiology, University of Patras, Patras, Greece

Mouse Embryonic Stem Cells (mESCs) have the ability to proliferate and self-renew indefinitely in culture and, when stimulated, to differentiate towards all three germ layers. They exhibit an unusual cell cycle which consists mainly of S phase cells, a short G1 phase and a lack of major checkpoint responses. Maintaining genome stability is pivotal for embryonic stem cells, as they give rise to all mature cell types. In order for committed cells to maintain genome integrity, DNA replication is restricted to only once per cell cycle. This is accomplished through the assembly onto chromatin of multisubunit protein complexes which license DNA for a subsequent round of replication. Replication licensing takes part in G1 phase and consists of the loading of the hexameric MiniChromosome Maintenance 2-7 (MCM2-7) complex onto chromatin, a step which is dependent on the licensing factor Cdt1. We previously showed that the loading of MCM2-7 onto chromatin takes place in two waves in live mammalian cells: upon mitotic exit and at the G1/S phase transition.

We are interested to understand the molecular mechanisms which ensure genome stability in mESCs, and govern DNA replication licensing, and how these are compared to differentiated and cancer cells. We show that mESCs have a very short G1 phase and move to S-phase with high synchrony following mitotic arrest. During S-phase, replication factories are visualized by immunofluorescence against the replication protein PCNA. They show characteristic early, middle and late S-phase localization, reminiscent of replication factory dynamics in differentiated and cancer cells. Cdt1 is specifically detected during the G1 phase of the mESC cell cycle and degraded following entry to S-phase. MCM2 and MCM7 can be immunodetected onto chromatin following mitotic exit and in S phase, and exhibit differential localization along the cell cycle. Following DNA damage by UV-irradiation in G1, Cdt1 is rapidly proteolysed, while changes in chromatin-loaded MCM proteins are evident. When mESCs are irradiated during mitosis, Cdt1 degradation is delayed until entry into G1, suggesting the Cdt1 is protected from proteolysis in mitosis. mESCs irradiated during mitosis or in G1 fail to progress to S-phase. We will be using functional live-cell imaging to assess licensing in mESCs by Fluorescence Recovery After Photobleaching (FRAP) of the GFP-tagged MCM protein subunits, through the cell cycle of uncommitted cells, or when cells are moving towards differentiation, with a concomitant lengthening of G1 phase.

Keywords: DNA replication licensing, mouse embryonic stem cells.

SUN-002
Analysis of the mechanism of DNA damage and replication arrest-induced histone mRNA decay

P. Panomwan, C. Smythe
Biomedical Science, University of Sheffield, Sheffield, UK

Histone mRNA decay (HD) is the process which ensures that histone mRNA is rapidly degraded following completion of DNA replication at the end of S-phase. Strict coordination between histone protein production and DNA replication is essential for the correct packaging of newly replicated DNA, as imbalances can lead to deleterious effects such as genomic instability. Interestingly, histone mRNA stability is controlled by the presence of a stem-loop structure at the 3′ end of histone mRNA, and a protein, HBP/SLBP (hairpin/stem loop binding protein) which specifically binds to this structure, plays a major role in histone mRNA metabolism. Importantly, previous studies have shown HD is also one functional target of an intra S-phase checkpoint activated when DNA synthesis is inhibited, ensuring that histone mRNA is rapidly destroyed when global DNA replication is blocked. Consistent with this, replication stress-induced histone mRNA decay is blocked in the presence of inhibitors of the PIKK family of checkpoint protein kinases, implicating PIKK family members in the regulation of this process. Therefore, we aim to utilise a proteomic approach to to identify HBP/SLBP-associated proteins and post-translational status in order to elucidate the detailed mechanism of checkpoint activated HD. We have established isogenic cell lines stably expressing functional, tagged HBP/SLBP by using the Flp-InTM T-RexTM Expression system. Our results indicate that isogenic Flp-In HeLa cell lines inducibly expressing tagged forms of SLBP under the control of a doxycycline promoter are a useful model system for the molecular analysis of SLBP function during replication stress.

Antioxidant and anticancer effects of *Pterocarpus mildbraedii* (Papillionaece) extracts

C. A. Otuechere
Division of Biochemistry, Department of Chemical Sc iences, Redeemer's University, Mowe, Ogun State, Nigeria

The incidence of cancer in Nigeria is about the highest in sub-saharan Africa. There are growing concerns over the harmful side-effects of synthetic drugs used in cancer therapy. Consequently, there is focus on plants with antioxidant properties as potential therapeutic agents against cancer and other diseases.This study investigates the antioxidant activity of *Pterocarpus mildbraedii* extracts (PME) in vitro. Our study also reports the cytotoxicity of PME in five human tissue cancer cell lines namely, promyelocytic leukemia (HL-60), monocytic leukemia (THP-1), prostrate adenocarcinoma (PC-3), colon adecarcinoma (COLO-205) and lung carcinoma (A549) by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Changes in mitochondrial membrane potential (MMP) and morphological alterations associated with apoptosis were examined by flow cytometry and phase contrast microscopy, respectively.Total phenolic and flavonoid contents were calculated using the Folin-Ciocalteu and the aluminum chloride colorimetric methods and found to be 0.215 ± 0.005 and 0.082 ± 0.003 mg GAE/g respectively. The PME showed a maximum 1,1-diphenyl-2-picryl hydrazyl (DPPH) radical scavenging activity of 55%. Furthermore, the extract exhibited a promising activity against HL-60 cells with IC_{50} value of 8.5 μg/ml. The mechanism of antiproliferative activity revealed that after 24 h, at a concentration of 30 μg/ml, the extract induced apoptosis in HL-60 cells by loss of mitochondrial membrane potential. Microscopic examination of cells revealed the presence of nuclear fragments- containing apoptotic bodies. In conclusion, extract of *P. mildbraedii* showed evidence of antioxidant activity in vitro as well as anticancer effect against HL-60 cell lines and shows great potential for the treatment of leukemia, which still has a high mortality rate, in Nigeria.

SUN-005
BubR1 deacetylation is a crucial signal for spindle assembly checkpoint silencing

H. Lee, I. Park
Biological Sciences, Seoul National University, Seoul, Korea

BubR1 acetylation is essential in mitosis. We have shown previously that the mice heterozygous for BubR1 acetylation deficiency (*K243R*/+) succumb to high incidence of tumorigenesis due to chromosome mis-segregation, manifested by aneuploidy and broken chromosomes. Detailed investigation of BubR1 acetylation revealed that it is required both for stable chromosome-spindle attachment and in maintaining SAC. For chromosome congression, BubR1 acetylation was required to recruit PP2A-b56alpha to kinetochores to counteract excessive Aurora B activity and stabilize kinetochore-microtubule (KT-MT) attachments. Thus, *K243R*/+ cells have very high chances of chromosome mis-attachments but chromosomes segregate with these errors due to weakened SAC. Biochemical analysis of the mitotic checkpoint complex (MCC) showed that acetylation-deficient BubR1 was readily degraded by APC/C-dependent ubiquitination, resulting in failure to sustain MCC. These data strongly suggested that BubR1 acetylation at K250 is required for SAC maintenance and deacetylation may be a cue to SAC silencing, the mechanism less understood compared to SAC activation. Here we report that BubR1 is deacetylated for MCC disassembly and SAC silencing. We found that HDAC2 binds to BubR1 in metaphase when SAC is satisfied. Cells expressing acetylation-deficient form of BubR1 (K250R) fail to maintain MCC in the presence of microtubule poison, the situation when SAC should be active. On the contrary, introduction of acetylation-mimetic form (K250Q) resulted in arrest in mitosis even though the chromosomes were congressed. Furthermore, we show that there is an BubR1 acetylation-phosphorylation code in SAC activation and silencing in cell division. Collectively, we suggest that BubR1 acetylation/deacetylation is a critical decision point for cells to be in mitosis or exit from mitosis.

Keywords: BubR1, deacetylation, mitosis.

SUN-006
CCAAT/Enhancer-binding protein beta is a critical regulator of Wee1 in G2/M cell cycle progression

E. Choi, on behalf of Kyungsil Yoon, K. Yoon
National Cancer Center-Korea, Goyang, Korea

CCAAT/enhancer-binding proteinβ (C/EBPβ) is a transcription factor implicated in the regulation of cellular proliferation, differentiation and development. Mitosis is regulated by cyclinB/CDK1. The Wee1 kinases phosphorylate cyclinB/CDK1 at tyrosine-15(Tyr15) and/ or threonine-14(Thr14) and dephosphorylation of Tyr15 and Thr14 by the Cdc25 is required for the activation of CDK1 and further entry into mitosis. In this study we investigated the roles of C/EBPβ in non-small cell lung cancer cells, as a regulating factor of molecules associated with cell cycle. We found that knockdown of C/EBPβ by RNA interference arrested A549 cells at the G2/M phase of cell cycle. Also, C/EBPβ-deficient cells displayed increased Tyr15 phosphorylation of CDK1 and, at the same time, increased expression of Wee1 at the mRNA and protein levels and decreased protein levels of CDC25B. To demonstrate that C/EBPβ regulates Wee1, a key regulator of G2/M progression, we have conducted cell cycle analysis using flow cytometry with C/EBPβ knockdown cells treated with a Wee1 inhibitor. We observed that in C/EBPβ knockdown cells treated with MK-1775, Tyr15 phosphorylation of CDK1 was reduced to the similar levels to that in wild-type cells treated with control and that C/EBP β knockdown cells were recovered to from G2/M arrest. Taken together, these results indicate that C/EBPβ is a potential regulator of mitosis inhibitor protein, Wee1, ultimately regulating G2/M progression.

Keywords: C/EBPbeta, cell cycle, G2/M transition.

Cdc25 inhibitors in melanoma cells

A. Capasso[1], C. Cerchia[2], C. Di Giovanni[2], G. Granato[1], A. Bertoni[1], F. Albano[1], E. De Vendittis[1], M. R. Ruocco[1], A. Lavecchia[2]
[1]*Department of Molecular Medicine and Medical Biotechnologies,* [2]*Department of Pharmacy, University of Naples Federico II, Naples, Italy*

Cell division cycle 25 (Cdc25) proteins are dual specificity phosphatases involved in the progression of the cell cycle. In particular, mammalian cells express three isoforms of Cdc25, called Cdc25A, -B and -C: Cdc25A mainly controls G1/S progression, whereas Cdc25B and Cdc25C predominantly activate G2/M transition. Moreover, over-expression of Cdc25A and B activities has been frequently observed in a wide variety of human tumors with poor prognosis. Thus, the design and study of small molecules endowed with an inhibitory activity towards Cdc25 proteins represent a promising strategy for the development of new anti-cancer therapies. A previous work from this group described the

© 2014 The Authors. FEBS Journal © 2014 FEBS

properties of a set of small molecules, which were able to inhibit Cdc25 functions (Lavecchia et al. *J Med Chem* **55**, 2012, 4142–4158). Among them, compound **11**, possessing a quinonic structure, acted as an irreversible inhibitor of Cdc25B and showed a strong antiproliferative action on some cancer cell lines.

To expand the structure-activity relationship study and to explore potential new structure analogues of **11**, we performed a multiple ligand-based chemoinformatics approach against full ZINC database (~35 million purchasable compounds) and NCI Open database (~260 000 compounds). 25 structures identified from these searches (hereafter called **AL1–AL25**) were analyzed, and selected compounds were tested in vitro to assess the Cdc25B inhibition activity. In particular, compounds **AL11**, **-12**, **-13**, **-14**, **-15**, **-16**, **-23**, **-24** and **-25** maintained a percentage of Cdc25B inhibition comparable to that exerted by compound **11**, and some of them were even more powerful. The effect of these active analogues was also evaluated on melanoma cell lines (A2058 and SAN), because of the limited information on the effect of Cdc25 inhibitors in this cellular system. In both melanoma cells, after 48-h treatment with 100 mM of each inhibitor, a significant reduction of cell growth was observed only with **AL11**, whereas the other active analogues, as well as compound **11**, were ineffective. Furthermore, cytofluorimetric analysis and measurements of the activity of caspase-9 and -3 indicated that **AL11** exerted a pro-apoptotic effect on melanoma cells. In addition, the cellular treatment with **AL11** produced an alteration of the cellular redox state and a reduction of the mitochondrial membrane potential. Studies are in progress to clarify the mechanisms involved in the cytotoxic potential of **AL11** and other related molecules in melanoma cell lines, with the aim at the refinement of the inhibitory action of the studied compounds.

Cell-cycle arrest at the G1-S phase boundary through mimosine-induced ATM activation

S. Kubota, K. Ishibashi, S. Kubota, R. Yuki, N. Yamaguchi, N. Yamaguchi
Department of Molecular Cell Biology, Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan

The pre-replication complex (pre-RC) is assembled on the replication origin during G1 phase. In S phase, activation of the pre-RC triggers unwinding of DNA, and a bidirectional replication fork is formed. Excess thymidine is widely used for cell synchronization in G1/S phase. Mimosine is also used for cell synchronization in late-G1 phase by preventing the formation of replication forks. However, the mechanisms of G1 arrest remain unclear.

Using highly synchronous cell populations, we show here that mimosine arrests cells at the G1-S phase boundary through ATM activation [1]. HeLa S3 cells are exposed to thymidine for 15 h, released for 9 h by washing out the thymidine, and subsequently treated with 1 mM mimosine for further 15 h (Thymidine→Mimosine). In contrast to thymidine-induced S-phase arrest, mimosine treatment synchronizes >90% of cells having G1-phase DNA content. Cdc45, one of the pre-RC-activating factors, is not loaded onto chromatin in mimosine-synchronized cells, suggesting that mimosine treatment arrests cells at the G1-S phase boundary by blocking the activation of the pre-RC.

Since mimosine treatment strongly activates ATM-mediated checkpoint, we treated mimosine-synchronized cells with the ATM-specific inhibitor KU-55933 and shRNA for ATM. Inhibition of ATM activity is found to induce mimosine-arrested cells to enter S phase. Intriguingly, ATM activation by mimosine treatment is induced without DNA damage. The levels of DNA damage in mimosine-synchronized cells are much lower than those in thymidine-synchronized cells.

The method presented in this study enables us to highly enrich cells at the G1-S phase boundary. After release from mimosine treatment, cells can progress through the cell cycle in a highly synchronous manner. Thus, mimosine synchronization enables us to examine the initial events in DNA replication, which include the activation of the pre-RC and the loading of the replication fork proteins onto chromatin. In thymidine-synchronized cells, these initial events take place prior to release from thymidine treatment. Further studies using mimosine synchronization will help us to gain new insights into the precise mechanisms that control the onset of DNA replication.

Depletion of biliverdin reductase sensitizes glioma cells to chemotherapy

S. Y. Kim
Department of Biochemistry, School of Medicine, Konkuk University, Seoul, Korea

Enhanced cellular cytoprotective activities are reported to play a major role in the development of intrinsic drug resistance in malignant glioma. Here, we show that human biliverdin reductase (hBVR), recently identified as a major redox regulator, play a key role in the developmenet of multidrug resistance in glioma. Using stepwise-selected drug-resistant human glioma cell lines, we show that hBVR activity increased in the drug-resistant sublines and knock down of hBVR led to a significant increase in chemosensitivity in response to chemotherapeutic drugs and drug-induced cell death. We further found that this sensitizing effect was associated with increased ROS generation and dissipation of mitochondrial transmembrane potential. These results show that hBVR is an important regulator of glioma resistance to chemotherapy.

Depletion of SUMO ligase hMMS21 inhibits HCT116 colorectal cancer cell growth

S.-P. Chai, E. Lee, W.-H. Cheng, J. C. Fong
Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan

We demonstrate that depletion of SUMO ligase hMMS21 leads to a slower growth of HCT116 cells by reducing S phase progression, which involves a decrease in the amount of thymidylate synthase (TYMS) and inhibition of CDK2 by an increased amount of p27. The decrease in TYMS is caused by a faster degradation, rather than an effect on gene expression. In addition, we showed that although the decrease in TYMS amount caused by depletion of hMMS21 provoked a low degree of DNA damage, preventing DNA damage by supplementing thymidine did not rescue the growth rates of HCT116 cells. Moreover, ectopic expression of TYMS did not rescue the slow growth of HCT116 cells depleted of hMMS21, consistent with the notion that other factor, e.g., p27, may also be involved. Thus this study may provide a new perspective for treating colorectal carcinomas.

Differential proliferative responses of fetal and adult human skin fibroblasts to TGF-β: implications for wound healing

H. Pratsinis[1], A. Armatas[1], E. Mavrogonatou[1], M. T. Angelopoulou[1], A. Kouroumalis[1], A. Tsantikidi[1], N. K. Karamanos[2], **D. Kletsas**[1]
[1]Institute of Biosciences & Applications, NCSR 'Demokritos', Athens, [2]Department of Chemistry, University of Patras, Patras, Greece

Wound healing in adults is characterized by intense inflammation, collagenous scar formation and contraction, while fetal repair – in the first two trimesters of gestation – is marked by minimal inflammatory reactions and the absence of scar formation. Transforming growth factor-β (TGF-β) is a cytokine with a broad range of activities in tissue repair and a pleiotropic regulator of cell proliferation. In this context we have shown previously that TGF-β regulates the proliferation of normal human skin fibroblasts according to their developmental origin, i.e. it inhibits fetal fibroblasts via the activation of Protein Kinase A (PKA) and the induction of the cyclin-dependent kinase inhibitors (CKIs) $p21^{CIP1/WAF1}$ and $p15^{INK4B}$, while it stimulates the proliferation of adult donor cells by the release of basic Fibroblast Growth Factor (bFGF) and – through the FGF receptor-1 (FGFR-1) – the subsequent activation of the MEK-ERK pathway. Recently, we have shown that both signalling pathways are SMAD-dependent.

During the early wound healing phases fibroblasts grow and migrate on a provisional extracellular matrix (ECM) containing mainly fibronectin, while at the late stages they are surrounded by a matrix containing mostly fibrils of polymerized collagen. Accordingly, we investigated the interaction of these ECM components with TGF-β and found that the responses of fetal and adult cells remain unaltered when cultured either on plastic surfaces or on surfaces coated with fibronectin or collagen type-I, as well as, on top or within three-dimensional matrices of polymerized collagen. Moreover, the differential effect of TGF-β persists in both stressed and relaxed collagen lattices.

Chronic wounds in adults have been linked to the existence of senescent cells in the wound area. On the other hand, it has been recently reported that senescence may control the quality of tissue repair by inhibiting fibrosis. In this vein, we have found that a long-term exposure to TGF-β provokes premature senescence in both fetal and adult skin fibroblasts. The mechanisms underlying this phenomenon will be discussed.

In conclusion, these data indicate a dynamic interplay between skin fibroblasts, ECM components and TGF-β at different developmental stages towards tissue repair and remodeling.

SUN-012
Dihydroxynaphthyl aryl ketones as tubulin polymerization and cancer cell growth inhibitors

O. Monasterio[1], E. Gutierrez[2], J. Benites[2], J. A. Valderrama[3], P. B. Calderon[4], J. Verrax[4], E. Nova[1], F. Villanelo[1], D. Maturana[1], R. Lagos[1]
[1]Departamento de Biologia, Facultad de Ciencias, Universidad de Chile, Santiago, [2]Facultad de Ciencias de la Salud, Universidad Arturo Prat, Iquique, [3]Facultad de Química, Pontificia Universidad Católica de Chile, Santiago, Chile, [4]Toxicology and Cancer Biology Research Group, Louvain Drug Research Institute, Université Catholique de Louvain, Brussels, Belgium

Dihydroxynaphthyl aryl ketones (arene = 2/3 thiophene, **1** and **2**; furane, **3**; pyrrol, **4**; 3,4,5 trimethoxybencene, **5**) have been evaluated for their ability to inhibit tubulin polymerization and colchicine binding, their ability to bind tubulin and their cytotoxic activity against the cancer cell lines DU-145 (prostate), T24 (bladder) and MCF7 (breast). These compounds are of interest because they are readily available via our synthetic method and because they are structurally related to several molecules that are known to inhibit tubulin polymerization. Compounds **4** and **5** displayed competitive inhibition against colchicine binding, and docking analysis showed that these compounds bind to the colchicine binding site pocket of tubulin. Remarkable differences in biological activity were observed between the assayed compounds, and these differences are related to the structure and position of the aryl substituent bonded to the carbonyl group. For compounds **2**, **3** and **4**, which contain a heterocyclic ring, higher affinity was observed compared to that of carbocyclic analogue **5**. The compound with the best affinity of the series was compound **4**, which exhibited an IC_{50} value of 2.1 mM for microtubule polymerization inhibition and a tubulin dissociation constant of 1.0 ± 0.2 mM, as determined by thermophoresis. Among these compounds, only ketone **5** showed selectivity for cancer cells over healthy, non-transformed cells. In T24 cancer cells treated with compound **5**, a concentration-dependent decrease in cell proliferation was observed. In addition, cells lost their ability to migrate when treated with compound **5**. While compound **4** is slightly more efficacious in disrupting tubulin polymerization in biochemical studies, the greater lipophilicity of compound **5** likely facilitated increased membrane penetration in cell-based assays for cytotoxicity, which showed compound **5** to be more potent.

Direct interaction between CENP-C and protein phosphatase 4 regulatory subunit 3 affects Drosophila kinetochore integrity

Z. Lipinszki[1], S. Lefevre[2], M. S. Savoian[1], M. R. Singleton[2], D. M. Glover[1], M. R. Przewloka[1]
[1]Department of Genetics, University of Cambridge, Cambridge, [2]London Research Institute, Cancer Research UK, London, United Kingdom

Reversible phosphorylation of proteins is one of the major intracellular regulatory mechanisms, which controls almost all cellular events, including progression through mitosis. Although roles of the multiple kinases responsible for protein phosphorylation are largely understood, the functions and substrate architecture of the multiple protein phosphatases (PPase) that reverse these events are for the most part mysterious. To fully understand mitotic progres-

© 2014 The Authors. FEBS Journal © 2014 FEBS

sion, it is necessary to comprehend mitotic PPase functions, one of the major remaining challenges in the field of mitosis. Protein Phosphatase 4 (PPP4) is an evolutionarily conserved multisubunit enzyme that has a relatively unexplored mitotic role. PPP4 belongs to the PP2A subfamily of Ser/Thr phosphatases and is composed of one catalytic (PP4c) and two regulatory (R2 and R3) subunits in *Drosophila melanogaster*. Although its role has been shown in various mitotic processes including centrosome maturation and nucleation of spindle microtubules, no mechanistic details or mitotic substrates have been revealed so far. In this study we found that PPP4 forms a complex with the key centromeric protein CENP-C, the major and essential link between the mitotic centromere and kinetochore network. We narrowed down this interaction to the very amino-terminus of the Regulatory 3 subunit of PPP4 and a 19 amino acid-long region within CENP-C. Then we solved the crystal structure of the heterodimer of these minimal regions, which helped us to better understand the molecular basis of the interaction. We unequivocally proved that the presence and catalytic activity of PPP4 at the centromere is essential for proper kinetochore integrity: depletion or deactivation of PPP4 causes partial removal of CENP-C and the entire kinetochore from the centromeres followed by accumulation on the mitotic spindle and around spindle poles during mitosis. We also revealed that CENP-C is a mitotic substrate of PPP4 and its phosphorylation status critical for kinetochore integrity. Therefore we propose CENP-C as a novel mitotic substrate of PPP4 and suggest PPP4 as a regulator of kinetochore integrity.

DNA repair in retinal pigment epithelial cells arrested in G0/G1 phase

P. A. Tokarz, A. Pietrzyk, J. Blasiak
Department of Molecular Genetics, University of Lodz, Lodz, Poland

DNA repair and cell cycle arrest are main responses to DNA damage in eukaryotic cells. Little is known about the DNA repair in cells arrested in G0/G1 phase. It is known, however, that all eukaryotic DNA repair systems operating in proliferating cells also operate in cells arrested in G0/G1 phase. Recent studies indicate a potential function of cell cycle checkpoints in the DNA repair in neurons arrested in G0 phase. The aim of our research was to investigate the kinetics of DNA repair in cells arrested in G0/G1 phase in response to acute and chronic oxidative stress. The cell response to acute stress determines the cell fate – to die or live, whereas the response to chronic stress may induce an adaptive response.

We employed ARPE-19 cell line, derived from retinal pigment epithelial cells and induced their cell cycle arrest through a combination of contact growth inhibition, restriction of growth factors and the presence of retinoic acid (RA). For the generation of acute oxidative stress we used hydrogen peroxide or *tert*-butyl peroxide and for chronic oxidative stress – glucose oxidase – which continuously produce hydrogen peroxide in the presence of medium. The cytotoxicity was assessed using trypan blue exclusion assay and DNA damage by comet assay.

RA induced density-dependent cell cycle arrest associated with morphological changes in APRE-19 resembling those featured in terminally differentiated cells in vivo. We observed that there was no difference in the level of DNA damage after the generation of oxidative stress and at the late stage of DNA repair (from 30′ to 60′) between ARPE-19 cells arrested in G0/G1 phase and cycling cells. Analysis of repair kinetics in ARPE-19 cells arrested in G0/G1 phase showed a clear defect at the intermediate (from 5′ to 15′) time points following generation of acute oxidative stress. In contrast, there was no repair defects at any time point in ARPE-19 cells arrested in G0/G1 phase after exposure to chronic oxidative stress.

The ability to cross G0/G1 checkpoint may be required for regular DNA repair in non-cycling ARPE-19 cells in response to acute oxidative stress.

Downregulation of NOX4 NADPH oxidase leads to senescence of vascular smooth muscle cells

D. Przybylska, E. Sikora, G. Mosieniak
Laboratory of Molecular Bases of Aging, Nencki Institute of Experimental Biology Polish Academy of Sciences, Warsaw, Poland

Senescence is proposed as one of the mechanisms that drives organism aging as well as age-related diseases. This process was shown to participate in pathogenesis of cardiovascular diseases since senescent vascular smooth muscle cells (VSMCs) were found in atherosclerotic plaques. Cellular senescence is related to unrepairable DNA double strand breaks and the activation of the DNA damage response (DDR) pathway as well as increased reactive oxygen species (ROS) production. Although defective mitochondria are considered to be the main source of ROS a number of studies prove that ROS-generating enzymes like NADPH oxidases (NOX) could also play an important role in this process. Data suggest that NOX4 could be involved in the regulation of both proliferation and aging. The aim of this study was to analyze the role of NOX4 in the senescence of human VSMCs (hVSMCs). We observed increased ROS production in VSMCs undergoing stress-induced and replicative senescence. Treatment of the cells with DPI – NOX family inhibitor, decreased the level of ROS in senescent as well as in proliferating hVSMCs, however did not affect senescence induction. In contrary, it caused permanent cell cycle arrest and increased the level of other senescence markers in proliferating VSMCs. The DPI-induced senescence was not correlated with activation of the DDR pathway. To address the NOX4 exclusive role in these process we downregulated its expression with siRNA. Cells with reduced NOX4 transcript accumulated in mitosis due to abnormal mitotic spindle formation. Downregulation of NOX4 correlated with the impaired level of SAC and CPC proteins involved in the regulation of mitotic checkpoint. After a few days of culture, cells transfected with NOX4 siRNA underwent senescence. Majority of those cells were multinucleated proving that they underwent improper mitotic divisions on the road to senescence. What is interesting, disturbed nuclei morphology was also observed in replicatively senescing hVSMC what corresponds with gradual decrease of NOX4 mRNA level. These findings suggest that NOX4-derived ROS play an important role in regulation of the cell cycle in VSMCs and decreased level of this enzyme could be responsible for senescence induction.

This work was supported by grant 0728/B/P01/2011/40 financed by the Polish Ministry of Science and Higher Education.

Early contribution of C1q and Calreticulin to the recognition and elimination of apoptotic cells

R. Osman, P. Delorme-Tacnet, J.-P. Kleman, P. Frachet
Institut de Biologie Structurale, Grenoble, France

Efferocytosis is an immunologically silent process by which phagocytes remove rapidly apoptotic cells before their entrance in secondary necrotic phase. C1q, the first component of complement cascade, enhances uptake by bridging the apoptotic cell to the phagocyte. C1q contributes also to the anti-inflammatory response by modulating cytokine release by phagocytes. Autoantibodies against C1q were found to target specifically early apoptotic cells, thus suggesting a fast involvement of this protein in the efferocytosis process. Furthermore, it was shown that C1q interacts with surface-exposed Calreticulin (CRT), an early eat-me signal capable of eliciting an immunogenic response. Based on these findings, we hypothesized that C1q acts early with CRT to remove apoptotic cells.

Jurkat cells were rendered apoptotic by 312 nm UVB-irradiation (1000 mJ/cm^2). PMA stimulated THP-1 cells were used as macrophages for in vitro efferocytosis assay. Binding of human serum-purified C1q or its globular heads (C1qGR), and CRT surface exposure were studied by flow cytometry and epifluorescence microscopy. The interaction between CRT and C1q was examined by fluorescence resonance energy transfer (FRET) confocal microscopy imaging. Our results indicate that opsonisation of 'freshly' UV-irradiated Jurkat cells by C1q significantly enhances their uptake by THP-1 macrophages. Moreover, as measured by flow cytometry, CRT is rapidly retained at the cell surface after UV irradiation, even before the phosphatidylserine exposure to the outer membrane leaflet. At this 'pre-apoptotic' stage, C1qGR highly bind to the cell surface and co-localize with CRT. Interestingly, data obtained by FRET experiences show efficient early interaction between C1q or C1qGR and cell surface-exposed CRT.

Taken together, these results point to the fast contribution of C1q on efferocytosis, by acting with CRT to the recognition and elimination of early very apoptotic cells.

Keywords: efferocytosis, early apoptotic cells, C1q, Calreticulin.

Effect of a cathepsin L variant on colorectal cancer HCT116 cell proliferation

V. Morin, on behalf of Proteases Labs, O. Riquelme, on behalf of Proteases Labs, C. Reyes, on behalf of Proteases Labs, S. Bustamante, on behalf of Proteases Lab, E. Uribe, on behalf of Enzymology Lab, S. Gutiérrez, on behalf of Epigenetics Lab, A. Castro, on behalf of Signal Transduction and Cancer Lab
Bioquímica y Biología Molecular, Universidad de Concepción, Concepción, Chile

We have studied a variant of cathepsin L protease homologous to SpH protease, a kind of protease initially described in sea urchin. This variant of cathepsin L is entitled SpH-Cathepsin-L, and has been also identified in cancer cells. This particular protease has a molecular weight of 60 kDa, and has nuclear localization during S phase of the cell cycle; it colocalizes with alpha-tubulin during mitosis in colorectal cancer and cervical cancer cell lines. SpH-Cathepsin L was also identified the colorectal cancer HCT116 cell line.

To analyze the effect of SpH-cathepsin L on cell proliferation of the HCT116 cell line, we silenced the SpH-cathepsin L gene by using siRNA technique. Cell proliferation was measured by means of bromodeoxyuridine (BrdU) incorporation to DNA. In addition, we analyzed cell viability by using a MTT assay.

Our results show that siRNA-mediated depletion of SpH-cathepsin L decreases HCT116 cell proliferation reflected by diminished incorporation of BrdU. Besides, we show that siRNA-mediated depletion of SpH-cathepsin L did not generate a cytotoxic effect in HCT116 cells. Based on these results, we concluded that SpH cathepsin L participates in proliferative processes of the HCT116 cell line, which is consistent with results obtained with other variants of cathepsin L.

Effects of bisphenol a (BPA) on SHSY5Y cells: evaluation of nitric oxide related pathways

B. Ayazgok, T. Tuylu Kucukkılınc
Faculty of Pharmacy Department of Biochemistry, Hacettepe University, Ankara, Turkey

Bisphenol A (BPA) is a chemical widely used as monomer of polycarbonate plastics, nylon and PVC. It is clearly known that BPA is endocrine disrupting chemical reacting with estrogen and androgen receptors. Endocrine disruptors have been widely reported to effect nitric oxide synthase (NOS) activity but the mechanism hasn't been explained cleary yet.

In this study we aimed to enlight BPA's effect on SHSY5Y cells through cell viability and nitrite concentration of cells. The cytotoxicity of BPA on SHSY5Y cells was evaluated by MTT assay. MTT assay was performed in a 96 well plate for 24 h at increasing concentrations of BPA(1 nM–100 mM), and calculated as percentage of the viability of untreated cells. Cell viability was reduced significantly to % 50 with 10 μM BPA. Nitrite concentration of SHSY5Y cells were determined according to colorimetric Griess's reaction spectrophotometrically at 540 nm with reference to a standard curve. Preliminary results show a relation between BPA concentration and nitrite levels on SHSY5Y cells. Relation between decreased cell viability and nitrite concentration is assumed to be a result of increased nitrosative stress of cells and altered nitrosylation of proteins. Further studies will be done to investigate detailed interactions of BPA and NOS related pathways.

Keywords: Bisphenol A, Nitric Oxide, SHSY5Y Cells.

Elucidating the impact of tumor marker nucleoporin Nup88 on the pRb pathway, cell proliferation and nuclear organization

E. Bonnin[1], Y. Lussi[2], B. Fahrenkrog[1]
[1]*Laboratoire de biologie du noyau, Institut de Biologie et Médecines Moléculaires, Université Libre de Bruxelles, Charleroi, Belgium,* [2]*Biotech Research and Innovation Centre, University of Copenhagen, Copenhagen, Denmark*

Nuclear pore complexes (NPCs) are macromolecular structures that are embedded in the double membrane of the nuclear envelope (NE) and mediate bidirectional nucleocytoplasmic transport. The vertebrate NPC consist of about 30 nucleoporins (Nups). Nup88 is found over-expressed in a wide variety of cancers characterized by their high aggressiveness and metastatic potential; within the tumors, Nup88 expression levels are particularly high at the tumor periphery and their invasive front. In tumors, Nup88 is partly displaced from its localization at the NPC and is also found in the cytoplasm. Nup88 has been proposed as a tumor marker, but its physiological

© 2014 The Authors. FEBS Journal © 2014 FEBS

function is poorly understood and the regulation of its expression has remained elusive. We have previously identified Nup88 as a novel lamin A interacting partner. Since the lamin A-LAP2α complex is known to repress pRb and to regulate G1-S transition, we investigated whether modulating Nup88 expression affects the lamin A-LAP2α complex and cell cycle progression. In this context, we studied the impact on a selection of pRb/E2F target genes. In addition, we aimed at further characterizing the role of Nup88 in nuclear organization in particular via its effect on lamin A interactors. By ectopical expression of Nup88 and siRNA-mediated Nup88 depletion, we could show that over-expression of Nup88 leads to a destabilization of the lamin A-LAP2α complex, possibly by recruiting lamin A to the nuclear periphery, and a weakening of its repressor function at pRb/E2F gene loci, which in turn leads to accelerated G1/S progression. On the other hand, depletion of Nup88 slows down S-phase, leaving the lamin A-LAP2α complex intact. Consistently, cyclin E1, TK1 and PCNA mRNA levels were increased in Nup88 knock-down cells, as shown by RT-qPCR. In addition, over-expression of Nup88 was shown to mislocalize emerin, a protein of the inner nuclear membrane, which specifically needs lamin A for proper localization at the NE. Here, we propose Nup88 as a regulator of the pRb/E2F pathway via its ability to regulate the repressor complex lamin A-LAP2α activity and as a key player in the organization of nuclear lamina.

Essential functions of Orb2 in spermatogenesis of *Drosophila melanogaster*

G. A. Nosov[1], L. V. Olenina[2]
[1]Biochemistry, Lomonosov Moscow State Uiversity, [2]Institute of Molecular Genetics, RAS, Moscow, Russian Federation

During this work, we investigate functions of CPEB family Orb2 protein in spermatogenesis of *Drosophila melanogaster*. CPEB family proteins are known to participate in cytoplasmic polyadenylation of mRNA tails and in masking of mRNAs. However, it is not shown for Orb 2 to date. Using whole-mount immunostaining and confocal microscopy we analyze patterns of Orb2 distribution in the wild-type testes and characterize a failure of spermatogenesis in flies with different Orb2 mutations (1793, 6090 and 36). We reveal that Orb2 in spermatocytes localizes in germinal granules, in which processing of short RNAs (part of piRNA-pathway) also occurs. Nevertheless, the absence of Orb2 doesn't lead to disruption of germinal granules and disturbances in the piRNA-pathway with further derepression of harmful transcripts stellate. We also determine a meiotic arrest on two stages of spermatogenesis in the absence of Orb2 (line 36): about 60% of mature cysts arrested in G2-phase and about 40% in prometaphase. Arrest in prometaphase is assosiated with failures of meiotic spindle formation. Using PAT-analysis (analysis of the length of poly-A tails in mRNA) we find some potential targets of Orb2 in the testes. There are cyclines A and B, and another CPEB – Orb. We showed shotering of poly-A tails in mRNAs of the both cyclines in mutants without Orb2. According to previous data, Orb2 in brain forms functional amyloid aggregates. We display for the first time that in the testes Orb2 also forms amyloid aggregates.

Keywords: CPEB, Orb2, Spermatogenesis.

Glutathione is essential to preserve nuclear function and cell survival under oxidative stress

E. Hatem[1], V. Berthonaud[1], M. Dardalhon[2], G. Lagniel[1], P. Baudouin-Cornu[1], M.-E. Huang[2], J. Labarre[1], **S. Chédin**[1]
[1]IBITECS, CEA, Gif-sur-Yvette, [2]Institut Curie, Orsay, France

Organisms growing in an aerobic environment must cope with Reactive Oxygen Species (ROS), such as superoxide, hydrogen peroxide and hydroxyl radical. Although ROS damage all the cellular macromolecules, they play a central role in a range of biological processes, including signaling. This later process requires a tight control of their abundance. Thus, redox homeostasis is achieved by antioxidant systems involving a large collection of enzymes that scavenge or degrade the ROS produced endogenously during cell growth. In addition to this enzymatic protection against ROS, cells also contain small antioxidant molecules, such as glutathione (GSH). With an intracellular concentration between 1 and 10 mM, GSH is the most abundant non-protein thiol in the cell and is considered as the major redox buffer of the cell. To better characterize its essential function during oxidative stress conditions, we studied the physiological response of H_2O_2-treated yeast cells containing different amounts of GSH.

We showed that the transcriptional response of GSH-depleted cells is severely impaired, despite an efficient nuclear accumulation of the transcription factor Yap1. Moreover, oxidative stress generates high genome instability in GSH-depleted cells, but does not activate the checkpoint kinase Rad53. Surprisingly, scarce amounts of intracellular GSH are sufficient to preserve cell viability under H_2O_2 treatment. In these cells, oxidative stress still causes the accumulation of oxidized proteins and the inactivation of the translational activity, but nuclear DNA and nuclear functions are protected against oxidative injury, as exemplified by low mutation frequency, moderate histone carbonylation, activation of the checkpoint kinase Rad53 and of the H_2O_2 transcriptional response.

We conclude that the essential role of GSH is to preserve nuclear function, allowing cell survival and growth resumption after oxidative stress release. We propose that cytosolic proteins are part of a protective machinery that shields the nucleus by scavenging reactive oxygen species before they can cross the nuclear membrane.

Keywords: Glutathione, Oxidative stress, Rad53.

GNL3L is nucleo-cytoplasmic shuttling protein: role in cell division cycle regulation

I. Jose T, M. R. Subba Rao, A. Kumaraswamy, R. Krishnan, R. Vijayakumaran, S. Mahalingam
Biotechnology, IIT-Madras, Chennai, India

GNL3L (Guanine Nucleotide Binding Protein-Like-3-Like) is an evolutionarily conserved high molecular weight nucleolar GTP binding protein belonging to HSR1-MMR1 subfamily of GTPases. Given the increasing importance of nucleolar proteins in the regulation of cell growth and proliferation, we have attempted to address the relationship between nucleo-cytoplasmic transport of GNL3L and its functional significance during cell proliferation. Employing a combination of immunofluorescence, mutagenesis and protein-protein interaction assays, current investigation demonstrates that GNL3L shuttles between nucleus and cytoplasm in a CRM1-dependent manner. Deletion mutagenesis analysis reveals that the C-terminal domain (amino acids 501–582) is necessary and sufficient for the export of GNL3L from the nucleus

© 2014 The Authors. FEBS Journal © 2014 FEBS

and the exchange of hydrophobic residues (M567, L570 and L572) within the C-terminal domain impairs this process. In addition, our data indicates that the C-terminal domain encodes a non-canonical nuclear localization signal (NLS), and is able to import cargoes into the nucleus in an importin-alpha and importin-beta independent manner. Cell cycle analysis indicated that less number of cells accumulated in S-phase upon overexpression of nuclear export defective GNL3L, which is localized in the nucleus. Interestingly, BrdU labeling assay showed a significantly higher amount of DNA synthesis despite the fact that less number of cells accumulated during 'S' phase of cell cycle. Furthermore, the expression of E2F1, cyclin A2 and cyclin E1 were up-regulated along with phosphorylation of Rb protein upon ectopic expression of $GNL3L^{\Delta NES}$, resulting in faster 'S' phase progression. Collectively, the present study provides evidence that GNL3L is exported from the nucleus by a CRM1 dependent mechanism and the nuclear localization of GNL3L is critical to promote 'S' phase progression during cell division cycle.

Keywords: Cell cycle, nucleo-cytoplasmic shuttling, nucleolar GTPase.

Green tea, coffee and cocoa polyphenols exhibit different effects on HeLa cell viability and proliferation

M. Krstic, M. Stojadinovic, K. Smiljanic, D. Stanic-Vucinic, T. Cirkovic Velickovic

Biochemistry, Faculty of Chemistry, Belgrade, Serbia

One of the leading causes of cancer death within female population is cervical cancer, especially in developing countries. Therefore, lot of effort has been invested in understanding of molecular mechanism of cancerogenesis and development of mechanistically targeted therapies. Common beverages such as green tea, coffee and cocoa are rich in antioxidants, especially phenolic acids and derivatives of catechins, known for their health promoting properties. Epidemiological and experimental studies indicate that green tea extract acts as effective chemo preventive agent targeting different organ specific cancers. In accordance with the claims set forth above, the aim of this investigation is to identify and confirm if there is any significant biological effects of cocoa, coffee and green tea extracts on cervical cancer cell (HeLa cell line) survival.

Total phenolics of extracts were determined by Folin-Ciocalteu's method. Cytotoxic activity of extracts in HeLa cell line was assayed by viability testing using MTT. Estimation of cell proliferation was assayed using flow cytometry and CFSE dye diluting metod. For detecting cells in early stages of apoptosis and for distinguishing them from dead cells, Annexin V-FITC was employed. All tested extracts exhibited cytotoxic activity in HeLa cell line, with green tea extract (GT) having the highest cytotoxic activity followed by coffee (CF) and cocoa extract (CC). Statistically significant decrease in proliferation was observed only with GT, while increase in proliferation index occurred in the case of CF and CC after 72 h of treatment. Quantification of apoptotic effect *via* Annexin-FITC labeling, showed that all three tested extracts behaved as apoptotic agents for HeLa cell line. As expected, GT induced the highest degree of apoptosis, while CF and CC induced similar degrees of apoptosis after 72 h of treatment.

As a conclusion, GT provides the most potent apoptotic signals to the tumor cells, coffee extract shows modest effects on cell viability and apoptosis induction, while the weakest effects shows cocoa extract.

HCF-1 cleavage and glycosylaton are distinct activities of OGT

V. Kapuria[1], T. Bhuiyan[1], U. Roehrig[2], V. Zoete[2], W. Herr[1]

[1]Centre for Integrative Genomics, [2]Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, Switzerland

O-GlcNAc Transferase (OGT) catalyzes a dynamic and a reversible glycosylation of cellular proteins that regulate intracellular signaling, transcriptional regulation and stress responses. Structural features of OGT include a N-terminal tetra-tricopeptide repeat (TPR) domain and a C-terminal catalytic domain. While the TPR domain of OGT is involved in substrate recognition and binding, the catalytic domain is required for substrate glycosylation. Recently, a novel proteolytic activity of OGT was described for a transcriptional co-factor called Host Cell Factor-1 (HCF-1) (Capotosti et al; *Cell 2011*). HCF-1 also undergoes OGT-mediated glycosylation during this process. X-ray crystallography analysis shows a unique interaction between OGT and HCF-1 proteolytic site (Lazarus et al; *Science 2013*). Using molecular dynamics simulations, we observed a strong interaction between OGT TPR domain and the HCF-1 proteolytic site. However, the mechanism of OGT's-dual activities against HCF-1 (proteolysis and glycosylation) remains unexplained. We performed extensive mutational analysis of OGT and assayed the mutant OGTs for HCF-1 cleavage and glycosylation activities. Certain mutants of OGT retained HCF-1 cleavage activity despite losing HCF-1 glycosylation activities or vice-versa, suggesting that glycosylation and cleavage of HCF-1 are two distinguishable properties of OGT. Interestingly, mutational analysis of the TPR domain suggests a critical role of the TPR domain for the proper presentation of the HCF-1 proteolytic site within OGT catalytic core.

Hormonal signalling and nuclear receptor: new players in the regulation of intestinal crypt cells division

E. Kress, J. Nadjar, M. Plateroti

Centre de Genetique et Physiologie Moleculaire et Cellulaire, Université Lyon 1, Lyon, France

The intestinal epithelium is characterised by a continuous renewal dependent of the multipotentes stem cells residing at the bottom of intestinal crypts. They give rise to proliferative progenitors that differentiate while migrating along the crypts. The intestinal homeostaαsis is achieved by balanced proliferation and differentiation processes, which are tightly controlled by signalling pathways such as Wnt, BMP and Notch. Our group identified the thyroid hormones (TH) and their nuclear receptor TRalpha1 as a regulator of intestinal homeostasis, acting in particular via cross talks with the Wnt pathway. Mice overexpressing TRα1 in intestinal epithelium (vil-TRα1 mice) display increased cell proliferation and develop adenomas; in a Wnt-activated background, TRα1 overexpression accelerates tumorigenesis (vil-TRα1/Apc+/1638N mice). Intriguingly, the epithelium of the vil-TRα1 mice displays an aberrant architecture suggesting an alteration of crypt cells division axis.

In order to characterize the effects of TRα1 on cell division, we used an approach of *in toto* crypt immunolabelling and analysed in vivo the division axis of stem and progenitors cells in the colon of wild type or vil-TRα1 mice, by measuring the angle between the spindle poles (the centrosomes) and the apical pole. We confirmed that at anaphase the mitotic spindle aligns with the apical pole in both types of cells in a control situation. In contrast, we observed that upon overexpression of TRα1 this planar orientation is lost. Interestingly, we already described that Aurora kinase A (AURKA) and TACC3, regulators of the cen-

© 2014 The Authors. FEBS Journal © 2014 FEBS

trosomes, are positively-regulated TH target genes. By immunolabelling, we showed increased centrosomal levels of both in vil-TRα1 compared with WT crypts.

Taken together, our current hypothesis is that overexpression of AURKA and TACC3 in vil-TRα1 mice disturbs the mechanism of centrosomes-driven spindle orientation thus leading to an aberrant division. The misplaced daughter cells within the crypts might escape the control of their physiological microenvironment, triggering colon tumorigenesis.

Our results demonstrate yet another level of the function of thyroid hormones signalling in the intestinal epithelial physiology and pathology. They also highlight a new role of a nuclear receptor in the control of cell division mechanisms.

How curcumin induces senescence of vascular smooth muscle cells – searching for the mechanism

W. Grabowska, E. Sikora, A. Bielak-Zmijewska

Laboratory of Molecular Bases of Aging, Nencki Institute of Experimental Biology Polish Academy of Sciences, Warszawa, Poland

Curcumin, a natural polyphenol has documented anti-inflammatory and anti-oxidant properties. A plethora of studies revealed its potential in therapy of many diseases with inflammatory origins – cancer and cardiovascular disease. Curcumin, consumed in a diet, is believed to be safe even in high doses (8–12 mg/day). Plasma concentrations of this compound do not exceed 2 μM. Recently, we showed that curcumin can induce, not only cell death, but also senescence of cancer cells.

The aim of this study was to investigate if curcumin can also induce senescence of normal cells and if so to find a mechanism of this action. Vascular smooth muscle cells (VSMCs) isolated from human aorta were relatively sensitive to curcumin. Already 2.5 μM curcumin inhibited proliferation, 5 μM was cytostatic and concentrations higher than 10 μM induced cell death. In cytostatic concentration of curcumin cells exhibited several features characteristic for senescence: increased activity of senescence-associated-β-galactosidase (SA-β-gal); senescence associated secretory phenotype (SASP) manifested by an elevated level of proinflammatory cytokines – IL-6, IL-8; an increased level of the marker specific for VSMCs senescence – AGTR1 (receptor for angiotensin II). Moreover a significant number of cells was arrested in the G2/M phase of the cell cycle and had a slight increase in cell granularity. We showed that neither prolonged mitotic arrest nor DNA damage were the causes of curcumin induced senescence. What's more, in cells undergoing senescence upon curcumin treatment a lower number of DNA DSB was observed. However the DNA damage response (DDR) pathway was activated. It is believed that curcumin apart from its antioxidative properties can act in the first phase of its action as a prooxidant. Therefore we analyzed if increased reactive oxygen species (ROS) production can lead to curcumin-induced senescence. To this end, we pre-treated cells with ROS scavengers, N-acetylcysteine as well as trolox, before adding curcumin, however none of them was able to prevent or ameliorate curcumin induced senescence.

Our results suggest that VSMCs are very sensitive to curcumin and cytostatic doses can induce senescence but the mechanism has not been elucidated.

Financial Support: This work was supported by grant 2011/01/B/NZ3/02137 from the National Centre for Science.

Influence of TP53 mutations on hematopoiesis in myelodysplastic syndromes (MDS) and acute myeloid leukemias (AML)

A. Salari[1], K. Thomay[1], M. Hagedorn[1], A. Schambach[2], B. Schlegelberger[1], G. Goehring[1]

[1]Institute of Human Genetics, [2]Institute of Experimental Hematology, Hannover Medical School (MHH), Hannover, Germany

Patients with MDS and complex karyotype have a short median survival of under 12 months and a high risk of transformation into AML. *TP53* mutations are associated with complex karyotype, resistance to chemotherapy, short survival, disease progression and poor outcome. However, the pathogenesis of the *TP53* mutations on the hematopoietic stem cells (HSCs) and their cell fate is poorly understood. Thus, we established a cell culture model and investigated the overexpression of wild-type *TP53* and four different hot spot mutations in human CD34+ cells isolated from cord blood. The CD34+ cells were transduced, sorted and co-cultured with irradiated stromal feeder cells for 6 weeks and half the cells were harvested weekly for examination. As a control we analyzed cells transduced with an empty vector and non-transduced cells. To better understand the influence of different *TP53* mutations on HSCs, we analyzed the colony-forming capacity, rate of apoptosis and proliferation. We also analyzed the *TP53* expression (RT-PCR and Western blot), the *BAX* expression as a marker for the apoptosis pathway triggered by *TP53* and *CDKN1A* expression regulated by *TP53* as a marker for the cell cycle arrest.

Using the colony-forming cell assay, we identified fewer colonies in all transduced cells, especially those overexpressing wild-type, R273H and R175H *TP53* variants. Although the ability to induce erythroid differentiation is affected in all cells during follow-up, cells overexpressing wt*TP53* and cells carrying the R273H mutation already showed impaired erythroid differentiation at an early timepoint.

We detected a higher rate of apoptosis in the cells with overexpression of wt*TP53* and cells expressing the mutations than in the cells carrying the empty vector. In concordance with these data, we identified a *BAX* overexpression in all cells with higher apoptosis. We could also show reduced cell proliferation due to the overexpression of wt*TP53* or *TP53* mutations. An elevated expression of *CDKN1A* confirms these data.

To better understand the influence of *TP53* on the development of complex karyotypes, we also performed cytogenetic banding analyses of all long-term cell cultures during follow-up. We saw an increased number of chromosomal breakages but no development of stable clonal abnormalities.

In summary, overexpression of wt*TP53* and its mutations leads to impaired hematopoiesis with decreased erythroid differentiation, increased apoptosis and decreased proliferation. However, the mutation alone did not lead to the development of complex karyotypes. In conclusion, a *TP53* mutation seems to need additional passenger mutations in order to lead to MDS or AML with complex karyotype.

Keywords: Chromosomal instability, Hematopoietic stem cells, TP53 gene.

SUN-028
Inhibition of oncoprotein Cdc25 and G2/M transition of the cell cycle by hydrogen sulfide

A. Gelaude, A. Martoriati, K. Cailliau Maggio, P. Vandame, M. Marin, A. Lescuyer, B. Jean-François
EA 4479 – Laboratoire de Régulation des Signaux de Division, Lille 1, Lille, France

The hydrogen sulfide (H_2S), a modulator of the cellular proliferation, is a member of the gazomessenger family, including the nitric oxide and the carbon monoxide. The increase of the level of H_2S inhibits the proliferation either by blocking the cells in G1 on lung fibroblasts (MRC-5, IMR-90 and WI-38) or G2/M for breast cancer cells (MCF-7). The inhibitory effect of H_2S on the proliferation is associated to an increase of cells entering into apoptosis. The apoptotic mechanisms induced by H_2S are widely studied but the action of H_2S on cell cycle remains unexplored. H_2S may influence the progression on the cycle by a direct inhibition of the component of the cell cycle or by an indirect mechanisms depending on the DNA damage induced by the genotoxic effect of H_2S. We used the paradigm of the xenopus oocyte that doesn't show a response to the DNA damage to study the G2/M transition without genotoxic effects. We have shown that in this model, NaHS (H_2S donor) has no effect on apoptosis. Our preliminary experiments allowed us to determine Cdc25 (Cell Division Cycle 25) as a target of H_2S.

The NaHS induces a reduction or a total inhibition of the progesterone induced meiosis resumption associated with an inactive MPF (Cdc2 phosphorylated). Micro-injection of active MPF in a prophase I oocyte triggers Cdc25 activation which in turn activates pre-MPF (inactive stock of MPF) by dephosphorylation and permits oocyte maturation. It's the auto-amplification loop of MPF. The increase of H_2S totally inhibits this maturation suggested that H_2S targeted the mechanisms of auto-amplification loop of MPF. The inhibition of the phosphatase Cdc25 could be the target of H_2S. This hypothesis was tested by measuring the activity of a GST-Cdc25C protein in a cell-free environment in vitro by the colorimetric technique OMFP (O-MethylFluoroPhosphate). In the presence of NaHS, a decrease of the activity of GST-Cdc25C protein was observed in a dose-dependent manner.

Cdc25 presents, in its catalytic domain, an essential cysteine amino acid for its activity. In the presence of SOD (superoxide dismutase) and catalase, which remove ROS (Reactive Oxygen Species), the activity of NaHS on cell cycle is suppressed. Thus, ROS may alter the activity of Cdc25 via an action on the cysteine, as it does for some phosphatases. However, it is not exclude that sulfonation is also involved in this mechanism.

Keywords: Cdc25 phosphatase, Cell cycle, G2/M transition.

Inhibitor-3 ensures bipolar spindle attachment by limiting association of SDS22 to kinetochore-bound PP1

J. Seiler, A. Eiteneuer, M. Weith, H. Meyer
Molecular Biology I, University of Duisburg-Essen, Essen, Germany

Faithful chromosome segregation during mitosis is tightly regulated by opposing activities of Aurora B kinase and protein phosphatase-1 (PP1). PP1 function at kinetochores has been linked to SDS22, but the exact localization of SDS22 and how it affects PP1 is controversial. Here, we confirm that SDS22 is required for PP1 activity, but show that SDS22 does not normally localize to kinetochores. Instead, SDS22 is kept in solution by formation of a ternary complex with PP1 and inhibitor-3 (I3). Depletion of I3 does not affect the amount of PP1 at kinetochores but causes quantitative association of SDS22 to PP1 on KNL1 at the kinetochore. Such accumulation of SDS22 at kinetochores interferes with PP1 activity and inhibits Aurora B threonine-232 dephosphorylation, which leads to increased Aurora B activity in metaphase and persistence in anaphase accompanied with segregation defects. We propose a model in which I3 regulates an SDS22-mediated PP1 activation step in solution that precedes SDS22 dissociation and transfer of PP1 to kinetochores, and which is required for PP1 to efficiently antagonize Aurora B.

Interaction of IFI16 and various DNA substrates

J. Coufal, T. Selinger, V. Brázda
DBCMO, Institute of Biophysics ASCR, v.v.i., Brno, Czech Republic

IFI16 is a member of interferon inducible HIN-200 protein family. These proteins are involved in tissue differentiation, apoptosis, cell proliferation, senescence and they also play role in tumor growth and autoimmunity. They can also interact with various target proteins like signaling proteins, tumor suppressor proteins, oncoproteins and others. IFI16 can interact with BRCA1 and p53 via ...binding regions' and it can stimulate p53 binding to DNA. IFI16 itself can also interact with DNA via DNA binding domains localized in the HIN repeats and it can interact with p53 and cMYC promoters.

We investigated interaction of IFI16 protein with DNA by electromobility shift assay with oligoinucleotides in aPAGE gels and with long DNA targets on agarose gels and confocal microscopy. We used various DNA substrates including different structures frequently located in gene promoters that influence binding of transcription factors like cruciform, quadruplex and triplex. Our preliminary results show that p53 interact the best with cruciform structure.

Keywords: IFI16, cruciform.

Interplay between ROS, DNA damage, p38MAPK and mitochondria is required for premature senescence of endometrial stem cells

E. Burova, A. Borodkina, A. Shatrova, N. Nikolsky
Institute of Cytology RAS, Sankt-Petersburg, Russian Federation

Recently, we have shown that endometrium-derived human mesenchymal stem cells (hMESCs) under sublethal oxidative stress enter the premature senescence but underlying mechanism remains unknown. Herein, we for the first time examine the signaling pathways which provide establishing and maintaining of H_2O_2-induced premature senescence of hMESCs. Understanding of the interplay between various signaling pathways should be highly useful to determinate the strategy for the reversal of cellular senescence. Our results demonstrate that the induction of senescence includes a prompt activation of DNA damage response (DDR) and following signal transduction via p53/p21 and p38/MAPKAPK-2 (MK-2) pathways which are necessary and sufficient to establish the irreversible cell cycle arrest that is typical of senescence. In senescent cells, we observed the prolonged induction of p21, as well as the concurrent activation of p38/MK-2 that may be indispensable to maintain the persistent proliferative block. Moreover, there was a correlation between

© 2014 The Authors. FEBS Journal © 2014 FEBS

the persistence of DDR signaling and permanently elevated ROS, presuming that the feedback loop between DDR and ROS production is necessary to stabilize the senescent growth arrest. In senescent cells, the specific inhibition of p38/MK-2 activity with SB203580 (SB) had a pronounced negative effect on the intracellular ROS production while the mitochondrial ROS production was diminished just in part. Similarly, mitochondrial mass and mitochondrial membrane potential were partially decreased. In senescent cells preserving the metabolic activity, we revealed the significant increase in the amount of functional mitochondria which might be responsible, at least in part, for long-term ROS production. These findings suggest that activated p38/MK-2 may regulate ROS generation via functional mitochondria. In this study, the inhibition of p38/MK-2 activation, as well as ROS scavenging with antioxidant N-acetylcysteine (NAC) was considered as a possible strategy for senescence prevention. Blocking of p38/MK-2 activity abrogated H_2O_2-induced cell enlargement and flattened morphology, but did not produce any significant effect on SA-β-Gal activity. At the same time, SB treatment allowed to avoid an irreversible cell cycle arrest in response to H_2O_2 however the recovery of proliferation was incomplete. On the other hand, the contemporary cell treatment with H_2O_2 and NAC was sufficient to essentially block the elevated ROS levels, to suppress the H_2O_2-induced senescent phenotype and to recover proliferation. Thus, suppression of p38 kinase activity as well as ROS scavenging with NAC can rescue hMESCs from the growth arrest and entering H_2O_2-induced premature senescence.

Interplay between ROS, DNA damage, p38MAPK and mitochondria is required for premature senescence of endometrial stem cells

E. Burova, A. Borodkina, A. Shatrova, N. Nikolsky
Institute of Cytology, Sankt-Petersburg, Russian Federation

Recently, we have shown that endometrium-derived human mesenchymal stem cells (hMESCs) under sublethal oxidative stress enter the premature senescence but underlying mechanism remains unknown. Herein, we for the first time examine the signaling pathways which provide establishing and maintaining of H_2O_2-induced premature senescence of hMESCs. Understanding of the interplay between various signaling pathways should be highly useful to determinate the strategy for the reversal of cellular senescence. Our results demonstrate that the induction of senescence includes a prompt activation of DNA damage response (DDR) and following signal transduction via p53/p21 and p38/MAPKAPK-2 (MK-2) pathways which are necessary and sufficient to establish the irreversible cell cycle arrest that is typical of senescence. In senescent cells, we observed the prolonged induction of p21, as well as the concurrent activation of p38/MK-2 that may be indispensable to maintain the persistent proliferative block. Moreover, there was a correlation between the persistence of DDR signaling and permanently elevated ROS, presuming that the feedback loop between DDR and ROS production is necessary to stabilize the senescent growth arrest. In senescent cells, the specific inhibition of p38/MK-2 activity with SB203580 (SB) had a pronounced negative effect on the intracellular ROS production while the mitochondrial ROS production was diminished just in part. Similarly, mitochondrial mass and mitochondrial membrane potential were partially decreased. In senescent cells preserving the metabolic activity, we revealed the significant increase in the amount of functional mitochondria which might be responsible, at least in part, for long-term ROS production. These findings suggest that activated p38/MK-2 may regulate ROS generation via functional mitochondria. In this study, the inhibition of p38/MK-2 activation, as well as ROS scavenging with antioxidant N-acetylcysteine (NAC) was considered as a possible strategy for senescence prevention. Blocking of p38/MK-2 activity abrogated H_2O_2-induced cell enlargement and flattened morphology, but did not produce any significant effect on SA-β-Gal activity. At the same time, SB treatment allowed to avoid an irreversible cell cycle arrest in response to H_2O_2 however the recovery of proliferation was incomplete. On the other hand, the contemporary cell treatment with H_2O_2 and NAC was sufficient to essentially block the elevated ROS levels, to suppress the H_2O_2-induced senescent phenotype and to recover proliferation. Thus, suppression of p38 kinase activity as well as ROS scavenging with NAC can rescue hMESCs from the growth arrest and entering H_2O_2-induced premature senescence.

Investigation of EGF A61G gene variation and serum EGF level on gastric cancer susceptibility and clinicopathological parameters

C. Cacina[1], S. Arıkan[2], Y. Düzköylü[2], E. Okay[3], S. Turan[1], T. Isbir[4], I. Yaylim[1]
[1]Department of Molecular Medicine, Institute of Experimental Medicine, Istanbul University, [2]Surgery Clinic, Istanbul Research and Teaching and Research Hospital, Istanbul, [3]Surgery Clinic, Kocaeli University Medical Faculty, Kocaeli, [4]Department of Medical Biology, Yeditepe University Medical Faculty, Istanbul, Turkey

Gastric cancer is one of the most common malignancies and the second most common cause of cancer-related death worldwide. Carcinogenesis process including gastric cancer, are known to arise through multiple genetic and epigenetic alterations and these molecular changes eventually affect the expression of cancer-associated genes, such as oncogenes and tumor-suppressor genes. Epidermal growth factor (EGF) is an important member of the epidermal growth factor superfamily, which acts several roles in the growth, proliferation and differentiation of numerous types of cells and cancers. In present study we have examined EGF A61G gene polymorphism and EGF serum level as a marker of tumour risk and progression in gastric cancer. We used polymerase chain reaction- restriction fragment length polymorphism (PCR, RFLP) and gel electrophoresis techniques to detect EGF A61G gene variation in 84 gastric cancer patiens and 146 healthy controls. EGF serum levels in patients and control subjects were examined by ELISA method. The distribution of EGF A61G genotypes were different between gastric cancer patients and controls ($p = 0.039$). The frequencies of the AA, AG and GG genotypes were 20.2%, 53.6%, 26.2% in cases and 32.9%, 52.1%, 15.1% in control group respectively. According the our study the variant GG genotype was associated with a near 1.7-fold higher risk of gastric cancer. When the analyses were stratified we didn't observed any significant association between prognostic parameters and EGF genotypes. EGF serum levels in gastric cancer cases were significantly lower than those in controls $p = 0.012$). Our results have suggested that EGF A61G gene variation might be associated with the risk of gastric cancer.

Keywords: gastric cancer, gene,serum level.

Is there any relation between CDKN2 p16 and MDM2 variants and the development of primary brain tumors?

A. Kafadar[1], **O. Kucukhuseyin**[2], C. Cacina[2], E. N. Yenilmez[2], S. Turan[2], D. Kafadar[3], E. Ozkok[4], I. Yaylim[2]
[1]Neurosurgery, Cerrahpasa Faculty of Medicine, Istanbul University, [2]Molecular Medicine, The Institute of Experimental Medicine/Istanbul University, [3]Family Medicine, Bagcilar Training and Research Hospital, [4]Neuroscience, The Institute of Experimental Medicine/Istanbul University, Istanbul, Turkey

Primary brain tumors, classified as glioma, meningioma and intracranial neoplasms, composed of different cell types. With the advent in neuroradiological imaging, the natural course of these tumors are now partially described. However, maybe because of low and different incidances according to ethnic/geographic origin and high mortality rate their etiology and molecular mechanism remains unclear. There is a set of data about the importance of tumor suppresor p53 pathway and cell cycle regulatory genes such as MDM2 and p16 (CDNK2) in brain tumors. p16 plays a pivotal role in G1/S-transition by regulating p53 pathway which was regulated by a nuclear phospho-oncoprotein, mouse double minute 2 (MDM2). Two adjacent polymorphism of p16 gene, 540C>G (rs11515) and 580C>T (rs3088440) were identified. Both polymorphisms were located in the 3′UTR region of exon3 and shown to affect the activation of p16 and contribute to cancer development, prognosis and the tumor aggressiveness. A single nucleotide polymorphism in the promoter of MDM2, SNP309T>G (rs2279744) has shown to alter protein expression and p53 activity which regards possible roles in carcinogenesis. The aim of this study is to investigate the association of p16 540C>G, p16 580C>T and MDM2 SNP309T>G polymorphisms with the risk of brain tumor development. 67 primary brain tumor patients and 71 control were included in this study. The gDNA was isolated by salting-out procedure. p16 and MDM2 polymorphisms was analyzed by PCR-RFLP based techniques. The allelic or genotypic frequencies of MDM2 SNP309T>G and p16 580C>T were balanced among the study groups. The frequency of p16 540GG genotype was lower in primary brain tumor patients and 540G allele frequency (GG+CG) was higher in controls. Thus it was found that possesing p16 540CC genotype ~2fold increases the risk of primary brain tumor development. In contrast, possesing p16 540G allele and GG genotype ~2.3fold and ~7fold increases the prevention from meningioma and glioma, respectively. Although this report was the first one to determine the relation between p16 540C>G, p16 580C>T or MDM2 SNP309T>G polymorphisms and primary brain tumors: glioma and meningioma, it was found that CDKN2 p16 540C>G may more risky for the development of brain tumors. Further studies with large cohorts are necessary to determine the genetic factors affectting the development and prognosis of brain tumors and to promote the effective therapy strategies.

Keywords: Brain tumors, MDM2, p16.

Methionine sulfoxide reductase B3 deficiency inhibits cell growth through the activation of p53-p21 and p27 pathways

H.-Y. Kim, E. Lee, G.-H. Kwak, K. Kamble
Biochemistry and Molecular Biology, Yeungnam University, Daegu, Korea

Methionine sulfoxide reductase B3 (MsrB3) is an oxidoreductase in the endoplasmic reticulum that catalyzes the stereospecific reduction of methionine-R-sulfoxide to methionine. Here, we report the critical role and mechanisms of MsrB3 in cell proliferation. The deletion of MsrB3 led to a significant decrease in cell proliferation in mouse embryonic fibroblast (MEF) cells. MsrB3-knockout MEF cells showed increased p53 protein levels, compared to wild-type MEF cells, which subsequently elevated the protein level of cyclin-dependent kinase inhibitor p21. In addition, MsrB3 deficiency enhanced the protein level of p27, another cell cycle regulator, and caused cell cycle arrest at the G1 stage. The inhibitory effect of MsrB3 deficiency on cell proliferation through the activation of p53-p21 and p27 pathways was also confirmed in primary human dermal fibroblasts. Collectively, the data suggest that MsrB3 is a regulator of cell growth through the p53-p21 and p27 pathways.

SUN-036
Nek7 is possibly involved in UV damage response

A. Perez, E. E. de Souza, J. Kobarg
LnBio, CNPEM, Campinas, Brazil

The Neks are a family of vertebrate protein kinases similar to fungal NIMA, which activity is essential for the G2/M checkpoint progression and mitosis entry. The NIMA protein has been implicated in chromatin condensation, microtubule dynamics and cell division regulation. In mammals, there are 11 Neks, of which only Nek 2, 6, 7 and 9 have been directly implicated in mitotic regulation. Futhermore, the importance of the Nek1, 4, 10 and 11 in the DNA damage response, checkpoint control, mitosis and progression and regulation of the cell cycle, has been underscored in several experimental systems. Specificy, Nek7 regulates mechanisms of centriole duplication and microtubule nucleation from centrosomes. Studies show the involvement of Nek7 is over-expressed in breast, colorectal, laryngeal and lung cancer and non-Hodgin lymphoma. Thus, the employment of functional and cellular studies aiming to unravel the Nek7 signaling pathway in regulating cell division, is necessary to clarify the function of Nek7 in carcinogenesis. Based on all these data, HeLa and Hek293 cells were transfected or not with Flag-Nek7 for protein over-expression or silenced using shRNA specific for Nek7, and exposed or not to UV light. Treated cells were submitted to apoptosis assays based on flow cytometry. Our results suggest that Nek7 plays a role in protecting cells of such damage, since the cultures over-expressing Nek7, showed a decrease in the number of cells undergoing apoptosis, after exposure to UV light. On the other hand, in cells in which Nek7 was silenced, an increase of apoptotic cells was verified. Thus, our experiments suggest a role of Nek7 in the maintenance of apoptosis mechanisms. Confirmative assays are underway to explore this potential new function in molecular detail.

The serine-threonine Aurora kinases A and B were proven to play an important role in regulating normal cell division. Aurora A regulates centrosome maturation, division and required for the spindle checkpoint. Aurora B plays role in the chromosome condensation, segregation and crucial for cytokinesis. It is well known, that deregulation of Aurora kinases fosters malignant transformation, while their inhibition promotes apoptosis in experimental models. Indeed, Aurora gene amplification and/or protein overexpression is commonly found in human tumors and correlates with poor prognosis; therefore Aurora kinases emerged as potential targets in personalised cancer therapy.

In the last decade several small molecule inhibitors of Aurora A or B were published, however most of them failed in clinical experiments and there is still no Aurora inhibitor drug in the market. The aim of our work was to design and synthesise new ATP analogue inhibitors endowed with Aurora kinase inhibition properties.

Screening the Nested Chemical Library© of Vichem Ltd.'s using recombinant Aurora A kinase assay we identified a benzothiophene-3-carboxamide based compound with nanomolar inhibition potency on Aurora kinases. Further 35 analogues were synthesised, showing even better enzyme inhibition, however only a subset exhibited cell viability inhibition as well. These later compounds generated multinucleated cells stucked in G2/M and induced apoptosis according to flow cytometry, equipotent to VX-680 pan-Aurora inhibitor. Western blot analysis confirmed that these new molecules indeed diminish Aurora A and B autophosphorylation and histone H3 phosphorylation (a well known aurora B substrate).

In all, we present a family of new, patentable benzothiophene-3-carboxamide derivatives as potent, pan-Aurora kinase inhibitiors.

Nobiletin, a polymethoxy flavone, suppresses glioma cell growth through the inhibition of cell cycle

W.-J. Lu[1], K.-H. Lin[2]

[1]Department of Pharmacology, School of Nutrition and Health Sciences, Taipei Medical University, [2]Central Laboratory, Shin-Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan

Nobiletin is a polymethoxy flavone extracted from citrus. Although nobiletin has a potent antitumor activity against several types of human cancers, its inhibitory effects on glioma cells remains incompletely understood. In this study, we systemically examine the inhibitory effects of nobiletin on U87 glioma cells. Our data revealed that nobiletin (20–100 μM) could inhibit glioma cell proliferation detected by MTT. Nobiletin arrested cell cycle at the G0/G1 phase detected by propidium iodide (PI) staining. Using the PI-Annexin V staining, we found that nobiletin did not cause glioma cell apoptosis. These observations suggest that nobiletin inhibit glioma cell growth possibly via regulating cell cycle, but not apoptosis. In the western blot experiments, our results showed that nobiletin significantly reduced the expression of cyclin D1, CDK2, CDK4, and E2F1. In addition, nobiletin inhibited the phosphorylation of Akt and mitogen-activated protein kinases (MAPKs), including Erk, JNK, and p38. In conclusion, our findings suggest that nobiletin may suppress glioma cell proliferation by inhibiting cell cycle and MAPK signaling pathway. Thus, nobiletin may represent a high therapeutic potential for treatment or prevention of glioblastoma multiforme.

Nucleolar GTP binding protein (NGP) promotes cell cycle progression through activation of p53-p21 pathway

D. Datta, A. Kumarasamy, M. Sundarasamy

Biotechnology, Indian Institute of Technology Madras, Chennai, India

Nucleolar GTP binding protein (NGP) is a putative nucleolar GTPase belonging to the HSR1_MMR1 family of GTPases. Other proteins of the same family such as Nucleostemin are known to regulate cell proliferation in stem cells as well as various cancer cells. NGP has been shown to be overexpressed in breast cancers and colon cancers. Nevertheless, the function of this protein remains unknown. In this study, we show that NGP modulates cell proliferation in MCF-7 cells. Ectopic expression of NGP resulted in increased G2/M phase of cell cycle, whereas knockdown of NGP caused G1/S arrest. Surprisingly, in both instances the tumor suppressor p53 was upregulated. The NGP induced p53 was found to be functional in a luciferase based reporter assay system. Furthermore, our data suggests that NGP overexpression results in upregulation of p53 target genes such as p21 and MDM2. It is interesting to note that overexpression of NGP results in cell cycle progression despite upregulating canonical cell cycle inhibitory proteins, p53 and p21. p21 is a CIP/KIP inhibitor through which p53 mediates its tumor suppressor function. p21 binds and inactivates the G1-cyclin–CDK kinase complexes. However, increasing evidence from literature show the existence of a stoichiometric model of p21 function, where p21 acts as a positive regulator of cell cycle at lower than inhibitory concentration in cells by aiding the assembly of cyclinD-CDK 4/6 complexes. Our data suggests that NGP upregulates the cyclinD-CDK 4/6 kinase activity resulting in elevated levels of phosphorylated Rb (S780) subsequently activating E2F target genes such as cyclin A, cyclin E, E2F etc., thereby promoting cell cycle progression. Additionally, knockdown of NGP upregulates p53 resulting in cell cycle arrest further strengthening the hypothesis that NGP regulates the p53 mediated p21 stoichiometry, which determines the fate of the cell.

Keywords: Cell cycle, NGP, p53.

Phosphorylation of barrier-to-autointegration factor by the vaccinia related kinase 3 and its role in cell cycle

K. Kim[1], C. Park[1], H. Song[2], M. Kang[2], Y. Jeong[2], D. Lee[2]
[1]*Division of Integrative Biosciences & Biotechnology,* [2]*Department of Life Sciences, Postech, Pohang, Korea*

Barrier-to-autointegration factor (BAF) is an essential nuclear envelope protein which link the nuclear envelope and with the chromatin. Phosphorylation and dephosphorylation of BAF are required for disassembly and reassembly of the nuclear envelope during mitosis. Mitotic phosphorylation of BAF by the vaccinia related kinase 1 (VRK1) has been reported. However, BAF is also phosphorylated on Ser4 during interphase and the kinase mediating this role remains elusive. Here we demonstrate that the vaccinia related kinase 3 (VRK3) also phosphorylates BAF on Ser4. The expression of VRK3 is increased during interphase whereas VRK1 is enriched in late G2 phase. Ectopic expression of VRK3 induces the relocalization of BAF from the nucleus to the cytoplasm. In addition, depletion of VRK3 decreases the population of proliferating cells. These data suggest that VRK3-mediated phosphorylation of BAF may facilitate DNA replication or gene expression by weakening the association between nuclear envelope proteins and chromatin during interphase.

Proliferation control of tetraploid cells

A. Y. Kuznetsova, **K. Seget**, C. Kuffer, Z. Storchova
Max Planck Institute of Biochemistry, Martinsried, Germany

Most eukaryotic cells are diploid: they contain two sets of chromosomes. However, exceptions can be found. Tetraploid cells that contain four haploid sets of chromosomes can arise as a final differentiation stage in specialized tissues. In contrast, erroneous tetraploidy may lead to aneuploidy and chromosomal instability (CIN), which are frequently associated with cancer. Tetraploid cells usually undergo a p53-dependent cycle arrest after the first tetraploid mitosis, but the triggers of this arrest are not understood. Using high-throughput RNAi-based screen, we identified 140 candidate genes that restrict proliferation of tetraploid cells after abnormal mitosis. Many of these candidates are components of signaling pathways or are involved in cancer. We are currently validating the candidates and determining the mechanisms of their effects on tetraploid cell proliferation.

Remarkably, around 1% of tetraploid cells escapes the arrest and proliferates further. These post-tetraploid cell lines share some features frequently observed in cancer: they have a near-triploid karyotype and show high CIN. We found that post-tetraploid cells are more tolerant to mitotic defects than progenitor diploid or the newly formed tetraploid cells. Remarkably, we found that the regulation of the p53 pathway is altered in post-tetraploids. In particular, the nuclear accumulation of p53 after abnormal mitosis is diminished in post-tetraploids compared to diploids. The identified changes may be at least partially responsible for the tolerance. The mechanisms of cellular tolerance to mitotic defects and the contribution of the candidate genes identified in our screen will be discussed. Taken together, our results show that the deregulation of the p53-dependent cell cycle arrest contributes to survival and CIN in tetraploid progeny. In addition, our genome-wide screen data suggest that alternative mechanism responsible for tetraploid cell cycle arrest might exist.

Keywords: Cell cycle arrest, tetraploidy.

SUN-042
Protein tyrosine phosphatase PTPN13 and its interaction partner SDCCAG3 are involved in the regulation of cytokinesis

F. Yu[1], N. Hagemann[2], N. Ackermann[3], K. S. Erdmann[1]
[1]*Transpol Biomedical Science, University of Sheffield, Sheffield, UK,* [2]*Clinic for Neurology, University Hospital Essen, Essen,* [3]*Biochemistry, Ruhr Universitat Bochum, Bochum, Germany*

Cell division is a vital step in cytokinesis, failure of which is believed to contribute to the development of cancer. PTPN13, a protein tyrosine phosphatase, is previously implicated in the regulation of cytokinesis, carcinogenesis and tumor aggressiveness. Besides it N-terminal phosphatase domain, PTPN13 also contains an N-terminal KIND domain, followed by a FERM domain and five PDZ domains. Here we demonstrate that the serologically defined colon cancer antigen-3 (SDCCAG3) is a new interaction partner to the FERM domain of PTPN13.

We show that SDCCAG3 is a novel endosomal protein, primarily localized at the early/recycling endosomal compartment. It undergoes dynamic localization during cell division with strong accumulation at the midbody during cytokinesis. Altered SDCCAG3 expression, either overexpression as well or downregulation, increases the number of multinucleated cells. Furthermore, we identify interaction of SDCCAG3 with the ArfGAP protein GIT1. Overexpression of an ArfGAP negative version of GIT1 or downregulation of GIT1 have a similar phenotype as the SDCCAG3, leading to the formation of multinucleated cells. Thus, we suggest that PTPN13, SDCCAG3 and GIT1, possibly through the formation of a complex, play a regulatory role in cytokinesis.

Keywords: cytokinesis, endosomal protein, midbody.

SUN-043
Replication aberrations linked to genome plasticity: modeling DNA re-replication across a complete genome

M. A. Rapsomaniki[1], **M. Ramirez**[1], K. Koutroumpas[2], S. Maxouri[1], N. N. Giakoumakis[1], S. Taraviras[1], J. Lygeros[2], Z. Lygerou[1]
[1]*School of Medicine, University of Patras, Patras, Greece,* [2]*ETH, Zurich, Switzerland*

DNA replication in eukaryotes initiates from hundreds of sites along chromosomes, called origins of replication, ensuring complete and accurate duplication of the genome during S-phase. DNA replication along the genome is complex and uncertain: a small fraction of putative origins is selected to fire in each cell in a population and the progression of DNA replication along the genome is unique in every cell. Aberrations in the control mechanisms ensuring once per cell cycle replication allow re-firing of origins within the same S-phase, leading to genome overreplication, which can result in genomic instability, closely connected to tumorigenesis and cancer.

To capture how re-replication progresses along the genome, we have developed a stochastic hybrid model of DNA re-replication which permits genome-wide analysis of re-replication kinetics. The model accurately portrays the interplay between discrete dynamics (origin states), continuous dynamics (movement of the replication forks) and stochastic events (uncertainty in firing events) and permits insight into unknown mechanisms underlying DNA re-replication at the single cell level. We have used experimental data on origin locations and efficiencies from fission yeast to simulate re-replication along the complete fission yeast genome. Monte-Carlo simulations permit analysis of re-replication kinetics genome-wide. Comparison of simulated to experimental

© 2014 The Authors. FEBS Journal © 2014 FEBS

population-level data on copy-number variations shows a good correlation along the genome, validating our approach. Sensitivity analysis and implementation of different model variations have permitted insight into the key parameters affecting re-replication dynamics. Analysis of simulated data allows us to visualize how different regions along the genome respond to over-replication at the single cell level. Our analysis reveals great variations in copy number along the genome from cell to cell, and a unique pattern of over-replication events in each cell in a population. Sites of increased copy-number along the genome are affected by intrinsic properties of each locus, cis effects from adjoining loci and trans effects from distant loci. Single-cell visualization of copy-number variations in multiple loci along the genome in live fission yeast cells have been used to validate model predictions.

Our analysis shows that cell-to-cell heterogeneity is inherent in re-replication and can lead to a high degree of genome plasticity. It also permits us to define principles governing rereplication genome-wide.

Stimulation of GDNF production by tricyclic compounds in retinal cells

T. Sukhanova[1,2], P. Baranov[2], J. McNeish[3], D. Morrow[3], A. Herrera[3], H. Lin[3], M. Young[2]
[1]Laboratory of Cell Interactions, Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation, [2]Department of Ophthalmology, Schepens Eye Research Institute, Boston, MA, [3]GlaxoSmithKline Plc, Philadelphia, United States

Retinal degeneration and vision lost is one of the important problems of medicine. Probably one of best way of resolving this problem is a range of prophylactic measurements against retinal cell degeneration process. Glial derived neurotrophic factor (GDNF) is a member of the transforming growth factor-beta family. It is secreted not only in various classes of neuronal and glial but in other types of cells. GDNF shows antiapoptotic properties, reduces damage from oxidative stress, increases cell viability and takes part in providing cell proliferation in retina. Application of various compounds is responsible for direct and indirect impact and protection of retinal cells by stimulating GDNF secreting.

We tested 2 tricyclic (Amitriptyline, Cyclobenzaprine) and 2 tetracyclic compounds (Amoxapine and Loxapine succinate) for stimulation of GDNF production in neuronal and glial cells (ARPE-19 and SVG respectively) and human retinal progenitor cells (hRPC). GDNF content was evaluated by ELISA, cell growth rate by CyQuant and compounds toxicity by MTT. GDNF intracellular level measured in cell lysate, and GDNF secretion was evaluated by GDNF content in supernatant.

We observed significant increasing of GDNF level inside of ARPE-19 after 10–25 μM Amitriptyline, SVG after 0.5–50 μM Amitriptyline, 0.5–50 μM Cyclobenzaprine and 1.0–50 μM Amoxapine. hRPC was non-sensitive to 3 abovementioned compounds, but 100 μM Loxapine succinate increased GDNF intracellular level. Studying of GDNF secretion showed what 0.5–5 and 25–50 μM Amitriptyline stimulated GDNF secretion in ARPE-19, 0.5–50 μM Cyclobenzarpine, 1–100 μM Amoxapine and 10–100 μM Loxapine succinate in SVG (Amitriptyline hasn't been tested for SVG), 1–100 μM Amoxapine and 10, 50–100 μM Loxapine succinate in hRPC. Thus glial cells are more sensitive to tri- and tetracyclic antidepressants, antipsychotics and muscular relaxants. Interestingly, increasing of GDNF intracellular level and its secretion was registered even at toxic and subtoxic concentrations of applied compounds (10–50 μM dependently of compound and cell line). It could be a reason of prediction what at toxic concentrations of abovementioned compounds GDNF didn't self-bound by cellular specific receptors. Stimulation of cell growth after application of Amitriptyline to hRPC without increasing of GDNF secretion and increasing of GDNF secretion level in ARPE-19 without stimulation of cell growth could be indirect evidence of GDNF involvement of autocrine loop and this loop disruption at high concentrations of the compounds.

Keywords: cell growth, GDNF, tricyclic compounds.

Structural and functional investigation of the role of the transmembrane domain in the VEGF receptor 2 activation

K. S. Mineev[1], S. Manni[2], D. R. Usmanova[1,3], E. N. Lyukmanova[1], M. A. Shulepko[1,4], X. Deupi[5], K. Ballmer-Hofer[2], A. Arseniev[1]
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation, [2]Biomolecular Research, Paul Scherrer Institute, Villigen, Switzerland, [3]Moscow Institute of Physics and Technology, Dolgoprudnyi, Russian Federation, [4]Lomonosov Moscow State University, Moscow, [5]Condensed Matter Theory Group, Paul Scherrer Institute, Villigen, Switzerland

Vascular Endothelial Growth Factor receptors, VEGFRs, regulate blood and lymphatic vessel development and homeostasis and belong to receptor tyrosine kinase (RTK) family of integral membrane proteins. Transmembrane signaling by RTKs entails ligand-mediated dimerization and structural rearrangement of the extracellular domain. RTK activation also depends on specific orientation of the transmembrane domain (TMD) helices, as suggested by pathogenic, constitutively active RTK mutants. Such mutants carry polar amino acids in the TMD, promoting stable transmembrane helix dimerization, which is essential for kinase activation. Here we investigated the spatial structure of the TMDs and the activity of VEGFR-2 constructs, where we mutated the wild-type sequence by replacing specific amino acids in the TMD with glutamate residues. Our data revealed that single-point mutations V769E, I767E and L768E are capable to activate the VEGFR-2 receptor with deleted extracellular domain, but not the full-size receptor. On the other hand, double mutations G770E/F777E and T771E/F778E triggered the ligand-independent activation of the full-size VEGFR-2.

With this respect we then investigated the spatial structure of the dimers and the dimerization propensities for three transmembrane peptides, corresponding to the wilt-type TMD of VEGFR-2 and to V769E and G770E/F777E mutant TMDs with solution NMR spectroscopy. As a result we found that three major aspects distinguish the G770E/F777E TMD dimer from the wild-type: (1) dimerization propensity is enhanced; (2) dimerization occurs via a completely different interface; (3) the spatial structure of this dimer is flexible. On the other hand, we found that V769E substitution in the VEGFR-2 TMD does neither substantially enhance its propensity for dimerization nor change the preferred dimeric conformation. This mutation creates additional surface for helix-helix interactions, which is manifested in the observed trimer formation by the mutant TMD. Further molecular dynamics simulations confirmed the structural interpretation of the NMR data.

The obtained structural and functional data on the VEGFR-2 TMD, both wild-type and carrying various mutations, were then summarized to propose the new mechanism for the VEGFR-2 activation, involving the ligand-induced reorientation of TMDs in the pre-formed VEGFR-2 dimers.

'**Keywords:** activation mechanism, membrane domain, VEGFR.

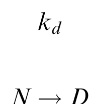
Studies of acrylodan labeled cAMP-dependent protein kinase A catalytic subunit (PKAc-acr) conformational changes

R. Kivi, on behalf of Jaak Järv's Group in Institute of Chemistry
Faculty of Science and Technology, University of Tartu, Tartu, Estonia

PKAc-acr fluorescence spectrum is sensitive to the environment that surrounds the fluorescent label, and this property can be used to study conformational changes of the protein. Significant change in fluorescence can be monitored if native (N) PKAc-acr goes through to denatured state (D) (Figure 1).

The process of protein denaturation can be described by a simple reaction scheme, where k_d denotes kinetic constant:



$$N \xrightarrow{k_d} D$$

Since ligands bound to PKAc affect rate of this reaction, it was possible to study ligand binding by measuring the rate constant k_d. Using this method, binding of ATP and inhibitory peptide PKI [5–24] were studied and the allosteric effect of their simultaneous binding was analyzed. Kinetic measurements were performed at different temperatures and enthalpic and entropic components of the allosteric effect were calculated.

Keywords: fluorescence based assay, High throughput screen, Ligand binding, allostery.

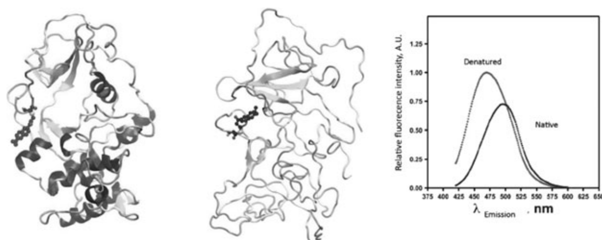


Fig. 1. Computer models of PKAc-acr in native (left panel) and denatured (middle panel) conformations. Fluorecencent label acrylodan was noted as ball-and-stick model. It can be seen from these structures that environment around the acrylodan dye is different in native and denatured states. This change was also detected from changes in fluorescence spetra (right panel). Computer models of PKAc-acr were prepared by A. Kuznetsov.

Suppression of tumorigenesis in mitochondrial NADP+-dependent isocitrate dehydrogenase knock-out mice

S. Kim, H. J. Ku, **J.-W. Park**
Kyungpook National University, Daegu, Korea

The tumor host microenvironment is increasingly viewed as an important contributor to tumor growth and suppression. Cellular oxidative stress resulting from high levels of reactive oxygen species (ROS) contributes to various processes involved in the development and progress of malignant tumors including carcinogenesis, aberrant growth, metastasis, and angiogenesis. In this regard, the stroma induces oxidative stress in adjacent tumor cells, and this in turn causes several changes in tumor cells including modulation of the redox status, inhibition of cell proliferation, and induction of apoptotic or necrotic cell death. Because the levels of ROS are determined by a balance between ROS generation and ROS detoxification, disruption of this system will result in increased or decreased ROS level. Recently, we demonstrated that the control of mitochondrial redox balance and cellular defense against oxidative damage is one of the primary functions of mitochondrial $NADP^+$-dependent isocitrate dehydrogenase (IDH2) that supplies NADPH for antioxidant systems. To explore the interactions between tumor cells and the host, we evaluated tumorigenesis between IDH2-deficient (knock-out) and wild-type mice in which B16F10 melanoma cells had been implanted. Suppression of B16F10 cell tumorigenesis was reproducibly observed in the IDH2-deficient mice along with significant elevation of oxidative stress in both the tumor and the stroma. In addition, the expression of angiogenesis markers was significantly down-regulated in both the tumor and the stroma of the IDH2-deficient mice. These results support the hypothesis that redox status-associated changes in the host environment of tumor-bearing mice may contribute to cancer progression.

Keywords: apoptosis, redox status, tumorigenesis.

The Cep192-organized Aurora A-Plk1 cascade is essential for centrosome cycle and bipolar spindle assembly

V. Joukov[1], J. C. Walter[2], A. De Nicolo[3,4]
[1]Department of Biological Chemistry and Molecular Pharmacology, [2]Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Howard Hughes Medical Institute, [3]Department of Cancer Biology, Dana-Farber Cancer Institute, [4]Department of Medicine, Harvard Medical School, Boston, MA, USA

Centrosomes are non-membrane-bound organelles of animal cells that function as the major microtubule (MT)-organizing centers (MTOCs) and participate in spindle assembly, cell division, polarity, and motility. Centrosomal abnormalities, both numerical and functional, have been linked to cancer and other diseases.

Centrosomes consist of one or two (depending on the cell cycle stage) centrioles surrounded by pericentriolar material (PCM). Prior to mitosis onset, the two centrosomes separate and grow dramatically, each forming a nascent spindle pole that nucleates a radial array of MTs. Centrosome growth (and the associated microtubule nucleation surge), termed maturation, involves the recruitment, via a hitherto unknown mechanism, of additional PCM components. Among them, the most prominent is the γ-tubulin ring complex (γ-TuRC), which serves as a MT template.

In *Xenopus* egg extracts, we found that the key regulator of centrosome biogenesis, Cep192, via its N-terminal domain, binds the two major mitotic serine/threonine kinases, Aurora A (AurA) and Plk1, and organizes them in a multistep signaling cascade that underlies centrosome maturation and culminates in MT assembly. Specifically, following their pericentrin-mediated recruitment to centrosomes, Cep192 complexes undergo local oligomerization/clustering, which promotes AurA activation via T-loop autophosphorylation. AurA then phosphorylates Plk1 in its T-loop, turning it on and facilitating its docking onto a conserved threonine in the N-terminus of Cep192. The active, Cep192-bound Plk1, in turn, phosphorylates Cep192 at several serine residues to generate the attachment sites for γ-TuRC and, possibly, other PCM components, thus promoting their recruitment and subsequent MT nucleation. Cep192 mutants lacking the binding sites for AurA, Plk1, or γ-TuRC failed to promote centrosome maturation and

© 2014 The Authors. FEBS Journal © 2014 FEBS

MT assembly in Cep192-depleted cycling egg extracts. Our Cep192 siRNA knockdown/rescue experiments in mammalian cells corroborated these results and demonstrated that the Cep192-organized AurA-Plk1 cascade is conserved in vertebrates and is essential for: i) centrosome maturation, ii) kinesin 5-mediated centrosome separation, iii) bipolar spindle assembly, and iv) equal centrosome/centriole segregation into daughter cells.

Our study unveils a Cep192-organized signaling cascade that underlies centrosome maturation and that is integral to the centrosome cycle and to bipolar spindle assembly in vertebrates. It also offers a framework for further dissection of the mechanisms of mitotic MTOC formation in a cell-free system.

The evaluation of cell viability and anticancer properties of calcium ions transported by electroporation into human breast adenocarcinoma cell lines: MCF-7/WT (wild type) and MCF-7/DX (resistant type)

K. Bieżunska- Kusiak[1], J. Saczko[1], J. Kulbacka[1], N. Rembiakowska[1], A. Choromańska[1], M. Dubińska-Magiera[2]
[1]Department of Medical Biochemistry, Wroclaw Medical University, [2]Developmental Biology Animal, Experimental Biology, Wrocaw, Poland

Calcium is an important factor that can play different functions in human organism, both systemically and within a single cell. It is both a primary and a secondary messenger which participates in many processes.

The main objective of the presented work was evaluation of cell viability and the investigation of anticancer activity of calcium introduced to malignant cells with electroporation into breast adenocarcinoma cell lines: wild type and doxorubicin-resistant type.

Two human adenocarcinoma cell lines were used: MCF-7/WT and MCF-7/DX. To electroporation following parameters were selected: 800, 1000, 1200 and 1400V/cm; by 8 pulses of 100 μs, pulse duration 1 Hz. The following calcium concentrations were applied: 0.25, 0.5, 1 and 5 mM. Due to viability analysis MTT assay. CLSM method was used to evaluate the effect of calcium and EP on cytoskeleton proteins: α-actin and β-tubulin.

The cytoskeleton studied indicated that cellular morphology after EP exposition only remained unchanged. The changes in the cytoskeleton and the nucleus were observed only when cells are treated with calcium solution and electroporated (weaker fluorescence signal actin and tubulin).

The best anticancer effect was observed after the application of EP + Ca^{2+}. The cell survival rate was lower in comparison with the method using only one. EP with calcium stimulated antitumor responses: after 24 h even 80% cells were eliminated (both cell lines). After 48 h the number of viable cells decreased significantly; in resistant-type cells survival reached 10%. The satisfactory results were obtained at higher voltages-1200 and 1400 V/cm (independent of the concentration of calcium). At lower voltages marked decline in survival occurred with 5 mM solution of calcium. Lower survival rate was observed after 48 h, especially at high voltages.

The application of EP does not cause changes in the cytoskeleton; even high intensity electric field (1400 V/cm) does not affect destructive to the cells. Only after the addition of calcium observed microtubules system disorders, and thus a weaker fluorescence signal.

EP or Ca^{2+} application alone did not cause such a strong antitumor effect. EP with a voltage 1400 V/cm induced changes in cellular viability especially after 48 h. MCF-7/WT cell lines were more sensitive to EP. EP assisted by calcium solution induced decrease of the amount of surviving cells even with 800 V/cm. In these conditions more sensitive occurred the line MCF-7/DX.

The obtained results present a preclinical study of electroporation application to introduce calcium as an efficient anticancer drug in cancer cells.

Keywords: calcium, cell cytoskeleton, electroporation.

The HERCulean E3 ligase HERC2 acts as a fate switch controlling the RB/E2F signaling network

D. H. Siepe[1], R. Pferdehirt[1], V. G. Anania[1], D. Kirkpatrick[1], P. K. Jackson[2]
[1]Department of Protein Chemistry, Genentech Inc., South San Francisco, [2]Department of Microbiology & Immunology, Stanford University School of Medicine, Stanford, CA, USA

The retinoblastoma tumor suppressor protein (RB) plays an integral role as a regulatory node controlling proliferation, quiescence and differentiation, the G1-S checkpoint control and consequently is a frequent target for inactivation in cancer. Post-translational modifications (PTM) play a critical role in modulating RB activity. Although multisite phosphorylation of RB by CDKs has been extensively studied, activities regulated by other PTMs remain largely enigmatic. Understanding the molecular mechanisms and effects of RB modulation by PTMs is therefore imperative.Here we identified HERC2, a giant (0.5 MDa) and highly-conserved member of the eukaryotic HECT E3 ligase family, acting as a fate switch by regulating the RB/E2F signaling network. We found that HERC2 associates with RB via it's RCC domain and modulates levels of RB in a cell cycle and phosphorylation dependent manner. Mechanistically, in quiescent (G0) cells the retinoblastoma tumor suppressor RB becomes a target of hypophosphorylated HERC2, which consequently leads to binding and subsequent proteasome dependent degradation of RB: low HERC2 activity results in accumulation of both RB and hyperphosphorylated RB (pRB) and therefore renders cells unable to exit the cell cycle and properly transition into quiescence. By contrast, high levels of HERC2 correlate with loss of RB/pRB. Furthermore, gene expression profiling and global proteome analysis reveal that loss of HERC2 concomitantly leads to a fundamental change in the transcriptional program downstream of RB/E2F with detrimental consequences for critical cell cycle licensing factors. Thus our findings suggest that HERC2 activity plays a pivotal role in regulating the balance of RB and therefore E2F mediated transcriptional control, cell cycle progression and cellular quiescence.

The impact of CAFFEINE mediated Cdc25 STABILIZATION on cell cycle kinetics in *Schizosaccharomyces pombe*

J. P. Alao, P. Sunnerhagen
Department of Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden

Caffeine has generated much interest, by virtue of its ability to override the replication and DNA damage checkpoints in both *Schizosaccharomyces pombe* (*S. pombe*) and mammalian cells. In *S. pombe*, cell progression and mitosis are regulated by Cdc2.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Mik1 and Wee1 negatively regulate Cdc2 by phosphorylating Tyr15. Conversely, Cdc2 is positively regulated by Cdc25 which dephosphorylates Tyr15. Proper activation and enforcement of checkpoints thus requires inhibition of Cdc25 and activation of Mik1 and or Wee1. Following its activation by stalled replication or DNA damage, Rad3 activates the downstream kinases Cds1 and Chk1. These kinases in turn, inhibit Cdc25 by phosphorylation and simultaneously activate Mik1 and Wee1. Previous studies suggested that caffeine ov errides checkpoints by inhibiting Rad3, the major regulator of the replication and DNA damage checkpoints in *S. pombe*. We recently demonstrated however, that caffeine induces the stabilization of Cdc25 contributing to the checkpoint override. Paradoxically, Caffeine also activates Sty1 leading to the phosphorylation and partial inhibition of Cdc25. To better understand how caffeine- induced Cdc25 stabilization contributes to checkpoint override, we compared its effect on the wt isoform of the phosphatase and a 12A mutant lacking all 12 inhibitory phosphorylation sites. We have also investigated the effect of caffeine on Mik1 and Wee1 stability. Additionally, we investigated the effects of Mik1 and Wee1 on the ability of caffeine to modulate Cdc25 activity during the normal cell cycle and following activation of the replication or DNA damage checkpoints.

Keywords: Caffeine, Cdc25 phosphatase, cell cycle.

The impact of tubulin heterogeneity on the biophysical properties of the microtubule cytoskeleton

S. Chakraborti[1], K. Scheffler[2], A. Wehenkel[1], P. Tran[2], C. Janke[1]
[1]Signalling Neurobiology and Cancer, Institut Curie, Orsay, [2]Department of Subcellular Structure and Cellular Dynamics, Institut Curie, Paris, France

Microtubules are subject to extensive heterogeneity due to expression of multiple tubulingenes and to posttranslational modifications. Our present understanding of how the diversity ofthe tubulin molecules affects microtubule functions is very limited. The bottleneck is the absence of experimental system that would allow direct measurements of the impact of tubulin heterogeneity on microtubule properties and functions. Thus, it is urgent to develop a system where recombinant tubulin can be generated and be used for functional and biophysical studies. Here we develop fission yeast as amodel system to express recombinant tubulin. Using this system, we will first focus onthe roles of tubulin C-terminal tails (CTT), their heterogeneity and posttranslational modifications. To get insights into the microtubule functions that are sensitive to tubulin heterogeneity, we will replace the yeast CTTs with different mammalian counterparts by expressing tubulin chimera, and study the microtubule phenotypes by live microscopy. We will also study the behavior of a set of microtubule interacting proteins in these cells.CTTs are major sites of posttranslational modification in higher eukaryotes and thus CTTs are critical regulator for microtubule function.We would like to explore the specific function of different regions CTTs in vivo using a systematic collection of point mutated tubulin in conjunction with tubulin-modifying enzymes in yeast cells, to (i) study the specificity of the enzyme, and (ii) investigate the potential roles of these enzymes in the regulation of microtubule functions.In parallel, we will optimize the yeast expression system to purify recombinant chimeric tubulin for *in-vitro* biophysical experiments.

The interaction between ELK-1 and mitotic kinases

O. Ari Uyar[1], Ö. Demir[2], E. Kon[3], I. Aksan Kurnaz[1]
[1]Genetics and Bioengineering, Yeditepe University-Biotechnology, Istanbul, Turkey, [2]Molecular Cell Biology and Genetics, Max Planck Institute, Dresden, Germany, [3]Mammalian Development and Cell Biology Unit, Université catholique de Louvain-Institute of Neuroscience, Brussels, Belgium

Elk-1 is a member of the ETS domain superfamily of transcription factors and involved in many biological processes, such as cell growth, differentiation, apoptosis, survival, angiogenesis and cancer. Activation of the Elk-1 requires phosphorylation, in particular on Serine 383 and Serine 389 residues within the activation domain, by ERK, JNK or p38 pathways and this activation was shown to induce its binding to DNA. However, when the Elk- 1 protein sequence was bioinformatically analyzed, a number of other potential phosphorylation motifs were identified, including consensus motifs for mitotic kinases Aurora and Plk. Mitosis is tightly regulated to prevent improper segregation of sister chromatids as any errors in this process leads to chromosomal instability, aneuploidy or even tumorigenesis. Mitotic kinases have pivotal roles during regulation of this mechanism as well as cell cycle progression, centrosome maturation and microtubule dynamics, which is pivotal for the formation of bipolar mitotic spindle and accurate segregation of chromosomes. It has been previously demonstrated in our laboratory that Elk-1 interacts with neuronal microtubules as well as motor proteins, dynein and kinesin, in a serum dependent manner. Furthermore, Elk-1 was shown to colocalize and interact with Aurora kinase. Such an interaction of Elk-1 with mitotic apparatus brings to mind a possible role during mitosis. In this study, we have shown that Elk-1 phosphorylated in some of these potential motifs was also colocalized with the mitotic spindle, using phospho-specific antibodies. We will discuss our findings on the interaction of Elk-1 with Plk and Cdk kinases.

Keywords: Elk-1, Kinases, Mitosis.

The p97-Ufd1-Npl4 ATPase complex ensures robustness of the G2/M checkpoint by facilitating CDC25A degradation

A. Dressler[1], A. Riemer[1], G. Dobrynin[1], S. Bremer[1], A. Soni[2], G. Iliakis[2], H. Meyer[1]
[1]Molecular Biology, University of Essen, [2]Institute for Medical Radiation Biology, University Hospital Essen, Essen, Germany

The p97-Ufd1-Npl4 ATPase complex is associated with the response to DNA damage and replication stress, but how its inactivation leads to manifestation of chromosome instability is unclear. Here, we show that p97-Ufd1-Npl4 has an additional direct role in the G2/M checkpoint. Upon DNA damage, p97-Ufd1-Npl4 binds CDC25A downstream of ubiquitination by the SCF-βTrCP ligase and facilitates its proteasomal degradation. Depletion of Ufd1-Npl4 leads to G2/M checkpoint failure due to persistent CDC25 activity and propagation of DNA damage into mitosis with deleterious effects on chromosome segregation. Thus, p97-Ufd1-Npl4 is an integral part of G2/M checkpoint signaling and thereby suppresses chromosome instability.

Keywords: checkpoint, DNA damage, ubiquitin.

The role of central carbon metabolism in the regulation of human DNA replication

A. Konieczna, A. Szczepańska, K. Sawiuk, R. Łyżeń, G. Węgrzyn
Department of Molecular Biology, University of Gdansk, Gdańsk, Poland

DNA replication is one of fundamental and important processes occurring inevery living cellular organism. The process of DNA synthesis has been thesubject of many works and is relatively well studied. However, the controlmechanisms of the regulation of this process remain poorly understood.Perturbations in the regulation of DNA replication lead to theaccumulation of harmful mutations, often leading to severe diseases, including cancer. Therefore, it seems important to investigate themechanisms that regulate this fundamental biological process. Experimentsperformed with bacterial models indicated that there is a direct linkbetween central carbon metabolism and regulation of DNA replication.Impairments in particular genes coding for enzymes involved in centralcarbon metabolism (CCM) influenced DNA replication.The aim of this study was to understand the global regulatory processesthat control DNA replication in eukaryotic organisms, and to answer thequestion whether such mechanisms are universal. Since glycolyticmetabolism of glucose is a major pathway for the generation of energy, andits intermediates serve as precursors for biosynthetic processes of thecell, our work was focused primarily on connection between glycolysis andDNA replication.The expression of particular isoforms of genes of the glycolysis pathwaywas reduced at the level of up to 95% by using siRNA. Then, thequantification of cell proliferation, based on the measurement of BrdUincorporation during DNA synthesis, was performed. Additionally, the cellcycle was analyzed with particular regard to the transition of the cellsinto the S phase. The most pronounced difference in the transition ofcells treated with siRNA into the S phase was observed in the case of thegene encoding glyceraldehyde 3-phosphate dehydrogenase (GAPDH), itamounted to about 50%. This result was also confirmed by the use of thecell proliferation assay. In the case of other glycolytic enzymes, however, the difference was also observed in some particular cases.Surprisingly, silencing the expression of the gene encoding the enzyme GPIresulted in enhancement of the replication phase.These results facilitate understanding of the correlation betweenmetabolic processes and DNA replication in eukaryotic cells. This can bepractically used in studies on carcinogenesis and its prevention as wellas in biotechnological use of cell cultures.

Keywords: DNA replication, glycolysis.

The role of HSP90 in quercetin-induced apoptosis in human papillary thyroid (B-CPAP) cancer cells

E. Mutlu Altundağ[1,2], T. Kasaci[1], A. M. Yilmaz[1,2], C. Corek[1,2], Y. Taga[1,2], A. Suha Yalcin[1,2]
[1]*Department of Biochemistry, School of Medicine, Marmara University, Istanbul, Turkey,* [2]*Genetic and Metabolic Diseases Research and Investigation Center, Marmara University, Istanbul, Turkey*

As in many other cancers, genetic alterations that occur in genes encoding for key proteins of major signalling pathways are the driving force for the tumorigenesis of thyroid cancer. HSP90 is an emerging therapeutic target of interest for the treatment of cancer and is responsible for modulating cellular response to stress by maintaining the function of signalling proteins. In this study, we have worked with B-CPAP, a thyroid papillary cancer cell line which is known to have BRAF V600E mutation. We have administered the flavonoid *Quercetin*, which is known to induce apoptosis by inhibiting HSP production on various cancer cell lines, at different concentrations (between 10 and 75 μM) for 24 hours. We have measured cell viability using WST-1 assay. We found that the viability decreases in a dose dependent manner. Then, we chose *Quercetin* concentrations between 10–75 μM for 24 hours, for the apoptosis and cell cycle analysis in flow cytometry by Annexin V and propidium iodide. We have also applied Hoechst (33342) stain to cancer cells for visualizing them on fluorescence microscopy and confirmed apoptosis with the presence of apoptotic signs in nuclei of cancer cells. Finally, we used Western blotting to compare HSP90 and Cleaved-PARP levels in cells treated with *Quercetin* and the control group. In the light of the obtained data, our results suggest that in future studies it would be useful to investigate the apoptotic mechanisms of *Quercetin* and use combinational therapies on BCPAP cells.

The *S. pombe* mitotic exit scaffold protein regulates mitotic entry

K. Y. Chan, M. A. Núñez, K. Tanaka, I. Hagan
Cell Division Group, Cancer Research UK Manchester Institute, Manchester, UK

Cdk1/CyclinB is the key regulator for mitotic entry. Cdk1/CyclinB is controlled primarily by the coordinated action of the Wee1 kinase and Cdc25 phosphatase. While the molecular basis of Cdk1/CyclinB activity is well characterised, how the initial activation is triggered is less clear. There is increasing evidence that events at the centrosome may play an important role. Work performed in fission yeast has shown that artificially activating Plo1 or Cdk1 at the yeast centrosome drives mitotic entry, overcoming some of the barriers to mitotic entry.

The fission yeast spindle pole body (SPB), analogous to the eukaryotic centrosome acts as a platform to regulate events that occur throughout the mitotic cell cycle. The SPB component, Cut12 play a key role as a regulator for mitotic entry because mutations disrupting its PP1 phosphatase binding site result in the bypass for the requirement for Cdc25 phosphatase activity for mitotic entry. Conversely, enhancing PP1 affinity for Cut12 with the loss of function mutant *cut12.1* blocks mitotic progression where only the older SPB is activated resulting in monopolar spindles. This monopolar phenotype can be rescued by increasing Cdc25 phosphatase activity. In contrast, the SPB component Sid4 is involved with signalling pathways that regulates mitotic exit. Mutations that disrupt Sid4 function such as *sid4.SA1*, leads to defects in cytokinesis resulting in multi-nucleate cells. Both Cut12 and Sid4 are scaffold proteins that act as a platform where a variety of proteins can be recruited in a context depend manner. Scaffold proteins are important as they allow for the integration of signals from multiple signalling pathways. We now report that a Sid4 loss of function mutant *sid4.SA1* rescues the mitotic commitment monopolar spindle phenotype caused by *cut12.1*. More importantly, we have isolated Sid4 mutants that rescue *cut12.1* monopolar spindle defect but are not defective in mitotic exit.

This suggests that Sid4 may play a role in mitotic entry and cross-talk involving Cut12 and Sid4 is important for the formation of a bipolar spindle.

Keywords: mitosis, Spindle pole body.

The stability of the binding of p53 protein to DNA. The importance of binding domains of p53

P. Sebest, H. Pivonkova, M. Fojta
Institute of Biophysics ASCR,V.V.I., Brno, Czech Republic

The tumor suppressor protein p53 is a transcription factor involved in regulation of crucial processes, like cell cycle and programmed cell death. It plays critical roles in preventing malignant transformation and maintaining genomic integrity. The function of p53 is closely related to its ability to bind DNA in sequence-specific manner via its core domain. The C-terminal domain has a regulatory function towards the sequence-specific DNA binding and is responsible for the ability of p53 to bind DNA structure-selectively.

We studied the interactions of full-length wtp53 protein and deleted p53 constructs (cΔ30 p53 (without last 30 amino acids), core domain, C-terminal domain) with different DNA substrates (supercoiled, sc or linear, lin DNA containing or lacking specific p53 target sequence – p53CON) towards increased salt concentrations using an immunoprecipitation assay on protein G magnetic beads. We observed an importance of binding domains of protein p53 and an influence of different antibodies on the stability of protein complexes with DNA. The preformed immunocomplexes of p53-DNA with DO-1 antibody (mapping to N-terminus, aa 21–25) and antibody mapping to C-terminus (Bp53-10.1, aa 375–379; Bp53-6.1, aa 381–390; PAb421, aa 371–380; ICA-9, aa 388–393) were exposed to various salt concentrations. The complexes were prepared in two ways: ad1) immunocomplexes of p53 with antibody were incubated with DNA followed uptaking by magnetic beads or ad2) p53 was incubated with DNA followed uptaking by magnetic beads with bound antibody.

We found differences between stability of p53-DNA complexes formed in different ways. The immunocomplexes of DO1-p53 (full lenght and cΔ30) with scDNA are stable at high concentration of salt. The blocking of C-terminus by antibody results in a destabilizing of p53 complexes with DNA at higher concentration of salt maybe due to conformational changes in p53.

Keywords: p53, binding stability, immunoprecipitation.

Theoretical studies and pharmacological characterization of a new antagonist 'C9' of vasopressin receptors

M. Martinez, J. Correa
Deparment of Pharmacology, National Polytechnic Institute, Mexico City, Mexico

G protein coupled receptors (GPCRs) are involved in a wide variety of physiological disorders. The vasopressin receptors are classified into V1, V2 and V3 subtypes. All these types of receptors are expressed in the central nervous system. However at the periphery, V1aR is mainly expressed in vascular smooth muscle cells and and hepatocytes, whereas V1bR is exclusively located in pituitary corticotrophs, and V2R is mainly expressed in the kidney.

Vasopressin receptor antagonists (VRAs) are drugs that block these receptors to treat diseases like hyponatremia, congestive failure, etc.

The synthesis of a new putative antagonist of vasopressin receptors (1-[(4-methyl phenyl)sulfonyl]-5-oxo-2,3,4,5-tetrahydro-1*H*-1-benzazepine-4-carbonitrile, named C9 was carried out in our group. Such compound was characterized through ^{1}H and ^{13}C nuclear magnetic resonance (NMR) and spectrometric mass.

Due to C9 has a moiety core similar to vaptans, theoretical studies were achieved using this compound on V1aR, whose three-dimensional (3D) model was built, refined through molecular dynamics simulations and validated through docking studies. With such studies we could determine the free binding energy values of this compound on such vasopressin receptor and the key amino acids involved in their molecular recognition.

Moreover, radio-ligand binding assays were performed to determine its pharmacological properties on the different vasopressin receptors: V1aR, V1bR and V2R to study selectivity of such compound. Firstly, saturation binding assays were carried-out using membranes expressing the human vasopressin receptors in order to obtain the maximun number or receptors (Bmax) and the affinity of the tritiated vassopresin (^{3}H AVP) for the different receptors (Kd). Furthermore, competition experiments were carried out to determine the inhibition constant (Ki) of this compound on the different vasopressin receptors. At the end of these assays we could determine that the affinity of C9 for the different vasopressin receptors is as follows: V2R>V1aR>V1bR.

Our studies will serve as basis for the design of new selective antagonists for the vasopressin receptors, for example by making some modifications on C9 compound in order to improve its affinity for any of the vasopressin receptors.

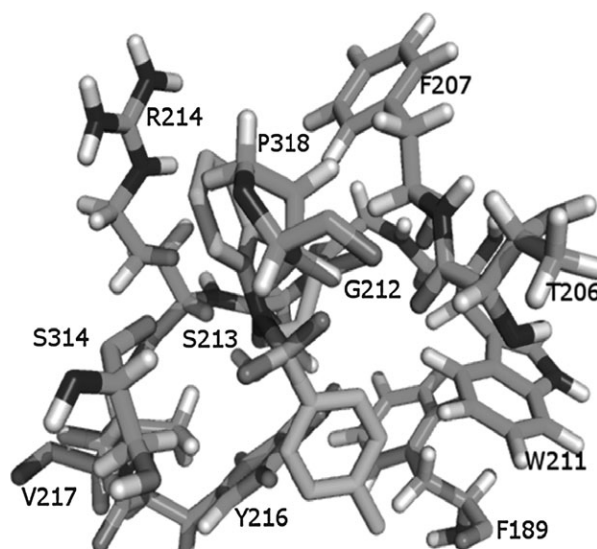

Fig. 1. Residues involved in the binding of C9 compound on V1aR.

Keywords: antagonist, drug design, vasopressin receptors.

Let-7 is involved in regulation of many cellular processes, such as proliferation and differentiation. In addition, let-7 has been iden-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tified as a tumor suppressor miRNA in various human tumor types. Excessive proliferation rate of tumor cells is often associated with chromosomal instability and mitotic defects. Spindle assembly checkpoint (SAC) works to maintain genomic balance by preventing chromosome segregation in the presence of mitotic spindle errors and chromosome misalignment. In cancer cells, SAC function may become compromised allowing chromosome missegregation and aneuploidy in daughter cells. In our study, we found that excess let-7b affects mitosis and SAC signalling in cancer cells by targeting Aurora B kinase. Let-7b binds to Aurora B kinase 3′UTR leading to suppression of the kinase mRNA and protein levels. The reduced Aurora B activity in let-7b overexpressing HeLa cells can lead to premature inactivation of SAC indicated by forced exit from microtubule drug induced mitotic arrest. In non-perturbed culture conditions, excess of let-7b resulted in multipolarity and aneuploidy. Interestingly, let-7b had an additive effect on the rate of polyploidy induction in cells together with a chemical Aurora B inhibitor. In vivo, significant negative correlation was observed between let-7b and Aurora B kinase expression in different breast cancer tumor grades. Aurora B was overexpressed in grade 3 tumors whereas let-7b was downregulated in grade 3 tumors as well as in the most aggressive breast cancers determined by clinicopathological markers. Our data suggests that increased let-7b expression can lead to reduction of Aurora B levels and thereby may suppress tumorigenesis.

Keywords: Aurora B, let-7b, mitosis.

Ubiquitin receptor protein UBASH3B determines mitotic localization of Aurora B

K. Krupina[1], C. Kleiss[1], T. Metzger[1], K. Hofmann[2], B. Fischer[1,3], N. Paul[1,4], O. Poch[4], L. Brino[1], I. Sumara[1]
[1]IGBMC, Illkirch, France, [2]Institute for Genetics, Cologne, Germany, [3]NIBR, Basel, Switzerland, [4]University of Strasbourg, Strasbourg, France

Mitosis ensures equal segregation of the genome to daughter cells, and defects in mitotic pathways can lead to aneuploidy and polyploidy, frequently observed in cancers. Ubiquitin attachment to substrate proteins regulates fidelity of mitotic division through proteolytic and non-proteolytic mechanisms. However, it remains unexplored how the fate of ubiquitylated substrates is determined during mitosis and what are the mitotic roles of intracellular ubiquitin receptors in mammalian cells. Using high content visual siRNA screening approach, we identified ubiquitin-binding domain (UBD) protein UBASH3B that critically regulates chromosome segregation, acting as a receptor for the key mitotic kinase Aurora B. Essential functions of Aurora B in chromosome segregation are dependent on its dynamic localization to centromeres and midzone microtubules. UBASH3B directly binds Aurora B, and this interaction is dependent on CUL3 E3-ubiquitin ligase and on ubiquitin recognition. Unlike known UBDs, transferring substrates for the proteolytic degradation, UBASH3B does not regulate protein levels of Aurora B. Instead, UBASH3B localizes to the mitotic spindle and is both required and sufficient to transfer Aurora B to microtubules. Our data also show that redistribution of Aurora B from centromeres to microtubules controls timing and fidelity of chromosome segregation and thereby euploidy of cells. Thus, our findings explain how ubiquitin attachment regulates localization and function of Aurora B, linking receptor-mediated ubiquitin signaling to mitosis.

Memantine changes lipids spectrum and lipid peroxidation in animal brain and plasma of patients with Alzheimer's disease

N. Snalina[1], **A. Alessenko**[1], S. Gavrilova[2], S. Gurianova[1], A. Prochorov[1], E. Kononova[1], Y. Fedorova[2]
[1]Institute of Biochemical Physics, [2]Mental Health Research Center, Moscow, Russian Federation

Alzheimer's disease (AD) leads to a dramatic decline in cognitive abilities and memory. Amyloid beta-protein (Abeta) and oxidative stress induced by proinflamatory citokines is thought to be main primary factors causing neurodegeneration in AD. At the moment the attention of many studies of neurons death mechanisms at Alzheimer's dementia concentrate on the function of lipids which is supposed to play a key role in amyloidogenesis and neuronal disfunction. There has been increasing interest in studying the effect of drugs using for AD treatment on lipid metabolism.

The main goal of our study was detection of influence of memantine – inhibitor of NMDA receptors- on changes in molecular species of phospholipids (phosphatidylcholine, lysophosphatidylcholine, sphingomyelin and phosphatidylethanolamine) and rate of lipids oxidation in blood plasma during treatment of patients with AD and changes in phospholipids and ceramide contents and level of lipids peroxides products in brain regions of mice (hippocampus, cerebellum and cortex).

This study included 18 pathients with AD. The plasma levels of total phospholipids and their molecular species were measured in plasma AD patients that were untreated (control) and were orally treated with memantin in dose of 20 mg daily during 6 months by chromato- electrospray ionization mass spectrometry screening.

Our results have shown that memantine considerably differentiated influence on phospholipids with various set of fatty acids and decrease oxidation rates of plasma lipids of AD patients in compare with untreated patients. It was shown that memantine obtains antioxidant properties. Given results reflect the ability of memantine to inhibit oxidative stress, induced in AD.

Changes in the level of phospholipids (phosphatidylcholine, lysophosphatidylcholine, phosphatidylethanolamine, sphingomyelin) and ceramides in hippocampus, cerebellum and cerebral cortex of mice brain within 4 and 24 hours after injection of memantin in doses of 20 mg per mice were detected by HPTLC. Maximal changes in sphingomyilins and ceramides after single administration of memantine were found in the hippocampus, and were less expressed in the cerebral cortex and cerebellum after 4 and24 hours. Memantine decreased level of ROS products in brain regions after 24 hrs. According to our results lipids may serve as a new target for memantine and may interfere with lipid metabolism in AD patients.

Keywords: Alzheimer's disease, ceramides, memantine.

1,25-dihydroxyvitamin D3 inhibits macrophage-induced inflammatory response in human adipocytes via NF-κB and MAPK pathways

C. Ding, C. Bing, J. P. Wilding
Obesity and Endocrinology, University of Liverpool, Liverpool, UK

Introduction: Obesity is characterised by the accumulation of macrophages in adipose tissue. As adipose tissue makes up the largest endocrine organ in the body, the increased accumulation of macrophages in adipose tissue in obesity is now known to be a major contributor of chronic systemic inflammation. Higher circulating levels of inflammatory mediators are strong risk factors for the development of metabolic disorders. 1,25-dihydroxyvitamin D_3 is the active metabolite synthesised from vitamin D_3 obtained from the diet or skin exposure to UVB radiation. It is suggested that 1,25-dihydroxyvitamin D_3 may have immunoregulatory effects and may reduce inflammation in adipose tissue. This study investigated the effects of 1,25-dihydroxyvitamin D_3 on macrophage-elicited inflammatory response in adipocytes and the signalling pathways involved.

Method: Human primary adipocytes were pre-treated with 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) (10 nM) for 48 h or vehicle control and then cultured with THP-1 (a human myelomonocytic leukaemia cell line) macrophage-conditioned (MC) medium (12.5% or 25% with adipocyte maintenance media) for 24 h. Cytokine release was measured by ELISAs, intracellular signalling proteins were determined by western blotting and monocyte migration was assessed using a chemotaxis cell migration assay.

Results: MC medium dose-dependently increased secretion of all cytokines and chemokines tested (27–368-fold; all $P < 0.001$) and all secreted levels were reduced by $1,25(OH)_2D_3$: IL-6 (29%, $P = 0.019$ and 34%, $P < 0.001$), IL-8 (43% and 26%, $P < 0.001$), MCP-1 (36%, $P < 0.001$ and 36%, $P = 0.002$) and RANTES (54% and 50%, $P < 0.001$) compared with controls. Monocyte migration elicited by the culture media of adipocytes treated with $1,25(OH)_2D_3$ was also decreased (21%, $P < 0.001$). $1,25(OH)_2D_3$ inhibited macrophage-induced activation of the NF-κB signalling pathway, increasing IκBα (2.7-fold, $P = 0.005$) and reducing phosphorylated NF-κB p65 (by 68%; $P < 0.001$). MAPK signalling activated by MC medium was also decreased by $1,25(OH)_2D_3$, with a downregulation of phosphorylated p38 MAPK (32%, $P = 0.005$) and phosphorylated p44/42 ERK (49%, $P = 0.001$).

Conclusion: The results suggest that 1,25-dihydroxyvitamin D_3 may be anti-inflammatory in adipose tissue, decreasing macrophage-induced release of proinflammatory cytokines by adipocytes and monocyte migration. The inhibitory effect of 1,25-dihydroxyvitamin D_3 on NF-κB and MAPK signalling pathways suggests there may be therapeutic advantages to vitamin D supplementation and enhancing its bioavailability within tissues.

Inflammatory signal pathway changes in midkine silenced and overexpressed rat alveolar macrophages

N. Yazihan[1], F. Sahin[2], on behalf of Ankara University, E. Kaya[1], E. Akcil[1], on behalf of Ankara University, M. Kacar[3], D. Mimiroglu[1], H. Mairbeurl[4], E. Baloglu[4], Ankara University
[1]Pathophysiology, [2]Microbiology, Ankara University Faculty of Medicine, Ankara, [3]Pathophysiology, Yeditepe University Faculty of Medicine, Istanbul, Turkey, [4]Sports Medicine, Heidelberg University, Heidelberg, Germany

Evidence obtained in intact animals and in primary cell cultures indicate that alveolar macrophages activated by hypoxia release mediator(s) into the circulation. Molecular mechanisms of the inflammatory reaction in hypoxia-induced lung injury are not well defined. Midkine is one of the molecules playing a significant role in the control of inflammatory processes and promotes cellular migration, proliferation and survival. In this study we aimed to evaluate effect of midkine in p38 MAPK and NFkb related signal pathways in alveolar macrophages in normoxia and hypoxia. Midkine expression in rat alveolar macrophage cell line NR8383 was silenced using midkine siRNA sequence primers and overexpressed. Quantitative RT-PCR assay was performed to quantify the mRNA expression of midkine. Cells were exposed to *K. pneumonia* lipopolysaccaride (LPS) in normoxic and hypoxic conditions to induce inflammation. Cytokine secretion, p38MAPK and NFkb levels were evaluated. Cell proliferation rate was higher in midkine overexpressed cells. Basal and LPS induced cytokine secretion levels were found increased in midkine overexpressed cells and decreased in midkine silenced cells. Our results showed that midkine is important for cytokine secretion functions and survival of alveolar macrophage cells.

This study was supported by TUBITAK-BMBF (SBAG108S262).
Keywords: alveolar macrophages, hypoxia-inducible factor-1 (HIF-1), Midkine.

2S Albumin from *Jatropha curcas* L.: structural characterization, and mapping of allergenic epitopes

L. M. Crespo, N. Deus-de-Oliveira, **O. L. Machado**
Laboratory of Protein Chemistry, Universidade Estadual do Norte Fluminense (UENF), Campos dos Goytacazes, Brazil

Increasing energy demand has contributed to the use of bioenergy consciousness. *Jatropha curcas* L., (physic nut) an oilseed, not edible, is mentioned as one alternative resource. This oilseed Euphorbia contains allergens belonging to the family of 2S albumin that need characterization. The 2S albumins are storage proteins present in seeds of various plants and the recognition of allergen epitopes is of fundamental importance to the development of new strategies for the elimination of allergens and the development of new drugs for the treatment of allergy. The aim of this study was to elucidate possible IgE-binding epitopes in Jat c 1, a 2S albumin allergen from *J. curcas*. Jat c 1 protein from *J. curcas* seeds was isolated by size exclusion chromatography (Sephadex G-50) followed by reversed-phase chromatography in a C_2C_{18} column. The partial primary structure of the 2S albumin was elucidated employing the automatic sequencing and its complete sequence was obtained by search in protein databank. From this primary structure were synthesized peptides (P1, P3, P4, P5, P6 and P8). Based on the prior knowledge that, the 2S albumin from *Ricinus communis* Ric c 1 and Ric c 3 posses amino acids (Glutamic [E] or Aspartic [D]) in the constitution of their allergenic epitopes, we seek the same amino acids in the primary structure of *J. curcas*. Synthetic peptides were treated with Woodward's Reagent K (WRK) a compound that reacts with the carboxylic acid grouping of these amino acids and their potential allergenic properties were investigated by rat mast cells degranulation assay. To prove the role of these amino acids, peptides were synthesized change Glu by Leucine residue (P1Leu, P3Leu, P5Leu, P6Leu e P8Leu). It was observed that the modified peptides and samples treated with WRK had a lower degranulation percentage compared to the initial sample. Immunoassays (ELISA) were done and allowed to detect and quantify the binding capacity of specific antibodies against Jat c 1. Molecular modeling studies were employed to identify the peptides in the three-dimensional structure of Jat c 1. We observed the presence of at least two glutamic acid residues in these peptides and demonstrated the fundamental role of these negative amino residues, in the IgE –binding. The sequences LEKQLEEGEVGS, P5 peptide and sequence VGSEDEARR, part of peptide P6, composes a random loop that is located in the most exposed part of the protein, probably this region is the most important epitope to the outbreak of allergic response.The recognition of allergen epitopes could be employed for the development of future vaccines and pharmacological agents for alergy terapy.
Keywords: 2s albumin, Allergy, *Jatropha curcas*.

SUN-067
5Alpha-tetrahydrocorticosterone: mechanisms of action of a new selective anti-inflammatory drug

A. Gastaldello, D. E. Livingstone, A. Abernethie, N. Tsang, B. R. Walker, K. E. Chapman, R. Andrew
University of Edinburgh, Edinburgh, UK

Glucocorticoids (GCs) are a highly effective treatment for inflammatory conditions. However, prolonged use causes serious side effects and more selective anti-inflammatory drugs are needed. A promising candidate is 5α-tetrahydrocorticosterone (5αTHB), a metabolite of the endogenous glucocorticoid, corticosterone (B). In studies in mice we have shown that 5αTHB is as potent as hydrocortisone in reducing inflammation in a model of irritant dermatitis, while not causing skin thinning. Here, the mechanisms of action of 5αTHB as a topical anti-inflammatory drug were investigated.

Right ears of C57Bl/6 male mice were treated for 6 or 24 h with the irritant croton oil alone (CO, 300 μg) or together with B or 5αTHB. Left ears were untreated. Swelling was assessed at cull by weighing ears. B was applied at its EC50 dose (6 h, 10 μg; 24 h, 5 μg) and the dose-response to 5αTHB (5–50 μg) was explored. Ears were frozen for myeloperoxidase (MPO) assay or qPCR, or formalin fixed for haematoxylin & eosin staining. Data are mean ± SEM expressed as % of response induced by CO (set to 100%); *P < 0.05 versus CO.

At 6 h, 5αTHB did not reduce swelling at any concentration. At 24 h 5αTHB decreased swelling to a similar extent to B, but at a five times higher dose (25 μg 5αTHB 65 ± 8%* versus 5 μg B 57 ± 4%*). Cellular and molecular responses were investigated at 24 h, comparing equipotent doses of steroids.

Under these conditions, B (5 μg) and 5αTHB (25 μg) reduced cellular infiltrate in ears (52 ± 4%* and 58 ± 4%* respectively), and decreased MPO activity, a measure of granulocyte infiltration (68 ± 4%* and 39 ± 3%* respectively). B and 5αTHB reduced amounts of mRNA encoding the pro-inflammatory cytokines IL1β and INFγ (B 25 ± 5%* and 51 ± 7%*, 5αTHB 31 ± 13%* and 59 ± 10%* respectively), and decreased abundance of *Vegfα*, *Icam1* and *Pecam1* mRNAs (B 55 ± 5%*, 67 ± 6%* & 68 ± 5%*; 5αTHB 68 ± 5%*, 65 ± 3%* and

© 2014 The Authors. FEBS Journal © 2014 FEBS

67 ± 5%* respectively), encoding factors that modulate vasculature permeability and inflammatory cell recruitment.

Classical GC anti-inflammatory effects are mediated by the glucocorticoid receptor (GR). To establish if 5αTHB effects are mediated via GR, the experiment was repeated in adrenalectomised mice given a subcutaneous injection of RU486 (a GR antagonist; 0.5 mg/mouse), 15 min before topical application of CO or CO + steroid. RU486 limited the effect of B on ear swelling (5 μg, B 40 ± 9% versus B+RU486 82 ± 17%; $p < 0.05$) but did not prevent the effect of 5αTHB (25 μg, 5αTHB 51 ± 4% versus 5αTHB+RU486 54 ± 9%).

In conclusion, B and 5αTHB target similar pathways to reduce skin inflammation. However, 5αTHB acts more slowly than B and is not antagonised by RU486. These differences may underpin the selective actions of 5αTHB and indicate an alternative mode of action from conventional GCs.

8-hydroxy-2′-deoxyguanosine, malondialdehyde and protein carbonil levels as indicators of oxidative stress in patients with sickle cell anemia

H. Ecevit[1], O. Ozcan[2], M. Izmirli[1], Y. Can[2], A. B. Gurpinar[2], **O. Ozturk**[3]

[1]Molecular Biochemistry and Genetics, Mustafa Kemal University Health Sciences Institute, [2]Biochemistry, Mustafa Kemal University Medical Faculty, Hatay, [3]Biochemistry, Akdeniz University Medical Faculty, Antalya, Turkey

Background: Hemoglobinopathies are the most common genetic diseases in Cukurova region, south of Turkey. Sickle cell anemia and beta-thalassemia are prevalent in this region. The oxidative phenomena play a significant role in its pathophysiology. This study was performed in order to determine 8-hydroxy-2′-deoxyguanosine (8-OHdG), Malondialdehyde (MDA) and protein carbonyl (PC) levels as indicators of oxidative stress from serum samples of SCA patients.

Methods: Patients, who suffer from SCD (n = 45), and healthy controls (n = 38) under the age of 18 were included the study. 8-OHdG levels were measured by ELISA method, MDA and PC levels were measured by spectrophotometric method from serum samples.

Results: 8-OHdG ($p < 0.05$) PC and MDA ($p < 0.001$) levels were higher in SCA group when compared with the control group.

Conclusion: Elevated 8-OHdG (forms as a result of oxidative modification of guanine in DNA structure), MDA (the product of lipid peroxidation) and PC (occurs as a result of protein oxidation) levels in patients with SCA support the agreed evidence that oxidative stress is very crucial for pathophysiology of SCA.

Keywords: 8-hydroxy-deoxyguanosine, Oxidative Stress, Sickle Cell Anemia.

A (S)-(+)-decursin derivative, (S)-(+)-3-(3,4-dihydroxy-phenyl)-acrylic acid 2,2-dimethyl-8-oxo-3,4-dihydro-2H,8H-pyrano[3,2-g]-chromen-3-yl-ester, attenuates the development of atopic dermatitis-like lesions in NC/Nga mice

I. S. Kim[1,2], S. Y. Baek[1], E. J. Kim[1], D.-H. Kim[3], C.-Y. Yun[4], J.-S. Lee[5]

[1]Department of Senior Healthcare, BK21 Plus Program, Graduated School, [2]Biomedical Laboratory Science, Eulji University, [3]Pathology, [4]Biology, Daejeon University, Daejeon, [5]Wonkwang Health Science University, Iksan, Korea

(S)-(+)-decursin is a biological coumarin compound isolated from *Angelica gigas Nakai*. (S)-(+)-decursin and its analogue have a variety of pharmacological activities. In the present study, the anti-inflammatory effect of a (S)-(+)-decursin derivative, (S)-(+)-3-(3,4-dihydroxy-phenyl)-acrylic acid 2,2-dimethyl-8-oxo-3,4-dihydro-2H,8H-pyrano [3,2-g]-chromen-3-yl-ester (Compound 6, C6), on in vitro and in vivo atopic dermatitis was investigated. C6 suppressed the secretion of IL-6, IL-8, and monocyte chemotactic protein-1 increase by the house dust mite extract in the eosinophilic leukemia cell line and THP-1 cells. C6 inhibited the production of TARC, IL-6, and IL-8 increase by IFN-γ and TNF-α in the human keratinocyte cell line. In the in vivo experiment, NC/Nga mice were sensitized to 2,4-dinitrochlorobenzene, and then C6 or dexamethasone (Dex) were orally and dorsally administered for three weeks. C6 treatment reduced the skin severity score compared with that of the control group. C6 inhibited the thickening of the epidermis and inflammatory cell infiltration into the dermis by evaluating the histological examination. The serum immunoglobulin E (IgE) level decreased in the C6–treated group compared with that of the control group. The inhibitory effect of C6 on IgE concentration was similar to that of Dex. Taken together, C6 may attenuate atopic dermatitis-like lesions through its anti-inflammatory effect, such as inhibition of IgE and inflammatory cytokines, and it may be valuable as a therapeutic drug for the treatment of atopic dermatitis.

[1]Institute for Genetics, University of Cologne, Cologne, [2]Physical Chemistry, Ruhr-University Bochum, Bochum, Germany

Guanylate-binding proteins (GBPs) are interferon-inducible large GTPases of the dynamin superfamily. Recent data show that human and murine GBPs mediate antimicrobial resistance against

© 2014 The Authors. FEBS Journal © 2014 FEBS

intracellular pathogens at multiple levels. Several GBPs are subjected to C-terminal isoprenylation. In the case of human GBP1 the CaaX motif serves as a signal for farnesylation, which is necessary for the recruitment to cellular membranes. In addition to that, our research revealed that the lipid modification changes the nucleotide binding and GTP hydrolysis activity of hGBP1.

Both factors, i.e. the lipid modification as well as the GTPase activity are important for the association with membranes, which only occurs in the activated state. Therefore, we have established a fluorescence assay to monitor this transient membrane association of lipid-modified hGBP1 during GTP hydrolysis in real time. Using this assay we show that solvent exposure of the farnesyl anchor is significantly increased in the activated state and during GTP hydrolysis enabling transient membrane binding of hGBP1. Inversely, this interaction of the protein with membranes has an influence on the hydrolytic activity. We therefore conclude that the farnesyl anchor is switchable and regulated by the nucleotide state of the GTPase domain.

Furthermore, fluorescence microscopy of hGBP1 together with several endo- and phagolysosomal markers revealed that human GBP1 localizes to diverse endo-lysosomal compartments and is recruited to phagosomes during the uptake of latex beads. Transient and fast dynamics could also be observed on the intracellular level. Applying Fluorescence recovery after photobleaching (FRAP) revealed a fast and constant activation-dependent exchange of hGBP1-molecules on membranes along the phagolysosomal compartment.

Keywords: Antimicrobial activity, GTPase, Membrane interaction.

A longitudinal study to examine the exome of a good responder CML patient under imatinib at diagnosis and under remission

A. R. Chacko[1], S. Patil[1], S. Srivastava[2], D. Arya[1,3], A. Upadhayay[1], A. Nagrajan[1], C. Ross[2], S. Krishna[1], R. Sowdhamini[1]

[1]National Centre for Biological Sciences, [2]St. John's Medical College and Hospital, Bangalore, [3]Manipal University, Manipal, INDIA

Very few genomic studies have looked at the progression of cancer with treatment. We have undertaken a longitudinal case study by carrying out the exome sequencing of a patient with Chronic Myeloid Leukemia (CML). We attempt to understand from a genomics perspective, the changes in the exome of a CML patient in response to imatinib. This will enable us to look at the genetic makeup of CML patients that make them sensitive to lower dosage. Ultimately this will help in better prognosis and precision medicine for this category of patients who are better responders to imatinib.

Our study involves a patient with BCR–ABL positive CML who had been diagnosed in the blast stage. Subsequent to treatment with Imatinib, the subject is now responding to a dosage as low as 200 mg per a day, lower than the recommended 400 mg/day. At the end of three years, there has been no progression of disease with the bone marrow aspirate and biopsy being normal and the BCR-ABL transcript being below detectable levels. We have the used the bone marrow aspirate of this unique responder CML patient at the stage close to diagnosis and two years post treatment (remission) for exome sequencing. Matched skin biopsy was used as a control. This study has been approved by the Institutional Ethical Review Board of St. John's Medical college and Hospital.

We observe genome instability with time in terms of single nucleotide variants (SNVs) and insertions and deletions (indels). The SNVs picked up by exome sequencing were contrasted at the stage of diagnosis and post treatment and compared to dbSNP, allowing retention of only novel SNPs. This finally gave rise to three discreet sets of SNVs to consider: Unique in the genome of the patient at 1) Diagnosis 2)Post treatment, and 3)Persisting throughout the longitudinal study. The non-synonymous coding mutations with high confidence of call of SNP were shortlisted for validation by Sanger sequencing. These shortlisted ones were prioritized based on their relevance in CML via involvement in apoptosis, cancer signaling and cell differentiation. The novel mutations were mapped on the protein structure where possible to provide insight from a structural basis for the deleterious effects of such mutations. These mutations, after validation by Sanger sequencing will be tested in a cohort with similar prognosis to be validated as a probable marker for screening patients. We hence attempt to understand this clinical case with an integrated view involving basic experimental biology, bio-informatics and structural biology.

A prospective role of citrate treatment for PKC β II inhibition in hyperglycemia-damaged endothelial cells

A. Gryn, G. Bazylak
Department of Pharmaco-Bromatology & Molecular Nutrition, Faculty of Pharmacy, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

Introduction: Organic acids present in *Morus alba* (Moraceae) possess multiple biological effects. Scientific reports have been focused on flavonoids, which have always been considered to be the most crucial rich elements responsible for the pharmacological effects in *M. alba* leaves, while low molecular weight organic acids (LMWOA) were forgotten.

Background: Endothelial dysfunction is a potential contributor to the pathogenesis of cardiovascular disease. Chronic hyperglycemia is an important factor which plays a major role in induced vascular endothelial damage. Elevated glucose levels lead to increase the content of diacylglycerol (DAG), an activator of the protein kinase C (PKC), which plays a key role (particularly PKC β II) in the etiology of diabetic vascular complications [1]. Some recent studies demonstrated the crucial function of citrate treatment of cardiovascular-damaged cells (cardioprotective, anti-inflammatory, anti-platelet aggregation) but predominantly on the hyperglycemia-damaged endothelial cells (HDEC). Residual reports informed that citric acid may be responsible in HDEC for decreasing PKC β II expression down to background level and mitigates process of apoptosis and necrosis [2].

Obtained Results: The objective of our study were to evaluate the therapeutic efficacy of aqueous extracts from various genotypes of *M. alba* leaves for hyperglycemia-damaged cardiovascular endothelial cells. Such extracts are used in some countries as a pharmaceutical materials possessing cardioprotective and antidiabetic activity and known as a rich source not only phenolic compounds but also LMWOA. Thus, our assays included determination of *M. alba* metabolites, antioxidant activity (IC_{50}), the total flavonoids and polyphenols content. Our research [3] revealed that citric acid is the predominant constituents among LMWOA (17.05 mg/mL), representing 25.68% all of them. Furthermore, we determined that citric acid occurs in higher quantities than the total flavonoids (12.25 mg/mL) and polyphenols content (17.46 mg/mL). The antioxidant ability of *M. alba* leaves extract scavenging the DPPH radical measured as IC50 varied significantly from 0.80 to 1.16 mg/mL. Carried studies so far are extremely promising and they are required to be continued.

Future Experiment: The last stage of our experiment will be an assessment of protective and anti-inflammatory activity of citric acid obtained from *M. alba* leaves carried on the Human Aortic Endothelial Cells (HAEC) lines.

A rapid and reproducible standardized procedure for MALDI-TOF profiling of gingival crevicular fluid

M. Preianò, G. Maggisano, D. Falcone, S. Paduano, R. Savino, R. Terracciano
Health Sciences, University Magna Graecia of Catanzaro, Catanzaro, Italy

Gingival crevicular fluid (GCF) has captured an increasing interest for its potential diagnostic and prognostic value in periodontal diseases. Comparative MALDI-TOF MS analysis of GCF between healthy and periodontal diseases subjects may help in monitoring changes of expression patterns of disease specific peptides and proteins. However, the sub-microliter volumes of GCF obtained from healthy subjects limit significantly proteomic analysis. As a part of an ongoing project aimed to identify disease-related biomarkers in biological fluids [1–3], in this study we describe a rapid and standardized procedure to obtain reproducible MALDI-TOF MS peptidome profiles from the limited volume of GCF obtained from clinically healthy gingival tissue. We carefully evaluated analytical variables during sample collection and sample processing which could significantly influence the quality and the reproducibility of MALDI-TOF profiles. GCF was collected from the four maxillary incisors in 4 healthy subjects according to two common sampling techniques based on the use of paper strips and paper points in a sampling time of 30 seconds. To measure the amount of GCF we introduce the use of analytical balance as a method for the differential weighing of the device before and after the fluid collection. Contrary to staining techniques, that may induce fluid evaporation end errors in measurements [4], this approach is able to estimate very small amounts of fluid with higher accuracy and, unlike dental instrument such as the electronic measuring device Periotron®, the analytical balance is easily available in many research laboratories, thus making this protocol feasible in a larger number of laboratories. Peptides and proteins were extracted by centrifugal elution in different acidic solutions with and without protease inhibitor cocktail. MALDI-TOF MS analysis was performed varying matrix composition. We found that MALDI-TOF fingerprints of GCF were most largely influenced by extracting solution and matrix composition. In conclusion, we proposed a rapid and an optimized procedure enabling the generation of qualitative and reproducible MALDI-TOF fingerprints from limited volume of GCF which could be useful for high-throughput screening for the identification of peptide-biomarkers of gingival inflammation.

A recombinant human IgM crosses blood brain barrier, promotes survival and protects spinal cord anterior horn cells in two transgenic murine models of amyotrophic lateral sclerosis

B. Wootla[1], A. Denic[1], X. Xu[1], L. R. Jordan[2], N. J. Wittenberg[2], A. E. Warrington[1], J. O. Watzlawik[1], L. J. Zoecklein[1], L. M. Papke[1], S.-H. Oh[2], M. Rodriguez[1,3]
[1]Neurology, Mayo Clinic, Rochester, [2]Laboratory of Nanostructures and Biosensing, University of Minnesota, Minneapolis, MN, [3]Immunology, Mayo Clinic, Rochester, MN, USA

Amyotrophic lateral sclerosis (ALS) is a severe progressive, neurodegenerative disease. There is increasing evidence that inflammation accompanies the death of motor neurons in ALS. However, anti-inflammatory strategies to treat ALS yielded no results, suggesting that targeting just inflammation is not sufficient to improve ALS phenotype. An elusive goal of neuro-protection is a reagent effective across multiple diseases. Our laboratory discovered human monoclonal antibody (sHIgM12) that binds to the surface of neurons and promotes remarkable neurite outgrowth. The recombinant version, rHIgM12, binds to the ganglioside GT1b with high affinity by TLC. We demonstrated a therapeutic role for rHIgM12 in a murine model of demyelination with axon loss. Here we expand the use of this natural human IgM as a strategy to treat murine models of ALS. SOD1*G86R and SOD1*G93A transgenic mice were obtained from the Jackson Laboratory (Bar Harbor, ME, USA). We first verified that rHIgM12 crosses the blood-brain barrier (BBB). To this end we generated ^{35}S-labeled rHIgM12 antibody and treated wild type and SOD mice. ^{35}S-rHIgM12 was found in the CNS in both 90-day old SOD1 mice and wild type mice. In sick SOD1 transgenic animals, a 0.03%> to 0.2% >dose was detected in CNS 20 hr after administration. In a blinded study, 8-week animals received i.p., 200 µg of rHIgM12, or isotype-control human IgM that does not bind to neurons or saline. Interestingly, the single 200 µg dose of rHIgM12 treated before the onset of deficits increased survival in the two independent genetic-based mutant SOD1 mouse strains by 8 and 10 days (Fig. 1). Importantly, the increased lifespan correlated with improved function (for 16 days) assessed by continuous monitoring of spontaneous activity. Finally, rHIgM12 preserved spinal cord axons and neurons of the anterior horn. We validated the specificity of rHIgM12 to gangliosides presented in a membrane platform by nanohole SPR. rHIgM12-GT1b SPR-binding curves were fit to a biphasic exponential model. The apparent dissociation constant (K_D), calculated for rHIgM12 to GT1b was 24.8 ± 7.9 nM, values suggestive of a strong binding. To our knowledge, this is the first demonstration that a single dose of a fully recombinant human monoclonal neuron-binding antibody is efficacious in a model of demyelination with axon loss and in increasing survival of two transgenic models with an ALS phenotype.

Abnormal correlation between COX activity and prostaglandin E2 level in colon tissue of rats fed diet containing bioactive substances

D. Kamola, J. Wilczak
Faculty of Veterinary MEdicine, Warsaw University of Life Sciences, Warszawa, Poland

Inflammation and colon cancer are very important problem in human public health. One of the most effective methods of colon diseases prevention is diet and regular physical exercises. Cyclooxygenase (COX) is an enzymatic complex responsible for formation of important biological mediators called prostanoids, such as prostaglandins, prostacyclin and thromboxane. Prostaglandin E2 is one of the most important prostanoids taking part in modulation of inflammation process.

The aim of the present study was to evaluate the influence of long-term complex supplementation of diet with bioactive compounds on COX activity and prostaglandin E2 (PGE2) level in rats' colon tissue. The following sources of bioactive substances were used: puree from pumpkin (*Cucurbita maxima*) as a source of -carotene and prebiotics fiber, hydrolysed water extract from linden (*Tilia cordata*) inflorescence as a source of flavonoids, rapeseeds oil, salmon fat as a source of DHA, EPA and other n-3 and n-6 fatty acids and two strains of bacteria with proven probiotic properties: *Lactobacillus acidophilus* LA-5 and *Bifidobacterium animalis* ssp. lactis BB-12.

8-weeks old Spraque–Dawley rats were fed for 14 months with standard semi-synthetic diet (control), which was enriched with above mentioned sources of bioactive substances (experimental group). After 14 months first group was sacrificed and examined.

The enzyme-linked immunosorbent assay (ELISA) analyses revealed that the diet supplementation with investigated bioactive substances caused statistically significant decrease of COX activity (t-test, $p < 0.05$), but the level of PGE2 in that same tissue significantly increased (t-test, $p < 0.05$).

The presented study assessed the potential protective effect of diet supplemented with bioactive compounds against inflammation in colon tissue. Data received showed decreased COX activity and decreased levels of other investigated inflammation markers (data not presented) in rats receiving the supplemented diet, which confirms its protective activity. The observed increase in PGE2 concentration in colon tissue was surprising, because PGE2 is synthesized via biotransformation of arachidonic acid by COX enzymatic complex. Available literature data confirm our findings, showing that all used bioactive substances have the ability to decrease COX activity. We hypothesize that the observed unexpected increase in PGE2 concentration and

© 2014 The Authors. FEBS Journal © 2014 FEBS

reversed correlation between COX activity and PGE2 level may results from interactions between bioactive compounds, but the mechanisms of this process remains unknown, and requires further research.

Activation of TLR4 induces VEGF expression via Akt pathway in nasal polyps

J.-H. Park[1], J.-S. Cho[1], J.-Y. Um[1], J. A. Kim[1], H.-M. Lee[1,2]

[1]Biomedical Science, [2]Department of Otorhinolaryngology-Head and Neck Surgery, College of Medicine, Korea University, Seoul, Korea

Background: Nasal polyposis is characterized by tissue remodelling and oedematous nasal mucosa. Vascular endothelial growth factor plays a significant role in the regulation of remodelling in nasal polyps. TLR4 activation is associated with VEGF expression in murine macrophages and odontoblasts.

Objective: This study aimed to evaluate whether lipopolysaccharide, an inducer of TLR4, stimulates VEGF expression and to determine the mechanism underlying VEGF production in nasal polyps.

Methods: Nasal polyp-derived fibroblasts were isolated from 10 patients with nasal polyps and exposed to LPS. LPS from Rhodobacter sphaeroides was used to inhibit the expression levels of TLR4, MyD88 and VEGF. Messenger RNA expression levels of TLRs, MyD88 and VEGF were determined by gene expression microarray and semiquantitative reverse transcription-PCR. Protein expression levels of TLR4 and VEGF were analysed using western blot, immunofluorescence staining and enzyme-linked immunosorbent assay. Activation of MAPKs and Akt was examined using western blot analysis. The expression level of VEGF was measured by ELISA and western blot analysis in ex vivo nasal polyp organ culture.

Results: The protein expression level of VEGF was increased in nasal polyp tissues compared with inferior turbinate tissues. LRS inhibited the mRNA and protein expression of TLR4, MyD88 and VEGF in LPS-stimulated NPDFs. LPS-activated MAPKs and Akt signals, whereas MAPK inhibitors did not inhibit VEGF expression, and only Akt inhibitor blocked VEGF production. LRS reduced the production of VEGF in LPS-stimulated ex vivo organ culture.

Conclusions and Clinical Relevance: These results suggest that LPS stimulates the production of VEGF through the TLR4-Akt signalling pathway in nasal polyps. LPS may be involved in the pathogenesis of nasal polyp remodelling.

Keywords: nasal polyposis, TLR, VEGF.

Adenosine affects the slit diaphragm and podocyte cytoarchitecture

R. San Martín, C. Jaramillo, S. Alarcón, C. Quezada

Instituto de Bioquimica y Microbiología, Universidad Austral de Chile, Valdivia, Chile

Introduction: Diabetic Nephropathy (DN) continues being the major cause of terminal kidney disease worldwide, and it remains incurable. It is well known that DN progresses with alterations of the podocyte cells function. The most remarkable feature is the deterioration of the filtration barrier leading to proteinuria. Interestingly, the nucleoside adenosine increases locally during progression of diabetic glomerulopathy, most likely affecting podocyte cells function. Our aim was to determine the role of adenosine on the physiology of this cell type.

Methods: Glomeruli were isolated from male rats by a differential sieving method. Podocytes were primary cultured and used at passage 2. Glomeruli or podocytes were exposed to adenosine 10 μM and MRS1754 50 nM, a selective antagonist of adenosine A_{2B} receptor subtype. Fluorescence microscopy was used to evidence cell type specific markers and evaluate fibrillar actin staining using phalloidin-FITC. Activated RhoA was measured using a pull-down coupled to western blot system. The expression of adenosine receptors and integrin α3 were measured using western blots. Differences in protein composition of slit diaphragm-enriched fractions were determined by comparative shotgun proteomics using spectral count data and Quasi-Likelihood modeling. Experimental diabetes was induced in rats using streptozotocin (65 mg/kg). Following two months, diabetic rats were treated with MRS1754 (i.p. 0.2 mg/kg) or vehicle for 4 weeks. Urinary proteins and creatinine were quantified by the Pyrogallol red-molybdate method and Jaffe reaction, respectively, and proteinuria expressed as the ratio.

Results: Exposure of podocytes to adenosine 10 μM triggered a biphasic response consisting of a transient induction of actin stress fibers and the activation of RhoA GTPase, whiles long term exposure led to a loss of fibrillar actin and cell transition to an elongated morphology. Correspondingly, long term exposure to adenosine decreased the expression of the adhesion integrin α3 and increased adenosine A_{2B} receptor subtype. All these effects were blocked using a selective antagonist of the adenosine A_{2B} receptor. Furthermore, the protein composition in a slit diaphragm-enriched fraction derived from glomeruli was changed following exposure to adenosine, suggesting altered interaction with cytoskeleton. In vivo blockage of adenosine A_{2B} receptor inhibited the increased levels of proteinuria in diabetic rats.

Conclusions: Adenosine mediates the induction of a motile phenotype in podocytes in vitro. This effect affects the integrity of the glomerular filtration barrier because in vivo intervention using an adenosine A_{2B} receptor antagonist ameliorates the proteinuria in diabetic animals.

Age-linked spontaneous rat prostate inflammation is concomitant with an increase in the expression of several specific pro-inflammatory cytokines

J. M. Fernandez Novell[1], M. M. Rivera del Álamo[2], L. Ferré-Dolcet[2], J. E. Rodríguez-Gil[2]

[1]Biochemistry and Molecular Biology, University of Barcelona, Barcelona, [2]Animal Medicine and Surgery, Autonomous University of Barcelona, Bellaterra, Spain

Age-linked spontaneous prostatitis (ASP) is an inflammation of the prostate. This disease in men is characterized by irritative voiding symptoms, and sexual dysfunction. It is known that histological prostate inflammation analysis shows neutrophils, lymphocytes, macrophages and plasma cells infiltrates. In fact, this type of inflammation is in itself of low risk. However, its importance lies in the fact that a few epidemiological studies indicate that ASP is associated with increased risk of prostate cancer. Taking this into account, our main aim was to determine if the appearance of ASP is concomitant with changes in the presence of any tissue inflammatory marker. For this purpose, prostatic tissues from healthy rats (Wistar rats are a good model for studying and comparing prostate inflammation disease) were taken and a mini-array analysis of 21 specific cytokines was carried out. Rats were divided into two groups. The first group com-

© 2014 The Authors. FEBS Journal © 2014 FEBS

prises 5 animals with a body weight of 187.4 ± 9.8 g (young adult rats). The second group was formed with 8 rats with a body weight of 371.8 ± 21.8 g (adult rats). Simultaneously, a standard histological analysis of prostatic tissue was performed in order to determine the presence of ASP. Histological analyses revealed that all of the analysed adult rats, but none of the young adult ones, showed the presence of ASP in their prostate samples. Concomitantly, prostate from adult rats showed a significant ($P < 0.05$) increase in the specific expression of cytokines PDGF-AA (increase of about 90%), TIMP-1 (increase of about 80%), Cd86 (increase of about 55%), NGF (increase of about 45%), CINC-3 (increase of about 50%) LIX (increase of about 60%) and VEGF (increase of about 60%). These results indicate that ASP is associated with and specific and significant increase in the expression of several important cellular inflammatory mediators.

Keywords: Inflammation, prostate, age.

AGE-RAGE induced oxidative alterations associated with diabetes complications are modulated by heat shock proteins

L. Stanca[1,2], O. I. Geicu[1,2], F. Barbuceanu[2], A. Dinischiotu[1], A. I. Serban[2]

[1]Department of Biochemistry and Molecular Biology, Faculty of Biology, University of Bucharest, [2]Preclinical Sciences, Faculty of Veterinary Medicine, University of Agronomical Sciences and Veterinary Medicine Bucharest, Bucharest, Romania

Diabetes complications are generally accompanied by up-regulated expression of receptor for advanced glycation end products (RAGE). This acts as a mediator of AGEs deleterious effects.

Our aim was to identify a link between the heat shock proteins (Hsp) levels and oxidative changes leading to diabetic nephropathy.

Human embryonic kidney cells were exposed for 12, 24 and 48 h to 200 μg/ml glycated-bovine serum albumin (AGE-BSA). RAGE expression augmented in a time -dependent manner, with maximal increases of 2.25 fold in mRNA levels and 2.01 fold in protein expression after 48 h. RAGE activation is known to trigger pro-inflammatory signaling pathways and reactive oxygen species (ROS) production. Consequently, the reduced glutathione pool depleted by 70% after 48 h, hindering the cellular anti-oxidative defenses.

The superoxide dismutase (SOD) activity increased in a time dependent manner by 18%, 30% and 33% after 12 h, 24 h respectively 48 h. SOD zymography revealed that after 12 h of exposure, Cu,Zn SOD contribution to the total SOD activity was more significant than Mn SOD one, whereas after 48 h the two isoenzymes contributed equally. After 24 and 48 h advanced lipid peroxidation end products (MDA) raised by 75% and 129% respectively. Catalase activity increased over 200% after 12 h and remained over 50% higher than controls thereafter. In contrast, glutathione peroxidase activity increased in a time dependent manner, after 48 h, being higher by 50% compared to control, probably due to its involvement in MDA detoxification. Glutathione reductase and glucose 6-phosphate dehydrogenase activities increased only after 48 h by about 35%, probably under Hsp 70 chaperone action.

The Hsp70 maximal mRNA levels of 2.07-fold and protein of 2.78-fold were registered after cells exposure to AGE-BSA 200 μg/ml for 48 h, and seemed to be associated with several altered biochemical parameters. Hsp 27 gene and protein expressions increased after 12 h of treatment by 1.93 and 1.52-fold, but decreased to 0.45 and 0.16-fold after 48 h. Hsp 60 had a similar profile, suggesting that the exposure of human embryonic kidney cells to AGE-BSA up to 48 h could activate pro-apoptotic pathways.

Our data suggest that RAGE activation increased ROS, and consequently antioxidant enzyme activities were modulated. Possibly the oxidative damage of proteins could not be avoided completely. Although protective and antiapoptotic Hsps can improve some of the ROS deleterious effects, therapeutic approaches based on Hsp overexpression must be addressed with caution, as apoptosis inhibition could invoke cancerous transformation.

Aggregation prone human interferon gamma and its mutant show native-like solubility and biological activity after sumo tag removal

M. Tileva[1], E. Krachmarova[1], E. Filipova[1], I. Ivanov[1], K. Maskos[2], **G. Nacheva**[1]

[1]Gene Regulation, Institute of Molecular Biology 'Roumen Tsanev', Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]Proteros Biostructures, Martinsried, Germany

The *E. coli* expression system is a preferable choice for production of therapeutic proteins due to the low cost and simplicity of cultivation. The high expression level and lack of glycosylation, however, often lead to increased aggregation of the target protein in the form of 'inclusion bodies' (IBs) where the protein is biologically inactive. Protein purification out of IBs requires additional technological steps such as solubilisation and refolding, which are crucial for the properties and the yield of the final product.

The aim of our study is to develop a strategy for production of biologically active, soluble and stable in solution recombinant proteins. To this end two highly prone to aggregation proteins were studied: human interferon gamma (hIFNγ) and its mutant analogue K88Q (Q substitution for K in position 88). The therapeutic applications of hIFNγ, an antiviral proinflammatory cytokine, have challenged scientists for years to develop and optimize methods for its production, which are however mainly based on purification from IBs. Our previous results show that when constitutively expressed in *E. coli* LE 392 at 37°C 60–70% of hIFNγ and up to 95% of K88Q aggregate in IBs. Whereas hIFNγ has been successfully recovered from IBs, the mass recovery of K88Q showed to be ineffective upon numerous conditions. In order to avoid the renaturation step and to increase the share of the soluble fraction, we constructed fusion expression vectors bearing three different solubility tags: N-terminal His-FLAG, C-terminal RTX(protease)-His-tag and N-terminal His-SUMO (small ubiquitin-like modifier) tag. The first two expression systems showed no sufficient increase in solubility and/or major difficulties in tag cleavage, while His-SUMO-tag demonstrated high efficiency for both hIFNγ and K88Q proteins. The expression system thus selected was further optimized towards growth conditions and *E. coli* host strain. Expression in the strain BL21(DE3)pG-KJE8, co-expressing two chaperone systems, at 24°C lead to significant increase in solubility of both target proteins from 1.5-fold for hIFNγ up to 8-fold for K88Q. Two-step chromatography (affinity and ion-exchange) with on-dialysis His-SUMO cleavage was applied for protein purification from the cytosolic fraction. It led to a high yield of 99% pure products demonstrating completely preserved biological activities as estimated by kynurenine bioassay.

SUN-082
Alterations in liver gene expression profile in streptozotocin-induced diabetic rats

G. Sadi[1], M. C. Baloglu[2]
[1]Department of Biology, Karamanoglu Mehmetbey University, Karaman, [2]Department of Genetic and Bioengineering, Kastamonu University, Kastamonu, Turkey

Microarray technology has been applied to study the genome-wide gene expression levels in streptozotocin (STZ) induced diabetic liver tissues, which plays a key role in glucose metabolism and homeostasis. The rats were fed with a standard diet and were randomly divided into two groups: (1) non-diabetic control group (2) diabetic group received STZ (55 mg/kg). After STZ injection, rats whose blood glucose concentration above 300 mg/dl was considered as diabetic. After four weeks of diabetes, rats were decapitated and liver tissues were removed for microarray analysis.

Among significantly expressed probe sets, fold change of at least two was considered as differentially expressed probe sets. Principal components analysis revealed clustering of the two different groups and it has been found that there were 273 genes with at least ±2-fold significantly altered expression (90 increases, 183 decreases). Gene ontology groups with significant over-expression with respect to control were responsible for cellular catalytic activities (35 genes), oxidation-reduction reactions (11 genes), co-enzyme binding (7 genes) and terpenoid biosynthesis (3 genes). Whereas; genes responsible for cellular carbohydrate metabolism (11 genes), regulation of transcription (9 genes), cell signal transduction (9 genes), calcium independent cell-to-cell adhesion (3 genes) and lipid catabolism (3 genes) had at least two fold decreased expression. Microarray data were also validated using Real-time PCR for the gene expression of catalase (CAT), ubiquitin specific peptidase 2 (Usp2), insulin-like growth factor binding protein 2 (Igfbp2), cytochrome P450 8B1 and 1A1 isoforms (CYP8B1 and CYP1A1). Real-time PCR confirmed the directionality of changes in expression of the genes tested.

As a conclusion, global gene expression in the liver tissues is affected by streptozotocin induced diabetes in several specific areas, including catalytic activities, oxidation-reduction reactions, co-enzyme binding, cellular carbohydrate metabolism, regulation of transcription and signal transduction. The present data suggest the presence of several processes which contribute and possibly interact to impair liver function in type 1 diabetes, several of which are potentially amenable to therapeutic interventions.

Altered activation of monocytes from the patients with antiphospholipid syndrome induced by LPS and ATP

A. Martirosyan[1], M. Petrek[2], Z. Navratilova[2], A. Blbulyan[3], **G. Manukyan**[1]
[1]Molecular and Cellular Immunology Group, Institute of Molecular Biology, National Academy of Sciences, Yerevan, Armenia, [2]Laboratory of Immunogenomics and Immunoproteomics, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic, [3]Department of Obstetrics, Institute of Perinatology, Obstetrics and Gynecology, Yerevan, Armenia

The antiphospholipid syndrome (APS) is an acquired autoimmune disorder of unknown etiology. Growing evidences support the involvement of monocytes in APS pathogenesis. Inflammatory activation of monocytes promotes thrombus formation and other APS complications. However, mechanisms underlying their activation are poorly investigated. We therefore determined spontaneous and induced by LPS (10 ng/ml) and LPS+ATP (100 μM) expression of IL-1β, IL-6, IL-23, TNFα and CCL2 in circulating monocytes isolated from APS patients (n = 10) and healthy (n = 7) subjects using comparative qRT-PCR method. Spontaneous expression of all candidate genes ($p < 0.05$) in APS monocytes was significantly lower than in healthy cells. LPS and LPS + ATP stimulation had no significant effect on gene expression in healthy cells, while in APS monocytes LPS and ATP had profound effects. LPS significantly increased expression level of all genes ($p < 0.05$). Exposure of APS monocytes with LPS + ATP decreased mRNA levels of IL-1β and CCL2 compared with untreated cells ($p < 0.05$) and levels of IL-1β, IL-23 and CCL2 compared with LPS induction ($p < 0.05$). LPS-induced mRNA levels of IL-23, CCL2 were significantly higher in diseased cells than those in healthy cells ($p < 0.05$), in opposite LPS+ATP induced expression of IL-1β, IL-6, CCL2 was higher in healthy controls than those in APS monocytes ($p < 0.05$). Thus, present study revealed an increased sensitivity of APS monocytes to bacterial LPS. Presence of low concentrations ATP appears to diminish LPS-induced inflammatory state of diseased monocytes, suggesting that ATP-mediated inhibition of inflammatory processes in monocytes may provide protection and limit tissue injury in autoimmune APS.

Altered production of reactive oxygen species and release of extracellular traps by neutrophils under the influence of selected mucolytic, anti-inflammatory, anti-histamine and cardiovascular drugs

M. Zawrotniak, A. Kozik, M. Rapala-Kozik
Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Kraków, Poland

Introduction: Neutrophils, the first line of the host defense against pathogens, circulate in the bloodstream and can also infiltrate other tissues and organs, e.g., the lungs. These defense cells exploit various mechanisms for pathogen killing, including the phagocytosis, the degranulation with a release of numerous microbicidal agents and the formation of neutrophil extracellular traps (NETs). NETs play important role in capturing pathogens and are also responsible for the increase of the mucus viscosity in the lungs as well as for intravascular clot formation by binding morphotic blood elements. Many of drugs commonly used in the therapy of various diseases can interact with neutrophils, with modulatory effects on the NET formation. Mucolytic drugs help to reduce mucus viscosity, e.g., in cystic fibrosis, cardiovascular drugs improve the condition of the heart as well as of the circulatory system, likewise anti-inflammatory and anti-histamine drugs extinguish the immune response.

Objective: Determination of the effects of mucolytic (N-acetylcysteine), anti-inflammatory (ketoprofen, hydrocortisone), anti-histamine (clemastine) and cardiovascular (etamsylate, dopamine) drugs on the ability of neutrophils to produce reactive oxygen species (ROS) and release NETs.

Results: In the response to contact with pathogens, neutrophils produce high amounts of ROS. With the use of the chemiluminescence and flow cytometry methods, we found that this activity of neutrophils was markedly reduced after their pretreatment

© 2014 The Authors. FEBS Journal © 2014 FEBS

with N-acetylcysteine, ketoprofen, etamsylate and dopamine. Selected drugs seemed also to modulate the NET production, with N-acetylcysteine, etamsylate and dopamine inhibiting this process, in contrast to ketoprofen which markedly promoted the NET release.

Conclusions: The decrease of ROS production by neutrophils under the influence of anti-inflammatory and anti-histamine drugs helps to prevent the development of inflammation. Similarly, the inhibition of ROS generation by mucolytic drugs protects the lung against the adverse action of neutrophil antimicrobial factors on the host tissue. On the other side, the inhibition of ROS production by cardiovascular drugs seems to exert the adverse effect in systemic infection (sepsis) where these drugs are very often applied. Inhibition of NET release by mucolytic drugs helps to reduce mucus viscosity; however, the same action of cardiovascular drugs can cause development of infection (dopamine administration during sepsis) or reduce the ability of clot formation (etamsylate treatment in bleeding).

Ameliorative effects of Naltrexone on CCl4-induced liver cirrhosis in an animal model study

F. Sarhaddi Khollari[1], A. R. Dehpour[2], **M. Nourbakhsh**[3], M. Bagherieh[1], A. Golestani[1]

[1]Department of Clinical Biochemistry, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, [2]Department of Pharmacology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, [3]Department of Biochemistry, School of Medicine, Iran University of Medical Sciences, Tehran, Iran

Introduction: Hepatic cirrhosis is a common pathological feature of progressive chronic liver disease. Naltrexone (NTX), (a μ-opioid antagonist) attenuates hepatocellular injury. Since there is evidence about the role of oxidative stress in this disease, we aimed to determine if NTX affects on CCl4-induced cirrhotic rats by ameliorating oxidative stress.

Material and Methods: In this study, 124 male Wistar rats were divided into six groups (7rat/group) and the groups received drugs and reagents (i.p.) as follows: 1- Control, 2- 150 mg/kg CCl4 every other day, 3- 1 ml Mineral oil (as a carrier of CCl4) every other day, 4- NTX 10 mg/kg daily, 5- Nal+CCl4, and 6- NTX+Mineral oil as described. After 2, 6 and 8 weeks, the animals were sacrificed and the blood samples were collected. Total antioxidant capacity of plasma (FRAP), and the activity of alkaline phosphatase (ALP), alanine aminotransaminase (ALT), aspartate aminotransaminase (AST) and gamma-glutamyl transferase (GGT), were assessed in plasma. Metabolites of nitric oxide were evaluated in plasma as well. Also, erythrocyte membrane composition i.e. protein carbonyl and MDA were assessed in RBC ghosts.

Results: The plasma enzyme activites were significantly higher in CCl4 group when compared to the other groups ($P < 0.05$) showing the progression of liver injury ($P < 0.05$). NTX severely diminished carbonyl content of erythrocytes of CCl4-induced cirrhotic rats after 8 weeks of injection, but increased it significantly after 2 and 6 weeks when used as control ($P < 0.05$).

Discussion: The results show that upon treatment with CCl4, antioxidant capacity of erythrocytes is depleted and oxidative stress markers especially protein carbonyl content of RBC membrane increase at the early stages of cirrhosis. It seems that NTX could ameliorate these alterations.

Acknowledgments: This work was supported by Research Council of Tehran University of Medical Sciences (Grant No. 15244).

SUN-086
Analysis of GOLPH3 depletion in human glioblastoma multiforme T98G cells

C. Arriagada, A. González, V. Cavieres, M. Aguilar, P. Burgos, G. Mardones

Physiology, Universidad Austral de Chile, Valdivia, Chile

Glioblastoma multiforme (GBM) is the most common and most aggressive malignant primary brain tumor in humans. Despite enormous advances on our understanding of this type of brain cancer, little is known about the different aspects of the secretory pathway in GBM tumorigenesis, and in particular the contribution of the Golgi apparatus is poorly understood. GOLPH3 is a highly conserved phosphoprotein of the Golgi apparatus originally identified in proteomic analyses. Importantly, GOLPH3 is overexpressed in several tumor types, including breast, lung, melanoma, ovarian, prostate, and GBM, but its function in malignant cells is little known. GOLPH3 is a peripheral membrane protein enriched at the trans-Golgi network that has been implicated in several cellular functions, such as in the retrograde transport of Golgi sugar transferases, or in the maintenance of the structure of the Golgi apparatus through its interaction with the actin cytoskeleton. To understand the possible role of GOLPH3 in GBM tumorigenesis, we analyzed the effect of GOLPH3 depletion in the GBM cell line T98G. Depletion of GOLPH3 by RNAi resulted in a distinct change in morphology of T98G cells, accompanied by a reorganization of the actin cytoskeleton. Depletion of GOLPH3 also resulted in a different steady-state distribution of several transmembrane proteins, suggesting an effect on protein trafficking. Strikingly, the analysis of the protein expression pattern in cells depleted of GOLPH3 showed either downregulation or upregulation of several proteins. We propose that overexpression of GOLPH3 is related to the tumorigenic phenotype of T98G cells by means of reorganization of gene expression that affect membrane trafficking.

Annexin A8 controls leukocyte recruitment to activated endothelial cells via cell surface delivery of CD63

U. Rescher[1], M. Poeter[1], I. Brandherm[1], J. Rossaint[2], V. Shahin[3], B. Skryabin[4], A. Zarbock[2], V. Gerke[1]

[1]Institute of Medical Biochemistry, University of Münster, [2]Department of Anesthesiology, Intensive Care and Pain Medicine, University Hospital of Münster, [3]Institute of Physiology II, [4]Institute of Experimental Pathology, University of Münster, Münster, Germany

Proinflammatory activation of endothelium releases the bleukocyte receptor P-selectin from Weibel-Palade bodies (WPB) to the endothelial cell surface, with CD63 acting as a stabilizing co-factor. we find that loss of annexin A8 (anxA8) in human umbilical vein endothelial cells (HUVEC) strongly decreases cell surface presentation of P-selectin, with a concomitant reduction in leukocyte rolling and adhesion. We confirm the compromised leukocyte adhesiveness in inflammatory-activated endothelial venules of anxA8-deficient mice. We report that WPB of

© 2014 The Authors. FEBS Journal © 2014 FEBS

anxA8-defient HUVEC contain less CD63. This is caused by improper tranport of CD63 from late multivesicular endosomes to WPB, with CD63 being retained in intraluminal vesicles. Consequently, reduced CD63 cell surface levels cause enhanced P-selectin re-internalization. Our data support a model in which anxA8 affects leukocyte recruitment to activated endothelial cells by supplying WPB with sufficient amounts of the P-selectin regulator CD63.

Annexin V and anti-Annexin V Antibodies in acute myocardial infarction

A. Sotoodeh Jahromi, M. Shojaei
Jahrom University of Medical Sciences, Jahrom, Iran

Background: Myocardial infarction is the combined result of environmental and personal factors. Prothrombotic factors might play an important role in this phenomenon. Annexin V (ANV) is a calcium-dependent glycoprotein widely present in various tissues exerting a potent anticoagulant effect in vitro by reducing plaque adhesion and aggregation. Anti-annexin V antibodies (aANVAs) are detected in various diseases like rheumatoid arthritis, systemic lupus erythematosus and anti-phospholipid antibody syndrome. The study of ANV in Acute Myocardial Infarction (AMI) might shed light on hypercoagulability mechanisms in the pathogenesis of acute coronary syndromes. This study was conducted to investigate the association of plasma ANV, aANVAs and anti-cardiolipin antibodies (aCLAs) with AMI.
Methods: This study recruited 45 patients with the diagnosis of AMI according to WHO criteria in their first 24 hours of admission. 36 matched individuals were studied as the control group with normal coronary artery angiography. Plasma levels of ANV, aANVAs and aCLAs were determined by enzyme-linked immunosorbent assay and the results were compared.
Results: Plasma ANV levels in the patients with AMI on admission were significantly lower than those in the control group ($p = 0.002$). Positive test for aANVAs were found to be present in a significant number of our patients ($p = 0.004$). The studied groups were similar in their rate of patients with positive aCLAs tests. ANV, aANVAs and aCLAs were not correlated with hypertension, diabetes mellitus, hyperlipidemia, sex, age and smoking.
Conclusion: Our findings suggest that low plasma ANV levels along with positive aANVAs tests in patients with AMI are indicative of hypercoagulable state that is not related to the traditional cardiovascular risk factors.
Disclosure of interest: None declared.

Antibodies against neurotrophin receptor p75 and the prion protein protect memory impairment in mouse model of Alzheimer's disease

A. Kamynina[1], Y. Zaporozhskaya[1], T. Volkova[1], D. Koroev[1], N. Medvinskaya[2], I. Aleksandrova[2], P. Nekrasov[2], O. Tatarnikova[2], O. Volpina[1], N. Bobkova[2]
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, [2]Institute of Cell Biophisics RAS, Puschino, Russian Federation

Alzheimer's disease is characterized by beta-amyloid binding with cell surface proteins in the brain of patients which leads to pathological changes inside the cells followed by Alzheimer's disease progression. p75 receptor involved in cell balance support and the prion protein are both the targets for toxic beta-amyloid. We proposed that prevention of beta-amyloid binding with the extracellular proteins such as neurotrophin receptor p75 and the prion protein by means of induction of antibodies against the proteins can be a promising approach towards development of new anti-Alzheimer's disease treatment. We investigated the effect of induction of antibodies against p75 or prion in preventing the development of several Alzheimer's disease features in the mouse model of the disease. Four potentially immunoactive fragments of p75 and one fragment of the prion protein were chosen and chemically synthesized. Investigation of immunoprotective effect of the peptide fragments was carried out in mice with experimentally induced form of Alzheimer's disease and revealed that immunization with two fragments of p75 (155–164 and 167–176) conjugated with a carrier protein and the prion fragment (17–33) in a conjugated and non-conjugated form induced anti-peptide antibody formation and effectively preserved murine memory from impairment. Results obtained by ELISA biochemical analysis showed that only immunization with fragment p75 155–164 conjugated with a carrier protein led to significant decrease in beta-amyloid level in the brain of the experimental mice. We also demonstrated that immunization with prion fragment 17–33 in a conjugated and non-conjugated form significantly improved morphofunctional state of neurons in the experimental mice. To reveal the role of antibodies against the two proteins, the level of the antibodies in patients with Alzheimer's disease is currently under investigation. Thus, immunization with both fragments of p75 receptor and the prion fragment provides a new insight into anti-Alzheimer's disease drug design.

Anti-obesity effect of *Allomyrina dichotoma* (Arthropoda: Insecta) larvae on high-fat diet induced obese mice

E. Yun, M. Chung, J. Hwang, T. Goo, M. Kim
Agricultural Biology, National Academy of Agricultural Science, Suwon, Korea

We tested whether *Allomirina dichotoma* larvae (AD) prevents obesity in high fat diet (HFD) induced obese mice and further investigated the underlying mechanisms for its body weight lowering effect. All of the mice were maintained on normal diet (ND) for 1 week and then fed with ND, HFD, or HFD + AD (100 mg/kg and 3000 mg/kg) for 6 weeks, respectively. The body weights of HFD-induced obese mice were monitored after daily oral administration of AD for 6 weeks. Blood lipid profile and plasma leptin levels, as well as expressions of genes involved in lipogenesis were examined. The results showed that AD significantly reduced body weight and fat mass in HFD-fed mice. Moreover, mice fed with HFD + AD had lower concentrations of triglyceride in their blood and lower serum leptin levels compared with the HFD-fed mice. Real-time PCR analysis showed that the expression levels of peroxisome proliferators-activated receptor γ (PPAR γ) and CCAT/enhancer binding protein α (C/EBP α) genes in the epididymal fat tissue of mice fed with the HFD+AD (3000 mg/kg) were reduced approximately 73% and 37%, respectively, compared to mice fed with HFD only. Additionally, HFD + AD oral administration significantly decreased the mRNA expression of lipoprotein lipase (LPL) as compared with the mRNA levels in the HFD group. These results sug-

© 2014 The Authors. FEBS Journal © 2014 FEBS

gest that AD has a possibility of development as alternative medicine for preventing obesity in the future.

Antioxidant compounds suppress diamine oxidase activity

J. M. Gostner[1], J. E. Fuchs[2], K. Becker[3], Ü. Florian[1], H. Schwelberger[4], D. Fuchs[3]

[1]Medical Biochemistry, Medical University Innsbruck, Innsbruck, Austria, [2]Department of Chemistry, Centre for Molecular Informatics, University of Cambridge, Cambridge, UK, [3]Division of Biological Chemistry, [4]Department of Visceral, Transplant and Thoracic Surgery, Molecular Biology Laboratory, Medical University Innsbruck, Innsbruck, Austria

Dysregulated signalling via biogenic amines is associated with the development of several human pathologies. The biochemical routes for the interconversion and elimination of biogenic amines share high similarities among different species. Oxidative degradation of biogenic amines is catalysed by two types of amine oxidases: quinoprotein copper-containing amine oxidases (CAO) and flavoprotein polymamine oxidases (PAO).

Diamine oxidase, which belongs to CAO, catalyzes the oxidative deamination of diamines like putrescine and histamine to the corresponding aldehyde via Schiff base formation of the oxidized topaquinone (TPQ) cofactor with the substrate amine [1]. Histamine is a potent mediator of inflammation and allergic reactions. The large amount of histamine in certain foods is suggested to be responsible for the symptomatology of histamine intolerance (HIT) or sensitivity, a food intolerance affecting about 1% of the population [2]. In healthy people, DAO provides an enzymatic barrier function to prevent histamine resorption in the intestine. Inefficient degradation gives rise to high intestinal histamine, however there is equivocal information regarding the role and diagnostic relevance of DAO in HIT [3].

Recent studies already discuss the involvement of exogenous antioxidants and 'antioxidative stress' in the development of allergies [4]. By using DAO as a model enzyme we analysed the influence of selected food-contained antioxidants such as preservatives and colorants on the enzymatic activity by applying radiolabelled putrescine as a substrate. Exposure to most antioxidant compounds resulted in a dose-dependent reduction of enzyme activity. If this in vitro effect on DAO can be extrapolated to in vivo, it opens another possibility how overload with antioxidants may interfere with biogenic amine metabolism. In addition, although in vitro only, our results emphasize an additional effect to the suppression of Th1-type immune reactions and cytokines by antioxidant compounds, which was demonstrated earlier for food preservatives, colorants, phytochemicals and drugs [5], thus promoting a shift of the Th1-Th2-type immune balance towards Th2-type immunity.

Anti-phosphatidylethanolamine antibodies in acute myocardial infarction

A. Sotoodeh Jahromi

Jahrom University of Medical Sciences, Jahrom, Iran

Background: Acute myocardial infarction (AMI) is a clinical manifestation of coronary atherothrombosis and is the important causes of death. Many factors play a role in AMI. Anti-Phospholipid (aPL) antibodies may act in the induction of immunological response leading to the development of AMI. Anti-Phosphatidylethanolamine (aPEA) antibody has been detected in various autoimmune diseases and anti-phospholipid antibody syndrome. The study of aPEA antibody in AMI might shed light on etiologic mechanisms in the pathogenesis of coronary atherothrombosis and AMI. This study was aimed to evaluate whether prevalence of aPEA antibodies, in patients with AMI and to analyze their relationship with traditional cardiovascular risk factors.

Methods: The prevalence of aPEA IgG and IgM in a well characterized group of patients with AMI as a case group and in age and sex matched healthy subjects as a control group. Sera from two groups were tested to evaluate the presence of aPEA IgG and IgM isotypes by ELISA method.

Results: The frequencies of positive test for aPEA IgG were 12.22% and 2.22% among patients and controls respectively with significant difference ($P = 0.007$).

The aPEA IgM frequencies were 3.33% and 0.00% in patients and the controls, with significant difference ($P = 0.005$).

Conclusion: According to the results of this study, aPEA antibodies have a role in AMI, independent risk factors for AMI, which may represent a link between autoimmunity and coronary atherothrombosis. Further studies with larger sample size of patients and healthy people are needed to explore the role of aPEA antibodies in coronary atherothrombosis.

Anti-phosphatidylserine antibodies in acute myocardial infarction

S. Sobhanian, A. Sotoodeh Jahromi

Jahrom University of Medical Sciences, Jahrom, Iran

Acute Myocardial Infarction (AMI) is the combined result of environmental factors and personal predispositions. Many factors play a role in AMI including anti-Phospholipid (aPL) antibodies, that may act in the induction of immunological response leading to the development of AMI. Anti-Phosphatidylserine (PS) antibody is detected in various diseases like rheumatoid arthritis, systemic lupus erythematosus and anti-phospholipid antibody syndrome. The study of anti-PS antibody in AMI might shed light on etiologic mechanisms in the pathogenesis of acute coronary syndromes. This study was conducted to evaluate whether prevalence of anti-PS antibodies, in patients who had AMI and to analyze their relationship with traditional cardiovascular risk factors. The prevalence of anti-PS IgG and IgM in a well characterized group of patients with AMI as a case group and in age and sex matched healthy subjects as control group. Sera from two groups were tested to evaluate the presence of IgG and IgM isotypes to anti-PS by ELISA method. The frequencies of positive test for anti-PS IgG were 26.70 and 8.90% among patients and controls respectively with significant difference ($p = 0.003$). The anti-PS IgM frequencies were 12.20 and 1.10% in patients and the controls, with significant difference ($p = 0.005$). The findings of this study suggest that anti-PS antibodies seemed to play a role in AMI, independent risk factors for AMI, which may represent a link between

© 2014 The Authors. FEBS Journal © 2014 FEBS

autoimmunity and atherosclerosis in patients with AMI. Further studies with bigger sample size including patients with AMI and healthy people are recommended to explore the exact role of anti-PS antibodies in AMI.

Keywords: antibody, infarction.

Apoptotic and pro-/antioxidant processes depends on the vitamin D3 availability in the liver of diabetic mice

D. Labudzynskyi, M. Veliky
Medicine biochemistry, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kyiv, Ukraine

Precise mechanism by which oxidative stress could facilitate and accelerate the development of hepatic lesions in diabetes is not fully clarified. The present study was performed to determine the relationship between 25-hydroxyvitamin D_3 ($25(OH)D_3$) availability, apoptosis and *pro-/antioxidant* profile in liver of diabetic mice.

Type 1 diabetes was induced in male C57BL/J6 mice (weighing 25.0 ± 1.5 g) by i.p. injection of multiple low dose streptozotocin (40 mg/kg b.w.). Control and STZ-diabetic mice were treated with or without vitamin D_3 (15 IU/mouse per os, for 8 weeks). Serum $25OHD_3$ was assessed by ELISA. The levels of Casp3, poly(ADP-ribose)polymerase 1 (PARP-1), poly-ADP-ribosylated *and nitrosylated proteins* were *measured* by Western-blot analysis. Intracellular reactive oxygen and nitrogen species (ROS and RNS) production were detected by 2′,7′-dichlorofluorescin (DCF) and 4,5-diamino-fluorescein diacetate (DAF-DA) fluorescence respectively using flow cytometry. Activities of pro-/antioxidant enzymes in liver were measured spectrophotometrically.

Serum level of $25OHD_3$, the main circulating metabolite of D_3, was shown to be reduced to 23.8 ± 1.9 in diabetes versus 39.7 ± 2.9 nmol/l in control, that reflects reliably vitamin D_3 deficiency ($p < 0.05$). As a strong evidence of diabetes-induced oxidative stress that may lead to liver lesions, increased hepatocytes ability to oxidize the fluorogenic substrate DCF and DAF was found. These changes were accompanied by a significant rise in the levels of protein nitrotyrosine, carbonyl groups and poly-ADP-ribose by 42, 38, and 61% respectively versus control, $p < 0.05$. Diabetes also caused more than 1.67-fold increase in the level of 89 kDa apoptotic cleavage fragment of PARP, as well as 1.51- and 2.04-fold overactivation of Casp3 cleavage fragments respectively as compared to control ($p < 0.05$), indicating connection between proapoptotic process and oxidative stress. The diabetes-associated increase in the activities of key pro- and antioxidant enzymes in the liver was also established. Vitamin D_3 treatment completely restored blood serum $25OHD_3$ level, partially decreased PARP-1 and Casp3 activity and counteracted diabetes-induced abnormalities of pro-/antioxidant profile in liver tissue. Normalization of vitamin D_3 availability strongly correlated with a significant decrease in ROS and RNS generation in hepatocytes as compared with diabetic mice.

The findings indicate that diabetes-associated vitamin D_3 insufficiency can be related, at least in part, to increased proapoptotic and prooxidant status of liver cells. Our data suggest a potential role of vitamin D_3 treatment in the regulation of impaired oxidative metabolism in diabetes.

Keywords: diabetes mellitus, vitamin D3, liver, oxidative stress, apoptosis.

SUN-095
Assessing immunogenicity of enzymatically cross-linked beta-lactoglobulin using dendritic-cell derived endolysosomal degradome

M. Stojadinovic[1], R. Pieters[2], J. Smit[2], T. Cirkovic Velickovic[1]
[1]Department of Biochemistry, Faculty of Chemistry, University of Belgrade, Belgrade, Serbia, [2]Toxicology, Institute for Risk Assessment Sciences, Utrecht, The Netherlands

The growing number of novel protein derivatives with potential applications in food industry or for the treatment of allergic diseases imposed a dramatic increase in the demand for assessment of immunogenicity of novel proteins. Since efficient antigen processing is of crucial importance for immunogenicity of proteins we subjected cow's milk beta-lactoglobulin, BLG, and its laccase cross-linked derivative, CL-BLG, to proteolysis by endolysosomal enzymes isolated from dendritic cells derived from bone marrow cells of BALB/c mice.

SDS-PAGE electrophoresis of digested samples revealed that BLG was degraded slowly in time with half-time >48 h, but also that some proteolysis of CL-BLG occurred. BLG peptides identified in the samples were used for generation of peptide maps that provide insight into peptide profile and identification of potential T-cell determinants. Peptides from both BLG and CL-BLG appeared in seven nested clusters (start-end amino-acid): 1–19, 20–42, 42–57, 58–81, 83–103, 123–145 and 146–162. Peptides from one cluster share common core and have variable lateral regions. The most abundant peptide cluster for BLG was 123–145, while peptides from C-terminus (146–162) where the least present. Although CL-BLG releasing peptides share common clusters with BLG, their overall distribution is different. When compared to BLG, CL-BLG provided higher number of peptides in clusters 42–57 (dominant), 20–42 (abundant) and 146–162. For prediction of core sequences of peptides binding to H-2 class II molecules IAd and IEd that are MHC II molecules expressed in BALB/c mice we used RANKPEP and IEDB analysis resource SMM-Align. Peptides from clusters 1–19, 20–42, 58–81 and 123–145 were listed as possible candidates.

Finally, we investigated whether cross-linking of BLG interfered with antigen presentation by DCs in vitro. Peptides occurring from CL-BLG endolysosomal digestion when presented with MHC II complex on the surface of DCs induced stronger activation and Th2 response of BLG-specific $CD4^+$ T cells. Therefore, in agreement with previously published results, we report that cluster 42–57 for which CL-BLG provided constantly higher number of peptides is probably T-cell immunodominant epitope. Also, after aligning our data with theoretical predictions, we propose that peptides in the cluster 20–42 may (co-) determine higher immunogenicity of CL-BLG.

From our experience, when examining differences in immunogenicity between two structurally different proteins, except for monitoring resistance to intracellular cleavage by endolysosomal proteases, it is important to analyze and identify released peptides.

Supported by the MESTD of Serbia (GA 172024) and FP7 RegPot project FCUB ERA (GA 256716).
Keywords: beta-lactoglobulin, endolysosomal degradome, immunogenicity.

SUN-096
Assessment of TNF-α genotypes and serum level of patients with cardiac syndrome X

A. G. Akkan[1], B. Demir[1], B. Onal[1], S. Özyazgan[1], O. Karakaya[2], H. Uzun[3]
[1]Medical Pharmacology, Istanbul University, Cerrahpaşa Medical Faculty, [2]Cardiology, Bakirkoy Education and Research Hospital, [3]Biochemistry, Istanbul University, Cerrahpaşa Medical Faculty, Istanbul, Turkey

Introduction: Patients undergoing the non-invasive tests for angina typical showed ischemia with normal coronary angiograms, these patients may feature cardiac syndrome X (CSX) or microvascular angina. The pathogenesis of cardiac X syndrome is still unresolved, although in the presence of culprit factors like inflammation, endothelial dysfunction, increased oxidative stress, diffuse atherosclerosis and microvascular dysfunction. It is a well-known fact that inflammation plays an important role in endothelial dysfunction and leads to the development of microvascular dysfunction. In the present study we aimed to investigate the relationship between cardiac X syndrome and inflammation.

Materials and Methods: The present study was conducted on 111 patients diagnosed with stable angina pectoris and 97 control patients registered with chest pain and exercise stress test was negative for ischemia, with Framingham Risk Score lower than 10% for 10-year cardiovascular risk. DNA was isolated from peripheral blood samples to study the TNF-α genotype polymorphism using PCR and RFLP techniques. ELISA technique was performed to determine the serum TNF-α levels in 78 patients with CSX and 80 healthy individuals.

Results: There was no significant difference between CSX and control group in terms of age, sex, BMI, diabetes mellitus, hypertension, hyperlipidemia, family history, cardiovascular drugs in use, fasting plasma glucose, creatinine, total cholesterol, HDL, LDL, triglycerides, GGT, white blood cell count, hemoglobin, platelet count, mean platelet volume and C-Reactive Protein levels ($p > 0.05$). TNF-α -308 G> A polymorphism genotype in patients with CSX were GG (85.6%), GA (14.4%) and AA (0%) whereas GG (88.7%), GA (9.3%) and AA (2.1%) in control group. There was no significant difference in genotype distribution of TNF-α between patients and control groups ($p = 0.510$). The serum levels of TNF-α in CSX patients and control group were 83.1 ± 2.3 pg/mL and 84.9 ± 3.5 pg/mL respectively. TNF-α levels of control group were significantly higher than that of the patients ($p < 0.05$).

Conclusion: Inflammation plays an important role in endothelial dysfunction and leads to the development of microvascular dysfunction. However, the present study exhibited contradictory result such as low concentration of serum TNF -α in patients with respect to control. The underlying cause of low levels of TNF-α can be relatively small number of patients included in the study. In addition, local microvascular inflammation thought to play major role in the development of cardiac x syndrome than that of systemic inflammation.

SUN-097
Association of Lp-PLA2-mass, vitronectin and PAI-1 activity with maternal endothelial dysfunction in patients with preeclampsia

H. Ekmekçi[1], O. Balcı Ekmekci[1], Z. Gungor Ozturk[1], A. Tüten[2], M. S. Toprak[1], M. Korkmaz[1], M. Oncul[2], O. Çalışkan[1], M. Kucur[1], O. Donma[1], R. Madazli[2], H. Sönmez[1]
[1]Biochemistry, [2]Obstetrics and Gynecology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Although the cause of pre-eclampsia remains largely unknown, the leading hypothesis strongly rely on abnormal physiologic transformation of spiral arteries, anti-angiogenic state, uthero-placental ischemia, excessive intravascular inflamation and disruption of endothelial and haemostatic function. Links between abnormal activation of haemostatic and inflammatory systems in preeclampsia may help to elucidate some questions in pathophysiology of the disease.

Lipoprotein associated phospholipase A2 (Lp-PLA2) is an enzyme produced by inflammatory cells and degrades oxidatively modified phospholipids in oxidized LDL and oxidized lipoprotein (a), leading to formation of proinflammatory and cytotoxic products. Plasminogen activator inhibitor-1 (PAI-1) is inhibit fibrinolysis in the blood by blocking this plasminogen activators. Antifibrinolytic activity of PAI-1 facilitated by vitronectin that binds the inhibitor and may regulate its activity by the stabilizing the active PAI-1 conformation. In addition, several studies have demonstrated that PAI-1 play a key role in the regulation of local inflammatory process.

The aim of the present study; was determining, correlating and comparing the plasma Lp-PLA2, vitronectin, tissue-type plasminogen activator (t-PA) and PAI-1 activity levels in early-onset preeclampsia, late-onset preeclampsia and in control pregnant women.

A total of 79 individuals, 30 early-onset, 22 late-onset preeclamptic and 27 control pregnant women were included into the scope of this study. Enzyme-linked immunosorbent assay (ELISA) procedure was used to determine the serum Lp-PLA2 and plasma vitronectin, t-PA antigen and PAI-1 activity levels.

Major findings of this study; 1) In patients with preeclampsia, Lp-PLA2, PAI-1, t-PA, blood pressures and urine protein levels were increased ($p < 0.001$) and correlated with each other. 2) Vitronectin levels was decreased ($p = 0.045$) but not correlated with other parameters in preeclamptic patients. 3) Biochemical data obtained from early-onset and late-onset preeclamtic patients are not statistically significant.

We think that increased Lp-PLA2 levels may partially contribute to endothelial dysfunction by the progression of inflammation. In addition, high levels of Lp-PLA2 may also as a result of endothelial dysfunction due to impaired levels of the angiogenic and increased levels of the anti-angiogenic factors in eary stage of disease. Moreover, increased t-PA and decreased vitronectin levels may the results of compensatory mechanisms against disease progression.

Keywords: Lp-PLA2, PAI-1, Vitronectin.

Association analysis of GSTO2 Asn142Asp genetic polymorphism and ischemic stroke risk in Turkish population

B. Can Demirdöğen[1], E. Bilgin[2], A. Özçelik[2], S. Demirkaya[3], O. Adalı[2]
[1]Biomedical Engineering Department, TOBB University of Economics and Technology, [2]Biochemistry Department, Middle East Technical University, [3]Neurology Department, Gülhane Military Medical Academy, Ankara, Turkey

Aim: Stroke is described as an interruption or severe reduction of the blood supply to cerebral arteries of brain. Free radicals are continuously produced during normal biochemical reactions and are known to cause oxidative stress in the body. Oxidative stress has an important role in initiation and pathogenesis of atherosclerosis leading to ischemic stroke. Glutathione S-transferases (GSTs) are a superfamily of polymorphic enzymes catalyzing the detoxification of metabolites produced by oxidative stress. The polymorphisms in genes coding GSTO2 have been shown to cause reduction in enzyme activity. Therefore, this study was aimed to investigate the possible association between GSTO2 Asn142Asp polymorphism and ischemic stroke risk in Turkish population.

Materials and Methods: Genomic DNA was isolated from whole blood samples of 239 ischemic stroke patients and 130 controls and the genotypes of subjects were determined by using PCR-RFLP technique.

Results: For the GSTO2 Asn142Asp (A→G) polymorphism, the genotype frequencies of wild type (AA), heterozygous genotype (AG) and homozygote polymorphic genotypes (GG) found in patient and control groups were found as 40.6%, 44.8%, 14.6% and 38.5%, 42.3%, 19.2%, respectively. The frequency of the wild type allele, A, was 0.63 and 0.596 and the frequency of the polymorphic allele, G, was 0.37 and 0.404, respectively in patients and controls. The polymorphic allele was not significantly associated with ischemic stroke in this study (OR = 0.866, $P = 0.118$ and CI: 0.724–1.037). This polymorphism was also analyzed in subgroups. Presence of the polymorphic allele increased stroke risk for diabetics and smokers.

Conclusion: No significant difference was found between patient and control groups with respect to A and G allele frequencies in GSTO2 Asn142Asp polymorphism. Therefore, it could be concluded that Asn142Asp polymorphism may not play an important role in the pathology of ischemic stroke in the studied Turkish population.

Keywords: GSTO2, ischemic stroke, polymorphism.

Association between TLR-3 gene polymorphism rs3775291 and progression of hepatitis C virus infection

F.-Z. Fakhir[1,2], M. Lkhider[3], P. Pineau[4], S. Nadir[5], S. Ezzikouri[2], S. Benjelloun[2]
[1]Chouaib Doukkali University, Faculté des Sciences, ElJadida, [2]Laboratoire des Hépatites Virales, Institut Pasteur du Maroc, Casablanca, [3]Université Hassan II Mohammedia, Faculté des Sciences et Techniques, Mohammedia, Morocco, [4]Organisation nucleaire et oncogenese, Institut Pasteur de Paris, Paris, France, [5]Service medecine B, CHU Ibn Rochd, Casablanca, Morocco

Background: Hepatitis C virus (HCV) is a major global health problem with about 210 million people infected worldwide, and constitute the most important cause of chronic liver disease. HCV is an enveloped positive-strand RNA virus belonging to the genus *Hepacivirus* of the family Flaviviridae. During the viral replication cycle, double-stranded RNA (dsRNA), produced as an intermediate, is sensed by several pattern recognition receptors (PRRs) of the innate immune system including Toll-like receptors (TLR). TLRs constitute a family of receptors playing a key role in innate and adaptive immune response, among them TLR3,-7 and -8, which are expressed on endosomal membrane, and have been suggested to play an important role in antiviral immune responses based on their recognition of dsRNA and single-stranded RNA (ssRNA). Single nucleotide polymorphisms (SNPs) may shift balance between pro- and anti-inflammatory cytokines, contributing to successful resistance to infection or leading to chronic inflammation and cancer. The aim of this study was to investigate the association between the TLR-3, -7 and -8 polymorphism and the outcome of HCV infection.

Materials and Methods: 517 patients were enrolled in the study and genotyped for the TLR3, -7 and -8 SNPs. Logistic regression was used to assess the association between the polymorphisms and the outcome of the infection.

Results: A significant association between TLR-3 SNP at rs3775291 and risk of advanced liver disease was identified. The rs3775291-A/A genotype was more common in subjects with advanced liver disease than subjects with mild chronic hepatitis C (OR = 3.81; 95% CI, 2.16–6.72; $p = 0.000004$) and this difference was higher with healthy controls (OR = 5.34; 95% CI, 2.70–10.58; $p = 0.000002$).

Conclusions: Our findings indicate that a TLR-3 SNP rs3775291 is associated with progression of HCV infection to cirrhosis and hepatocellular carcinoma.

Association of insulin resistance with serum interleukin-6 level during normal pregnancy

A. Sotoodeh Jahromi
Jahrom University of Medical Sciences, Jahrom, Iran

Objectives: The purpose of this study was to evaluate the role of interleukine-6 (IL-6) in insulin resistance (IR) during normal pregnancy.

Approach: This cross sectional study was carried out on 86 healthy pregnant women including 26, 23 and 37 individuals in the 1st, 2nd and 3rd trimesters, respectively, and in 21 healthy non pregnant women. Serum IL-6 concentration was measured by Enzyme Linked Immunosorbent Assay (ELISA) method.

Results: There were significant differences between serumIL-6 level in pregnant women as compared with maternal healthy controls. There was significant correlation between gestational age and Body Mass Index (BMI) ($r = 0.28$, $P = 0.01$). There was no significant correlation between gestational age and insulin resistance (IR). We also did not find correlations between IR and TNF-α and IR and IL-6 in pregnant women.

Conclusion: In conclusion, our findings suggest that IL-6 are not greatly contributed to pregnancy induced insulin resistance in normal pregnancy.

Keywords: il-6, ir, pregnancy.

Association of single nucleotide polymorphism rs10896449 on prostate cancer in Turkish population

E. Ozkan[1], A. Erdemir[1], B. D. Torer[2], A. I. Tasci[3], Y. Baskin[4], H. Ellidokuz[4], D. Turgut-Balik[1]
[1]Department of Bioengineering, Yildiz Technical University, [2]Urology Department, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, [3]Faculty of Medicine, Bezmialem Vakif University, Istanbul, [4]Institute of Oncology, Dokuz Eylul University, Izmir, Turkey

Prostate cancer is one of the most prevalent of all human malignancies and it is the second cause of death because of cancer among men in Turkey. Its incidence is rising rapidly in most countries. Age, ethnicity, diet, environment, lifestyle, family history, and genetic susceptibility are risk factors for the development of prostate cancer. It is well known that genetics play important roles in susceptibility to almost all human cancers. Recently, several single nucleotide polymorphisms (SNPs) associated with prostate cancer have been identified in genome-wide association studies. However, the effect of these SNPs on prostate cancer risk in Turkish population is largely unknown. In this study, genotyping of rs10896449 was conducted using the hME/iPLEX assay in study group which consists of prostate cancer patients and healty controls (total 175 individual). Per-allele odds ratio (OR) and 95% confidence interval (CI) were calculated between cases and controls. Associations between genotypes of rs10896449 and clinico-pathological variables of cases such as age at diagnosis, family history, PSA level, Gleason score, smoking and alcohol consumption were determined by using chi square test and Fisher's exact test. Results showed that rs10896449 variant significantly associated with prostate cancer and genotypes of rs10896449 were significantly associated with smoking in prostate cancer cases ($p \leq 0.05$).

Keywords: Prostate cancer, single nucleotide polymorphisms (SNP), SNP genotyping.

Autoantibodies in rheumatoid arthritis may arise from immunogenicity of peroxynitrite-modified IgG

M. Y. Arfat, K. Alam
Department of Biochemistry, Aligarh Muslim University, Aligarh, India

Peroxynitrite (PON) is a potent oxidizing and nitrating agent with a biological half life of approximately 10 ms. It is produced in vivo by diffusion-controlled reaction of nitric oxide and superoxide anion. It can oxidize and/or nitrate many amino acids causing changes in protein structure and function. The changes may lead to the pathogenesis of several inflammatory diseases including Rheumatoid Arthritis (RA). In this study, IgG was isolated from healthy subjects' sera on protein A-agarose affinity column and PON was synthesized by rapid quenched flow method. PON-modified IgG (PON-IgG) was prepared by incubating IgG with PON at 37°C for 30 min and maintaining pH at 10–11. Physicochemical alterations in PON-modified IgG were monitored by UV, fluorescence, CD and FT-IR spectroscopy, and SDS-PAGE. Oxidation and aggregation were assessed as free thiols, protein carbonyls, and thioflavin T and congo red binding. Nitrotyrosine, dityrosine and nitrotryptophan were also quantified. Formation of 3-nitrotyrosine was verified by LC-MS and HPLC, and attachment of PON to IgG was elucidated by MALDI-TOF mass spectrometry. PON-modified IgG exhibited hyperchromicity at 278 nm along with bathochromic shift and appearance of a new peak at 420 nm, decrease of tryptophan and tyrosine fluorescence, loss in β-sheet and appearance of new peak in FT-IR, compared to native IgG. SDS-PAGE results revealed concentration dependent decrease in the band intensity of PON-IgG compared to native IgG. Experimentally induced antibodies against PON-IgG showed high titre antibodies and specific binding may be due to generation of highly immunogenic neo-epitopes on PON-IgG. PON-IgG binding with circulating autoantinbodies of RA patients were compared with the experimentally induced antibodies against PON-IgG and its significance was analysed using biostatistical tools. The results so far suggest likely involvement of PON-IgG as an autoantigen in the induction and/or progression of RA.

Keywords: autoantibodies, peroxynitrite, rheumatoid arthritis.

Autotaxin and adiponectin expression in neuroinflammation and its effects on microglial cells

A. Parimisetty, R. Awada, D. Girard, A. Catan, C. Planesse, P. Rondeau, N. Diotel, C. Lefebvre d'Hellencourt
EA 4516 – Groupe d'Etude sur l'Inflammation Chronique et l'Obésité (GEICO), University de La Reunion, Saint Denis, France

Many chronic neurodegenerative diseases such as Amyotrophic lateral sclerosis, Alzheimer and Parkinson diseases have been associated with inflammation in the Central Nervous System (CNS). The balance between pro and anti-inflammatory factors is tightly controlled as dysregulation of this equilibrium may lead to progressive neurodegenerative disorders. Autotaxin (ATX) and adiponectin (ADIPO) have anti-inflammatory properties, but the precise mechanisms mediating this response in the CNS remains to be determined.

Here, we propose to use two distinct inflammatory stimuli to characterize the expression of ATX and ADIPO in mouse CNS. Acute intraperitoneal (ip) injection of lipopolysaccharide (LPS) (100 μg/Kg bwt) mimics gram negative bacterial infection, while acute ip injection of organometal trimethyltin (TMT) (2 mg/kg bwt), induces hippocampal neurodegeneration. Microglial cells are the major source of inflammatory factors in the brain and to investigate the role of ATX and ADIPO on these cells in inflammatory condition, we generated stable over-expressing transfectant in murine microglia BV2 cells for these two factors. BV2 and stably transfected, overexpressing clones were treated with LPS (1 μg/mL) and TMT (10 μM). The inflammation status and the expression of ATX and ADIPO in vivo and in vitro were determined by qRT-PCR.

Here, we show that ip injection of LPS in mice, results in an early response of TNFα and iNOS in the hippocampus, cortex and cerebellum with a peak at 2–4 hours, while ADIPO showed its expression peak at 6 hours only in hippocampus while no significant changes were observed for ATX. We confirmed that an acute ip injection of TMT induces an increase in TNFα mRNA (peak at 24 h). Elevated ATX and ADIPO mRNA levels in the hippocampus were demonstrated in mice 5 and 8 days respectively following the injection. ATX expression was significantly enhanced in LPS or TMT treated BV2. TNFα and IL-6 were inhibited in LPS or TMT treated BV2 overexpressing autotaxin, while IL-10 level was increased. Experiments with ADIPO overexpressing BV2 are in progress.

All together, these results demonstrated that ATX and ADIPO are expressed in vivo in the brain and that ATX inhibits microglia induced inflammation, suggesting that ATX and ADIPO could play a role in controlling neuroinflammation.

Alzheimer's disease (AD), the most common form of dementia in the elderly, is characterized by neurofibrillary tangles, extracellular amyloid-beta (Abeta) plaques, and neuroinflammation. The accumulation of Abeta in the brain of patients with sporadic Alzheimer's disease (SAD) seems to reflect a defective clearance. In this process, cells of monocytes-macrophage lineage exert a relevant role. Saffron, the dried stigma of *Crocus sativus* L., is a naturally derived plant product with several biological properties such as anti-inflammatory and antioxidant activity. The present study investigates the possible reversal effects of saffron in the reduced amyloid-beta degradation by monocytes of SAD patients.

Crocus sativus L. was collected from Umbria (Central Italy) and kindly provided by the *Associazione dello Zafferano di Cascia – Zafferano Purissimo dell'Umbria.*

Cytotoxicity of saffron extract was first assessed, and then amyloid-beta (1–42) HiLyte Fluortm 488 – labeled (FITC-Abeta42) degradation rate by monocytes after saffron treatment was analyzed by flow cytometry (Beckman Coulter EPICS XL). Monocytes from SAD subjects pre-treated with low concentration of saffron extract (5microM referred to *trans* crocine amount) showed an improved ability to degrade FITC-Abeta42 and an increased level of lysosomal protease Cathepsin B, one of the key Abeta42 degrading enzyme.

Even though more studies are needed to identify the active molecules, or their combinations, responsible for the enhanced Aβ42 degradation, these data suggest a potential beneficial effect of saffron on AD patients in terms of Aβ42 increased clearance.

Keywords: amyloid-beta, monocytes, Saffron.

Bioactive fractios of *Zanthoxylum acanthopodium* modulated biomarkers of obesity in 3T3-L1 preadipocytes

Y. Yanti[1], R. Rendy[1], M. T. Suhartono[2], O. Rostiana[3]
[1]Biotechnology, Atma Jaya Catholic University, Jakarta, [2]Food Science and Technology, Bogor Agricultural University, [3]Indonesian Center for Estate Crops Research Development (ICECRD), Ministry of Agriculture, Bogor, Indonesia

Obesity is marked by chronic low-grade inflammatory response, excessive production of proinflammatory cytokines (interleukin (IL)-1β, IL-6, and tumor necrosis factor (TNF)-α). Obesity is also linked by process called adipogenesis, which is differentiation of preadipocytes to adipocytes. Therapeutic strategy using spice-derived compounds which are naturally occurring phytochemicals and biomolecules may elicit antiobesity properties. In this study, the antiobesity effect of bioactive fractions, i.e. essential oil and polyphenol fractions, isolated from lemon pepper (*Zanthoxylum acanthopodium*) was evaluated through modulation of proinflammatory cytokines, adipogenic enzymes, and adipogenic transcription factors in 3T3-L1 preadipocytes in vitro. Bioactive fractions of essential oils and polyphenols from lemon pepper were done by using solvent extraction and identified for their contents by using chromatographic technique (pyGC-MS). Cytotoxicity of lemon pepper fractions (1–100 μg/ml) was measured using MTT assay. Bioactive lemon pepper fractions at 1–25 μg/ml were tested for their anti-obesity effects on the modulation of IL-6, IL-1b, TNF-a, leptin, adiponectin, sterol regulatory element-binding protein (SREBP)-1, and MCP (monocyte chemoattractant protein)-1 at protein and gene levels in 3T3-L1 preadipocytes by conducting ELISA and Real Time-PCR assays. ELISA profiles demonstrated that both essential oil and polyphenol fractions from lemon pepper dose-dependently upregulated adiponectin and leptin levels. Meanwhile, bioactive fractions decreased the expression of IL-6 protein. Secretion of leptin and adiponectin was tended to increase in 3T3-L1 preadipocytes when treated with essential oil and polyphenol fractions. SREBP-1c is known for its role as adipogenic transcription factor, while IL-1β, IL-6, and MCP-1 are major adipocytokines that promote inflammatory action in adipocytes. In order to know whether bioactive fractions has anti-adipogenic activity, the mRNA levels of SREBP-1c and proinflammatory cytokines after treatment were quantified. RT-PCR profiles showed that SREBP-1c mRNA was significantly decreased by lemon pepper fractions of essential oil and polyphenol. Both fractions were also found to suppress the mRNA expression of proinflammatory cytokines, including IL-6, IL-1b, and MCP in 3T3-L1 preadipocytes. In summary, these results indicate that essential oil and polyphenol fractions derived from lemon pepper can be applied for natural materials for weight reducing diet via modulating the expression of proteins and genes regulating obesity.

Biohybrid LeukoLike vector molecular characterization to improve the therapeutic efficacy and biocompatibility of current drug delivery systems

C. Corbo[1,2,3], A. Parodi[2,3], R. Molinaro[3,4], M. Evangelopoulos[3], D. Engler[3], S. Scaria[3], F. Salvatore[1], A. Engler[3], E. Tasciotti[3]
[1]CEINGE, Advanced Biotechnologies, [2]Fondazione IRCCS SDN, Naples, Italy, [3]Houston Methodist Research Institute, Houston, United States, [4]Azienda Ospedaliera di Padova, Padova, Italy

The ultimate goal of nanomedicine is to improve the therapeutic biocompatibility and targeting while decreasing the potential side effects. In order to provide drug delivery systems with the aforementioned properties, various surface modification strategies based on antibodies, polymers, and peptides were developed. However, multiple surface modifications increased the complexity of the synthesis process and were very often incompetent in avoiding the immune response activation and the targeting of the diseased tissue. Bio-inspired approaches to develop a new generation of drug delivery system is currently being investigated to enable synthetic particles to achieve functional targeting and

© 2014 The Authors. FEBS Journal © 2014 FEBS

increase carrier biocompatibility. LeukoLike Vectors (LLV) are nanoporous silicon particles coated with purified leukocyte membranes. These were shown previously to inhibit immune system recognition and possess superior targeting ability towards the inflamed endothelium. The coating composition was characterized and the results unveiled self-tolerance biomarkers and targeting receptors through the Western Blotting assay and high-throughput proteomic analysis. These were performed to identify the proteins that can be purified from leukocyte membranes and consequently, transferred onto the silicon surface. We demonstrate an enrichment of leukocyte membrane proteins on the LLV surface in their intact native, active configuration with the appropriate post-translational modification and orientation. Among them, CD45 favors extended circulation time and avoids unspecific clearance, while Leukocyte Associated Function-1 (LFA-1) facilitates the targeting to and permeability of the tumor inflamed vasculature. These findings will advance the field of bio-engineering to provide a strategy to enhance the therapeutic efficacy of many drug delivery systems.

Biological activities of Moroccan vipers' venoms and their purified fractions

B. Makran[1], L. Fahmi[1], L. Boussadda[2], M. Lkhider[3], N. Ghalim[4]

[1]Biotechnology, Biochemistry and Nutrition Laboratory, Faculty of Sciences El Jadida, Chouaib Doukkali University, El Jadida, [2]Animal Unity of the Pasteur Institute of Morocco, Casablanca, [3]Department of Biology, Faculty of Science and Technology, Mohammedia, [4]Venoms and Toxins Laboratory, Pasteur Institute of Morocco, Casanblaca, Morocco

In Morocco, ophidian envenomation are often attributed to the bites of the Moorish viper (*Macrovipera mauritanica*), the horned viper (*Cerastes cerastes*), and sometimes to snakes of the genus Bitis and Echis. The diagnosis of these types of bites is mainly based on the recognition of local or systemic signs of bleeding, an acute inflammation (pain, swelling) and necrotic complications at the bite site that can spread to internal organs.

To determine the biological activities of the venoms of Moroccan vipers, we conducted a biological and toxicological characterization of the venom of *Macrovipera mauritanica* (VMm) and *Cerastes cerastes* (VCc) and their purified fractions the venom by using chromatographic techniques and in vivo and in vitro physiological tests.

The results of this work showed a similar toxic power between the two venoms. Only fractions VCF1 and VCF2 from VCc venom and VMF1, VMF2 and VMF3 from VMm venom feature toxic and biological activities. Both venoms and their toxic fractions have shown hemorrhagic, necrotic, edematous, myotoxic, coagulant, proteolytic, hemolytic and phospholipasic activities.

Microscopic studies of intradermal and muscle section from mice envenomed by VCc and VMm venoms and their toxic fractions showed signs of intense hemorrhage and necrosis manifested by increased thickness of the epidermis due to edema, disruption of muscle fibers, the occurrence of bleeding sites and inflammatory infiltrates.

The diversity of biological effects of venoms and their toxic fractions confirms the complexity and richness of Moroccan vipers' venoms by proteolytic enzymes responsible for the pathophysiological effects observed in viper envenomation.

Bone-marrow derived cells expressing TLR4 are important for the induction of obesity-associated hypothalamic inflammation

J. C. Moraes, D. S. Razolli, L. A. Velloso

UNICAMP, Campinas, Brazil

Dietary long-chain saturated fatty acids are known to induce hypothalamic inflammation and dysfunction through a mechanism dependent on the activation of microglial TLR4. Diet-induced hypothalamic inflammation contributes to the progressive loss of the coordinated control of food intake and energy expenditure, resulting in obesity. Thus, characterizing the mechanisms involved in the generation of diet-induced hypothalamic inflammation may provide an important advance in the understanding of the pathophysiology of obesity. TLR4 mutant mice are protected from diet-induced hypothalamic inflammation and obesity. Transplanting bone marrow derived cells harboring a functional TLR4 to TLR4 mutant mice recapitulates diet-induced hypothalamic inflammation and obesity, suggesting that bone marrow derived cells are important components of the hypothalamic inflammation associated with obesity. Here asked if the presence of a functional TLR4 in bone marrow derived cells would modulate markers of inflammation, chemotaxis and apoptosis in the hypothalamus of mice fed on high fat diet. TLR4-mutant ($TLR4^{-/-}$) and wild-type (WT) mice were irradiated in a cobalt 60 source and submitted to bone marrow transplantation (BMT). $TLR4^{-/-}$ received BM from WT and vice-versa. After recovery, mice were fed on a HFD or standard chow for 8 weeks. To evaluate inflammation and quimiotaxy markers, RT- PCR was performed. We also investigated in microglia (BV-2) and neurons (CLU189) cell culture lineage the mechanism and temporal inflammatory process initiation after palmitic acid (PA-500uM) time-course treatment (by RT-PCR and immunoblotting). In mice, when TLR4 mutant mice received BM from WT donors, microglial cells harboring WT-TLR4 were detected in the hypothalamus after 8 weeks. Differently of TLR4 mutant mice, which are protected from diet-induced obesity (DIO), these chimeric mice presented increased body weight when fed on HFD. So, functional TLR4 expression is required to warrant of adiposity increase during HFD. Fractalkine (CX3CL1) presented highest and earliest RNAm levels in DIO mice hypothalamus. In cell culture, neurons cells produced the highest levels of the CX3CL1 RNAm after 6 h of incubation with supernatant from BV-2 cells previously treated with PA. Bax apoptotic protein expression was increased after 12 h following by decreased Bcl-2 anti-apoptotic protein expression, suggesting that microglial immune factors are quickly released in high-levels after PA stimulation. Thus, hypothalamic monocytic cells involved in hypothalamic inflammation in obesity are derived from the bone marrow and depend, at least in part from neuron-produced fractalkine.

Can cathepsin-D a new inflammation biomarker in detection of lysosomal storage diseases?

P. Ergün[1], M. Kağnıcı[2], S. K. Uçar[2], M. Çoker[2], Y. D. Akçay[1], E. Y. Sözmen[1]

[1]Medical Biochemistry, [2]Department of Inherited Metabolic Disease, Ege University Medical School, Izmir, Turkey

Background: Lysosomal storage diseases (LSDs) comprise a group of at least 50 distinct genetic diseases and the incidence is about 1:7000. LSDs are characterized by inappropriate lipid storage in lysosomes, due to specific enzyme deficiencies or associated

© 2014 The Authors. FEBS Journal © 2014 FEBS

cofactors as a result of a mutation in encoding genes of lysosomal enzymes. The lysosome is commonly referred to as the cell's for intracellular digestion and recycling of macromolecules. When the lysosome doesn't function normally, excess products destined for breakdown and recycling are stored in the cell. Commonly, chitotriosidase activity measurement is a method of impression in the treatment of lysosomal storage diseases. But, approximately 6% of white race population has no plasma chitotriosidase activity as a result of a mutation and different tests may require for LSD diagnosis. In addition, chitotriosidase levels may be low in the monitoring of treatment. We aimed to investigate/compare possible markers (Cathepsin-D and chitotriosidase) in diagnosing/monitoring of two different lysosomal storage diseases (Gaucher and Niemann Pick).

Methods: Blood samples into EDTA tubes and dried blood specimens were collected from 43 subjects (between 0 and 50 years old) as 25 patient (17 Gaucher, 8 Niemann Pick) and 18 healthy individuals. Plasma chitotriosidase enzyme activities were determined fluorometrically in all subjects. Plasma chitotriosidase enzyme protein levels were also determined by using spectrophotometric ELISA kit. Cathepsin-D activities were determined by using Cathepsin-D ELISA kit. The test results were analyzed statistically by means of the SPSS 18 Program.

Results: Plasma Chitotriosidase enzyme activities and Chitotriosidase enzyme protein levels were statistically significant higher ($p < 0.001$) in patients (Gaucher disease: 6226.36 ± 4935.52 ng/mL/h, 10.63 ± 5.59 ng/mL, Niemann Pick disease: 2548.3 ± 1359.18 ng/mL/h, 11.54 ± 2.78 ng/mL) when compared with control group (83.3 ± 66.2 ng/mL/h, 0.62 ± 0.28 ng/mL). Cathepsin-D activities were also statistically significant higher in patients (Gaucher disease: 348.57 ± 130.27 ng/mL, Niemann Pick disease: 455.24 ± 201.91 ng/mL) when compared with control group (157.24 ± 30.74 ng/mL), $p < 0.001$.

Conclusions: Chitotriosidase enzyme activities were comparable with chitotriosidase enzyme proteins in plasma, The enzyme activities in plasma samples seems were more reliable than DBS samples which having high variation. While It might be suggested to measure plasma chitotriosidase activities for Gaucher patients, Cathepsin-D seems as better indicator for Niemann Pick disease. The relationship between the disease severity and the enzyme activities is subject to further research.

Keywords: Cathepsin-D, Chitotriosidase, LSDs.

Can CD15s (sialyl Lewis x) be used as a potential marker for neonatal sepsis? Control study. Split, Croatia

S. Dujic-Bilusic[1], M. Pehlić[2], A. Markotić[1], V. Čikeš Čulić[1]
[1]Department of Medical Chemistry and Biochemistry, University of Split School of Medicine, [2]Department of Gynecology and Obstetrics, University Hospital Split, Split, Croatia

Objective: Neonatal sepsis carries a high mortality when diagnosed late. Early diagnosis is difficult because initial clinical signs are nonspecific. Consequently, physicians frequently prescribe antibiotic treatment to newborn infants for fear of missing a life-threatening infection. Current biomarkers are not infallible, however, and do not permit neonatologists to withhold antibiotics in sick neonates with suspected infection. In response to infection, circulating leukocytes tether to the vessel wall and then roll. Only certain adhesion molecules including (E) selectins and some integrins have been found to support rolling. E-selectins bind to carbohydrate ligands on leukocytes in which the sialyl Lewis x (sLex, CD15s) moiety is of key importance. The aim of this pilot study was to determine a diagnostic value of CD15s in detection of early onset neonatal sepsis.

Methods: A total of 25 neonates born in minimum 37th gestation week and <72 hours before sampling were enrolled in the study. One group of neonates had clinical signs or obstetric risk factors suggesting neonatal sepsis. The control group included healthy neonates with physiological hyperbilirubinemia and without clinical signs of infection. The percentage of CD15s+ leukocytes was measured by flow cytometry using monoclonal antibody. Data were analyzed using WinMDI v.2.9 software. Statistical differences among the groups were analyzed by t-test using MedCalc v.12.5 software.

Results: Statistically significant differences in percentage of CD15s+ total leukocytes, monocytes and granulocytes were observed between control and case group. We found an increased percentage of CD15s+ monocytes and granulocytes in neonates with suspected sepsis ($P < 0.0001$ and $P = 0.0338$, respectively). There was no statistically significance in percentage of CD15s+ total leukocytes between groups.

Conclusions: Recent research in immunology has led to the discovery of cell surface antigens, chemokines, cytokines and acute phase proteins that can potentially be used to 'rule in' or 'rule out' sepsis. These preliminary data show that CD15s has a diagnostic potential for an early identification of neonatal sepsis. Further studies with greater number of samples are required for potential inclusion of this marker in the currently used screening panels for the early diagnosis or the infection treatment in the neonates.

Keywords: Neonatal sepsis, Biomarkers, CD15s.

Capparis ovata water extract (MSCov) for the potential treatment of multiple sclerosis without drug interaction: molecular evidences

O. Ozgun, G. Celik, S. Arslan, A. Sen
Department of Biology, Pamukkale University, Denizli, Turkey

This study evaluates the effect of *Capparis ovata* water extract (*MSCov*) on the experimental animal model of multiple sclerosis at the molecular level and on the expression of drug metabolizing enzymes. For this purpose, *MSCov* was prepared by using the plant's fruit, bud and flower parts (Turkish Patent Institute, PT 2012/04 093). Animal MS model, experimental allergic encephalomyelitis (EAE) was induced in 6–8 weeks old C57BL/6 mice. *MSCov* was given to EAE-induced mice intragastrically for 21 days, at 500 mg/kg. At the end of the experimental period, the animals were sacrificed, the brain and liver tissues were isolated. The expression at the mRNA level was detected by qRT-PCR in brain and liver tissues of control, EAE and EAE+*MSCov* treated animals. Differential expression of MS marker genes such as 2′,3′-cyclic nucleotide 3′-phosphodiesterase (CNP), myelin associated glycoprotein (MAG), myelin basic protein (MBP), matrix metalloproteinase-2 (MMP-2), nuclear factor kappa B p50 and p65 (NF-kB p50 and p65), proteolipid protein (PLP), peripheral myelin protein (PMP) and tumor necrosis factor-α (TNF-α) and various drug metabolizing genes such as CYP1A1, 1A2, 2A4, 2B9, 2C37, 2C39, 2D9, 2D22, 2E1, 2F2, 2J5, 3A11, 4A14, 7A1, 7B1 were measured. We have observed that the expression levels of CNP, MAG, MBP, PLP and PMP22 was reduced 20%, 45%, 40%, 23% and 32%, respectively in EAE, which was returned to control levels by 14%, 65%, 32% 60% and 72%, respectively with *MSCov* treatment. In addition, it was observed that *MSCov* treatment reduced the 17%, 45%, 13% and 62% of induced MMP-2, NF-kB p50, NF-kB p65 and TNF-α expression levels seen in EAE by 100%, 79%, 100%, and 35%, respectively. Moreover, *Capparis ovata* extract did not significantly elicit the any major CYP450 enzyme expression. These result strongly suggest that *MSCov* has high potential as an alternative or com-

Catalase, carbonic anhydrase and xanthine oxidase activities in patients with mycosis fungoides

E. Terzi, B. E. Öz, F. P. Cengiz, S. Beyaztas, B. Gokce, O. Arslan, E. Simsek, O. O. Guler
Medical Biology, Health sciences, Ankara, Turkey

Mycosis fungoides (MF) is the most common form of cutaneous T-cell lymphoma. In several studies the relationship between catalase (CAT), human cytosolic carbonic anhydrases (hCA-I and hCA-II) and xanthine oxidase (XO) enzyme activities has been investigated in various types of cancers but carbonic anhydrase, catalase and xanthine oxidase activities in patients with MF have not previously been reported. Therefore, in this prelimanary study we aim to investigate CAT, CA and XO activities in patients with MF. This study was enrolled with 32 patients with mycosis fungoides and 26 healthy controls. According to the results, CA and CAT activities were significantly lower in patients with mycosis fungoides than controls ($p < 0.001$) ($p < 0.001$). There was no significant difference in XO activity between patient and control group ($p = 0.601$). Within these findings, we believe these enzyme activity levels might be a potentially important finding as an additional diagnostic biochemical tool for mycosis fungoides.

Keywords: Carbonic Anhydrase, Catalase, Mycosis Fungoides.

CD14-enriched microregions of the plasma membranes as places of PI(4,5)P2 accumulation in LPS-stimulated macrophages

A. Póciennikowska, M. I. Zdioruk, K. Kwiatkowska
Nencki Institute of Experimental Biology, Warsaw, Poland

Lipopolysaccharide (LPS) of Gram-negative bacteria induces pro-inflammatory responses of macrophages upon binding to Toll-like receptor 4 (TLR4)/MD-2 complex. Once activated, TLR4 triggers two signaling pathways which engage Mal/MyD88 or TRAM/TRIF adaptor proteins and are initiated at the plasma membrane and after endocytosis of TLR4, respectively. Binding of LPS to TLR4/MD-2 complex is facilitated by CD14, a GPI-linked protein anchored in cholesterol- and sphingolipid-rich microdomains of the plasma membrane, named rafts. A line of studies, including those of our group, indicated also that CD14 controls internalization of LPS and TLR4.

To reveal mechanisms underlying involvement of CD14 in LPS-triggered signaling, we followed dynamics of CD14 and PI(4,5)P_2 lipid, the latter known for its versatile functions, including recruitment of Mal/MyD88 adaptor proteins. LPS-stimulation of cells led to a moderate elevation of the amounts of CD14 on the surface of J774 cells, as indicated by laser scanning cytometry analysis. Confocal microscopy analysis indicated that LPS can up-regulate trafficking of CD14 from Golgi apparatus toward the plasma membrane. In agreement, biochemical analysis revealed that CD14 was enriched in raft fractions at the onset of cell stimulation with LPS.

To follow LPS-induced redistribution of CD14, we performed ultrastructural analysis of CD14 localization in the plane of sheets of the plasma membrane obtained by mechanical cleavage of J774 cells and subjected to immunogold labeling. Stimulation of cells with 100 ng/ml LPS induced rapid and transient clustering of CD14 in the plasma membrane. Double immunogold labeling revealed that CD14 aggregates co-localized transiently with PI(4,5)P_2 and its precursor PI(4)P. Specificity of LPS action was confirmed using antibody which inhibited binding of LPS to CD14 – no clustering of CD14 or PI(4,5)P_2 was found in these conditions. To reinforce the ultrastructural data, we developed a technique of PI(4,5)P_2 measurements based on binding of a fusion protein, GST-tagged PH domain of phospholipase C, to extracts of cellular lipids. Such quantitative analysis showed that the PI(4,5)P_2 level in cells slightly rose after short time of LPS action and increased significantly after 1 hour of cell stimulation with LPS. PI(4,5)P_2 level in cells was strongly diminished by LiCl which inhibited also LPS-induces production of pro-inflammatory mediators.

Taken together, our studies indicate that during stimulation of cells with LPS, CD14-enriched regions of the plasma membrane can serve as platforms for the initial generation of PI(4,5)P_2 which, in turn, plays essential role in signaling cascades of TLR4.

Keywords: CD14, lipopolysaccharide, phosphatidylinositol 4,5-bisphosphate.

Changes of serum alpha2-macroglubulin levels in rats induced acute inflammation

T. Kuribayashi[1], T. Seita[1], E. Momotani[2], S. Yamazaki[3], S. Yamamoto[1]
[1]*Azabu University, Sagamihara,* [2]*Tohto College of Health Sciences, Fukaya,* [3]*Kamakura Women's University, Kamakura, Japan*

α_2-macroglubulin (α2M) is a typical acute phase protein in rats. We investigated the characters of α2M in rats induced acute inflammation. The relationship between intensity of inflammatory stimulation and production of α2M in rats and the synthesis of α2M in hepatopathic rats were investigated. Sprague-Dawley rats were injected with turpentine oil at doses of 0.05, 0.2 or 0.4 ml/rat. Serum levels of α2M, interleukin (IL)-6 and cytokine-induced neutrophil chemoattractant-1 (CINC-1) were measured by ELISA. Hepatopathy was induced by oral administration of acetaminophen at a dose of 1 g/kg daily for 2 weeks or a 25% solution of carbon tetrachloride (CCl4) at 2 ml/kg body weight three times per week for 7 weeks. Acute inflammation was induced by intramuscular injection of turpentine oil at a dose of 1.0 ml/kg body weight. Peak serum levels of α2M and in rats injected at 0.05 ml/rat were significantly lower than those at 0.2 or 0.4 ml/rat. However, no significant difference was observed for peak serum levels of these acute-phase proteins between 0.2 and 0.4 ml/rat. Furthermore, peak serum levels of IL-6 and CINC-1 in rats injected at 0.05 ml/rat were significantly lower than those at 0.2 or 0.4 ml/rat. Thus, the production of α2M have upper limit even if increased the strength of inflammatory stimulation. Aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase and total protein differed significantly between acetaminophen or CCl_4-induced hepatopathic rats and acetaminophen-control (AA-control) or CCl4-control (CC-control) rats. Furthermore, pathological examination confirmed hepatopathy in rat livers. Peak serum concentrations and area under the time-concentration curve for α2M showed significant differences between hepatopathic rats and AA- or CC-control rats. Thus, serum concentrations of α2M did not increase when compared with non-treated rats. α2M is considered to be an useful as an acute phase protein in rats.

Keywords: inflammation, rats.

Characterization of a novel protein kinase D1 inhibitor using different inflammatory cell models

A. Varga[1], P. Gyulavari[1], Z. Greff[2], T. Nemeth[3], D. Brauswetter[4], M. Kokas[4], L. Orfi[2], A. Mocsai[3], G. Kéri[1,2,4], T. Vantus[4]
[1]MTA-SE Pathobiochemistry Research Group, [2]Vichem Chemie Research Ltd., [3]Department of Physiology, [4]Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University, Budapest, Hungary

Inflammatory diseases have severe effects on healthcare worldwide. Protein kinase D1 (PKD1) a member of protein kinase D family is a well characterized and validated target in inflammatory diseases. In endothelial cells PKD1 is a member of VEGFR2 signaling pathway, which has a critical role in angiogenesis and related inflammatory diseases. In neutrophils PKD1 has a positive regulatory role in superoxide production through Fcγ-receptor induced NADPH activation.

The aim of this study was to identify a novel PKD1 inhibitor drug candidate and characterize its effects on different inflammatory cellular models.

First applying recombinant kinase assay we screened a kinase specific inhibitor library against protein kinase D1 and identified some small molecule PKD1 inhibitor. We selected the best one for further investigation. Then we tested the effect of this inhibitor on different cellular assays.

Treatment with the inhibitor effectively inhibited the intracellular activation of PKD1 and also the proliferation of endothelial cells. Our compound was also an efficient inhibitor in in vitro angiogenesis assays interfering with endothelial cell wound healing and tube formation processes.

Inflammatory cellular model such as neutrophils were also applied to prove the anti-inflammatory effect of the inhibitor. The neutrophil study showed that the inhibitor could specifically diminish the immune-complex stimulated adhesion dependent neutrophil activation.

In the present study, we have identified and characterized a small molecular inhibitor of PKD1, which could efficiently inhibit pathological inflammatory pathways involving PKD1.

Keywords: Inflammation, inhibitor, PKD1.

Characterization of PERK-directed endoplasmic reticulum stress response to lipids

U. I. Onat[1], S. Koyuncu[2], S. Demirsoy[3], E. Erbay[2]
[1]Molecular Biology and Genetics, [2]Bilkent University, Ankara, Turkey, [3]Laboratory of Cell Death Research & Therapy, KU Leuven, Leuven, The Netherlands

Pathways that lie at the interface of metabolism, inflammation and stress have a profound influence on Cardiometabolic Syndrome (CMS). Metabolic overload initiates a chronic inflammatory response that promotes the complications of CMS. However, the molecular mechanisms linking metabolic stress to immune activation remain elusive. Earlier studies demonstrated metabolic overload leads to endoplasmic reticulum (ER) stress and activate the unfolded protein response (UPR). The UPR is essentially an adaptive signaling emanating from the ER to cope with cellular stress. In addition to its protective responses and role in ER biogenesis, the UPR can also impinge on inflammatory signaling. Prolonged ER stress is detrimental and contributes to obesity, diabetes and atherosclerosis in part by activating pro-inflammatory and pro-apoptotic pathways. Moreover, the existence of inflammatory mediators, chemotactic cytokines, reactive oxygen species and other stress signals in obesity make it even more challenging for the ER to establish and maintain a healthy metabolic equilibrium. Clarifying the regulatory mechanisms and novel players in a metabolically-driven ER stress response is needed to develop specific, new therapeutic strategies for CMS. Here, we investigated the UPR that can sense excess lipids and couple to inflammation, and whether its unique operation under metabolic stress can be suitable for therapeutic exploitation in CMS. We adapted a chemical-genetic approach to probe the full range of substrates of a proximal UPR kinase, protein kinase RNA-like endoplasmic reticulum kinase (PERK), during metabolic stress. This method, which yields a monospecific inhibitor or activator of a kinase involves targeting of a conserved 'gatekeeper' amino acid residue in the ATP binding pocket to a small amino acid, enlarging the pocket sufficient enough to accommodate bulky ATP analogs. Then PERK's potential substrates are identified by coupling this approach with proteomics. Furthermore, by using the same approach to specifically modify PERK kinase activity in macrophages, we investigated its direct contribution to inflammation. Our findings show that PERK is a critical modifier of lipid-induced ER stress and inflammation and substantiated through studies using complementary approaches to block PERK activity such as RNAi-directed knock-down and a specific inhibitor. The results of this study demonstrate the individual contribution of the PERK branch of the UPR to lipid-induced inflammation and underscore the importance of delineating specific UPR targets that could be therapeutically modified to treat CMS.

SUN-119
Cigarette smoke extract induces expression of HSP27 and HSP32 but not HSP70 in A549 alveolar epithelial cells

A. Somborac Bacura, L. Rumora, T. Zanic Grubisic
Department of Medical Biochemistry and Hematology, Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

Heat shock proteins (HSPs) are highly conserved proteins involved in folding of native and damaged cell proteins. HSPs participate in cellular responses to stress and can be induced by various stress conditions, including high and low temperatures, reactive oxygen species, hypoxia, infection, inflammation etc. Cigarette smoke is known to contain many different oxidants and reactive oxygen species, thereby causing oxidative stress, chronic inflammation and severe damage to proteins in the lungs of smokers and patients with chronic obstructive pulmonary disease (COPD).

The aim of this study was to find out whether exposure of A549 alveolar epithelial cells to increasing concentrations (1.25; 2.5; 5; 10 and 20%) of cigarette smoke extract (CSE) during 4, 6, 8, 24 and 48 h activates cellular defense mechanisms, including expression of HSP27, HSP32 (also known as heme oxygenase 1) and HSP70 in response to accumulation of damaged proteins.

Our study shows that exposure of A549 cells to 20% CSE for 24 h produced considerable damage to cellular membranes with increased permeability and leakage of LDH into the incubation medium, as compared to untreated cells ($P = 0.01$). Metabolic activity explored by MTT test was reduced at the same time point ($P < 0.01$). In addition, AnnexinV – propidium iodide double staining confirmed that 20% CSE during 24 h is causing primarily necrotic cell death ($P < 0.001$). However, cellular defense mechanisms were only partially activated. Expression of HSP32

© 2014 The Authors. FEBS Journal © 2014 FEBS

was induced 8 h after incubation with 20% CSE ($P = 0.029$) and 24 h after incubation with 10% and 20% CSE ($P = 0.019$). HSP27 was induced with 20% CSE only after 48 h ($P = 0.012$). Unexpectedly, we could not detect significant changes in HSP70 expression ($P > 0.05$).

The unchanged level of HSP70 expression might reflect lack of induction, or increased release of HSP70 from the damaged, necrotic cells.

We conclude that CSE-induced stress produces only limited activation of HSPs response indicating disturbed cellular defense mechanisms. It is possible that chronic exposure to CSE leads to the depletion of HSP-related defense mechanisms and contributes to the abnormal inflammatory response observed in lungs of smokers and COPD patients.

Keywords: chronic obstructive pulmonary disease, cigarette smoke extract, heat shock proteins.

Circulating biomarkers assessment for early diagnosis of vascular calcification in chronic kidney disease

S. Mihai[1], E. Rusu[2], E. Codrici[1], I. D. Popescu[1], A. Nita[1], M. Voiculescu[2], C. Tanase[1]
[1]Biochemistry-Proteomics, Victor Babes National Institute of Pathology, [2]Nephrology, Fundeni Clinical Institute, Bucharest, Romania

Background: Chronic kidney disease (CKD) describes the gradual loss of kidney function that typically evolves over many years due to its clinically silent behavior. CKD is associated with an increased inflammatory condition, which involves complex interactions among immune cells and soluble proteins. Accelerated vascular calcification (VC) is an important and devastating complication of CKD and contributes to the high mortality in these patients.

The aim of the present study is to assess a novel biomarker panel particularly useful for identification of VC early phases in CKD patients, having important consequences on the therapeutic interventional strategies, prognosis, and life-expectancy of patients with CKD.

Material and Method: Serum samples of 29 CKD patients (in stages II-IV, not undergoing dialysis) and 10 normal controls were analysed to simultaneously measure the level of 8 biomarkers (IL-6, IL-1β, TNFα, OPG-osteoprotegerin, OC-osteocalcin, OPN-osteopontin, PTH, FGF-23 – Milliplex MAP Human Bone Magnetic Bead Panel) using xMAP technology. Multiplexed data acquisition was performed on Luminex 200 platform using xPONENT 3.1 version.

Results: Mineral metabolism candidate biomarkers and molecules that actively regulate VC process (OPG, OC, OPN, PTH and FGF-23 respectively) showed an increased circulating level compared with control – between 1.66 and 12.37 fold higher, $p < 0.05$. The pro-inflammatory cytokines level (TNFα, IL-6) was also increased in CKD patients compared with control (1.96 and 7.03 fold higher, $p < 0.05$), with the mean values of 2.73 pg/mL and 6.96 pg/mL respectively in the CKD group, while for IL-1β no trend was visible so far. It has also been observed a positive correlation between the circulating biomarkers level and the stages inside the CKD group.

Conclusion: Detecting VC through its severe clinical manifestations may turn to be too late for any therapy to halt its progression or to reverse it. Thus, it would be particularly useful to develop a specific biomarker panel for identification of early phases of VC and for scoring its severity in CKD patients, which would allow developing further strategies aiming to control and even reversing some of the processes.

SUN-121
Circulating endothelial microparticles in patients with chronic hepatitis C infection

J. Zuwala-Jagiello[1], M. Pazgan-Simon[2], E. Murawska-Cialowicz[3], K. Simon[4]
[1]Department of Pharmaceutical Biochemistry, [2]Clinic of Infectious Diseases, Liver Diseases and Acquired Immune Deficiency, Wroclaw Medical University, [3]Department of Physiology and Biochemistry, University of Physical Education, [4]Division of Infectious Diseases and Hepatology, Wroclaw Medical University, Wroclaw, Poland

Aim: Endothelial microparticles (EMPs) can be involved in inflammatory process, blood coagulation, and regulation of vascular function. Inflammation and endothelial dysfunction have been reported in patients with chronic hepatitis C (CHC) infection, but their influence on circulating EMPs levels and diabetes prevalence remains unknown.

Methods: Seventy-four CHC patients, 30 with type 2 diabetes, and 40 healthy controls were enrolled in the study. Circulating levels of EMPs, ischemia-modified albumin (IMA), pro-inflammatory cytokines (interleukin-6, and tumor necrosis factor α), and high-sensitivity C-reactive protein (hsCRP) were assessed.

Results: Compared with the controls, the CHC patients with diabetes showed a significant increase in plasma concentrations of circulating of EMPs, IMA, tumor necrosis factor α and hsCRP ($P < 0.001$). The values of EMPs and IMA were more elevated in patients with diabetes than without diabetes (both $P < 0.01$). The positive relationships were found between tumor necrosis factor α and EMPs levels ($P < 0.01$) and the presence of diabetes ($P < 0.001$). Significant positive correlations between IMA and hsCRP levels and between EMPs and hsCRP levels were found in all patients with CHC infection.

Conclusion: We documented that significant elevation in plasma EMPs levels is associated with diabetes prevalence and increased inflammatory response reflected in tumor necrosis factor α levels in patients with chronic hepatitis C infection.

Keywords: diabetes mellitus, endothelial microparticles, HCV infection.

Clinical implication of afamin and its SNP rs4694619 G>C as a novel diagnostic marker for breast cancer

N. M. Hamdy[1], M. M. Swellam[2]
[1]Biochemistry, Faculty of Pharmacy, Ain Shams University, [2]Biochemistry, Genetic Engineering and Biotechnology Research Division, Cairo, Egypt

Comparative proteomics identified the vitamin E binding plasma protein, afamin, as a potential novel tumor marker. We aimed to identify the diagnostic utility of afamin in detection of breast cancer. Moreover, genome-wide association studies of breast cancer revealed that single nucleotide polymorphisms (SNPs) in some genes with novel association to disease susceptibility. Thus we attempt to study SNP in afamin gene (SNPrs4694619). Plasma concentrations of afamin using ELISA assay was measured in 240 breast cancer patients, 80 benign cases, and 60 controls and compared the results with conventional breast tumor markers; CA15.3, CEA, and angiogenesis; VEGF and NO. Genotyping of afamin rs4694619 G> C polymorphism was identified using poly-

© 2014 The Authors. FEBS Journal © 2014 FEBS

merase chain reaction (PCR). Afamin median concentrations were superior in healthy controls followed by benign cases and breast cancer patients (136, 105, 26 μg/mL, respectively, at $P < 0.001$). Receiver operating characteristic curve was used for differentiating malignant- from non-malignant breast patients, revealed 98.6% specificity, 98.3% sensitivity for afamin versus specificities at 91.7% and 98.3%, and sensitivities at 87.5% and 96.7% for CEA and CA 15.3, respectively. Concordance between investigated markers was statistically significant. Hetero-mutant SNP rs4694619 was significantly expressed in breast cancer patients as compared to either homo-wild or mutant SNP.

Conclusion: Afamin added independent diagnostic information to CEA and CA 15.3 for differentiating breast cancer from benign and healthy samples. Afamin and its SNPrs4694619 might have the potential to become valuable biomarker for diagnosis of breast cancer.

Comparative study of the biochemical and biological properties of *Bothrops jararaca* snake venoms milked and stored from 1963 up to 2008

A. M. Tanaka-Azevedo[1], D. Hatakeyama[2], C. Silva[2], W. Fernandes[2], A. Tanaka[3], R. Torquato[3,3], K. Morais-Zani[2]

[1]Laboratory of Herpetology, [2]Butantan Institute, [3]Unifesp, Sao Paulo, Brazil

Introduction: Bothropic envenomation is characterized by proteolytic, coagulant and hemorrhagic activities. Variations in the snake venom composition may cause an impact on primary venom research and antivenom production. Considering the potential applications of snake venom research and antivenom production, it is of huge importance that venom samples are stored correctly after collection. Proper storage may limit the need to collect additional samples from wild snakes. Additionally, as some snake species are infrequently encountered, it might be impossible to collect additional samples in the future. Studies indicate that, in order to preserve the biologic and enzymatic activities, venoms may be lyophilized and frozen. However, the effect of long-term storage conditions is not fully elucidated.

Fig. 1. *Bothrops jararaca* snake.

Objectives: The present study aims to investigate the longevity of the biochemical and biological activities present in *B. jararaca* venom.

Materials and Methods: Protein profile of *B. jararaca* venom from 1963, 1973, 1977–88, 1997 and 2008 was analyzed by HPLC (C18 column – ACE). The minimal coagulant dose (MCD) was determined upon human plasma and bovine fibrinogen. The proteolytic activity was evaluated using casein and gelatin as substrates. The immunogenicity was assessed by the immunization of Balb/C mice using *B. jararaca* venom and Al_2OH as adjuvant. Serum titers was determined by ELISA assay.

Results and Discussion: Venoms analyzed showed similar HPLC profile, with some differences in the relative abundance of molecules. The MCD-plasma is quite equivalent among the venoms, while the MDC-fibrinogen increases with the time of storage. The proteolytic profile was also similar, but the proteolytic active varies among the venoms. The same was observed for the venom immunogenicity, which differs among the venoms.

Conclusion: The results suggest that some venom activities may be affected by the period and conditions of storage. For further elucidation of this study, other experiments related to the biological activities will be performed.

Keywords: *Bothrops jararaca*, longevity, snake venom proteins.

Comparison of 'tim' gene of *Giardia lamblia* in laboratory animals and human and the importance of cross transmission probability in Iran

N. Einollahi, M. Zare bavani, N. Dashti, M. Rezaeian

Tehran University of Medical Sciences, Tehran, Iran

Background: Variably divided into two or three genotypes by different investigators, and each group can be divided into subgroups. *Giardia* has the ability to infect many mammals including the dog, cat, deer mouse, ground squirrel, chinchilla, swine, rabbit, pocket mouse, ox, guinea pig, and humans *Giardia lamblia* (also *Giardia duodenalis*, *G. intestinalis*) isolates have been.

Objective: The aim of the present study was to biotype groups of *G. lamblia* in laboratory animals which were used in research and the possibility of cross transmission between human and these animals and the importance of this transmission in research which was performed for the first time in Iran .Comparison of triose phosphate isomerase (tpi) sequences of these genotypes by polymerase chain reaction- restriction fragment length polymorphism (PCR-RFLP) was studied to determine *G. lamblia* genotype.

Methods: In this study 4 sets of primers were used in which 2 sets were designed by other investigator and 2 sets were designed by us to confirm the results of the first two primers and also to differentiate the subgroups.

Results: Two sets of primers were designed to differentiate between *Giardia* isolates. The PM924 primer set were used to differentiate between AC#L0210 (WB) and AC#U57897 (JH) isolates, and PM290 primer set were used to differentiate between C#AF069559, AC#AF069558. Among Giardia isolates, 20% and 5% of PCR-RFLP of rabbit and mouse was amplified with primer PM290 respectively.

Conclusion: There is an evidence that suggests the direct transmission from companion animals to human does occur. Zoonosis is controversial regarding *Giardia*, but most researchers believe that its zoonotic potential merits adequate precaution when working with feces of animals that may be infected.

Keywords: zoonose, *Giardia lamblia*, PCR- RFLP.

SUN-126
Comparison of hERG channel blocking effects of anti-arrhythmic mexiletine and its metabolite m-hydroxymexiletine (MHM)

R. Gualdani[1], G. Lentini[2], M. R. Moncelli[1]
[1]Department of Chemistry, University of Florence, Sesto Fiorentino, [2]Department of Pharmacy, University of Bari 'Aldo Moro', Bari, Italy

Mexiletine, 1-(2,6-dimethylphenoxy)-2-propanamine, is a class IB antiarrhythmic drug. In addition to well-known clinical application in treating ventricular arrhythmias, recent studies have suggested the use of mexiletine for the treatment of neuropathic pain and myotonia. However mexiletine was reported to cause a number of adverse effects such as nausea, hypotension, sinus bradycardia, paresthesia, atrioventricular heart block, ventricular arrhythmias.

Recently it has been demonstrated [1] that a minor metabolite of mexiletine, *m*-hydroxymexiletine (MHM), has twice the blocking activity of mexiletine on cardiac sodium ion channels – which may account for its increased antiarrhythmic and vasorelaxant activities on isolated cardiac tissues.

Since the cardiotoxicity of drugs is mainly due to blockade of K^+ channel currents in the human heart, in the present study we have compared the effects of mexiletine and MHM on the hERG (the human Ether-à-go-go-Related Gene) K^+ channel stably transfected into mammalian cells, using the patch clamp technique.

Our data showed that MHM and mexiletine block hERG tail currents, elicited on repolarization from positive voltage to -50 mV, with IC_{50} values equal to 2.33 ± 0.13 and 0.28 ± 0.02 μM, respectively. Moreover both compounds induced a shift of voltage dependence of steady-state activation, that was more pronounced for mexiletine. Finally the block of current induced by MHM and mexiletine required preferentially channel activation, suggesting that both compounds have a similar mode-of-action, but a different hERG binding site affinity.

In summary, our data suggest that MHM might be used in substitution of mexiletine ('metabolite switch'), because it might have similar therapeutic properties but fewer cardiotoxic effects.

The financial support of Ente Cassa di Risparmio di Firenze and MIUR (PON project 2007-2013, 01_00937) is gratefully acknowledged.

Comparison of the effects of quercetin derivatives on the formation of advanced glycation endproducts in vitro

M. Havlikova[1,2], J. Ulrichová[1,2]
[1]Department of Medical Chemistry and Biochemistry, [2]Faculty of Medicine and Dentistry, Institute of Molecular and Translational Medicine, Palacky University in Olomouc, Olomouc, Czech Republic

Hyperglycaemia causes increased protein glycation and the formation of advanced glycation endproducts (AGEs). Accumulation of AGEs in body tissue are believed to be responsible for long-term complications of diabetes and aging. The major AGE in vivo is carboxymethyllysine (CML), which is not a crosslink but formed by oxidative breakdown of Amadori products and its level increases two-fold in the skin of diabetic patients. As such, inhibition of the formation of AGEs represents a potential therapeutic target for the prevention and treatment of diabetic complications. Various pharmacological compounds have been evaluated for their antiglycative properties. However, natural inhibitors have been proven relatively safer for human consumption when compared with synthetic compounds.

In this study, the inhibitory effects of quercetin, isoquecitrin, 3-O-galloylquercetin, and 7-O-galloylquercetin on the formation of advanced glycation endproducts (AGEs) were compared. Besides polyacrylamide gel electrophoresis, inhibitory effects were studied using fluorometric and immunochemical detection of AGEs (non-competitive ELISA) in bovine serum albumin (BSA)/glucose, BSA/methylglyoxal and lysozyme/methylglyoxal systems. From the tested compounds, 7-O-galloylquercetin showed the most promising results.

The effect of quercetin derivatives on the formation of AGEs suggests their possible beneficial roles in the prevention of glycation-associated diseases. This effect will be further verified in vivo. Equally, the mechanism of action of quercetin derivatives will be studied.

Acknowledgement: We thank Prof. Vladimír Křen for providing us the derivatives of quercetin.

Computational association of autoimmune diseases: a case study

T. Sevimoglu, K. Y. Arga
BioEngineering, Marmara University, Istanbul, Turkey

Microarray technologies have enabled rapid and efficient expression profiling of thousands of genes simultaneously. Studies on disease datasets have already revealed genes that could potentially be implicated in the pathogenesis of that disease thus opening the path to accurate diagnosis and potential biomarkers. Autoimmune diseases have a complex genetic basis with multiple genes contributing to disease risk, each with generally modest effects independently. There is enough evidence indicating that common genes underlie multiple autoimmune diseases. Previous studies point to a greater frequency of autoimmune diseases among patients with psoriasis than in the general population and many inflammatory autoimmune diseases are a result of derangements in multiple cytokine pathways. This study examined the association between psoriasis and rheumatoid arthritis, both of which are declared inflammatory autoimmune diseases.

A comparison of gene expression data associated with psoriasis and rheumatoid arthritis (RA) from four independent studies, obtained from Gene Expression Omnibus has been performed. Each dataset was statistically analyzed in order to identify differentially expressed genes (DEGs). Proteins encoded by DEGs were determined and integrated with protein-protein interaction data for further analyses and hub proteins were identified. Enrichment analyses were performed to map the interconnectivities between diseases and biological pathways.

Comparative analyses indicated that psoriasis and rheumatoid arthritis have 20 common DEGs. 12 of these DEGS have previously been linked to RA and 9 have been linked to psoriasis. Related pathways of these DEGs are: chemokine signalling pathways and Cytokine-cytokine receptor interaction. Main hubs for the PPI network are STAT1, CEBPD, MMP1 and SERPINA1.

This study provides additional insight into the molecular mechanism of autoimmune diseases: psoriasis and rheumatoid arthritis. Results indicate that psoriasis has a strong association with rheumatoid arthritis thus suggesting a common genetic cause between

© 2014 The Authors. FEBS Journal © 2014 FEBS

them. Further evaluation of other autoimmune diseases may lead to a common mechanism between these diseases.

Keywords: autoimmune diseases, network analysis.

Crystal structure of human aminopeptidase ERAP2 in the absence of catalytic Zn(II) atom

N. Mathioudakis, E. Zervoudi, E. Saridakis, I. Mavridis, E. Stratikos

Protein Chemistry Laboratory, NCSR Demokritos, Athens, Greece

The human adaptive immune response recognizes diseased cells and eradicates them through the action of cytotoxic T-lymphocytes (CTLs). CTLs recognize small peptide fragments, arising from pathogen-derived proteins, bound onto molecules of the Major Histocompatibility Complex (MHC) Class I on the cell surface. These antigenic peptides are produced by complex intracellular proteolytic cascades. Aberrant antigenic peptide generation can contribute to pathogen evasion and autoimmunity, necessitating tight control of the antigen generation process.

Antigenic epitopes are initially degraded by the proteasome and immunoproteasome while the final processing step occurs within the endoplasmic reticulum (ER) by at least two highly homologous zinc aminopeptidases, namely ERAP1 and ERAP2 (~50% sequence identity). The two proteins are suggested to have a complementary role in the trimming of the large pool of antigens in the ER.

The crystal structures of ERAP1 and ERAP2 contributed to our understanding on how antigenic peptide precursors are bound and processed. ERAP1 has been crystallized in two conformations; the 'open' conformation is hypothesized to be inactive but to facilitate initial substrate capture while the 'closed' conformation is enzymatically active. The conversion inactive to active was suggested to center around the reorientation of a key Tyrosine catalytic residue. Structural analysis of ERAP2 showed a similar domain topology and highly conserved active site as ERAP1 and provided structural insight on the different substrate specificities between the two ER aminopeptidases. ERAP2, however, has only been crystallized in the 'closed', presumably active conformation.

We report here the X-ray crystal structure of apo-ERAP2, lacking the active site Zn(II) ion at 3.02 Å in a conformation resembling the 'closed' ERAP1. Overall, the structure is highly similar to the crystal structures of ERAP2 in complex with the product of a reaction and ERAP2 in complex with a transition-state analogue. However, while key residues comprising the zinc-binding motif remain unaffected, important residues for the enzymatic activity, stabilization of the tetrahedral intermediate and binding to the inhibitor are perturbed. Importantly, the key catalytic Tyr455 is shifted away from the active site, in a configuration resembling the ERAP1 'open' conformation. This finding suggests that the orientation of the catalytic site Tyrosine correlates to the presence of a substrate or transition-state analogue rather than to the overall conformational state of the proteins as was originally hypothesized for ERAP1.

Cytotoxic effects of cobalt chloride and ciprofloxacin in C6 glioma and vero cells: a preliminary study

A. Gurbay[1,2], B. Gonthier[1], I. Hininger -Favier[1], A.-M. Roussel[1]

[1]LBFA/INSERM, U1055, Grenoble, France, [2]Department of Toxicology, Hacettepe University, Faculty of Pharmacy, Ankara, Turkey

The objective of this study was to determine possible time- and dose-dependent cytotoxic effects of cobalt chloride ($CoCl_2$) and a fluoroquinolone antibiotic, ciprofloxacin (CPFX) in C6 glioma and vero cells. The C6 glioma cells were exposed to various concentrations of $CoCl_2$ (50–500 μM) and CPFX (10–150 mg/l) for 24, 48 and 72 h. However, as indicated in parenthesis, the concentrations of $CoCl_2$ (0.5–1000 μM) and CPFX (0.5–300 mg/l) and incubation times (24, 48, 72 and 96 h) were different with Vero cells. Cytotoxic effects of these substances were determined by MTT and/or rezasurin assays. Possible protective effects of vitamin E, coenzyme Q_{10}, and/or zinc chloride were also tested in vero cells. Our results showed that with MTT assay, in the presence of $CoCl_2$, a gradual decrease in cell survival was noted at concentrations 200 μM or higher in incubation periods of 24, 48, 72, and 96 h in vero cells. Similar results were obtained with $CoCl_2$-treated C6 glioma cells. With resazurin assay, $CoCl_2$-induced cytotoxicity was found similar to the results of MTT assay, particularly at high concentrations and long incubation periods. Pretreatment of vero cells with $ZnCl_2$ for 4 or 24 h provided significant protection against $CoCl_2$ induced cytotoxicity when measured with MTT assay. However, vitamin E or coenzyme Q_{10} was not protective. For CPFX-treated cells, a significant decline was noted in viability ≥50 mg/l of the drug at 24, 48 and 72 h for both cell types. With extended incubation period, decline in cell survival was more significant. Vitamin E or coenzyme Q_{10} pretreatment of cells for 4 h caused complete protection against CPFX-induced cytotoxicity. These preliminary results suggest that oxidative-stress might be involved in the cytotoxicity mechanism of $CoCl_2$ and CPFX in these systems.

DCC, MLH1, GSTT1, GSTM1, and TP53 genes polymorphisms and risk for development of colorectal cancer in population from Kazakhstan

L. Djansugurova[1], G. Zhunussova[1], B. Zhunusbekova Benazir[1], O. Iksan Olzhas[1], G. Afonin Georgiy[2], E. Khussainova[1]

[1]Laboratory of Molecular Genetics, Institute of General Genetics and Cytology, [2]Almaty City Oncology Clinic, Almaty, Kazakhstan

Association analysis between specific gene polymorphism and disease development is the leading focus in molecular epidemiology and one of the promising trends in predictive medcine.

Colorectal cancer continues to be one of the most common fatal types of cancer. The colorectal cancer (colon and rectal cancer) morbidity and significant rejuvenation have been considerable increased worldwide in recent years. Among Eurasian countries, Kazakhstan is in the seventh place regarding to the colorectal cancer incidence. There are many familial syndromes which predispose to colorectal cancer development, the percentage of patients with cancer burdened histories is 20–30%. But the majority of colorectal cancers cases are the sporadic forms. Colorectal carcinogenesis is characterized by the successive accumulation of mutations in genes controlling epithelial cell growth

© 2014 The Authors. FEBS Journal © 2014 FEBS

and differentiation leading to genomic instability whereby widespread loss of DNA integrity is perpetuated. In most familial cases there is a spectrum of expected mutations of key genes involved in disease pathogenesis. In sporadic cases there is no identifiable inherited gene involved, but the cancers developed as a result of accumulation of mutations in genes responsible for interaction with environmental factors.

Here we present the results of case-control study of 494 residents from Kazakhstan to reveal an association of the DCC G32008376A, MLH1 -93G/A, TP53 Arg72Pro single nucleotide polymorphisms, and GSTT1, GSTM1 genes deletion polymorphism with colorectal cancer risk. The blood samples were collected from the patient of cancer clinics of Almaty and Semey cities. Detailed questionnaires and informed consents were filled prior collection of samples. The clinical diagnosis of cancer patients was verified by the cytological or histological methods using biopsy and post-surgery materials. 16 patients (6.13%) with colorectal cancer cases in family history were excluded from the case-control analysis. The control groups of healthy individuals were selected in accordance to the ethnic and age data of cancer patients. 245 healthy persons were included to the control cohort and case cohort consists from 249 patients with sporadic colorectal cancer.

We found out the significant associations of increased risk of colorectal cancer and fallowing genotypes: DCC (32008376 G/G and G/A versus A/A – OR = 3.45, p = 0.0002), MLH1 (-93G/G, OR = 1.45, p = 0.04), TP53 homozygous (Pro72Pro, OR = 3.80, $p < 0.0001$), GSTT1 (deletions and heterozygous versus normal homozygous – OR = 1.43, p = 0.05) and GSTM1 deletions (OR = 1.83, p = 0.001).

Keywords: case-control study, colorectal cancer, gene polymorphism.

Decreased expression of heme oxygenase-1 as a putative risk factor linking redox imbalance and inflammation in depression. The role of HMGB1 signaling in progression of inflammation

J. Rybka[1], K. Kędziora-Kornatowska[2], M. Muszalik[1], J. Kędziora[3]

[1]Department and Clinic of Geriatrics, Collegium Medicum UMK, Bydgoszcz, Poland, [2]Hasselt University, Innovation Management Group, Hasselt, Belgium, [3]Professor Emeritus, Collegium Medicum UMK, Bydgoszcz, Poland

Objectives: Inflammation and oxidative stress are both related to the pathology of depression. The aim of this study was to examine selected parameters of redox homeostasis and inflammation in depressed patients and healthy controls and determine their association with the risk of depression. Furthermore, we assessed HMGB1 protein as a plausible signal for progressing inflammation.

Methods: The blood was collected from patients with depression (Group I, N = 18) and from healthy controls (Group II, N = 20). Antioxidant enzyme activities (gluatathione peroxidase, glutathione reductase, superoxide dismutase), reduced gluatathione, hydrogen peroxide and malondialdehyde were measured spectrophotometrically, heme oxygenase (HO-1), IL-6, IFN-gamma and HMGB1 were assayed with ELISA technique.

Results: In this study we observed significantly decreased activity of glutathione peroxidase, significantly increased activity of GR, significantly decreased activity of SOD-1, significantly decreased concentration of HO-1, significantly increased concentration of H_2O_2, significantly increased concentration of MDA in the group of depressed patients when compared with healthy controls. HO-1 was significantly correlated with the risk of depression such as decreased concentration of the enzyme increased the risk for depression. Moreover, decreasing activity of heme oxygenase was accompanied by increased severity of depression. In depressed patients IL-6 and IFN-gamma levels were increased when compared with healthy controls. HMGB1 remained in relation with redox potential and immune status of the blood.

Conclusions: Our observation of decreased activity of HO-1 in depression suggest significant role of this enzyme in maintaining the brain functions under the conditions of oxidative stress and inflammation. Immunomodulatory role of HMGB1 might be related to the change of its activity caused by redox imbalance in depressed patients.

Dehydroepiandrosterone has strong antifibrotic effects and is decreased in idiopathic pulmonary fibrosis

C. Mendoza-Milla[1], M. Montaño[1], C. Becerril[1], C. Ramos[1], A. Cruz-Lagunas[2], J. Zúñiga[2], J. Cisneros[1], A. Pardo[3], M. Selman[4]

[1]Fibrosis Pulmonar, [2]Inmunobiología y Genética, Instituto Nacional de Enfermedades Respiratorias, [3]Facultad de Ciencias, Universidad Nacional Autónoma de México, [4]Unidad de Investigación, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico

Introduction: Idiopathic pulmonary fibrosis (IPF) is a progressive and lethal disease of unknown etiology occurring in individuals older than 50 years old and reaching its peak at 60–65 years. The disease is characterized by epithelial cell injury/activation, expansion of the myofibroblast population and aberrant lung remodeling. Dehydroepiandrosterone (DHEA), a steroid pro-hormone, physiologically decreases with age, but an exaggerated decline has been associated with some chronic-degenerative diseases such as, atherosclerosis and diabetes.

Methods and Results: We quantified the plasma levels of DHEA and its sulfated form (DHEA-S) in 137 IPF patients and 58 controls and examined the effects of DHEA on human lung fibroblasts in vitro. Plasma DHEA/DHEA-S was significantly decreased in male IPF patients (median (range) DHEA: 4.4 (0.2–29.2) versus 6.7 (2.1–15.2) ng/mL, $p < 0.01$; DHEA-S: 47 (15.0–211) versus 85.2 (37.6–247.0) mg/dL, $p < 0.001$), while in females only DHEA-S was significantly decreased (32.6 (15.0–303.0) versus 68.3 (16.4–171) mg/dL, $p < 0.001$). DHEA caused a decrease in fibroblast growth rate (35% of decrease compared with controls), this finding was partially due to the induction (two-fold over the control) of fibroblast apoptosis as measured by Annexin V, probably through the intrinsic pathway with activation of caspase-9. This effect was accompanied by upregulation of several pro-apoptotic proteins (Bax and cyclin-dependent kinase-inhibitor CDNK1A) and downregulation of anti-apoptotic proteins, such as cellular inhibitor of apoptosis c-IAP1 and c-IAP2. DHEA also caused a significant decrease of transforming growth factorb1-induced collagen production, fibroblast to myofibroblast differentiation (measured by alpha-smooth muscle actin expression) and inhibited platelet-derived growth factor-induced fibroblast migration (measured in Boyden chambers covered by collagen).

Conclusions: These findings demonstrate a disproportionate decrease of DHEA/DHEA-S in IPF patients and indicate that this molecule has multiple antifibrotic properties.

Der f 2 directly binds to toll-like receptor4 and triggers phospholipase D1 activation leading to IL-13 production

H.-J. Choi, S.-Y. Park, Y. Y. Lee, S.-Y. Lee, M. J. Kang, J.-S. Han
Hanyang University, Seoul, Korea

Background: House dust mites (HDMs) are the most important source of indoor aeroallergens that contribute to the rising incidence of allergic diseases such as allergic asthma. The major HDM, Der f 2, induces inflammatory cytokine expression. Little is known about the signaling pathway involved.
Objective: We wanted to define the Der f 2 signaling pathway from its receptor to the transcription factor responsible for IL-13 expression and production.
Methods: Human bronchial epithelial cells were stimulated with Der f 2. The release and gene expression of IL-13 were measured by means of ELISA and RT-PCR, respectively. We investigated the ability of Der f 2 in the HDM mouse model of allergic airway inflammation.
Results: Here we show that Der f 2 binds to TLR4 and induces IL-13 expression and production. Activation of TLR4 by Der f 2 requires the recruitment and activation of Syk, which leads to phosphorylation of PLCγ and membrane translocation of PKCα. p38 MAPK is then activated by PKCα and stimulates PLD1 activity by phosphorylating the Thr147 residue of PLD1. PLD1 activation enhanced binding of ROCK1 to ATF-2 and leads to increased expression of IL-13. In the airway inflammation mouse model, IL-13 production significantly increased with treatment of Der f 2.
Keywords: Der f 2, TLR4, IL-13.

Deregulation of the PDK1/TACE α-secretase signaling axis at the cross-road of prion and Alzheimer's diseases

M. Pietri[1], A. Alleaume-Butaux[1], A. Baudry[1], S. Haik[2], Y. Bailly[3], J. M. Peyrin[4], J. M. Launay[5,6], O. Kellermann[1], **B. Schneider**[1]
[1]INSERM UMRS1124, UPD, Paris, France, [2]INSERM UMRS975, UPMC, Paris, France, [3]CNRS UPR3212, Strasbourg, France, [4]CNRS UMR7102, UPMC, Paris, France, [5]INSERM UMRS942, Hal Lariboisière, Paris, France, [6]Pharma Research Department, Hoffmann La Roche, Basel, Switzerland

Prion and Alzheimer's (AD) diseases are a group of pathologies characterized by separate etiologies with distinct pathophysiological features. Each disease has its own clinical manifestations but some common pathogenic cascades might occur and their identification would represent a biomedical challenge for therapies. The precise mechanisms by which PrPSc in prion diseases and the amyloid Ab peptides in AD exert their toxicity however remain unknown. By combining in vitro and in vivo approaches, we showed that PrPSc or Ab peptides trigger the overactivation of the 3-phosphoinositide-dependent kinase-1 (PDK1) in prion-infected or AD neurons, respectively. PDK1 then promotes the phosphorylation and displacement of TNFa Converting Enzyme (TACE) a-secretase from the plasma membrane to caveolin-1-enriched microvesicles, leading to TACE internalization. TACE thus loses its cell surface neuroprotective function. PrPSc- or Ab-induced TACE internalization indeed diverts TACE activity away from its substrates (i) the normal cellular prion protein (PrPC),

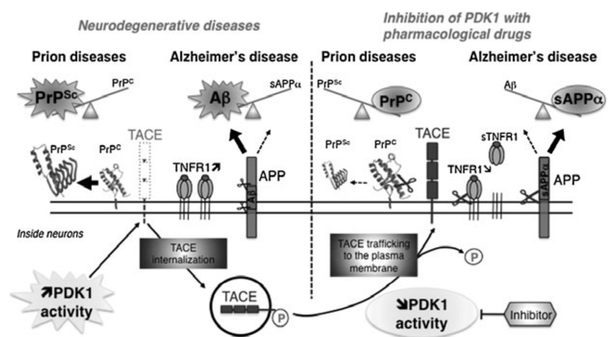

Fig. 1. In prion and Alzheimer's diseases, PDK1 triggers the internalization of TACE α-secretase in neurons. TACE dysregulation at the surface of neurons contributes to neurodegeneration by increasing the conversion of PrP^{c} into pathogenic prions PrP^{Sc} and the formation of neurotoxic amyloid Aβ peptides and reducing shedding of TNFα receptors (TNFR1). Inhibition of PDK1 promotes localization of TACE to the plasma membrane, restores TACE-dependent α-secretase activity and neuroprotective cleavage of APP, PrP^{c} and TNFR1, and attenuates PrP^{Sc}- and Aβ-induced neurotoxicity.

which amplifies the replication of PrPSc in prion diseases, (ii) the amyloid precursor protein (APP), which favors the production of Ab peptides in AD, and (iii) TNFa receptors (TNFR), which accumulate at the plasma membrane and render diseased neurons highly vulnerable to TNFa toxicity. Pharmacological inhibition of PDK1 is sufficient to target TACE back to the plasma membrane of diseased neurons, where it recovers its protective activity by triggering the cleavage of PrPC, APP, and TNFR, thus lowering the amount of amyloid proteins and desensitizing diseased neurons from TNFa toxicity. Inhibition of PDK1 in prion-infected mice increases the lifespan and counteracts motor deficits. In three transgenic mouse models of AD, PDK1 inhibition reduces AD pathology and memory impairment. We thus uncovered that deregulation of PDK1-dependent TACE activity is a central mechanistic event in neurodegenerative pathways involved in both prion diseases and AD. We also demonstrate that rescuing TACE activity at the plasma membrane upon PDK1 inhibition is a valuable entry point to fight these two neurodegenerative diseases. Importantly, the therapeutic relevance of targeting PDK1 in AD is supported by a rise in PDK1 activity and reduced TACE activity in the brain of AD subjects.

Development of a new microchip based ELISA platform for detection of NGAL: a biomarker of contrast-induced acute kidney injury

T. Radovanović, M. Liu, M. Franko
Laboratory for Environmental Research, University of Nova Gorica, Nova Gorica, Slovenia

Introduction: Contrast-induced acute kidney injury (AKI) presents a serious complication during the medical use of iodinated contrast media. At the moment renal disfunction is detected by the measurement of serum creatinine that is not a sufficiently sensitive marker for early detection of AKI. Neutrophil gelatinase-associated lipocalin (NGAL), a member of the lipocalin protein family emerged as early biomarker of AKI.

Currently, NGAL published studies have been performed mainly with commercial research-grade ELISA assays. These assays are accurate, but still not practical for clinical purposes

© 2014 The Authors. FEBS Journal © 2014 FEBS

because they are time demanding. For the determination of NGAL, we present here a combined microfluidic Flow Injection Analysis-Thermal Lens Microscopy (μFIA-TLM) as an alternative detection tool.

Materials and Methods: Blood plasma samples were collected from four patients admitted to General Hospital Dr. Franca Derganca (Šempeter pri Novi Gorici, Slovenia) for percutaneous coronary intervention (PCI). All patients received low-osmolar contrast medium (Iomeron-350). Plasma samples were collected before and up to 12 hours after PCI. For the control group were used six individuals with normal serum creatinine values before PCI.

We used commercial ELISA assay (BioPorto, Gentofte, Denmark) to measure NGAL levels in serum and plasma. The final reaction product from ELISA of each sample was also measured by the μFIA-TLM system on microchip to demonstrate possible advantages of TLM detection.The μFIA served only as a device for the delivery of final ELISA product to the TLM detector. In addition, an 'in-house' ELISA assay for NGAL detection was developed and validated in our laboratory. With this method we measured samples from six healthy individuals and performed a comparative analysis of obtained results with different experimental approaches to assess their capability and advantages/disadvantages.

Results: The presence of NGAL in blood samples was confirmed by SDS-PAGE and Western blot. The μFIA-TLM provided seven fold lower limits of detection (up to 1.5 $pgmL^{-1}$) compared to conventional ELISA limit values of 10 $pgmL^{-1}$. These data suggest that TLM could serve as a new, rapid and highly sensitive method for NGAL determination. It's use could be proposed not only for research but also for medical purposes and NGAL detection in real samples.

Conclusion: Development of 'in house' ELISA allow us to design a new lab-on-a-chip ELISA platform based on TLM detection of NGAL in biological samples enabling bed-side tests needed for example during coronarography.

SUN-139
Development of an anticancer agent targeting polo-box domain of polo-like kinase 1

E. K. Ryu, M. S. Yim

Korea Basic Science Institute, Chungbuk, Korea

Polo-like kinase 1 (Plk1) is a regulator of cell cycle progression during mitosis; it is overexpressed in many different tumors and has been implicated as a potential antimitotic target. Plks are characterized by the presence of a highly conserved C-terminal polo-box domain (PBD) that is involved in regulating kinase activity. The phosphopeptide Pro-Leu-His-Ser-p-Thr (PLHSpT) is a potent selective inhibitor of the PBD of human plk1 that acts by inducing mitotic arrest and apoptotic cell death in cancer cells. We synthesized cRGDyK-S-S-PLHSpT to exploit the drug delivery. In HeLa cells, the uptake of cRGDyK-S-S-PLHSpT was significantly increased, it localized in the nuclei and surroundings. We found that cRGDyK-S-S-PLHSpT inhibited cell survival in a dose-dependent manner, which was shown to significantly inhibit plk1 kinase activity in human HeLa and U87MG tumor cells. The cRGDyK-S-S-PLHSpT treated cells had multipolar spindles and misaligned chromosomes. Cell proliferation was also inhibited by cRGDyK-S-S-PLHSpT due to the induction of apoptosis. In the xenograft models mice treated with cRGDyK-S-S-PLHSpT (4 mg/kg body weight), tumor growth was significantly reduced compared with untreated and PLHSpT-treated mice. Our results demonstrated that the new peptide, cRGDyK-S-S-PLHSpT, is promising as an anticancer agent. We expect that our contribution will provide new insights into the design of novel plk1 peptide inhibitors.

Keywords: Anticancer, inhibitor, kinase inhibitor.

Development of LC-MS method for quantification of haemagglutinin in influenza vaccine

H. Kang

Biologics Division, Ministry of Food and Drug Safety (Republic of Korea), Chungcheongbuk-do, Korea

Influenza is a virus that infects 15% of the world population, causing 500 000 deaths annually. Haemagglutinin (HA) is a major antigen of this virus, and the potency of influenza vaccine is based on the content of HA. Although Single Radial Immunodiffusion (SRID) is a very specific and unique method that can be used to measure the HA content in influenza vaccine visually, it needs a long time and is very labor-intensive. Also, this method can be a hindrance to develop influenza vaccine rapidly because it takes several months to prepare standard antigen and antibody used in SRID. Against this backdrop, method using Liquid Chromatography-Isotope Dilution Mass Spectrometry (LC-IDMS) was developed to measure the HA content in influenza vaccines.To begin with, we performed a 10 year study since 2000 on the amino acid sequence of influenza virus to identify the least mutated parts of the sequence, and selected a target peptide in vaccines treated with trypsin and tested by Q-TOF MS method. Isotope-labeled target peptides were used as a internal standard to correct the variations of test results caused by experimental errors. For optimization of assay conditions, a series of preliminary tests were performed to determine appropriate LC-MS parameters as well as trypsin digestion conditions. To show the validity of this method, the linearity, accuracy, precision, limit of detection and limit of quantification were measured. It showed that RSD values measured over 3 days ranged between 3.0 ~ 12.7% and the r^2 value (linearity) was above 0.99, proving the validity of the assay conditions. The established testing method includes determining the content of hemagglutinin in 3 lots of H5N1 (A/Vietnam/1194/2004) vaccines produced in 2012 preparing for a possible outbreak and 10 lots of H1N1 (A/California/07/2009) vaccine bulk produced in 2013. Not only the results showed a high correlation with those of SRID, but this new method has been also proved to be more rapid and precise than SRID. In particular, it can be useful in addressing a potential influenza pandemic, as it makes it possible to immediately shift the target peptide to measure hemagglutinin through assaying the amino acid sequence in case where significant antigen mutations occur.

Therefore, in case of emergency such as a flu outbreak, more prompt response in terms of vaccine manufacturing and conducting clinical trials will be possible without having to be on a long waiting list for reference standards to be distributed by international organizations like the WHO.

We expect that this new testing method will contribute to enhancing public health by improving the efficiency of vaccine manufacturing process as well as building up trust on test results based on extensive monitoring.

Keywords: hemagglutinine, influenza, LC-IDMS.

Development of nuclear factor kappa B inhibitors: synthesis and evaluation of lantadene congeners as anticancer agents

M. Sharma
Pharmacy, Jaypee University of Information Technology, Waknaghat, India

The pentacyclic triterpenoids reduced lantadene A and B analogs were synthesized and evaluated in vitro for their NF-κB and IKKβ inhibitory potencies and cytotoxicity against A549 lung cancer cells. The lead analog showed sub-micromolar activity against TNF-α induced activation of NF-κB and exhibited inhibition of IKKβ in a single-digit micromolar dose. The physicochemical evaluation demonstrated that the lead analog was stable in the simulated gastric fluid of pH 2, while hydrolyzed at a relatively higher rate in the human blood plasma to release the active parent moieties. At the same time, molecular docking analysis showed that lead compound was hydrogen bonded with the Arg-31 and Gln-110 residues of the IKKβ. The preliminary results showed that the lead molecule can be developed as potent anticancer agents.

Keywords: Lantadene, nuclear factor kappa B.

Development of potent pseudopeptide phosphinic inhibitors of antigen-trimming aminopeptidases that can enhance cytotoxic t-cell responses against cancer cells

E. Zervoudi[1], E. Saridakis[1], J. Birtley[1], S. Seregin[2], P. Kokkala[3], Y. Aldhamen[2], A. Amalfitano[2], I. Mavridis[1], E. James[4], D. Georgiadis[3], E. Stratikos[1]
[1]*National Center for Scientific Research Demokritos, Athens, Greece,* [2]*Microbiology and Molecular Genetics, Michigan State University, MI, USA,* [3]*Chemistry, University of Athens, Athens, Greece,* [4]*Faculty of Medicine, University of Southampton, Southampton, UK*

ER aminopeptidase 1 (ERAP1), ER aminopeptidase 2 (ERAP2) and Insulin Regulated aminopeptidase (IRAP) are three homologous enzymes that play critical roles in the generation of antigenic peptides. These aminopeptidases excise amino acids from N-terminally extended precursors of antigenic peptides in order to generate the correct length epitopes for binding onto MHC class I molecules. Loss of ERAPs function substantially alters the repertoire of peptides presented by MHC class I molecules, affecting recognition by $CD8^+$ T cells. In addition, ERAP1 has been recently shown to be involved in the regulation of inflammatory innate immune responses. Genome-wide association studies have identified common variants of ERAP1 and ERAP2 to be associated with the predisposition to several human diseases, ranging from viral infections to autoimmunity and cancer. The important roles of these enzymes in regulating both adaptive and innate immune responses suggest that inhibition of their activity may constitute an innovative therapeutic approach for cancer immunotherapy or the regulation of inflammatory responses.

In this study we followed a rational-design approach and developed a series of phosphinic pseudopeptide transition state analogs that can inhibit this family of enzymes with nM affinity. Kinetic as well as X-ray crystallographic analysis of one such inhibitor in complex with ERAP2 validated our design, revealing a canonical mode of binding in the active site of the enzyme, and highlighted the importance of the S2' pocket for achieving inhibitor potency. Also these compounds did not inhibit equally all variants of ERAP1/ERAP2 and as a result inhibitor potency is variant dependent. Antigen processing and presentation assays in HeLa and murine colon carcinoma (CT26) cells showed that these inhibitors can induce increased cell-surface antigen presentation of transfected and endogenous antigens and enhance specific cytotoxic T-cell responses. Finally, pretreatment of mouse macrophages with the best inhibitor of ERAP1 significantly ablated macrophage phagocytosis activity in a dose-dependent manner suggesting a possible application of these compounds as anti-inflammatory molecules. This class of inhibitors constitutes a promising tool for controlling the cellular adaptive and innate immune response in humans.

Development of sustained release 'nanopolypill' for hypertension – an experimental study

A. A. Ahuja[1], S. S. Malhotra[1], N. Shafiq[1], S. Jain[2], G. Khuller[3], S. Sharma[3]
[1]*Pharmacology,* [2]*Internal Medicine,* [3]*Biochemistry, Pot Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, India*

Blood pressure control is the key element in any cardiovascular prevention strategy. The chronic nature of the therapy is responsible for problems like adherence to the treatment leading to sub-optimal BP control and several cardiovascular complications.The use of a fixed-dose combination therapy, targeting several risk factors, in the form of a 'polypill', was first proposed by Wald and Law as a concept in 2003. An extension of the concept of polypill would be a sustained release polypill.The present study was thus planned to formulate, characterize and evaluate the pharmacokinetics of a novel 'nanopolypill' comprising three commonly prescribed anti-hypertensive drugs, hydrochlorothiazide (a diuretic), candesartan (ARB) and amlodipine (a calcium channel blocker).The candidate drugs were loaded inside Poly (DL-lactide-co-gycolide) (PLGA) nanoparticles. The formulations were evaluated for their size, morphology, drug loading and in vitro release individually. Single dose pharmacokinetic profiles of the nanoformulations alone and in combination, as a nanopolypill, were evaluated in Wistar rats.The candidate drugs encapsulated inside PLGA showed entrapment efficiencies ranging from 30%, 33.5% and 32% for hydrochlorothiazide, candesartan and amlodipine respectively. The nanoparticles ranged in size from 110 to 180 nm. In vitro release profile of the nanoformulations showed 100% release by day 6 in the physiological pH 7.4 set up with PBS (phosphate buffer saline) and by day 4–5 in the intestinal pH 1.2 and 8.0 set up SGF (simulated gastric fluid) and SIF (simulated intestinal

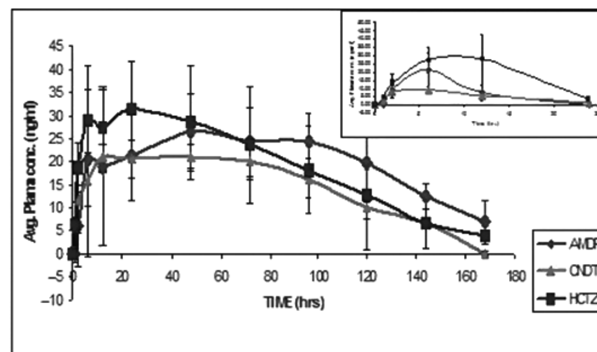

Fig. 1. Plasma concentration plot of drugs combined in the Hypertension 'Nanopolypill'; Inset – Free drugs. C_{max} – ng/ml; AUC – ng hr/L; *Free versus NP significant at $p < 0.05$ (n = 5).

© 2014 The Authors. FEBS Journal © 2014 FEBS

fluid) respectively. In pharmacokinetic analysis, a sustained-release for 6 days and significant increase in the mean residence time (MRT), as compared to the respective free drugs was noted [MRT of amlodipine, hydrochlorothiazide and candesartan changed from 8.9 to 80.59 hours, 11 to 69.20 hours and 9 to 101.49 hours respectively].We have shown for the first time that encapsulating amlodipine, hydrochlorothiazide and candesartan into a single nanoformulation, to get the 'nanopolypill' is a feasible strategy which has a potential of decreasing pill burden.

Diabetes-induced liver injury associated with inflammatory pathway activation: effects of chronic vitamin D3 administration

D. Labudzynskyi, I. Shymanskyy, M. Veliky
Medicine Biochemistry, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kyiv, Ukraine

Background and Aims: Diabetes is known to be characterized with the accumulation of pro-inflammatory factors in various tissues. It is known that nuclear factor kappaB (NF-kB) is a key regulator of the inflammatory process and its activation leads to the increased expression of inducible nitric oxide synthase (iNOS) and VEGF involved in inflammation. Vitamin D_3 (D_3) is currently recognized as a potent immunomodulator affecting various inflammatory and autoimmune diseases. However, the precise mechanisms of vitamin D_3 influence on immune homeostasis has not been clearly defined. We therefore investigated the role of D_3 in regulation of pro-inflammatory factors (NF-kb/p65, iNOS, VEGF) in liver of diabetic mice.

Materials and Methods: Type 1 diabetes was induced in male C57BL/J6 mice (weighing 25.0 ± 1.5 g) by i.p. injection of multiple low dose streptozotocin (40 mg/kg b.w.). Control and STZ-diabetic mice were treated with or without vitamin D_3 (15 IU/mouse per os, for 8 weeks). Serum 25-hydroxyvitamin D_3 ($25OHD_3$) was assessed by ELISA. The levels of cytosol and nuclear pNF-kB/p65 (pRelA), iNOS and VEGF were *measured* by Western-blot analysis. NO production was detected by DAF-DA (4,5-diamino-fluorescein diacetate) using flow cytometry.

Results: Serum level of $25OHD_3$, the main circulating metabolite of D_3, was shown to be reduced to 23.8 ± 1.9 in diabetes versus 39.7 ± 2.9 nmol/l in control, indicative of diabetes-induced D_3 deficiency ($p < 0.05$). These changes were accompanied by 1.51- and 2.04-fold overexpression of cytosolic and nuclear pRelA respectively. Diabetes was also associated with 1.32-fold increase in iNOS expression. It is worth noting that changes in iNOS expression most likely result in currently established 1.62-fold elevation of NO production in liver related to diabetes. In addition, 2.31-fold increase in VEGF was observed in hepatic tissue of diabetic mice. This finding taken together with previous data can indicate possible intensification of inflammatory processes. Full restoration of $25OHD_3$ content was achieved by D_3 treatment. Vitamin D_3 also caused partial normalization of pNF-kB/p65, iNOS and VEGF levels and NO production in liver.

Conclusions: The study confirmed that diabetes-induced liver abnormalities are associated with upregulation of inflammatory markers expression (NF-kB/p65, iNOS and VEGF) that correlated with insufficient vitamin D_3 availability. Our data suggest a potential efficacy of vitamin D_3 to counter hepatic inflammation associated with diabetes.

Keywords: Type 1 diabetes, vitamin D3, liver, proinflammatory factors, NF-kB-mediated pathway.

Diagnostic potential of new methods to detect stenosis of aortic heart valve

B. Veliká[1], Z. Gul'ášová[1], M. Bilecova-Rabajdová[1], P. Urban[1], V. Tomečková[1], A. Panagiotis[2], V. Komanický[3], F. Sabol[2,4], M. Mareková[1]
[1]Department of Medical and Clinical Biochemistry and LABMED, P.J. Šafárik University in Košice, [2]East Slovak Institute of Cardiovascular Disease, a.s., [3]Department of Condensed Matter Physics, [4]Department of Anaesthesiology and Intensive Medicine, P.J. Šafárik University in Košice, Košice, Slovakia

Aortic stenosis in heart valve is associated with the narrowing of the aortic heart valve and remodelation of the extracellular matrix. Emilin-1 is protein of extracellular matrix which is expressed in the endocardium, endothelial cells and smooth muscle cells. Emilin-1 can influence values of blood pressure, structure of vessels wall and it can cause the formation of cardiovascular diseases. A goal of our study is to detect the pathological changes in a blood of patients with heart valve stenosis by using determination of gene expression of Emilin-1 and perform fluorescence analysis together with detection of the molecular structural changes of blood proteins.

RNA was isolated from peripheral blood of patients with stenosis of aortic heart valve (10) and the control group of healthy 35 peoples. The reverse transcription from mRNA to cDNA was realized. The gene Emilin-1 and housekeeping gene β-actin (for the standardization) were amplificated by real-time PCR. Autofluorescence of the blood serum/plasma samples was analysed by synchronous fluorescence fingerprint on Luminescence Spectrophotometer Perkin-Elmer LS 55. The structure of blood serum/plasma was also analysed by atomic force microscope (ICON, Bruker, USA).

Expression of Emilin-1 gene at mRNA level was significantly increased (about 25.07 ± 0.05%) in comparison with healthy subjects evaluated by statistical analysis. Changes in nanostructure of blood was detected in the patients in comparison with healthy subjects. The autofluorescence of proteins was significantly increased in the serum ($p < 0.001$) but significantly decreased ($p < 0.001$) in the plasma and tissue of patients with stenosis of aortic heart valve in comparison with healthy subjects.

This pilot study uses the combination of several experimental techniques like RT-PCR, fluorescence analysis and atomic force microscopy which could be a prospective new screening procedure for the detection of aortic stenosis in heart valve. The formation of Emilin-1 will be correlated with the determination of transforming growth factor b (TGF-b). Emilin-1 influences the biosynthesis of transforming growth factor β_1 (TGF-β_1), whose deregulation results in the systemic hypertension accompanied with the structural changes and narrowing of the walls of arteries. These results can lead to the development of new and more sophisticated methods for detection of cardiovascular diseases.

Different sized silver-citrate nanoparticles kill cancer cells through the (re)activation of the p53 dependent apoptotic pathway

D. Kovács[1], C. Keskeny[1], N. Igaz[1], T. Tóth[2], Z. Kónya[2], I. M. Boros[1], M. Kiricsi[1]
[1]Department of Biochemistry and Molecular Biology, [2]Department of Applied and Environmental Chemistry, University of Szeged, Szeged, Hungary

Silver nanoparticles (AgNPs) are the most broadly used nanomaterials in industry and medicine due to their unique physical, chemical properties and their outstanding antibacterial and antifungal features. Recent studies suggest that AgNPs induce cellular stress in several mammalian cell types thus their cytotoxic properties could be exploited to kill cancer cells. AgNPs seem to be very promising novel chemotherapeutic agents however the exact molecular mechanisms behind their activity are still unclear. AgNPs kill cancer cells through a Trojan horse-like mechanism: after the cellular uptake, nanoparticles probably release a vast quantity of highly toxic silver ions within the cell, which eventually results in apoptosis mediated cell death. Although several studies describe the cytotoxic effect of AgNPs, it is still unclear how the size, the shape, the coating and the functionalizing groups might influence their anti-cancer activity.

In this study we used the biocompatible sodium-citrate as a reducing agent to synthesize different sized (~4 and 35 nm) quasi-spherical citrate coated AgNPs. We found that both 4 nm and 35 nm sized AgNPs kill osteosarcomic U2Os cells with the same extent in a concentration dependent manner. However, cleaved caspase 3 staining verified apoptosis during AgNP mediated cell death, in either 4 or 35 nm silver particle treated cancer cells, 4 nm sized AgNPs induces caspase 3 activation with a higher degree than 35 nm sized nanoparticles. Using transmission and scanning electron microscopy we observed aggregated nanoparticles both on the surface and inside the cells where the aggregated AgNPs were largely localized in membrane coated vesicles which suggest a receptor mediated uptake mechanism of AgNPs. During both sized AgNP treatments we detected degraded membrane structures and increased levels of reactive oxygen species suggesting the induction of the mitochondrial apoptosis pathway. Using Western blot analysis and reporter assay experiments we revealed that the p53 mediated apoptotic pathway is in fact involved in Ag-citrate NP triggered cell death.

Our results show that cancer cells are able to uptake both 4 nm and 35 nm spherical shaped silver-citrate nanoparticles which induce cancer cell death by apoptosis via the activation of p53 pathway. On a broad scale, AgNPs represent a feasible platform for the rational design of therapeutically useful anticancer agents so long as their actions are fine-tuned with bioactive functionalizing molecules.

Differential expression of ID gene family members in eutopic and ectopic endometrial tissue may be considered as probable casing factor of endometriosis

M. Ashini[1,2], M. Shahhoseini[2], S. Mahdian[3], F. Ramezanali[3], P. Afsharian[2], R. Aflatoonian[3]
[1]Faculty of Basic Sciences and Advanced Technologies in Biology, University of Science and Culture, ACECR, [2]Department of Genetics at Reproductive Biomedicine Research Center, [3]Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran

Inhibitors of DNA binding (*ID*) transcription factor are helix-loop-helix regulatory proteins that induce proliferation of cells during development.

Endometriosis is the gynecologic disorder characterized by the presence of the endometrial tissue outside of the uterus and causes 30–40% of infertility.

Due to the characteristic of the endometriosis and the regulatory role of *ID* genes, it seems that this gene family may have a role in occurrence of endometriosis as well as its infertility cause. The aim of this study is to determine whether expression of *ID* genes alter in endometriosis.

For this respect, eutopic and ectopic endometrium were obtained from 26 laparoscopically confirmed endometriosis patients. Also, endometrial tissues were collected from 18 healthy fertile women, between 20 and 45 years old, undergoing tubal ligation surgery. The Expression levels of *ID* genes were detected by real-time PCR technique, using designed primer. Ethical approval and informed patient consent was gained for the use of tissue samples.

Our results revealed that mRNA expression of all members of *ID* gene family were significantly lower in eutopic and ectopic samples during the secretory phase, compared with control group. Also in proliferative phase, *ID*1 and *ID*4 showed lower expression in comparison to control group; while, *ID*2 and *ID*3 pointed higher expression levels. On the other hand, *ID*2 showed more expression level in eutopic and ectopic samples and *ID*3 showed sizeable expression in ectopic phase.

The present findings suggest for the first time that deregulation of *ID* gene family members – especially *ID*2 and *ID*3 – can be listed as potential molecular markers of endometriosis and maybe contribute to the infertility that caused by this disorder.

DJ-1 protein and apolipoprotein A are targets for LVVYPW in the brain of streptozotocin-induced diabetic rats

N. Barkhudaryan[1], F. Sarukhanyan[1], J. Kellermann[2], F. Lottspeich[2]
[1]H. Buniatian Institute of Biochemistry NAS RA, Yerevan, Armenia, [2]Max-Planck Institute of Biochemistry, Martinsried, Germany

Earlier we have shown that hemorphins (LVVYPW, hemorphin-7 and LVV-hemorphin-7), demonstrating a wide spectrum of biological activity, are involved in pathophysiology of severe diseases (cancer, diabetes, stress) and act as homeostatic agents by modulation of protein phosphatase calcineurin activity, by affecting different receptors function and by regulation of hypothalamo-pituitary-adrenocortical axis activity. Very recently, by using the isotope-coded protein label (ICPL) quantitative proteomic technology (Lottspeich F. et al., 2005; Kellermann J. et al., 2012), the effect of in vivo treatment of diabetic rats by LVVYPW has been studied. Brain proteins from 3 rats (control

© 2014 The Authors. FEBS Journal © 2014 FEBS

rats, diabetic rats and diabetic rats, treated by LVVYPW) were labelled with the ^{12}C, ^{13}C and deuterium version of ICPL-label respectively. Then these three samples were mixed together and Triplex-ICPL aliquots were cleaved by combination of trypsin and endoproteinase GluC and analysed directly using LC-ESI mass spectrometry. In the experiments was used OFFGEL electrophoresis as well. Among the proteins differently regulated by LVVYPW in diabetic rat brain were identified DJ-1 protein and apolipoprotein E as well. It should be noted that differently regulated proteins were validated by immunological methods as well. The expression levels of both DJ-1 and apolipoprotein E (ApolipoE) were significantly down regulated in the brain of diabetic rats, treated by LVVYPW: 4.8 fold for DJ-1 and 5.6 fold for A-polipoE respectively. It is well known that DJ-1 and ApolipoE are involved in pathophysiology of neurodegenerative diseases (Parkinson's disease (PD) and Alzheimers disease (AD). ApolipoE is genetic risk factor for sporadic AD (Rebeck G., et al., 1993). It should be noted that the implication of DJ-1 with tumor progression was also demonstrated (Tillman J.E. et al., 2007). PD is a progressive neurodegenerative movement disorder characterized by selective loss of nigrostriatal dopaminergic neurons. By using in vivo microdialysis we have shown that intracerebroventricular administration of LVV-hemorphin-7 induces moderate, but statistically significant elevation of extracellular dopamine (DA) concentrations in the striatum of freely moving rats. As mentioned above hemorphins modulate calcineurin activity in the brain and immune system (Barkhudaryan N. et al., 1991; 2002), and calcineurin in turn participates in DA release (Day M. et al., 2002). Data obtained once again confirm that pleiotropic nature of hemorphins allows them to act as homeostatic agents by implication of different signalling pathways.

Dual oxidase 2 in lung epithelia is essential for hyperoxia-induced acute lung injury in mice

M.-J. Kim[1,2], J.-H. Ryu[1,2], J.-C. Ryu[1,2], Y. H. Kwon[1,2], J.-H. Yoon[1,2]
[1]*Brain Korea 21 PLUS Project for Medical Science, Yonsei University,* [2]*Research Center for Natural Human Defense System, Yonsei University College of Medicine, Seoul, Korea*

Acute lung injury (ALI) induced by excessive hyperoxia has been employed as a model of oxidative stress imitating acute respiratory distress syndrome. Under hyperoxic conditions, overloading quantities of reactive oxygen species (ROS) are generated in both lung epithelial and endothelial cells, leading to ALI. Some NADPH oxidase (NOX) family enzymes are responsible for hyperoxia-induced ROS generation in lung epithelial and endothelial cells. However, the molecular mechanisms of ROS production in type II alveolar epithelial cells (AECs) and ALI induced by hyperoxia are poorly understood. In this study, we show that dual oxidase 2 (DUOX2) is a key NOX enzyme which effects hyperoxia-induced ROS production, particularly in type II AECs, leading to lung injury. In DUOX2 mutant mice ($DUOX2^{thyd/thyd}$) or mice in which DUOX2 expression is silenced in lung epithelia, hyperoxia-induced ALI was significantly lower than in wild-type (WT) mice. DUOX2 was mainly expressed in type II AECs, but not endothelial cells, and hyperoxia-induced ROS production was markedly reduced in primary type II AECs isolated from $DUOX2^{thyd/thyd}$ mice. Furthermore, DUOX2-generated ROS are responsible for caspase-mediated cell death, inducing ERK and JNK phophorylation in type II AECs. To date, no role for DUOX2 has been defined in hyperoxia-mediated ALI despite it being a NOX homologue and major ROS source in lung epithelium. Here, we present the novel finding that DUOX2-generated ROS induce alveolar epithelial cell death, leading to hyperoxia-induced lung injury. Effect of arazyme on the lipopolysaccharide-induced inflammatory response

J.-S. Lee[1], D.-H. Shin[2], K.-H. Son[3], H.-Y. Park[3], E. J. Kim[4], S. Y. Baek[4], I. S. Kim[4,5]
[1]*Wonkwang Health Science University, Iksan,* [2]*Insect Biotech Co., Ltd,* [3]*Industrial Bio-material Research Center, Korea Research Institute of Bioscience and Biotechnology,* [4]*Department of Senior Healthcare, BK21 plus program, Graduated School,* [5]*Biomedical Laboratory Science, Eulji University, Daejeon, Korea*

Arazyme is a novel extracellular metalloprotease secreted by *Aranicola proteolyticus*. Endothelial cells are involved in the pathogenesis of various inflammatory diseases, induce uncontrolled cell viability, and express various inflammatory mediators, including cytokines, chemokines, adhesion molecules, and reactive oxygen species (ROS). In this study, human umbilical vein endothelilal cells (HUVECs) were used to investigate the anti-inflammatory effects of arazyme after lipopolysaccharide (LPS) stimulation. Apoptosis of HUVECs due to LPS was inhibited by arazyme. In various inflammatory responses induced by LPS, arazyme inhibited the secretion of the monocyte chemoattractant protein-1 and interleukin-6 and expression of vascular cell adhesion molecule-1 and intercellular adhesion molecule-1. Arazyme also suppressed ROS production in HUVECs. The action of arazyme was not associated with NF-κB activity in HUVECs. These results indicate that arazyme has anti-inflammatory properties in inflamed endothelial cells and may be useful as a therapeutic agent for inflammatory diseases associated with endothelial cells.

The liver is known as one of the regenerative organ. It is composed of parenchymal and non-parenchymal cells. The hepatic stellate cell (HSC), one of the non-parenchymal cells, is a key cellular element involved in wound healing by responding to various kinds of cytokines such as TGF-β and IL-6 in liver injured by viral, chemical and alcohol so on. However, as a consequence of

© 2014 The Authors. FEBS Journal © 2014 FEBS

excess inflammation, it develops hepatic fibrosis. We investigated response of primary human HSC (pHSC) and cell line LX-2 to various cytokines. pHSC was prepared from a piece of liver which was resected surgically from patients with metastatic liver cancer or with hepatocellular carcinoma. Expression of liver fibrosis marker genes, Matrix metalloprotease 1 (MMP1) and alpha-smooth muscle actin (α-SMA), were examined in pHSC and LX2 following exposure of cytokines. The each cytokine had some effects on MMP1 and α-SMA expression and, unexpectedly, a simultaneous treatment with cytokines had greater effects on their expression. The simultaneous treatment with cytokines synergistically induced MMP1 gene expression and reduced α-SMA in pHSC, suggesting these cytokines have anti fibrosis activity. Next, the signaling pathway for the synergistic effect was examined by using inhibitors for signaling protein-kinases. As a results, when Mitogen-activated protein kinase (MAPK) pathway, p38 and ERK1/2, were inhibited, the synergistic effect of the cytokines was decreased. From these results, it was suggested that the simultaneous treatment with the cytokines show the anti-fibrotic activity through MAPK pathway in pHSC.

Effect of melatonin on serum glucose, insulin and TNF-alpha levels in rats with impaired glucose tolerance

B. Djordjevic[1], D. Sokolovic[1], J. Basic[1], A. Veljkovic[1], M. Despotovic[1], T. Jevtovic Stoimenov[1], T. Cvetkovic[1], D. Djukic[2], N. Zivkovic[2], D. Virijevic[2]

[1]Department of Biochemistry, [2]Faculty of Medicine, University of Nis, Nis, Serbia

Impaired glucose tolerance is a pre-diabetic state of hyperglycemia associated with insulin resistance that may precede type 2 diabetes mellitus by many years. Tumor necrosis factor-a (TNF-α) over-secretion has already been implied in the pathogenesis of insulin resistance and diabetic complications. Melatonin is a circulating hormone that is mainly released from the pineal gland. It is best known as a regulator of seasonal and circadian rhythms, its levels being high during the night and low during the day.

Objective: The aim of the present work is to clarify whether treatment with melatonin has beneficial effect on serum glucose, insulin and TNF-α levels in rats with impaired glucose tolerance.

Methods: Twenty-eight 10-week-old male Wistar rats were divided into four groups, A (control), B (control receiving melatonin), C (pre-diabetic) and D (pre-diabetic receiving melatonin). Noninsulin dependent diabetes mellitus was induced by intraperitoneal streptozotocin injection following nicotinamide injection (groups C and D). All groups received standard diet for 4 weeks. After 4 weeks, when the model was fully developed, oral therapy with melatonin (2 mg/kg body weight) was introduced to groups B and D. Treatment with melatonin lasted for 2 weeks.

Results: Fasting serum glucose levels were significantly higher in group C when compared to the group A (group A, 4.81 ± 0.18 mM versus group C, 6.51 ± 0.32 mM; $p < 0.001$). Melatonin significantly reduced fasting serum glucose levels in diabetic group, but had little effect on fasting glucose levels in healthy rats (group D, 5.92 ± 0.28 mM versus group C, $p < 0.01$; group B 4.58 ± 0.39 versus group A, NS). Furthermore, melatonin significantly reduced serum TNF-α in pre-diabetic animals when compared to untreated group (group A, 11.27 ± 0.48 pg/ml versus group C, 13.21 ± 0.41 pg/ml, $p < 0.001$; group D, 11.34 ± 0.28 pg/ml versus group C, $p < 0.001$; group B, 10.95 ± 0.27 pg/ml versus group A, NS). No significant difference in insulin levels between pre-diabetic and healthy rats was found (group C, 1.09 ± 0.09 ng/ml versus group A, 1.24 ± 0.10, NS). However, insulin was significantly lower in groups treated with melatonin (group D, 0.69 ± 0.05 ng/ml versus group C,$p < 0.001$;group B, 0.98 ± 0.05 versus group A, $p < 0.01$).

Conclusion: Early application of melatonin may postpone the onset of diabetes type 2 by reducing serum glucose levels and prevent its complications due to TNF-α production and/or activity suppression. Furthermore, melatonin might play important role in regulating insulin secretion, linked to the fact that insulin levels are also adapted to day/night changes.

Keywords: diabetes mellitus, Melatonin.

SUN-154

Effect of NAC and curcumin on the increase of MMP-3 induced by oxidative stress in intestinal myofibroblasts

F. Fontani[1], T. Marcucci[2], M. T. Vincenzini[1], T. Iantomasi[1]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, [2]St. James Hospital, Pistoia, Italy

Matrix metalloproteinases (MMPs), proteins involved in the metabolism of extracellular matrix (ECM), are secreted as latent enzymes, activated extracellularly after the proteolytic cleavage. The rapid and excessive production of pro-inflammatory cytokines, such as the tumour necrosis factor (TNF)α, and the up-regulation of transcripts of matrix metalloproteinases (MMPs) play a crucial role in the ulcerations present in the gut of Crohn's Disease (CD) patients [1]. A pivotal role is attributed to increased MMP-3 (stromelysin-1) in fistulae formation in intestine of CD patients [2]. MMP-3 degrades a wide range of ECM components and is expressed by fibroblastic cells [2]. The oxidative stress is involved in the maintenance of chronic inflammation in CD [3] and plays an important role in the regulation of MMPs activity and expression [4]. Therefore, the aim of this study was to investigate the relationship among oxidative stress, activity of antioxidants and MMP-3 production in a myofibroblasts cell line derived from human colonic mucosa, CCD-18Co (Co) stimulated or not by TNFα. Oxidative state was modulated by buthionine sulfoximine, an inhibitor of glutathione (GSH) synthesis, N-acetylcysteine (NAC), GSH precursor, and curcumin, antioxidant with anti-inflammatory properties. An up-regulation of MMP-3 due to increased oxidative state was found in 18Co treated with BSO. Stimulation by tumor necrosis factor (TNF)α increased further MMP-3 levels. NAC and curcumin treatments removed BSO induced oxidative state and up-regulation of MMP-3. However, these antioxidants normalized MMP-3 levels mainly in TNFα stimulated cells. Moreover, the effects of NAC and curcumin on MMP-3 were not closely related to the change of redox state measured in these conditions. For this, we hypothesize a possible direct action of NAC and curcumin on transcriptional factors involved on MMP-3 production. Our data suggest that, in condition of oxidative stress, the antioxidants, by reducing and/or restoring to normal values the altered levels of MMP-3 may have a therapeutic use for the prevention and treatment of fistulae in intestine of CD patients.

Effect of obesity and tobacco smoke exposure on adipokines, cytokines and matrix metalloproteinases in a rat model

M. Montaño[1], A. L. Esquivel[2], J. Cisneros[1], C. Mendoza-Milla[1], C. Becerril[1], J. Pérez[2], C. Ramos[1]
[1]*Fibrosis Pulmonar, Instituto Nacional de Enfermedades Respiratorias,* [2]*Sistemas Biologicos, UAM Xochimilco, Mexico City, Mexico*

Obesity is characterized by hypertrophy of adipose tissue, while chronic obstructive pulmonary disease-(COPD) for induce lung damage, mainly emphysema. Both diseases are associated with systemic low-grade inflammation. There are not animal models combining obesity and COPD, therefore these diseases were induced simultaneously in rats to analyze their effects on expression of some inflammatory mediators and enzymes involved in lung tissue remodeling. Obesity was induced with sucrose (30%) for four months plus/minus tobacco smoke exposure (20 cigarettes/day, 5 days/wk) last two months. Body weight, abdominal fat, dyslipidemia, glucose tolerance test-(GTT) and histology were evaluated; inflammatory mediators were analyzed with qPCR and ELISA, while MMP-2, MMP-9, MMP-12, TIMP-1 and TIMP-2 by qRT-PCR; additionally, MMP-2 and MMP-9 by gelatin zymography. Rats with sucrose diet enlarged: body weight, abdominal fat, triglycerides, GTT, plasma levels of insulin, adiponectin, leptin, resistin, IL-6, IL-1β, TNF-α and IFN-γ, upregulating lung IL-6, IL-1β, TNF-α and IFN-γ, and showing hyperplastic bronchial and alveolar epithelium. In animals exposed to sucrose and tobacco smoke were reduced: body weight, abdominal fat, plasma levels of leptin, resistin, IL-1β, IFN-γ, reducing inflammation but exhibiting similar emphysematous lesions than tobacco smoke exposure. Expression of gelatinases and MMP-12 augmented in rats exposed to tobacco smoke alone or combined with sucrose; zymography showed prominent activity of MMP-2 and MMP-9 in all experimental groups. Results suggest that simultaneous exposure to sucrose and tobacco smoke diminish inflammation, but produce similar emphysematous lesions than observed with tobacco smoke exposure, evidencing that obesity did not confer any protector effect for lung damage.

Effect of therapeutic low-intensity pulsed ultrasound (LIPUS) after the treatment of rat extraction socket

K. Hidaka[1], C. Miyamoto[1], S. Wada-Takahashi[1], R. Kawamata[2], Y. Maehata[1], M. MInabe[1], S. Takahashi[1], Y. Mikuni-Takagaki[1]
[1]*Oral Science,* [2]*Radiopraxis Science, Kanagawa Dental University, Yokosuka, Japan*

Objective: Low-intensity pulsed ultrasound (LIPUS) has been widely accepted as a potent therapeutic tool to accelerate fracture healing. The effect of LIPUS on wound healing in the oral environment, however, has not been well explored. This study aimed to characterize the effect of LIPUS on tooth extraction sockets in aged rats.
Methods: Right maxillary first molars were removed from retired female breeder rats in 2 groups ($n = 5$), control and LIPUS. LIPUS was applied extrabuccally to the socket every 24 hrs starting one day after the extraction. The blood flow rate was measured by laser-Doppler flowmetry at the extraction socket, the dorsum of the tail base, and the dorsum of foot prior to and 20 min after the 20-min LIPUS treatment. We also evaluated cytokine mRNA levels in the cells at the remote sites.
Results and Discussion: On days 3 and 7 after extraction, the blood flow rate in the socket dropped significantly 20 min after LIPUS treatment. On day 3, the rate also dropped in the tail, which is remote from the wound/exposure site. The baseline flow rate in the tail in the LIPUS group was significantly higher than in the vehicle group on day 3. In the socket measurements, the LIPUS group showed a trend to higher baseline values that was not statistically significant. Cytokine messages at the remote sites also showed some changes as a result of LIPUS treatment. Mechanical stimulation at wound sites may have effects far away from the healing tissue through as-yet-unknown mechanisms.
Keywords: socket healing, laser-Doppler flowmetry, low-intensity pulsed ultrasound.

Effects of beta-hydroxybutyrate on brain vascular permeability in rats with traumatic brain injury

N. Orhan[1], C. Ugur-Yilmaz[2], O. Ekizoglu[3], N. Arican[4], B. Ahishali[5], I. Elmas[4], C. Gurses[6], M. Kucuk[2], M. Kaya[7]
[1]*Department of Neuroscience,* [2]*Department of Experimental Animal Biology and Biomedical Application Techniques, Institute of Experimental Medicine, Istanbul University,* [3]*Department of Forensic Medicine, Dr. Bakirkoy Sadi Konuk Training and Research Hospital,* [4]*Department of Forensic Medicine,* [5]*Department of Histology and Embrology,* [6]*Department of Neurology,* [7]*Department of Physiology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey*

Traumatic brain injury (TBI) causes various pathological conditions including increased blood-brain barrier (BBB) permeability and cerebral edema. This study investigates the effect of beta-hydroxybutyrate (B-OHB) treatment on the functional and structural BBB characteristics during TBI induced by lateral fluid percussion. Adult female rats were allocated into the following experimental groups: 1-Control, 2-Sham, 3-B-OHB, 4-TBI and 5-TBI + B-OHB. Evans blue (EB) and horseradish peroxidase (HRP) traces were used as determinants of BBB permeability. The intensity of immunostaining for occludin, aquaporin-4 (AQP-4), glial fibrillary acidic protein (GFAP) and c-fos were evaluated and gene expression levels of occludin AQP-4, c-fos, glucose transporter-1 (GLUT-1) and nuclear factor kappa-B (NF-κB) were analyzed. Lipid peroxidation and glutathione (GSH) levels were measured. Occludin and GFAP immunostaining intensities did not differ between experimental groups, while AQP-4 and c-fos immunostaining intensities were higher in TBI. MDA levels increased and GSH levels decreased in TBI ($p < 0.05$). c-fos, GLUT-1 and NF-κB expressions were increased in TBI and TBI+B-OBH ($p < 0.01$). EB dye extravasation into brain and HRP reaction products increased in TBI, while B-OHB administration caused alleviation of these findings. B-OHB treatment in TBI caused a reduction in c-fos immunostaining intensity accompanied by decreases in c-fos and NF-κB expressions and increase in GLUT-1 expression ($p < 0.01$). The results of this study indicate that transcellular pathway is primarily responsible for the increased BBB permeability in TBI and that B-OHB treatment may, at least partly, provide a protection of BBB integrity mainly by reducing the effects of free radicals and increasing GLUT-1 production.

Effects of feeding *Ricinus communis* seed meal on liver enzymes makers of albino rats

Y. Omeh, A. P. Ikeyi, E. Ejiofor
Biochemistry, Michael Okpara University of Agricutlture, Umudike, Umuahia, Nigeria

The effect of feeding a *Ricinus communis* seed meal on some liver enzymes was evaluated in albino Wister rats. Sixteen (16) male albino rats were randomly divided into 4groups of 4 rats each. Raw *Ricinus communis* seeds were incorporated into normal rat diet at 5%, 10% and 20% inclusion levels and fed to rats in groups 2, 3 and 4 respectively, while rats in group 1 (control) were fed normal rat chow. The study lasted for 28 days, after which the serum levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphate (ALP), serum bilirubin (conjugated and total) were determined using standard methods. The mean values for ALT and ALP, and those for conjugated bilirubin significantly decreased relative to the control. The mean AST and total bilirubin values significantly increased relative to the control group. The results of the experiment suggest that *Ricinus communis* meal may possess some hepatoprotective property.

Effects of indole α-lipoic acid derivatives on nitric oxide production in LPS/IFN-γ activated RAW 264.7 macrophages

A. Z. Karabay[1], A. Koc[2], S. Gurkan[2], Z. Buyukbingol[2], E. Buyukbingol[2]
[1]*Biochemistry,* [2]*Ankara University Faculty of Pharmacy, Ankara, Turkey*

In this study, nitric oxide inhibitory effects of indole α-lipoic acid derivatives in LPS/IFN-γ activated RAW 264.7 macrophages were investigated. Antioxidant effects of these derivatives were reported before and potential anti-inflammtory activities were examined in this study. Cell proliferation, nitric oxide levels and iNOS protein expression were examined with MTT test, griess assay and western blot respectively. Our results showed that, all of the α-lipoic acid derivatives showed significant inhibitory effects on NO production and iNOS protein levels dose dependently ($p < 0.05$). Compound III-5a was found to be the most potent inhibitory compound which showed %45 inhibition in NO levels at 2.73 μM concentration. In conclusion, these lipoic acid derivatives may have potential for the treatment of inflammatory conditions related with high NO production.

Effects of salicylic acid derivatives on reactive oxygen and nitrogen species and the redox state of mitochondria

J. Vašková[1], A. Fejerčáková[2], L. Vaško[2], P. Perjési[3]
[1]*Faculty of Medicine,* [2]*Pavol Jozef Šafárik University, Košice, Slovakia,* [3]*University of Pécs, Pécs, Hungary*

Salicylic acid (SA) and its metabolites, frequently found in fruit and vegetables, constitute a natural source of salicylates. SA itself and its salts are commonly used as drugs with vasodilatatory or anti-inflammatory activities. Their low solubility and possible side effects in the gastrointestinal tract force the requirement to find potential replacements. We therefore compared selected properties of SA and 4 other derivatives in vitro.

The ability of gentisic acid (GA) and hypogallic acid (HGA) to scavenge hydroxyl radical ($HO^{\cdot}$) increased with increasing concentration, exceeding 50% at the highest test concentration of 100 $\mu g.ml^{-1}$. However, the highest inhibition capacity, (up to 35%) in the case of protocatechuic acid (PCA) was recorded only at a concentration of 50 $\mu g.ml^{-1}$. SA and 2,4-dihydrobenzoic acid (2,4-DHBA) showed a similar trend, and their scavenging ability was only about 10%. The ability to convert NO to nitrites showed an opposing trend, decreasing from about 20 to 2%, with increasing SA concentration. Maximum values in PCA, 2,4-DHBA, HGA reached up to 27%. However, GA reached 51% efficiency. We therefore investigated the effect of derivatives 50 $\mu g.ml^{-1}$ in rat liver mitochondria as the location of 90% of total cell energy production, leading to the production of superoxide radicals ($O_2^{\cdot -}$) and precursors of other reactive particles. Activities of superoxide dismutase (SOD) were significantly increased, even with SA at $p < 0.001$, and HGA, 2,4-DHBA at $p < 0.01$. However, glutathione peroxidase activity (GPx) in SA did not change significantly and had a significant decreasing trend in comparison with other derivatives. In neither case were there significant changes in the activities of GR nor in reduced glutathione levels, except for increased levels in SA and 2,4-DHBA.

It was shown that acetate, salicylate and benzoate form Cu-complexes exhibited excellent SOD-mimicking activity. It is therefore possible that more active complexes can be formed, especially by 2,4-DHBA and HGA. According to the significantly lower GPx activity, a number of peroxides formed could cause substrate-inhibition, but could also be converted into $HO^{\cdot}$. Despite the potent ability of derivatives to scavenge $HO^{\cdot}$, especially GA and HGA, there is no implied offset of oxidative stress conditions. In this case, the relatively high ability of PCA, 2,4-DHBA, HGA and GA to convert NO to nitrites can be important. At the same time, a high concentration of peroxides and nitrites allows the catalase of their conversion to harmless nitrates. However, we would like to examine this more closely, as 2,4-DHBA seems to be a more effective derivative than GA, PCA or the HGA.

This study was supported by VEGA 1/1236/12.

Efficient therapeutic usage of pioglitazone to reduce the progress of neurodegenerative conditions in oligodendrocyte progenitor cells

M. Peymani[1,2], K. Ghaedi[1], M. H. NasrEsfahani[1], H. Baharvand[3]
[1]*Cellular Biotechnology at Cell Science Research Center, Royan, Isfahan,* [2]*Department of Biology, Shahrekord branch, Islamic Azad University, Shahrekord,* [3]*Department of Stem cells and Developmental Biology at Cell Sciences Research Center, Royan, Tehran, Iran*

One of the world wide neuropathologic diseases is Multiple sclerosis (MS) which is considered by inflammation of the central nervous system (CNS) and demyelination. Neurons and oligodendrocytes, which are CNS cells cooperated in MS. Lipopolysaccharide led to NO production and extensive oligodendrocyte and cells death and IFN gamma induce this death. We have focused on the therapeutic role of Peroxisome proliferator-activated receptor gamma (PPARγ) which is a nuclear receptor that response to inflammation. Recently demonstrated that PPAR gamma ligands can effects on viability of neurons and oligodendrocytes during inflammation. Thus as a step to obtain OPC cells, human embryonic stem cells were treated with specific factors and media to obtain OPC cells after 40 days. These cells

© 2014 The Authors. FEBS Journal © 2014 FEBS

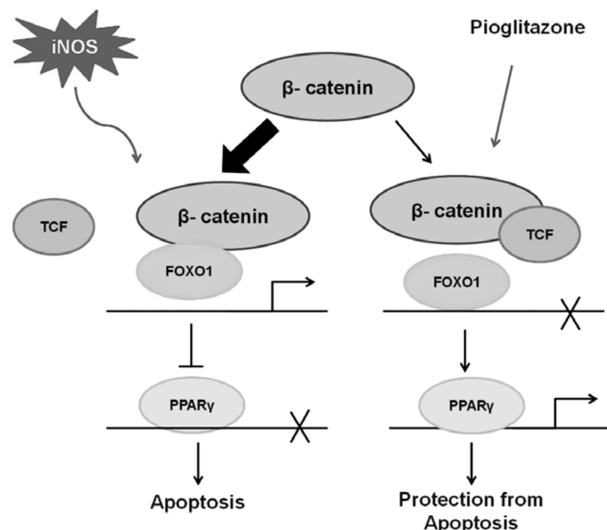

Fig. 1.

were characterized in terms of cellular and molecular analyses. The obtained OPCs were pretreated by one of the potent PPARγ agonists, Pioglitazone, at different concentrations. Then the pretreated cells were used for inflammation induction. Interestingly, pioglitazone reversed the inflammation conditions and enhanced OPC cells viability. Data showed that pioglitazone reduced NO production while did not change mRNA levels of inflammation markers. More over pioglitazone enhanced cell viability through different mechanisms including apoptosis reduction, anti-apoptotic marker increment and regulation of cell cycle markers. This study demonstrated that NO induced apoptosis through FOXO1 and degradation of β-catenin while presence of pioglitazone and CHIR limited this effect and saved hOPCs from apoptosis. Thus we suggest the therapeutic use of Pioglitazine to reduce the progress of neurodegenerative conditions.

Keywords: inflammation, oligodendrocyte, Pioglitazone.

EPA and DHA are able to modulate markers of insulin resistance in ageing 3T3-L1 adipocytes

A. Prostek, B. Baasińska

Department of Physiological Sciences, Faculty of Veterinary Medicine, Warsaw University of Life Sciences, Warsaw, Poland

Currently, the most frequent cause of insulin resistance is obesity. Adipocytes of obese individuals secrete higher levels of proteins which are involved in development of insulin resistance. On the other hand in obesity secretion of adipokines, which increase insulin sensitivity is decreased. A properly balanced diet and bioactive substances present in food are able to improve insulin sensitivity of body tissues. Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are nutrients which potentially decrease insulin resistance. EPA and DHA are able to modulate secretory functions of adipocytes. In most cases they decrease secretion of adipokines involved in development of insulin resistance, such as interleukin 6 (IL-6), and increase production of insulin sensitizers, like adiponectin. Effects of EPA and DHA on young adipocytes were investigated in several studies. However, influence of these fatty acids on old cells is still unknown. The impact of EPA and DHA on secretory functions and markers of insulin resistance in old adipocytes seems to be important because ageing is increasingly connected with fat mass accretion and insulin resistance. Also it was demonstrated in in vivo studies that the proliferation of preadipocytes and their ability to differentiate decreases with age. This observation suggests that old adipocytes could constitute a large part of the adipose tissue, especially in older individuals.

Therefore, the aim of the present study was to evaluate the influence of EPA and DHA on secretory functions and markers of insulin resistance in ageing 3T3-L1 adipocytes.

Differentiated young and old 3T3-L1 adipocytes were cultured for 48 h in the presence of 100 μmol/l EPA, or 50 μmol/l DHA complexed to albumin, whereas in control conditions only albumin was added to the medium. The concentration of adipokines (IL-6 and adiponectin) in conditioned media was measured using mouse-specific ELISA kits. The expression of IRS1 and GLUT4 genes in adipocytes was determined by real – time PCR.

Both investigated fatty acids increased the secretion of adiponectin compared with the control, but only by young cells. Moreover, EPA supplementation increased IL-6 concentration in conditioned medium, while DHA exerted an opposite effect in young and old adipocytes. The expression of IRS1 and GLUT 4 in cells was decreased by EPA and increased by DHA treatment in both examined time points.

In summary, to our knowledge this research is the first showing that the influence of investigated fatty acids on adipokines secretion is age dependent, and seems to be stronger in young adipocytes then old. Furthermore, we demonstrated that EPA and DHA may exert opposite effects on expression of genes connected with insulin resistance, which could be caused by different impact on secretion of IL-6.

Keywords: adipocytes, EPA, insulin resistance.

ERK phosphorylation is suppressed by H_2O_2 in human umbilical vein endothelial cells

B. K. Jeon[1], K. Kwon[2], Y.-H. Choi[1]

[1]Physiology, [2]Cardiology, EWHA Womans University School of Medicine, Seoul, Korea

The mitogen-activated protein kinases (MAPK) are key signaling transducers involved in various cellular events such as cell growth, proliferation and differentiation. MAPK signaling pathways are usually activated by a variety of extracellular stimulants including reactive oxygen species. Previous studies have reported that extracellular H_2O_2 leads to phosphorylation of extracellular signal-regulated kinase (ERK), one of the MAP kinases, in endothelial cells. However, in this study, we demonstrate that H_2O_2 suppressed ERK1/2 activation and phosphorylation in some concentration range especially in human umbilical vein endothelial cells (HUVEC), not in immortalized mouse aortic endothelial cells (iMAEC) and human astrocytoma CRT-MG. Physiological laminar flow abrogated H_2O_2-induced suppression of ERK1/2 phosphorylation, but oscillatory flow did not affect H_2O_2-induced ERK1/2 suppression. Decreased ERK1/2 phosphorylation level induced by H_2O_2 was inversely correlated with the level of Src Y530 phosphorylation. Blocking Src using pharmacological inhibitor PP2 abolished H_2O_2-induced phospho-ERK1/2 suppression, leading to a significant increase of ERK1/2 phosphorylation. Csk knock-down using siRNA also abrogated H_2O_2-induced suppression of ERK1/2 phosphorylation. Further study is in progress to identify the effect of H_2O_2 on the membrane translocation of Csk, which known as a kinase of Src Y530 residue, and the effect of H_2O_2-induced ERK1/2 suppression on endothelial cell permeability.

Keywords: ERK1/2, H2O2, HUVEC.

SUN-166
Evaluation of hyperkaliemia as an indicator of necrosis grade of caustic injuries in adults

S. Bouabdellah
Internal Medicine, CHU of Constantine- Faculty of Medicine-University 3 of Constantine, Constantine, Algeria

The caustic ingestion is often accompanied by severe metabolic disorders. In general, hyperkaliemia was always correlated with the severity of the tissular necrotic process but has never been studied as an indicator of severity of mucosal lesions in the caustic ingestions.

The aim of our study was to evaluate this biochemical marker as an indicator of severity in caustic digestive necrosis, especially in extreme cases or upper gastrointestinal endoscopy can not be performed.

Materials and Methods: This is a monocentric prospective study, which included all cases of caustic ingestion from January 1st, 2006, to December 31, 2008. All the patients were studied after their hospitalization; fibroscopic examination was performed immediately and an ionogram was performed on the first day from ingestion.

Results: 314 adult patients were hospitalized for caustic ingestion. Among these, 176 were women and 136 were men; their mean age was 28.12 ± 12.00 years (15–79 years).

The ionogram was performed in 255 patients. It was pathologic in 47.5% of cases.

We noted 2% cases of hyperkalemia.it was correlated with acid ingestion in 60% of cases and alkali ingestion in 40% others. The caustic substance was (battery acid: 40%), (chlorydric acid: 40%); (caustic soda: 20%) ($p < 0.00001$).

One patient died before the endoscopic examination.

In all other cases, the lesion stage was severe (>IIb) and the burns were diffuse to the entire upper digestive tract.

Conclusion: Hyperkaliemia has long been considered as a biochemical factor of the tissular necrosis, but it must be reconsidered as an indicator of the necrosis grade of caustic injuries in adults especially in cases where the endoscopy cannot be practiced.

Keywords: caustic, hyperkaliemia, necrosis.

Evaluation of oxidative stress markers in type-2 diabetic rat kidney with treated Δ^9-THC

Z. M. Coskun[1], K. Yanar[2], S. Aydın[2], S. Bolkent[3]
[1]Department of Molecular Biology and Genetics, Faculty of Arts and Sciences, Istanbul Bilim University, [2]Department of Medical Biochemistry, Faculty of Cerrahpasa Medicine, Istanbul University, [3]Department of Medical Biology, Faculty of Cerrahpasa Medicine, Istanbul University, Istanbul, Turkey

Oxidative stress plays a major role in the pathogenesis of diabetes mellitus. Impaired redox homeostasis can lead to the damage of macromolecules and insulin resistance. Thus, oxidative stress promotes the development of complication of diabetes. Δ^9-tetrahydrocannabinol (Δ9-THC) has been shown to interfere with both the function of insulin and its release. The activation of cannabinoid receptors stimulates insulin secretion to maintain glucose homeostasis. The current study, we aimed to evaluate effects of Δ^9-THC on oxidative stress markers with respect to antioxidant status in kidney tissue of streptozotosin + nicotinamid induced type 2 diabetic rats.

The male Sprague–Dawley rats (8–10 weeks) were arranged as Control, Δ^9-THC, Diabetes, Diabetes + Δ^9-THC groups. The type-2 diabetic rats were treated with a single dose nicotinamide (85 mg/kg) 15 min before the injection of streptozotocin (65 mg/kg). Δ^9-THC was administered intraperitoneally at 3 mg/kg/day for 7 days. On day 15 after the Δ^9-THC injections, kidney tissues were removed. Protein carbonyl (PCO), lipid hydroperoxide (LHP), malondialdehyde (MDA), Cu-Zn superoxide dismutase (Cu-Zn, SOD) and thiol fractions including total thiol (T-SH), protein thiol (P-SH) and nonprotein thiol (NP-SH) parameters were measured. Statistical analysis was performed using the SPSS version 21.0 program.

A significant increase was observed in PCO, LHP and MDA parameters of diabetic rats as compared to control rats. Moreover, PCO, LHP and MDA levels of kidney were significantly reduced in diabetes treated with Δ^9-THC compared to diabetic animals. The SOD activity and T-SH level were shown a significant increase in diabetic rats treated with Δ^9-THC as compared with diabetic group. On the other hand, P-SH and NP-SH levels were non-significantly higher in the diabetes treated with Δ^9-THC than in the diabetic rats.

According to the results, the renal tissue in type 2 diabetic animals is exposed to oxidative damage. This oxidative damage may be relieved in type 2 diabetic rats treated with Δ^9-THC.

Keywords: oxidative stress, Type-2 diabetes, Δ9-THC.

Evaluation of scaffolds for the delivery of mesenchymal stem cells in vivo

E. A. Wahl[1], T. L. Schenck[1], F. A. Fierro[2], T. R. Peavy[3], J. Dye[4], T. J. Egana[1]
[1]Department of Plastic and Hand Surgery, Klinikum Rechts der Isar/TU Munich, Munich, Germany, [2]Institute for Regenerative Cures, Davis, [3]California State University, Sacramento, USA, [4]RAFT Institute of Plastic Surgery, Mount Vernon Hospital, Northwood, UK

Mesenchymal stem cells (MSCs) have been shown to improve tissue regeneration in several preclinical and clinical trials. These cells have been used in combination with three-dimensional scaffolds as a promising approach in the field of regenerative medicine. In order to determine the most suitable scaffold for delivering the cells to dermal wounds, in this work we compare the behavior of human adipose-derived MSCs (AdMSCs) seeded on four different biomaterials that are commonly used in clinical settings. MSCs were isolated, characterized, and seeded onto scaffolds based on bovine collagen and glycosaminoglycans, fibrin, chitosan, or decellularized porcine dermis. In vitro results showed that the scaffolds strongly influence key parameters such as seeding efficiency, cellular distribution, attachment, survival, metabolic activity, and paracrine release. Chick chorioallantoic membrane assays showed that the scaffold composition also influences the angiogenic potential of AdMSCs in vivo. This work provides valuable information to improve wound healing in scaffold-based approaches, representing a step further for optimizing the use of AdMSC-seeded biomaterials in wound repair.

Keywords: biomaterials, mesenchymal stem cells (MSCs), wound healing.

Experimental pathology of Cardio-pulmonary damage induced by Moroccan vipers' venoms in rabbit model

L. Fahmi[1], B. Makran[1], L. Boussadda[2], M. Lkhider[3], H. Benomar[4], N. Ghalim[5]
[1]Biotechnology, Biochemistry and Nutrition Laboratory, Faculty of Sciences El Jadida, Chouaib Doukkali University, El Jadida, [2]Animal Unity of The Pasteur Institute of Morocco, Casablanca, [3]Department of Biology, Faculty of Science and Technology, Mohammedia, [4]Anatomopathology Laboratory, Pasteur Institute of Morocco, [5]Venoms and Toxins Laboratory, Pasteur Institute of Morocco, Casablanca, Morocco

Viper envenomations are often associated with complex local and systemic pathological events, including edema, dermonecrosis, myonecrosis and hemorrhage. In this study, the venom of the vipers *Cerastes cerastes* and *Macrovipera mauritanica* and their respective toxic fractions were tested for their ability to induce histopathological and biochemical changes after subcutaneously administration of a subléthal dose.

The histology of the studied organs revealed that both viper's venoms and their toxic fractions induce deep lesions in the tissue structures. Sections of the lung showed an enlargement of alveolar spaces, destruction of the walls lining the alveolar spaces, hemorrhage, intra-alveolar edema and inflammatory cell infiltration, with the exception of a strong hemorrhagic suffusion in the case of *Cerastes cerastes* venom and marked presence of lymphoid islets in the case of venom *Macrovipera mauritanica.* At heart level were observed cardiomyocyte injuries with fibromuscular degeneration, hemorrhagic areas, interstitial edema. The damage was more intense for fractions marked by a discrete inflammatory infiltrate.

Correlated with biochemical markers, the venom of both vipers caused a significant increase in levels of creatine phosphokinase with a concomitant decrease in lactate dehydrogenase 24 hours after envenomation.

Our results suggest that the venom of *Cerastes cerastes* and *Macrovipera mauritanica* are likely to cause severe histopathological changes in poisoned patients. Fast and appropriate management is crucial to prevent the sequelae and preserve the normal functioning of poisoned patients vital organs.

Expression and purification of α-1,2 mannosyltransferase for the development of antifungal drugs

P. A. Silva[1], A. K. Abadio[2], E. S. Kioshima[3], S. S. Felipe[2]
[1]Molecular Patology, [2]Departament of Cellular Biology, UnB, Brasília, [3]Department of Clinical Analysis and Biomedicine, State University of Maringá, UEM, Maringá, Brazil

The rise of the occurence of systemic infections has been the cause of great concern worldwide. The therapeutic options currently available are limited, and another problem is the pathogens resistance to the classical antifungal agents resulting in the requirement for the development of new antifungal agents. Preliminary results obtained by our group through *in silico* analysis identified four possible target genes which are present in seven relevant human pathogenic fungi and absent in the human genome. Among these target genes we found *Kre2 or Mnt1,* a gene highly conserved in pathogenic fungi which encodes a protein of approximately 49 kDa, the α – 1,2 mannosyltransferase. It is an important protein for cell viability and virulence of the pathogen within the host. The recombinant protein KRE2 with a degree of purity is of great importance to the knowledge of the main structural and functional characteristics of this protein *Paracoccidiodes lutzii* protein. The results obtained in this study indicate the success in obtaining this protein with high purity in heterologous expression *Escherichia coli*system. However, the refinement of purification in order to increase the purity and reduce potential future degradations are necessary. Heterologous expression of the gene of Paracoccidioides kre2 lutzii in Escherichia coli was performed in this work. Purification of the recombinant protein by affinity chromatography was also carried out. The pure protein enables the execution of other steps, such as enzyme activity to confirm the activity of the recombinant protein, circular dichroism and crystallographic assays may contribute to the knowledge of the main structural and functional characteristics of this protein. To verify possible degradation, MALDI TOFF MS technique was used, and using the software Mascot Search Results was confirmed that, the bands below the expected size of KRE2 belong to the same protein. Thus, the search continues for solving this problem, using such techniques as gel filtration, or by molecular exclusion chromatography. Additionally, DLS was performed, which the main objective of the technique is to observe the behavior of protein molecules in solution. Results generated by this work represents an advancement and may contribute to the development of new antifungal agents for the treatment of important fungal infections worldwide.

Keywords: drug target, new antifungal compounds, α – 1,2 mannosyltransferase.

Expression of cytokine IL-1alpha following cytotoxic treatment in vitro and in vivo

D. Dabkeviciene, V. Jonusiene, E. Kukcinaviciute, A. O. Jancauskaite, V. Kirveliene
Biochemistry and Molecular Biology, Vilnius University, Vilnius, Lithuania

Purpose: A number of cytokines are abundant at tumor sites, and they may influence the development of the malignant process as well as the tumor response to the treatment. Interleukin-1 (IL-1) acts as a major upstream cytokine that is involved in regulation of immune and inflammatory responses. Little is known about the role of IL-1alpha in various diseases, since most studies have concentrated on the role of IL-1beta. Here, we focused our study on the IL-1alpha expression in cells and tumors following treatment with conventional chemotherapeutic drug 5-fluorouracil (5FU) and photodynamic treatment (PDT) mediated by m-tetrakis-(3-hydroxyphenyl)-chlorin (mTHPC). PDT is an attractive addition to the conventional strategies of cancer treatment due to its specific mode of action.

Methods: Human colon tumor HCT116 cell line and its subline resistant to 5FU, *i. e.* HCT116/FU, as well as Lewis lung carcinoma LLC1 cell line and C57BL/6 mice bearing this tumor, were used for the experiments. In vitro, the cells were incubated with 5-FU or the photosensitizer mTHPC. In case of mTHPC-PDT, light emitting diode array was used for illumination. In vivo, anti-mouse IL-1alpha antibodies were injected after light exposure. The effect of the treatment was evaluated by comparison of viability of treated cells versus untreated ones, growth of tumors and survival of the treated mice versus untreated ones. Gene expression on mRNA and protein levels was revealed by qPCR and ELISA.

Results: It was shown that 5FU stimulated the expression of IL-1alpha in HCT116 and HCT116/FU cells in vitro. mTHPC-PDT significantly inhibited cancer cells survival in vitro and tumor growth in vivo. mTHPC-PDT induced overexpression of IL-

© 2014 The Authors. FEBS Journal © 2014 FEBS

1alpha. The blockade of cytokine IL-1alpha inhibited growth of both untreated and mTHPC-PDT-treated tumors.

Conclusions: IL-1alpha expressed in response to cytotoxic treatment promotes the tumor growth. Combination of cytotoxic agents with anti-IL-1alpha immunotherapy might be an effective therapeutic strategy.

Keywords: cancer immunotherapy, Interleukin-1.

Flavonoids from *Triticum aestivum* inhibit adipogenesis in 3T3-L1 cells

B. Poudel[1,2], S. Nepali[2], D.-K. Kim[2], Y.-M. Lee[1]
[1]*Wonkwang-Oriental Medicines Research Institute, Wonkwang University, Iksan,* [2]*Department of Immunology, Chonbuk National University, Jeonju, Korea*

Obesity is the most common metabolic disease worldwide. It is characterized with an excessive storage of body fat, and is associated with many metabolic complications, including type 2 diabetes, hypertension and cardiovascular diseases. The current study aims to uncover the effects and underlying mechanisms of flavonoids; leuteolin, isoscoparin and isoorientin isolated from *Triticum aestivum* Sprout (TA) in regulation of adipogenesis. 3T3-L1 cells were treated with different concentrations (0–10 μM) of flavonoids for 8 days. Cell viability was assayed on differentiating cells treated with or without the flavonoids using CCK-8 kit. Oil Red O staining was performed to visualize the lipid accumulation in the cells. We performed quantitative polymerase chain reaction and western blotting to examine expression of transcription factors and genes involved in adipogenesis. Flavonoids suppressed lipid accumulation in 3T3-L1 cells without affecting viability up to 10 μM. The flavonoids inhibited adipocyte differentiation by downregulation of adipogenic transcription factors such as peroxisome proliferator-activated receptor-gamma (PPARγ), CAAT/enhancer binding protein-alpha (C/EBPα) and sterol regulatory element binding proteins (SREBP)-1c and subsequent attenuation of expression of adipogenesis associated genes; activating protein (aP2), fatty acid synthase (FAS), hormone-sensitive lipase (HSL) and lipoprotein lipase (LPL). Of note, the flavonoids enhanced the expression of *insig-1* and *2* which, in turn, inhibited the transcription factor (SREBP-1c) activation, eventually leading to the suppression of adipogenesis in 3T3-L1 cells. Our study reveals an anti-adipogenic effect of the flavonoids from TA and suggests that they could be potential therapeutic agents for the prevention and treatment of obesity.

Keywords: anti-adipogenesis, flavonoids, *Triticum aestivum*.

Functional analysis of fractalkine gene promoter in human aortic smooth muscle cells exposed to pro-inflammatory conditions

A.-M. Gan[1], E. Butoi[1], A. Manea[2], M. Pirvulescu[1], D. Stan[1], V. Simion[1], M. Calin[1], M. Simionescu[1], I. Manduteanu[1]
[1]*Biopathology and Therapy of Inflammation,* [2]*Genomics, Transctiptomics and Molecular Therapies, Institute of Cellular Biology and Pathology, Bucharest, Romania*

Fractalkine (Fk) and its receptor CX3CR1 contribute effectively to the atherosclerosis process mediating the recruitment of leukocytes and promoting the interactions between monocytes/ macrophages and smooth muscle cells (SMC). Since Fk expression is significantly increased in SMC during atherogenesis, we aimed to uncover the advanced molecular mechanism of transcriptional regulation of Fk gene. To this purpose, we clone and characterized the human Fk promoter and investigated the role of various transcription factors in its regulation in human aortic SMC activated by IFNγ. *In silico* analysis of Fk promoter indicated the existence of binding sites for different inflammatory modulators such as nuclear factor (NF)-kB, activator protein (AP)-1, and signal transducers and activators of transcription (STAT)1/3. Using a luciferase reporter plasmid, we identified a 2046 bp region spanning the transcriptional start point of Fk gene, which has strong constitutive promoter activity in SMC. The effects of IFNγ on both, Fk reporter activity and endogenous transcription, were abolished by silencing the NF-kB, STAT1 and STAT3. Transient over-expression of p65/NF-kB, and STAT1/3, but not c-jun/AP-1, increased the Fk promoter activity. Chromatin immunoprecipitation demonstrated the existence of physical interactions of p65 and STAT1/STAT3 proteins with the predicted elements of the Fk promoter. Moreover, Fk-promoted monocyte chemotaxis was dependent on JAK-STAT pathway. Approaching the advanced molecular mechanisms by cloning and characterizing potential transcriptional response elements, the results identify the fractalkine regulatory mechanism in activated human SMC.

Keywords: fractalkine promoter, smooth muscle cells, interferon-gamma, STAT1/3, NF-kB.

Functional and structural insights into the NADPH oxidase family: new kids on the block!

C. Hajjar, J. Dupuy, F. Fieschi
Institut de Biologie Structurale, Grenoble, France

The reactive oxygen species (ROS) are known as highly reactive metabolites of oxygen that can attack proteins, lipids, and nucleic acids. This damage includes aging associated pathologies, cardiovascular disease, cancers and chronic inflammation. However, many researches seem to show that these ROS have also essential roles in normal physiological processes, such as redox regulation, cell differentiation, hormone synthesis, and probably the most documented is their role in the host defense [1]. Several ROS producing enzyme systems exist and the phagocytic NADPH oxidase (Nox) was the first identified example of a system that generates ROS not as a byproduct, but rather in a dedicated and oriented manner. Noxs are transmembrane proteins involved in the electron transfer across biological membranes. Usually the final acceptor is the molecular oxygen resulting in the production of superoxide anion that is the precursor of ROS. In addition to ROS related damages, dysregulation of Nox-dependant ROS production can induce pathological consequences related to specific physiological context (e.g., chronic granulomatous disease, hypothyroidism, cardiovascular and neurodegenerative diseases). Accordingly, the Nox family became one of the most potential drug targets, making the understanding of their function at molecular basis crucial.

In the litterature, it has always been reported that Nox proteins exist only in eukaryotes [1]. Eukaryotic membrane proteins have proven to be difficult to study due to their partially hydrophobic surfaces, flexibility and lack of stability, all the data available on Nox enzymes are obtained from putative assignements or structure-function studies.

In our project, to overcome the difficulty of working on eukaryotic membrane proteins, we used an original approach based on bioinformatic tools. Through using specific filters and a novel program, we were able to identify hundreds of prokaryotic candidates. SpNox, the prokaryotic model from *Streptococcus pneumoniae* was expressed in *E. coli* and the pure protein is obtained after several purification steps. Purified SpNox has an NADPH oxidase activity, produces superoxydes, and shares with

© 2014 The Authors. FEBS Journal © 2014 FEBS

eukaryotic Nox enzymes their major characteristics. Thus, through this work we are providing the first prokaryotic model for the functional and structural study of a Nox enzyme. Crystallization trials are performed and the understanding the biological and physiological function of a Nox protein in bacteria remains to investigate.

Background: While the role of common genetic variants is clearly established in multiple sclerosis (MS), the heritability of the disease is still poorly explained, suggesting the existence of rare variants implicated in the susceptibility to the disease.

Objective: To identify low-frequency and rare genetic variants contributing to MS susceptibility in an Italian multiplex family.

Methods: SNP microarray genotyping and whole-genome sequencing (mean coverage: 20×) in 4 MS patients and 4 unaffected individuals belonging to an Italian multiplex family originating from a first cousin consanguinueous marriage have been performed. The Merlin software was used for the linkage analyses and SNPeff and GATK software were applied to prioritize rare variants.

Results: Filtering criteria, narrowed down the list of variants up to a rare functional variant, which determines an amino acid change, S601P, at a unexplored gene, *GRAMD1B*. The mutation is in a context that is highly conserved across species, and it segregates along the family consistent with an autosomal recessive transmission ($p = 0.02$). By performing WG expression, we found that the gene was downregulated in affected relatives ($p = 0.01$) with the exception of the only case who was IFNβ treated. We performed an IFNβ stimulation of PBMCs isolated from 20 healthy controls, showing an increase in *GRAMD1B* expression ($p < 0.001$). We also observed a significantly higher expression of GRAMD1B in the brain tissue and in immune cells, compared to other cells and tissues ($p < 0.05$) and a significant increase of GRAMD1B expression in activated rat microglial cells compared to unstimulated ones ($p < 0.05$), suggesting a possible role of this protein in the context of glia activation. Ongoing experiments are aimed to investigate: 1) the intracellular localization of GRAMD1B 2) the function of GRAMD1B particularly the modulation of its expression under glia activation and IFNβ stimulation; 3) the effect of the S601P mutation on the expression, localization and function of GRAMD1B protein as well as its possible role in MS etiology.

Conclusions: We identified a novel rare variant in GRAMD1B, an unexplored gene recently found to be associated with IgE levels. Further investigations are ongoing to explore the role of this variant in MS.

Gene editing by CRISPR/Cas9: a novel approach complementing ES-cell based gene targeting technologies to efficiently modify the mouse genome

A. Flora, J. Seibler
TACONICARTEMIS, Cologne, Germany

The unique possibility to introduce virtually any modification in the mouse genome has provided investigators with invaluable tools to explore specific aspects of physiology and pathology in a mammalian system. One of the main limitations of gene targeting in mouse is the technical complexity of the entire procedure: steps such as targeting vector construction, ES cell manipulation, and blastocyst injection are rather time-consuming and require extensive effort from highly experienced scientists.

Here, we discuss the use of the clustered regularly interspaced short palindromic repeats/Cas9 (CRISPR/Cas9) technology as a complementary approach to ES cell manipulation by homologous recombination, and its advantages/disadvantages over standard gene targeting methods. As an example of CRISPR/Cas9 versatility, we describe the combination of this technology with standard gene targeting approaches to modify already existing mouse models, tailoring them to new experimental needs (model refitting). Along this line, we will also present our recent data on the use of CRISPR/Cas9 to generate conditional Knock-Outs, Knock-Ins, genomic deletions, and multiplex Knock-Outs.

Genetic association of SNPs in MMPs type polymorphisms with COPD secondary smoking

C. Ramos[1], J. Hernández[1], C. Mendoza-Milla[1], C. Becerril[1], J. Cisneros[1], J. Pérez[2], R. Falfán[3], M. Montaño[1]
[1]*Fibrosis Pulmonar, Instituto Nacional de Enfermedades Respiratorias,* [2]*Sistemas Biologicos, UAM Xochimilco,* [3]*Inmunogenética y Alergia, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico*

Introduction: Obesity is a major risk factor to respiratory disorders, with a pathophysiological link with chronic obstructive pulmonary disease (COPD). The prevalence of obesity increased in patients with mild to moderate forms of COPD (grades I and II; GOLD), but is lower in patients with severe impairment of lung function (grades III and IV, GOLD). Adipose tissue can respond to the presence of pro-inflammatory stimuli delivered by the lungs, secreting in turn inflammatory mediators including adipocytokines, cytokines and chemokines; which can regulated either positively or negatively lipid metabolism and may also exert immunomodulatory effect on the inflammation associated with COPD. Additionally MMPs act remodeling extracellular matrix in lung and airways as part of inflammation and develop of lesions in COPD, therefore the single nucleotide polymorphisms (SNPs) associated with MMPs genes could be involved in modulate pathogenesis of obesity an COPD through genetic expression.

Patients and Methods: Were evaluated 12 SNPs; 3 SNPs in each one of the genes to *MMP1*, *MMP2*, *MMP9* and *MMP12*, in 330 smokers with COPD (EP) and 658 smokers without COPD (FS) used as controls.The genetic material was obtained from the biobank samples of DNA at the HLA Laboratory of the National Institute of Respiratory Diseases (INER). Genotyping for SNPs was performed by real-time PCR (7300 Real Time PCR System). The association analysis of genotypes and alleles was done with Epi Info 7.0 software.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Results: Allelic frequencies of the polymorphisms evaluated were in Hardy-Weinberg equilibrium. Statistically significant differences in the frequency of TT genotype of rs3918253 in *MMP9* (11.21% versus 6.83%, p = 2.50E-02, OR = 1.72, 95% CI 1.08–2.71) when compare cases versus controls, showing this SNP is a genetic factor to COPD susceptibility in Mexican population.Two SNPs were found associated in *MMP2*, the GG genotype of rs243864 (EP = 10.3% versus FS = 1.51%, p = 1.00E-10, OR = 7.44, 95% CI = 3.62–15.26) and the GG genotype of rs116643 (EP = 15.45 versus FS = 10.33, p = 2.50E-02, OR = 1.58, 95% CI = 1.07–2.34) suggesting also genetic susceptibility to COPD in the Mexican population. There was not associated with genetic susceptibility to COPD in the *MMP1* and *MMP12* gene polymorphisms.The haplotype consisting of the polymorphisms in the *MMP1* and *MMP12* genes, located in different positions of chromosome 11 were calculated. No haplotype blocks were found in high linkage disequilibrium with r2 > 80.
Conclusion: There are polymorphisms SNP-type in *MMP2* and *MMP9* genes were associated with genetic susceptibility to COPD in the Mexican population.
Keywords: COPD, MMP, polymorphisms.

Glutathione intake promotes longevity through the activation of SIR-2.1 and DAF-16 (FoxO) pathway in *C. elegans*

R. Cascella, E. Evangelisti, M. Becatti, C. Fiorillo, C. Cecchi
Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy

Oxidative stress has a prominent role in lifespan regulation of the living organisms. One of the endogenous free radical scavenger systems is associated with GSH, the most abundant nonprotein thiol in mammalian cells, acting as a major reducing agent and antioxidant defence. We have recently designed a series of novel S-acyl-GSH derivatives capable to prevent amyloid oxidative stress and cholinergic dysfunction in Alzheimer disease models, upon the increase of GSH intake. In this study we show that the longevity of wild-type N2 *Caenorhabditis elegans* strain was significantly enhanced by dietary supplementation with linolenoyl-SG (lin-SG) thioester with respect to ethyl ester of GSH, linolenic acid or vitamin E. RNA interference analysis and activity inhibition assay indicate that lifespan extension was mediated by the upregulation of SIR-2.1, a NAD-dependent histone deacetylase ortholog of mammalian SIRT1. In particular, lin-SG-mediated overexpression of sir-2.1 appears to be related to the DAF-16 (FoxO) pathway. Moreover, lin-SG derivative protects N2 worms from the paralysis and oxidative stress induced by $A\beta/H_2O_2$ exposure. Overall, our findings put forward lin-SG thioester as an antioxidant supplement triggering sirtuin upregulation, thus opening new future perspectives for healthy aging or delayed onset of oxidative-related diseases.
Keywords: Glutathione, longevity, oxidative stress.

GM-CSF-induced CCL17 expression in monocytes/macrophages is IRF4 dependent: a pathway of potential significance in inflammation

A. Achuthan, P.-Y. Lam, M. W. Chang, A. J. Fleetwood, D. C. Lacey, A. D. Cook, J. A. Hamilton
Melbourne Academic Centre, University of Melbourne, Parkville, Australia

Clinical trials in rheumatoid arthritis (RA) targetting the cytokine, granulocyte macrophage-colony stimulating factor (GM-CSF), are showing promise although its mode of action remains largely unknown. Once responsive cell target type to GM-CSF is monocytes/macrophages. Increased macrophage numbers in the synovial fluid from RA knee joints is highly correlated with the severeity of the disease. The interferon regulatory factor (IRF) family of transcription factors is important in controlling expression of genes involved in immune functions. Their key role in controlling gene expression in monocytes/macrophages has recently become a major focus of research.

We report here that GM-CSF induced IRF4 expression, while suppressing IRF8 in primary human monocytes. We found that the chemokine CCL17 expression was induced in GM-CSF-treated human monocytes and largely dependent on IRF4 transcription factor. Significantly, a recent study reported that synovial fluid from knee joints of RA patients had elevated levels of CCL17 as compared to healthy controls. Interestingly, CCL17 gene is clustered together with CCL22 and CX3CL1 on human chromosome 16q13. The transcriptional regulation of these three chemokines by GM-CSF in human monocytes and their role in inflammation will be presented and discussed.
Keywords: inflammation, monocytes, transcription factors.

Granzyme B/perforin system and serpinB9: impact on inflammation and insulin resistance in coronary atherosclerosis

H. O. El-Mesallamy[1], N. M. Hamdy[1], Y. A. Ibrahim[2], A. K. Al-Etriby[3], S. A. Sebak[2], **E. F. Sanad**[1]
[1]Biochemistry Department, Faculty of Pharmacy, Ain Shams University, [2]Cardiothoracic Surgery Department, Kobry El-Kobba Military Hospitals, [3]Cardiology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background/Objectives: Pro-apoptotic protease granzyme B (GZB) and perforin (PRF) are the major mediators of cytotoxic T lymphocytes, the dominant immune cells accumulated in advanced atherosclerotic lesions. Protease inhibitor-9 (PI-9) or serpinB9, the only known inhibitor of human GZB, protects vascular cells against GZB-induced apoptosis. This study aims to explore the role of GZB, PRF and PI-9 in atherosclerosis through assessing their gene expression in peripheral leucocytes and atherosclerotic tissues as well as their contribution to atherosclerosis-related key regulatory processes.
Method: 69 patients with atherosclerotic coronary artery disease (CAD) divided into 26 non-diabetics and 43 diabetics were compared to 15 apparently healthy controls. 24 atherosclerotic tissues were compared to normal mammary arteries. Serum insulin, hsCRP and GZB levels were estimated by ELISA while mRNA expression levels of GZB, PRF and PI-9 were quantified by Taqman RT-PCR.
Results: Serum insulin, hsCRP and GZB levels were significantly elevated in atherosclerotic patients compared to control subjects ($P < 0.001$). There is a significant increase in GZB mRNA expression and a significant reduction in PI-9 mRNA in peripheral leucocytes and atherosclerotic lesions ($P < 0.001$). PRF mRNA levels increased significantly only in atherosclerotic tissues ($P < 0.001$). Also, diabetic patients showed lower levels of PI-9 mRNA in peripheral leucocytes and atherosclerotic tissues compared to non-diabetics ($P < 0.05$). Regression analysis revealed that GZB and PI-9 have opposite significant modulating effects on inflammation and insulin resistance markers. Interestingly, PI-9 mRNA expression in peripheral leucocytes was inversely contributed to CAD severity.
Conclusions: GZB and PI-9 are proposed key modulators for inflammation and insulin resistance in atherosclerosis. Low levels of circulating PI-9 mRNA might be a biomarker of CAD severity. Induction of PI-9 could be a novel therapeutic approach to attenuate atherosclerosis progression.
Keywords: Atherosclerosis, granzyme B, protease inhibitor 9.

Haemostasis disorders caused after envenomation by vipers' *Cerastes cerastes* and *Macrovipera mauritanica*

L. Fahmi[1], B. Makran[1], M. Lkhider[2], N. Ghalim[3]
[1]Biotechnology, Biochemistry and Nutrition Laboratory, Faculty of Sciences El Jadida, Chouaib Doukkali University, El Jadida, [2]Department of Biology, Faculty of Science and Technology, Mohammedia, [3]Venoms and Toxins Laboratory, Pasteur Institute of Morocco, Casablanca, Morocco

Envenomation by viper bites is an important cause of morbidity and mortality in tropical and sub-tropical countries including Morocco. Vipers venoms are a real source of proteolytic enzymes causing clotting, bleeding, nephrotoxicity, edema, necrosis, hemorrhage, pain at the bite site and systemic changes. This study was conducted to evaluate the changes induced in hematological parameters in rabbits after 1, 3, 6 and 24 hours of subcutaneously administration of a subletlal dose of *Cerastes cerastes* and *Macrovipera mauritanica* venoms.

Our results indicated that most hematological and hemostatic parameters showed significant changes 3 and 6 hours after envenomation. The hemoglobin, hematocrit, red blood cells, platelets and the Quick time were reduced significantly 3 hours after envenomation. A very significant increase in the rate of lymphocytes, monocytes, actived thromboplastin time and fibrinogen were recorded 6 hours following envenomation. However, no significant difference was found for the mean corpuscular volume, corpuscular hemoglobin content, mean corpuscular hemoglobin concentration and the levels of polymorphonuclear neutrophils, eosinophils, basophils throughout the whole duration of the experiment.

These results suggest that severe hematological and hemostatic changes may be initiated during the early stages of poisoning leading to local and systemic hemorrhages and coagulopathies which are the main cause of death in case of vipers envenomations.

Inflammatory bowel disease (IBD) is a chronic immune cell mediated autoimmune disorder affecting the western population with a rising incidence rate. Its etiology is estimated to result from intestinal loss of tolerance, in the presence of constant antigenic stimulus derived from gut-inhabiting bacteria. Our main goal is to develop a novel, versatile, and specific nanoparticle-based delivery strategy (tsNP) that will target the intestinal mononuclear phagocyte (iMNP) system, which is pivotal in the pathogenesis of intestinal auto-inflammation. We have identified a specific and highly expressed surface marker, Ly6C, which characterizes a pro-inflammatory subset of iMNPs. This subset is up-regulated during IBD and a major driver of the disorder, thus making it a promising therapeutic target.

The Ly6C^{high} population showed a high and rapid rate of receptor-mediated endocytosis following the Ly6C ligand binding. Thus, we have generated tsNPs targeting Ly6C in order to deliver cytotoxic doxorubicin (DOX) to this subset of pro-inflammatory iMNPs. Utilization of the tsNPs in ex-vivo studies resulted in an efficient internalization and cargo release of the tsNPs in IBD and not in steady state, enabling a selective and safe way to target the iMNP and consequently their pro-inflammatory activity. Moreover, employment of the anti-Ly6C-tsNPs in-vivo led to a specific targeting and elimination of the Ly6C^{+} iMNP population in IBD solely, leading to amelioration of the acute colitis and rescue of the mice.

These findings may contribute to a long-sought personalized medicine platform, by which therapies will be targeted to cells of choice, where they will release a customized therapeutic target, while minimizing collateral adverse effects.

Heterologous expression and enzymatic characterization of Trr1 as a target for antifungal drugs

C. P. Bravo Chaucanes[1], A. K. Abadio[2], E. S. Kioshima[3], M. S. Soares Felipe[2]
[1] Molecular Biology, [2]Molecular Biology, University of Brasília, Brasília, [3]Department of Clinical Analysis and Biomedicine, State University of Maringá, Maringá, Paraná, Brazil

Although fungal infections contribute substantially to human morbidity and mortality, the impact of these diseases on human health is not widely appreciated. *Cryptococcus neoformans* is a basidiomycete fungus that causes cryptococcosis worldwide in both immunocompromised and healthy individuals. It affects about one million people each year and kills about 650 000. Several factors are required for intracellular survival. The polysaccharide capsule is an established virulence-associated phenotype of *Cryptococcus*. Likewise, the abilities of the fungus to regulate oxidative stress responses and produce melanin are also important for virulence. The *TRR1* gene is essential and encodes the cytoplasmic thioredoxin reductase enzyme. This protein has a role in maintaining the redox balance of the cell and forms part of a complex, which contains thioredoxin (Trx), thioredoxin reductase (Trr) and NADPH, protecting cells against oxidative and nitrosative stress. Some drugs to treat systemic and superficial fungal infections are available; however, the emergence of *C. neoformans* drug resistance strains due to its inherent 'hetero-resistance' to azoles, the side effects of amphotericin B, and the ineffectiveness of the most recent antifungal echinocandins highlight the critical need of a new generation of antifungal agents. In this study, heterologous expression, purification and enzymatic characterization of Trr1 and its substrate Trx1 of the fungal pathogen *C. neoformans* were performed. The *TRR1* and *TRX1* genes were expressed in *Escherichia coli* using recombinant strategy. The gene fragments were obtained by assembling synthetic genes and these were inserted into pET21a vector. The expressed products were purified by affinity chromatography and detected by western blot. It was possible to identify a band of 39 kDa for Trr1 and another of 12 kDa for Trx1. The enzymatic activity of the recombinant protein was also carried out. As a result, the kinetic parameters K_m and $V_{máx}$ indicated that Trr1 was able to efficiently reduce Trx1. This work shows a viable system for the production of recombinant proteins providing amount necessary to perform three-dimensional structural studies. Results generated by this work represents an advancement and may contribute to the development of new drugs with broad-spectrum activity for the treatment of fungal infections of global significance. In addition, *C. neoformans TRR1* has no human homologs and could therefore be a promising target for new antifungal drugs.

Keywords: Antifungal drugs, *Cryptococcus neoformans*, Thioredoxin reductase.

Heterologous expression and purification of Ric c 1 and Ric c 1 mutant IN *Escherichia coli* and studies of defense and allergenic activities

T. P. Soares, A. O. Carvalho, O. L. Machado
LQFPP, UENF, Campos dos Goytacazes, Brazil

The 2S albumin isoforms from *Ricinus communis,* Ric c 1 and Ric c 3 are storage and defense proteins in castor seeds. Among the functions of defense, include the inhibition of α-amylase of larval insects. Ric c 1 and Ric c 3 have allergenic properties that promote health risks to farm workers and distributors of castor bean seed. Our group recently identified six epitopes responsible for triggering allergic (IgE-binding epitopes). The cross reaction between these allergens and IgE proteins, is mediated by two glutamic acid residues present in each of the six identified epitopes. We have verified, using docking analysis, that only one residue of glutamic acid of one of allergenic epitope is required for the interaction between Ric c 1 or Ric c 3 with α -amylase for enzyme inhibition. Molecular modeling studies indicated that substitution of some strategic glutamic acid by leucine residues in the IgE-epitopes do not interfere with the inhibitory activity of α-amylase, but possibly reduces the allergenicity. To validate the modeling studies this work aimed to suit the conditions for expression of allergenic proteins Ric c 1 and Ric c 1 mutated in *Escherichia coli*. Ric c 1 consists of two subunits linked by disulphide bonds whoever the recombinant protein was produced as a single protein containing the linked peptide present in its precursor. DNA extraction was performed using the DNeasy® Plant DNA kit and subjected to PCR. The PCR product was inserted into the expression vector pET 32 EK LI to transform *E. coli* (DE3). Induction of recombinant protein was performed by addition of IPTG into the culture. The recombinant proteins were purified by affinity chromatography on Ni-NTA column and by reverse phase chromatography in HPLC C_2C_{18} column. The purification was verified by SDS-PAGE, immunoblotting and checked by N-terminal partial sequence. The allergenic activity of recombinant Ric c 1 was measured by mast cell degranulation assay and inhibitory alpha amylase activity was tested against insect enzyme. These activities were then compared with those of the native component. Following successful cloning, Ric c 1 recombinant containing mutations in specific glutamic acid residues was performed. For this, synthetic gene using the GeneArt (Invitrogen) was marketed, already inserted into a cloning vector pMA. The pMA vector containing the synthetic gene was used to transform a strain XL -10 clones. Molecular studies showed that it was possible to express recombinant Ric c 1 and Ric c 1 mutant. The biological tests demonstrated the reduction of allergenicity and preservation of inhibition of α – amylase in the mutant variety.

High cholesterol diet induced endoplasmic reticulum stres related apoptotic process on cardiac myocyte failure

B. Yazgan[1,2], A. E. Sozen[2], B. Karademir[2], N. Kartal Ozer[2]
[1]*Central Research Laboratory, Amasya University, Amasya,*
[2]*Department of Biochemistry, Faculty of Medicine, and Genetic and Metabolic Diseases Research Center, Marmara University, Istanbul, Turkey*

The injured myocardium represents an environment in which there are various factors that promote cell apoptosis, such as oxidative stress, hypoxia and inflammatory reactions. High cholesterol raises important for cardiac dysfunciton, heart disease, heart attack, and stroke. Oxidative stress describes an imbalance between antioxidant defense and the production of reactive oxygen species (ROS), increased reactive oxygen species (ROS) production and the resulting oxidative cell stress has been shown to cell death/apoptosis, mitochondrial dysfunction, cardiac remodeling, and dysfunction. Protein kinase-like endoplasmic reticulum kinase (PERK) is an eIF2α kinase. PERK activation during ER stress correlates with autophosphorylation of its cytoplasmic kinase domain. pPERK has been implicated as a mechanism responsible for cardiomyocyte apoptosis. Process of apoptotic cell death shown that changes include blebbing, cell shrinkage, nuclear fragmentation, chromatin condensation, and chromosomal DNAfragmentation. Bcl-2-family proteins such as Bcl-2, Bcl-XL, Bax, Bak, Bad and Bid are central regulators of cell life and death. Caspases are a family of cysteine proteases that play essential roles in apoptosis which are cleavage some of the final targets such as lamins ICAD/DFF45 (inhibitor of caspase activated DNase or DNA fragmentation factor 45) PARP (poly-ADP ribose polymerase).

In our experiment twenty male albino rabbits (1–2 months old) were assigned randomly to four groups. The first group of rabbits, the control rabbits, was only fed with diet. The second group was fed with diet containing 2% cholesterol, third group diet and received injections of 50 mg/kg/day of vitamin E intramuscularly and the rabbits in the fourth group were fed with diet containing 2% cholesterol and received injections of 50 mg/kg/day of vitamin E intramuscularly. After 8 weeks; MDA and vitamin E in blood was detected by HPLC. Apoptosis of heart tissue showed by DNA fragmentation. The left ventricule of hearth tissues were removed and protein levels of Perk, pPerk, Bax, pBcl2, Procaspase-Caspase-9 and Procaspase-Caspase-3 measured by immünoblotting. The results, endoplasmic reticulum stress related apoptotic process for hypercholesterolemic rabbits will be discussed.

Homocysteine as a marker for inflammation in woman with polycystic ovary syndrome

A. M. Atanasova Boshku[1], D. Ivanova Panova[2]
[1]*Clinical Chemistry,* [2]*Gyn.Endocrinology, Clinic for Gynecology and Obstetric, Skopje, Macedonia*

Polycystic ovary syndrome is characterized by oligo-/anovulation and hyperandrogenism including hirsutism, and infertility. There are many studies suggesting that PCOS may increase risk for several conditions including insulin resistance, type 2 diabetes, dyslipidemia, obesity, hypertension, cardiovascular risk. Based on most of the risk factor profiles, woman with PCOS would be expected to be at significantly increased risk for atherosclerotic disease. Although a definitive link between PCOS and these chronic illnesses has not been demonstrated, there is significant overlap in the clinical characteristics of these disorders. Consequently, the issue of identifying and measuring potential conditions that may be associated with PCOS is a priority and should be the standard of practice in its management. Hyperhomocysteinemia has been shown as independent predictor of cardiovascular events in patients with atherosclerosis as a result of promotion of inflammation and direct injure of endothelial cells. The aim of our study was to determinate levels of homocysteine in woman with polycystic ovary syndrome compared with healthy woman. Thirty patients (age, 23.5 ± 5.5) with PCOS and twenty four (age, 25.5 ± 4.3) healthy woman were involved in the study. Blood samples were collected in early follicular phase. Total homocysteine was measured using fluorescent immunoas-

© 2014 The Authors. FEBS Journal © 2014 FEBS

say. Statistically significant differences in serum concentration of homocysteine were observed between groups. Mean homocysteine level we found as (10.2 ± 2.9 versus 7.0 ± 1.5) in PCOS and normal group respectively ($p < 0.05$). For Macedonian population we found statistically significant increased homocysteine levels in woman with PCOS. Although the mean homocysteine levels are within normal limits, there are significant higher mean homocysteine concentrations between these two groups. Because an increased concentration of tHcy has been shown as a independent risk factor for cardiovascular alterations, it is essential in this group of woman to be taken measures for early prevention.

Keywords: homocysteine, inflammation, Polycystic ovary syndrome.

Identification of complexes of antimicrobial proteins and peptides human milk

S. Fateeva, L. Leonova, I. Kurdyumova, T. Grishina
Biochemistry, Saint-Petrsburg State University, Saint-Petersburg, Russian Federation

Investigation of antimicrobial properties of minor human milk proteins and peptides is very important for understanding the role of breastfeeding in the development of infant immunity. In this research we analyzed human milk on the content of antimicrobial peptides and protein. Human milk was subjected to preparative continuous acid-urea polyacrilamide gel ectrophoresis. The main cationic fractions contained lysozyme and had antimicrobial activity against test bacteria *E. coli* (Gram-positive) and *L. monocytogenes* (Gram-negative). Moreover, human neutrophil peptides 1–4 were identified in low-mobility high molecular weight cationic fractions with myeloperoxidase, lactoperoxidase and lactoferrin by Dot-ELISA. That indicates availability the presence of protein complexes. We attempted destruction high molecular weight protein complexes by 2M sodium chloride and pH reduction to 2.5 with acetic acid. Then we fractionated human milk whey, high salt milk extract (native pH) and high salt with acetic acid milk extract (pH 2.5) by Vivaspin sample concentrators with a range of molecular weight cutoff (100, 50, 30, 10 kDa (GE Healthcare). As a result of ultrafiltration native human milk whey fractions more than 100 and 50–100 kDa had higher antimicrobial activity against L.monocytogenes compared to the native human whey. The 30–50 and 10–30 kDa fractions had not antimicrobial activity at all. Apparently, lysozyme is included in complex with other proteins with a total molecular weight of more than 50 kDa. In high salt extractions of milk there was a slight increase in antimicrobial activity against *L. monocytogenes* compared to native milk whey. 10–30 and 30–50 kDa high salt milk fractions had only small quantity of lysozyme compared to other proteins. There was the significant increase in antimicrobial activity against *E. coli* and *L. monocytogenes* in 30–50 and 10–30 kDa fractions of high salt with acetic acid extractions of milk. Milk proteins fractions with antimicrobial activity against the test bacteria were separated by RP-HPLC. As the results of chromatography the main component of the high salt with acetic acid 10–30 kDa fraction (pH 2.5) was lysozyme (about 70%) with high antimicrobial activity against *L. monocytogenes* and *E. coli*. The high salt with acetic acid 30–50 kDa fraction (pH 2.5) had about 30% of lysozyme, 60% of alpha-lactalbumin and a small quantity of proteins with a molecular weight from 6 to 29 kDa. Based on the obtained results we can assume that the main antimicrobial component of human milk is lysozyme, it is probably contained in milk in the form of macromolecular complexes, which are destroyed in the stomach in a low pH.

Keywords: antimicrobial proteins and peptides, innate immunity, lysozyme, human milk.

SUN-189
Identification of *E. coli* mimetics proteins that can inhibit phagocytosis mechanisms

J. Beppler[1], R. Giordano[2], R. Monteiro[3], I. T. Velasco[1], F. Pinheiro da Silva[1]
[1]*Emergency Medicine,* [2]*Laboratory of Vascular Biology, Institute of Chemistry, University of Sao Paulo, São Paulo, Brazil,* [3]*UMR 1149 Inserm, Université Paris Diderot, Paris, France*

Introduction: Sepsis is a complex syndrome defined by systemic inflammatory response syndrome of infectious origin and characterized by multiple manifestations that can determine dysfunction or failure of one or more organs or systems. It is the leading cause of death in intensive care units in critically ill patients and has represented a constant source of concern for health systems around the world, mainly due to high rates of morbidity and mortality. The treatment of sepsis is challenging and remains a difficult task due to numerous interfering factors. Studies have demonstrated the link between *Escherichia coli* (*E. coli*) and CD16 provides an increase in the inflammatory response resulting from inhibition of induction of phagocytosis, therefore seek to identify peptides and their CD16 binding proteins involved in phagocytosis of infectious agents to finding a possible therapeutic target.

Methods and Results: Using the methodology Phage Display which is a cloning technique that allows the expression of various peptide sequences on the surface of bacteriophage (phage) and selecting these on the basis of affinity for a target molecule sought peptides that interact with CD16. By biopanning found that two peptides obtained this interaction. The expectation is that these peptides found (previously called for: Peptide 3 and Peptide 19) mimics CD16 binding proteins, in particular proteins of E. coli, involved in the interaction with CD16.

Conclusion: The identification of proteins capable of inducing inhibition of phagocytosis through the CD16 receptor, can be used as a new treatment of sepsis, as well as exploited in the treatment of autoimmune diseases, there is seen that these proteins also increase CD16-inflammatory dependent.

Keywords: CD16, *E. coli*, Sepsis.

Identification of endocytic proteins involved in IFN-α stimulated JAK-STAT signaling

S. Stephen[1], M. Miaczynska[1], J. Cendrowski[1], D. Chmiest[2], C. Lamaze[3]
[1]*Laboratory of Cell Biology, IIMCB, Warsaw, Poland,*
[2]*Membrane Dynamics and Mechanics of Intracellular Signaling,*
[3]*Trafic, Signalisation, et Ciblage Intracellulaires, Institute Curie, Paris, France*

The role of endocytosis in signal transduction has been traditionally viewed as a mechanism for internalization and degradation of activated receptors in lysosomes. However, this model is changing with reports suggesting that endocytic proteins also participate in various aspects of cellular signaling and transcriptional regulation.

The aim of our study is to identify endocytic proteins involved in type-I interferon (IFN-α) stimulated signaling. IFN-α is a cytokine with potent anti-viral and anti-proliferative activities. It is produced in response to pathogenic antigens. In human cells, IFN-α induces the JAK-STAT signaling cascade after binding to the IFN-α receptor (IFNAR) complex, composed of IFNAR1 and IFNAR2 chains. It has been shown that, upon ligand binding, IFNAR1 receptor is internalized by clathrin- and dynamin-dependent endocytic pathway (Marchetti et al., 2006 Mol Biol Cell *17*, 2896–2909). Therefore, it is reasonable to suspect that IFNAR might exploit a broader spectrum of endocytic machin-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ery to modulate its signaling. However, so far there is little evidence to support this idea.

We performed small-scale RNAi-based screening to identify endocytic proteins that regulate the JAK-STAT pathway. The methodology included silencing of pre-selected genes encoding individual endocytic proteins followed by analysis of transcriptional response using luciferase-based reporter assay upon IFN-α stimulation. Genes that upon silencing manifested more than two-fold change in the transcriptional activity were considered as potential regulators of the JAK-STAT pathway. We identified both positive and negative regulators of the pathway, including previously reported dynamin and clathrin. Subsequently, expression of IFN-α target genes (such as OAS1, IFI44 and IFI6) and Stat1 phosphorylation were analyzed upon silencing of the novel potential regulators using real-time PCR and western blotting, respectively. Ongoing experiments aim to address whether known interacting partners of the identified endocytic regulators are similarly involved in the regulation of IFN-α signaling. Further investigation will focus on eliciting the mechanisms through which selected endocytic proteins modulate the IFN-α signaling pathway and what the biological outcome of this regulation is.

Identification of immunomodulators in liver infected with clonorchis sinensis by microarray and bioinformatics analysis

Y. Bae
Parasitology and Tropical Medicine, SNU College of Medicine, Seoul, Korea

Hosts secrete various immunomodulators when the parasite infection. Immunomodulators which secreted anti-inflammatory substances by acting on cells involved in innate immunity of the host to suppress the innate immunity mechanism. Based on this, it is possible to find the genes and proteins involved in immune suppression when parasitic infection in host. It is the basis for finding drug treatment of autoimmune diseases. In the present study, microarray profiling of gene expression was performed to identify the genes regulated by infected with *Clonorchis sinensis* in mouse livers. The DEG (differentially expressed genes) were further analyzed by bioinformatics tools for genetic functional clustering and gene to gene interaction. We selected the final immunomodulators candidate genes derived from *Clonorchis sinensis*. For the experiments, the mice were divided in two groups: C57BL/6 control, C57BL/6-*C. sinensis* infected. Thirty metacercaria of *C. sinensis* were infected orally to infected groups and extract liver tissue after maintained for 2 weeks. For gene expression profiling, microarray analysis using the Illumina MouseWG-6 v2.0 expression BeadChip. The differentially expressed gene were further analyzed for protein-protein interaction, integrative comparison among the biological function and genetic expression, pathway analysis using bioinformatics tools including STRING, DAVID and KEGG. The list of 329 genes (up regulated: 224, down regulated: 105) differentially expressed gene with a fold change>2.0, $p < 0.01$ was submitted to DAVID. Five annotation clusters were selected after gene functional annotation clustering with enrichment score>1.0. The 118 gene and interacting protein were submitted to STRING and explore the possible protein-protein interaction within these genes. In conclusion, we selected immunomodulators genes that expressed in a significant difference in the host when infected with *Clonorchis sinensis*. This would be the applied for candidate drugs for the treatment of autoimmune diseases.

Keywords: Bioinformatics analysis, immunomodulation, liver fluke.

Identification of regulatory mechanism of Src homology 2-containing protein tyrosine phosphatase 2 in brain astrocytes against ROS-mediated oxidative stress by using a systematic mutagenesis approach

H. Park[1], K. J. Ahn[2], S.-H. Ahn[1], J. L. Kang[1], Y.-H. Choi[1]

Reactive oxygen species (ROS), such as hydrogen peroxide (H_2O_2), superoxide (O_2^-), and hydroxyl radicals (OH·), are well-known regulatory signal molecules in the brain. ROS are involved in a wide range of cellular processes by triggering signal transduction events, such as Src and mitogen-activated protein (MAP) kinases.

Src homology 2-containing protein tyrosine phosphatase 2 (SHP-2) is known to protects neurons from neurodegeneration during ischemia/reperfusion injury. SHP-2 is composed of two src homology 2 (SH2) domains at the amino-terminus, a single protein tyrosine phosphatase (PTP) domain and a carboxy-terminal tail. We have recently reported that ROS-mediated oxidative stress promotes phosphorylation of endogenous SHP-2 in brain astrocytes and lipid rafts and caveolin-1 are involved in astrocyte-specific intracellular responses linked to the SHP-2-mediated signaling cascade.

To evaluate the precise function of SHP-2 in brain astrocytes against oxidative stress, we systematically mutated or deleted SHP-2 domains. We compared the caveolin-1 binding affinity of wild-type and mutants SHP-2 using flow cytometric competitive binding assay and surface plasmon resonance (SPR). Deletion of N-SH2 domain of SHP-2 and mutant 542/580 had lower affinities for caveolin-1 compared with wild-type. Wild-type SHP-2 directly bound to caveolin-1 and increased Src kinase activity by inducing phosphorylation at Tyr 419. Further study is in progress to identify and characterize the function of each variant of SHP-2 in ROS-mediated signaling pathways in brain astrocytes in vitro.

Keywords: Reactive oxygen species, astrocytes, SHP-2.

Recruitment of immune cells into solid tumors comprises an essential prerequisite of tumor development. Depending on the prevailing polarization profile of these infiltrating leucocytes tumorigenesis is either promoted or blocked. Here we identify IκB kinase α (IKKα) as a central regulator of a tumoricidal microenvironment during intestinal carcinogenesis. Mice deficient in IKKα kinase activity are largely protected from intestinal tumor development that is dependent on the enhanced recruitment of IFNγ expressing M1-like myeloid cells. In IKKα mutant mice M1-like polarization is not controlled in a cell autonomous manner but depends rather on the interplay of both IKKα mutant tumor epithelia and immune cells. Because therapies aiming at the tumor- microenvironment rather than directly at the mutated cancer cell may circumvent resistance development we suggest IKKα as a promising target for CRC therapy.

IL-10 gene knockout decreases the synthesis of spermine, changes the expression of mGlu receptor 1a/b, and reduces the glutamate-dependent production of nitric oxide in synaptoneurosomes

T. Barbakadze[1,2], S. Koriauli[2], N. Natsvlishvili[1,2], D. Mikeladze[1,2]

[1]Biochemistry, I. Beritashvili Center of Experimental Biomedicine, [2]Institute of Chemical Biology, Ilia State University, Tbilisi, Georgia

IL-10 provides trophic and survival effects directly on neurons, promotes axonal outgrowth, and stimulates neuroregeneration. In this study, we analyzed the activities of arginase and nitric oxide synthase (NOS) in synaptoneurosomes derived from C57BL/6 IL-10 gene-knockout (KO) and wild-type (Wt) mice and determined that the synaptoneurosomes derived from KO mice present lower arginase II activity and lower spermine content than those derived from Wt mice, whereas the basal NOS activity in the KO synaptoneurosomes is higher than that observed in the control synaptoneurosomes. Moreover, our results indicates that the plasma membranes isolated from the KO mice brain exhibit significantly lower spermine-induced enhancement of [3H]MK-801 binding than the plasma membranes from the brain of Wt mice. Glutamate increases the production of nitric oxide (NO) in Wt synaptoneurosomes in a dose-dependent manner, whereas in the KO synaptoneurosomes, this amino acid does not affect the synthesis of NO. The glutamate-dependent acceleration of NO synthesis in Wt synaptoneurosomes was abrogated by LY367385, an antagonist of mGluR1a/b. The western blot analysis of the synaptoneurosomal proteins demonstrates that the expression of the subunits of NMDAR (NMDAR2A and NMDAR2B), the level of NMDAR-bound nNOS, and the expression of iNOS are not changed in KO mice and that only the level of mGluR1a/b is markedly reduced in the synaptoneurosomes of KO mice. We conclude that a neuroprotective and neuroregenerative property of IL-10, in addition to its effects on polyamine metabolism and the spermine-dependent modulation of NMDAR, may involve the regulation of mGluR1a/b expression.

IL-18 gene expression levels are associated with patients with carotid atherosclerosis

B. Arapi[1], B. Bayoglu[2], **M. Cengiz**[2], K. H. Tuzun[1], C. Arslan[1]

[1]Heart and Vessel Surgery, [2]Medical Biology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Carotid atherosclerosis (CA) is the atherosclerotic stenosis of proximal internal carotid artery and is one of the main causes of stroke. Recent studies have indicated that levels of circulating pro-inflammatory cytokines are related to cardiovascular diseases. Interleukin-18 (IL-18) is a pleiotropic proinflammatory cytokine which plays an important role in the inflammatory cascade. IL-18 promotes Th1 immune response by inducing IFN-γ and also it enhances the expression of matrix metalloproteinases. Thus, IL-18 is thought to be a potent mediator of atherosclerotic plaque destabilization and vulnerability. Increased expression of IL-18 has been shown in human atherosclerotic plaque lesions where it is localized mainly in plaque macrophages. Thus, we aimed to determine the expression levels of IL-18 gene in both symptomatic and asymptomatic patients with CA.

The study is composed of 50 symptomatic and asymptomatic patients with CA and 52 healthy controls. IL-18 gene expression levels were determined by quantitative real-time PCR (qRT-PCR) from the venous blood samples of CA patients and healthy controls.

Fasting glucose, creatinin and CRP levels were found to be higher in CA patients compared to controls ($p < 0.05$). The IL-18 mRNA levels were significantly increased in CA patients compared to healthy controls ($p = 0.024$). The severity of internal carotid artery (ICA) stenosis was found to be higher in symptomatic patients compared to asymptomatic ones ($p = 0.016$). However, the mRNA levels of IL-18 did not show any significant difference between genders when CA patients and controls were compared ($p = 0.737$, $p = 879$). None of the samples of CA patient group showed any relation in IL-18 mRNA levels between symptomatic and symptomatic patients ($p = 0.965$). There was also no significant relationship between CA patients and controls when IL-18 mRNA levels were compared with ICA stenosis severity ($p = 0.096$). A positive correlation was found between IL-18 mRNA levels and serum CRP levels of CA patients ($r = 0.436$, $p = 0.029$). This study suggests that IL-18

© 2014 The Authors. FEBS Journal © 2014 FEBS

transcript may affect the pathogenesis of CA and serum CRP levels in carotid atherosclerosis.

Keywords: Carotid Atherosclerosis, gene expression, IL-18 gene.

IL-6 role in fibroblast-macrophage interplay in a fibrotic in vitro model

Z. Kechagia[1], G. Sharma[1], D. G. Ezra[1], M. Burton[2], M. Bailly[1]
[1]Institute of Ophthalmology, University College London (UCL), [2]London School of Hygiene and Tropical Medicine, London, UK

The onset of fibrotic conditions in many autoimmune and chronic disorders is characterized by the activation of the cells in the mesenchyme and the secretion of excess extracellular matrix (ECM), growth factors and cytokines, resulting in the formation of a stiff and contractile tissue. While fibrotic responses are involved in many pathological conditions, the underlying mechanism of fibroblast activation is still poorly understood. We isolated fibroblasts from patients with trachoma, a fibrotic blinding disease and leading cause of preventable blindness worldwide, to study the underlying molecular and functional characteristics of the fibrotic tissue. We developed an in vitro model using 3D collagen matrices to measure tissue contraction in response to different environmental stimuli. We found that fibrotic fibroblasts are more contractile than controls and respond better to PDGF stimulation.

In order to identify the molecular mechanisms underlying the fibrotic phenotype, we performed a microarray and a microRNA analysis of 4 trachoma lines and 4 matching control cell lines. We identified a differential expression of 187 genes and 54 miRNAs in trachoma. Amongst those genes, we identified a number of molecules that could be involved in the fibrotic response. IL-6 gene expression was upregulated 4 times in the cases compared to controls, and this was matched with a higher secretion level in trachoma cells. IL-6 inhibition using function-blocking antibodies did not affect fibroblast-mediated standard matrix contraction, but significantly increased contraction in a macrophage-fibroblast co-culture model. In order to study the role of IL-6 in macrophage-fibroblast interaction, fibroblast derived conditioned medium was added to U937 monocytes before or after differentiation to macrophages upon PMA activation. We found that trachoma derived conditioned medium differentially stimulated macrophages and promoted secretion of matrix metalloproteinase (MMP) through IL-6 and STAT3-Akt signaling pathways.

Immunogenicity of recombinant analog of lactaptin, a new potential anticancer peptide

O. Koval[1,2], A. Tkachenko[1], G. Sakaeva[1], A. Fomin[1], D. Semenov[1], E. Kuligina[1], V. Richter[3]
[1]Biotechnology, Chemical Biology and Fundamental Medicine SB RUS, [2]Molecular Biology, [3]Biotechnology, Novosibirsk State University, Novosibirsk, Russian Federation

Lactaptin, the proteolytic fragment of human milk kappa-casein, induces the death of various cultured cancer cells [1]. Following treatment with the recombinant analogue of lactaptin (RL2) strong caspase -3, -7 activation was detected [2]. Earlier we observed that RL2 constitutively suppressed *bcl-2* mRNA expression and down regulated Bcl-2 protein expression in MDA-MB-231 cells. We demonstrated that RL2 penetrates cancer and non-transformed cells. Identification of the cellular targets of the lactaptin analogue revealed that α/β-tubulin and α-actinin-1 were RL2-bound proteins [3]. We demonstrated that the recombinant analogue of lactaptin significantly suppressed the growth of solid tumours. In this study we investigate the potency of recombinant analog of lactaptin to involve immune system in apoptosis realization. Anti-RL2 antibodies production was estimated in blood serum of mice treating with various doses of RL2 and by various schemes of therapy. Titres of antibody were very low after four serial injections of RL2. Real-time RL2 cytotoxicity assay was performed with cultured cancer cells (MCF-7 and MDA-MB-231) and primary culture of normal human endometrium using impedance-based iCelligence equipment. Also cells were treated with RL2 and dynamic changes in the mRNA level of *NF-kB* cascade genes, as well as *IFIT2* and *IFIT3* genes were observed. RL2 treatment of cancer and normal cells did not induce changes in *IFIT2* and *IFIT3* mRNA level. It is known that anthracyclines induce calreticulin/ERp57 surface-exposure which is recognized by dendritic cells and signals potential immunogenicity. *CRT* gene expression was estimated to examine RL2 as inductor of immunogenic cell death. We found that RL2 treatment of MCF-7 cells resulted in the induction of *CRT* gene transcription after 5 h. After 24–48 h of incubation the *CRT* mRNA level in treated MCF-7 and MDA-MB-231 cells was significantly lower relative to the mRNA level in control cells ($p < 0.05$). Calreticulin translocation was observed by fluorescent microscopy using anti-CRT antibodies. Our results may indicate that RL2 is low immunogenic and unlikely induces immunogenic death of cancer cells.

Immunoregulation studies for biotherapy purposes by using a larval amphibian model

S. Benlamara[1], T. Scalvenzi[1], L. Vouillot[1], N. Pollet[1], **B. M. Colombo**[1,2]
[1]Institute of Systems & Synthetic Biology (iSSB), Metamorphosys Team, [2]University of Evry-Val d'Essonne, Department of Biology, Evry, France

Live animals have been of crucial importance, through the centuries, to study physiology and more recently to ensure human care by developing and testing new therapeutic approaches. Mice are widely exploited for medical studies but their use has always been a subject of debate. On the contrary, larval amphibians represent undoubtedly a more ethically acceptable model.

Our project aims at studying the immune tolerance to fight intestinal inflammation and to better understand the regenerative capacity by using amphibian *Xenopus tropicalis* tadpoles.

We are focused on the role of regulatory T lymphocytes (Tregs), which play an indispensable role in maintaining the immune tolerance. Tregs represent a subpopulation of $CD4^+$ T cells (5–10% in mice and 3–5% in humans), which are characterized by the expression of the IL-2 receptor alpha chain (CD25) and of the transcription factor Foxp3 (*Forkhead/winged-helix protein 3*). Foxp3 is presently the more specific molecular marker for Tregs and its expression is essential for Treg differentiation and functionality.

The *foxp3* gene is conserved in vertebrates. However, the functional activity of Tregs is poorly understood in non-mammalian vertebrates. We have recently identified a high level of gene synteny of the *foxp3* locus between amphibians and mammals. Cur-

© 2014 The Authors. FEBS Journal © 2014 FEBS

rently, we are determining the expression patterns of Foxp3 RNA in tadpoles during their development.

The first objective of our work is to study, in a model of intestinal chronic inflammation induced in tadpoles and mimicking inflammatory bowel disease (IBD), the role of 'immunosuppressive' probiotics on the activation of Tregs in the intestinal mucosa. Lactic acid bacteria will be genetically engineered, by synthetic biology, to produce natural 'immunosuppressive' molecules.

Our second objective is to investigate the contribution of Tregs in tissue regeneration, a necessary phenomenon in any inflammatory process. This aspect has recently emerged as an innovative conceptual axis. The regenerative capacity will be evaluated following the tail amputation during the larval development.

To achieve our goals, we will generate fluorescent tadpoles for the *Foxp3* gene from *X. tropicalis* embryos.

In conclusion, our fundamental project on immunoregulatory mechanisms would open new opportunities: (1) to improve tolerogenic biotherapies, in humans, in which Tregs play a central role (autoimmune diseases, food allergies, IBD, tolerance to transgenes and vectors used in gene therapy, ...); (2) to increase the knowledge linking immunosuppression with regeneration capacity and tissue repair, that would be applied in the regenerative medicine field.

Impact of hypokinesia on metabolic characteristics and gut microbiota composition of dairy cows

A. Z. Pepoyan, A. Yehya, A. Grigoryan, S. Petrosyan, G. Gasparyan

Food Safety and Biotechnology, Armenian National Agrarian University, Yerevan, Armenia

In the field of animal-breeding the 'stable keeping' has a negative effect on the overall functional state of the animal's organism. Hypokinetic conditions not only produce problematic effects upon the animals' immune status and metabolism, but also generate a range of economic damages relating to productivity and meat product quality and taste.

The influence of hypokinesia on metabolic indexes and gut commensal bacteria from Caucasus brown cows and their calves has been investigated.

The investigations testify that the changes in gut microbiota and in metabolic characteristics of the animals under the conditions of physical inactivity can cause an increased risk of infectious diseases of those animals.

SUN-200
Impact of intracellular localization dynamics of invasive bacterial pathogens on host immune response transcriptional signatures in single cells

J. Lippmann[1], F. Gwinner[2], C. Rey[1], H. K. Law[3], B. Schwikowski[2], J. Enninga[1]

[1]Cell Biology and Infection, Group Dynamics of host-pathogen interactions, [2]Group Systems Biology, Institut Pasteur, Paris, France, [3]Polytechnic University of Hong Kong, Hong Kong, Hong Kong

Intracellular bacterial pathogens, such as *Shigella flexneri*, enter host cells through tightly regulated, conserved molecular mechanisms. During the invasion process *Shigella* localize at different subcellular niches such as the host cell membrane, pathogen-containing vacuoles or the cytosol. The individual subcellular localization of the bacteria are instantly sensed by the host cellular immune system, which activates diverse signaling pathways. However, it has been insuffiently understood, how the differential orchestration of the host immune transcriptional response is individually determined by the dynamics of bacterial infection and intracellular localization within cellular compartments. Host gene expression has been measured from whole cell populations masking valuable information on subtle transcriptional changes upon individual compartmental changes of the bacteria. To overcome these limitations, we set out to perform a comprehensive study that integrates spatial-temporal information and transcriptomic profiling of the host immune response on the level of small cell populations and of single cells. Combining fluorescence-based approaches and multiplex qPCR single cell analysis identified localization-dependent host transcriptional signatures to *Shigella* infection, that correspond to each stage of bacterial infection, i.e. the membrane-bound and even the cytosolic bacterial localization as well as to yet non-infected bystander cells. Further characterization of individual transcriptional profiles during infection with different *Shigella* mutants gave new insights into how bacterial effectors manipulate localization-dependent host gene expression signatures. Single cell analysis revealed how the invading bacteira affected the coordination of gene expression in a localization-dependent manner. This study contributes to novel understanding of the orchestration and coordination of the host immune response gene expression signatures, determined by the bacterial localization with respect to the cell as well as by different bacterial effectors.

In silico anticancer drug discovery to find NFκB inhibitors

R. Moorad[1], G. Mugumbate[2], K. Chibale[2], L. Zerbini[1]

[1]Medical Biochemistry, University of Cape Town, International Center for Genetic Engineering and Biotechnology, [2]Chemistry, University of Cape Town, Cape Town, South Africa

Nuclear factor kappa B (NFκB) is a transcription factor that plays a significant role in the regulation of immune and inflammatory responses. It is constitutively activated in numerous diseases such as cancer, inducing the expression of genes that promote cell proliferation, regulate apoptosis, facilitate angiogenesis and stimulate invasion and migration of cancer cells. This makes NFκB an attractive target for drug intervention. In this study, computational methods were used to identify similar compounds to 6-Aminoquinazoline (6-Amino), a potent but toxic NFκB inhibitor.

Ligand Based Virtual Screening (LBVS) of the Zinc database was performed using vROCS and Pipeline Pilot. Prior to the similarity search the database was filtered with a drug-like filter to find chemically analogous compounds to 6-Amino. To further enrich our database with potential hits, structure based virtual screening was performed with the compounds identified in the LBVS. Firstly, the unknown target of 6-Amino was elucidated through a series of blind dockings on the available crystal structures of the NFκB pathway proteins. Control compounds with known targets in the NFκB pathway were used to validate our findings. Their targets correlated with what was known in literature, allowing us to identify a putative binding site on the p50/p65/IκBα complex. The binding site is in close proximity to the nuclear localisation signal of p65 and to the phosphorylation and ubiquitination site of IκBα. Binding of 6Amino may induce a conformational change that inhibits the translocation of p65 into the nucleus possibly by inhibiting the degradation of IκBα. Several compounds identified

© 2014 The Authors. FEBS Journal © 2014 FEBS

to have a high similarity score were also found to bind with a predictably higher affinity to the complex than 6-Amino.

In conclusion, results look promising and are being validated with in vitro inhibition assays. Validating the binding site by site directed mutagenesis or by obtaining a crystal structure will allow for a more targeted structure based drug design approach to inhibit NFκB.

Keywords: Cancer therapy, computer-aided strategy, NF-kB.

SUN-202
In vitro evaluation of proinflammatory effect of trivalent arsenical species at intestinal level

M. Calatayud, **M. Vázquez**, V. Devesa, D. Vélez
Food Preservation and Quality, Institute of Agrochemistry and Food Technology, Paterna, Spain

Chronic exposure to inorganic arsenic (As) is associated to type 2 diabetes, cardiovascular diseases and cancer. Ingested inorganic As is transformed within the gastrointestinal tract, and can give rise to more toxic species such as monomethylarsonous acid [MMA(III)] and dimethylarsinous acid [DMA(III)]. Thus, the intestinal epithelium comes into contact with toxic arsenical species, and the effects of such exposure upon epithelial function are not clear.

The present study has evaluated the effect of 1 μM arsenite [As(III)], 0.1 μM MMA(III) and 1 μM DMA(III) upon the release of cytokines [interleukin-6 (IL6), IL8, tumor necrosis factor alpha (TNFα)], using a compartmentalized co-culture model with differentiated Caco-2 cells in the apical compartment and peripheral blood mononuclear cells (PBMC) in the basolateral compartment. In addition, the combined effect of arsenical species and lipopolysaccharide (LPS), both added into the apical compartment, has been analyzed.

The results indicate that exposure to the arsenical forms induces a proinflammatory response. An increase in cytokine secretion into the basolateral compartment was observed, particularly as regards TNFα (up to 1600%). The cytokine levels on the apical side also increased, though to a lesser extent. As/LPS co-exposure significantly affected the proinflammatory response as compared to treatment with As alone. Treatment with DMA(III) and As/LPS co-exposure increased the permeability of the intestinal monolayer. In addition, As/LPS treatments enhanced As(III) and MMA(III) transport through the intestinal monolayer.

Keywords: Arsenic, cytokines, intestinal epithelium.

In vivo Keap1 S-glutathionylation

A. Neves Carvalho[1], C. Marques[2], M. Castro-Caldas[1,3], E. Rodrigues[4], C. J. Henderson[5], C. R. Wolf[5], P. Pereira[2], **M. J. Gama**[4,]
[1]Research Institute for Medecines (iMed.ULisboa), Faculty of Pharmacy University of Lisbon Portugal, Lisbon, [2]Centre of Ophtalmology and Vision Science, Institute of Biomedical Research in Light and Image – IBILI, Faculty of Medicine, University of Coimbra, Coimbra, [3]Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, [4]Research Institute for Medecines (iMed.ULisboa) and Department of Biochemistry and Human Biology, Faculty of Pharmacy University of Lisbon Portugal, Lisbon, Portugal, [5]Division of Cancer Research, Medical Research Institute, Level 9, Jacqui Wood Cancer Centre, Ninewells Hospital and Medical School, Dundee, UK

Parkinson's disease (PD) is a movement disorder resulting from severe dopamine (DA) deficiency arising from dopaminergic neuronal degeneration. The molecular mechanisms underlying DA cell death are still not fully understood, but mitochondrial dysfunction, oxidative stress, failure of proteolytic pathways and neuronal inflammation are involved in PD pathogenesis.

Glutathione S-transferase pi (GSTP) is a phase II drug metabolizing enzyme that catalyzes the conjugation of reduced glutathione to electrophilic groups on substrate molecules. GSTP expression is regulated by the nuclear factor-erythroid 2-related factor 2 (Nrf2) and plays an important defensive role against the accumulation of reactive metabolites that contribute to neuronal damage. Moreover, GSTP has been shown to protect cells from ROS by altering the levels of glutathione, by acting as an endogenous regulator of c-Jun N-terminal kinase catalytic activity and by modulating *S*-glutathionylation of proteins.

Aims: We hypothesized that in response to oxidative stress, increased GSTP expression may potentiate Kelch ECH associating protein 1 (Keap1) *S*-glutathionylation, leading to Nrf2 activation and neuronal protection.

Results: MPTP-induced oxidative stress leads to glutathione depletion and altered glutathione-dependent reactions including *S*-glutathionylation. Our results show that GSTP potentiates Keap1 *S*-glutathionylation in mice brain following MPTP administration with subsequent Nrf2 pathway activation, and increased expression of GSTP, in a positive feedback regulatory loop.

Innovation: Our data provide experimental evidence that Keap1 is modified by *S*-glutathionylation in vivo in a GSTP-dependent manner.

Conclusion: The presented results unravel a new mechanism contributing to GSTP-elicited neuronal protection.

Inflammatory milieu maintains hemangioma derived endothelial cells proliferative status and hinders regression in infantile hemangioma

M. Neagu[1], C. Caruntu[2], C. Matei[2], M. Tampa[2], C. Constantin[1], C. Ursaciuc[1], M. Surcel[1], A. Diaoneasa[3], D. Boda[2]
[1]Immunology, Victor Babes National Institute of Pathology, [2]Dermatology, Carol Davila University of Medicine and Pharmacy, [3]Dermatology, 'Gr. Alexandrescu' Children's Hospital, Bucharest, Romania

Infantile hemangioma is a vascular tumor that occurs in 5–10% of infants of European descent its defining feature being a dramatic growth of capillary endothelial cells and development into a disorganized mass of blood vessels. Afterward, a slow spontaneous involution begins around one year of age and continues for 4–6 years age. Acknowledging at molecular level the constitutively high expression levels of vascular endothelial cell growth factor (VEGF) and its specific receptor 2 (VEGFR2), we have searched the interrelation with other inflammatory factors that could positively modulate this VEGF-VEGFR2 couple. Our study focused on cellular characteristics of hemangioma-derived endothelial cells isolated from excised hemagiomas (HED). The primary cells isolated from hemangiomas were both in the proliferative and regression stage of the disease. From 21 children with age between 3 and 21 months several serum and urine markers were also evaluated (GLUT-1, MMP-1, TIMP-1, VEGF and MCP-1). Culture supernatants from hemangioma-derived endothelial cells isolated from HED were tested for angiogenic and inflammatory markers, morphological changes and apoptosis as well. As control cells we have

© 2014 The Authors. FEBS Journal © 2014 FEBS

used HUVEC cell line. Analyzing HED supernatants, GLUT-1 and MCP-1 were found in high concentrations. When applying ex vivo various concentrations of VEGF on HED there are a clear correlation of cell proliferation with the angiogenic factor concentrations, correlated moreover with decreased apoptosis, especially in the time range 3–24 hrs. When applying MMP-1 the effects are similar with the ones induced by VEGF in HED, while control cells display an inverse cellular behavior. When physiologically inhibiting MMP action with TIMP-1, there is a marked reduction of the cells proliferative capacity with an induction of early apoptosis mechanisms. Studying MCP-1 action, depending on the proliferative or regression tumor stage, its action is different. MCP-1 seems to be a factor that modulates positive the proliferative stage of the hemangioma. We can conclude that there is an intricate panel of pro-inflammatory factors displaying spatial and temporal action that converge towards the proliferative stages or to the regression one.

The study was partially supported by the following projects: POSDRU/159/1.5/S/141531 and PN. 09.33-01.01/2009.

Inhibition of MMP-9 gene expression and cancer cell proliferation by essential oils of *Ocimum sanctum*

K. M. S. ?????, J. Rajarajeswaran, T. Manaharan
Dept of Molecular Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia

Matrix metalloproteinases (MMPs) released from inflammatory cells are involved in the development and progression of human cancers. Among the various MMPs, MMP-9 is found to be involved in metastasis of breast, colon and ovarian cancers. Natural products are effective in reducing inflammation and carcinogenesis. Essential oil from *Ocimum sanctum* was tested for its effect on inhibiting the proliferation of human breast cancer cells and reducing the expression of MMP-9 in human lymphocytes. Lymphocytes were treated with lipopolysaccharide to induce inflammation and then treated with essential oils. The expression of MMP-9 was analyzed using gelatin zymography and real-time reverse transcriptase PCR. Gelation zymography showed that MMP-9 expression was completely inhibited at 250 ug/ml of essential oil. A dose dependent decrease in the expression of MMP-9 was observed in real-time RT-PCR. The inhibitory effects of essential oils on the proliferation of breast cancer cells (MCF-7) were tested using the MTT assay and real-time PCR analysis. *Ocimum sanctum* essential oil (OSEO) inhibited proliferation (IC_{50} = 170 µg/ml) and migration (IC_{50} = 250 µg/ml) of MCF-7 cells in a dose-dependent manner. OSEO also induced apoptosis as evidenced by the increasing number of propidium iodide stained apoptotic nuclei. Flow cytometry analysis revealed that treatment with OSEO (50–500 µg/ml) increased the apoptotic cell population dose-dependently (by 16%> 84%) compared to the control. Gene expression analysis showed that OSEO upregulated the apoptotic genes p53 and Bid and elevated the ratio of Bax/Bcl-2. The results of our study indicate that OSEO has the ability to express both anti-inflammatory and anticancer activities.

Innate immune response during NTM infections

S. D. F. Sousa[1,2], F. Martins[2], L. Jordão[2]
[1]Biologia Vegetal, Faculdade de Ciências da Universidade de Lisboa, [2]Doenças Infeciosas, Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisbon, Portugal

Background: As tuberculosis incidence declines in industrialized countries, nontuberculous mycobacteria (NTM) infections gained relevance. Human infection with NTM became relevant with AIDS pandemic, being currently recognized as a cause of pulmonary infection in humans. Despite this fact little is known about NTM pathogenesis. In the present work the role of innate immune response during NTM infection using THP-1 cells as a model of alveolar macrophages was evaluated.

Methods: *M. smegmatis* mc^2 155, 2 reference strains (*M. avium* ATCC25291; *M. fortuitum* ATCC6841) and 2 clinical isolates (*M. avium* 60/08; *M. fortuitum* 747/08) were used. Bacteria were grown until mid-exponential phase and stored at −80°C. Before each experiment an aliquot was thawed and diluted in RPMI with 10% HI- FCS in order to reach an $OD_{600\ nm}$ of 0.1. The inoculums were titrated by CFU enumeration on 7H10 medium supplemented with 10% OADC.

Briefly, 4×10^4 THP-1 cells were platted/well and incubated for 72 h with 100 nM PMA (37°C/5% CO_2) then fresh medium without PMA was added being the cells incubated for further 24 h. The cells were infected for 1 or 3 h for fast or slow growers, respectively. The intracellular persistence was evaluated by CFU enumeration at different time points from 1 to 24 h or 3–168 h for fast and slow growers, respectively.

Phagosome acidification was followed using confocal microscopy. The secretion of pro-inflammatory cytokines was assayed by ELISA, NO production using the Griess reagent and apoptosis was followed by flow cytometry and confocal microscopy. The ability of mycobacteria to persist at different pHs was evaluated using BACTEC-MGIT960.

Results: The mycobacteria experienced different fates within THP-1 macrophages. *M. smegmatis* and *M. fortuitum* ATCC6841 were cleared within 24 h, whereas 747/08 and the two *M. avium* strains were able to replicate. Despite this fact for the latest mycobacteria more than 50% of acidified phagosomes were present during the experience. Mycobacteria survival at acidic pHs (6.6; 5.4 and 4.6) was then evaluated. With the exception of *M. smegmatis* all strains grew at acidic pH showing that other factors than phagosome acidification were involved in mycobacteria killing.

Next, other components of the inflammatory response were evaluated. Measurable values of NO were present in supernatants of THP-1 infected for 3 days with 60/08 being this bacterium susceptible, to high concentrations of NO in vitro. Il-10 secretion was also assayed. For both fast growing NTM and *M. avium* ATCC25291 the production of IL-10 was not detectable. For 60/08 IL-10 production peaked at 3 days, decreasing afterwards until undetectable levels at 7 days.

Another factor being explored is apoptosis induction by NTM. Our preliminary results point to differential induction of apoptosis by different NTM.

Insights into haptoglobin: an interesting biomarker for predicting the prognosis of prostate cancer patients

N. Miyata[1], X. Pang[1], M. Takaki[1], K. Tashiro[1], H. Araki[1], N. Komatsu[2], T. Sasada[3], K. Itoh[3], S. Kuhara[1]
[1]*Agriculture, Kyushu University, Fukuoka,* [2]*Immunology and Imunotherapy,* [3]*Immunology and Imunotherapy, Kurume University, Kurume, Japan*

Personal Peptide Vaccination (PPV), a newly established cancer treatment, makes good use of immune systems we naturally have, reinforces the CTL activity, and has few side effects, which seems to be an attractive way to deal with cancer, but the effects vary among patients. Predicting the prognosis of patients before injecting of PPV is needed, and we would like to reveal if the vaccination is effective or not and specify what is causing such differences, so we held DNA microarray analysis and SNP analysis using samples from patients with advanced castration-resistant prostate cancer (CRPC).

We obtained peripheral blood mononuclear cells (PBMCs) from patients with advanced CRPC, and examined the gene expression profile. PBMCs were collected from advanced CRPC patients both who survived for more than 900 days and who died within 300 days after the peptide vaccination. We found 41 up regulated genes in short-term survivors to be differently expressed in pre- and / or post-vaccination. Haptoglobin (HP), a well-known immune response gene, was listed on these genes. Recently, HP has been attracted attention in cancer researches, but it is still unknown how HP expression pattern in CRPC patients is like. We focused on its expression in PBMCs from CRPC. Analysis of HP expression in PBMCs by qPCR method indicated patients with poor outcome had higher levels of HP mRNA expression in PBMCs. Moreover, from nucleotide sequence analysis of HP promoter region, we found there was HP promoter polymorphism which was significantly associated with overall survival. These suggested HP could be a prognostic biomarker for PPV.

Previous reports showed that serum HP was elevated in various cancer patients including prostate cancer compared to normal subjects and benign tumors. Taken together with previous reports, this study suggests HP in peripheral blood of CRPC patients may have an impact on the immune response to PPV based on either or both of tumor progressive function and immune suppressive function. However, it is obscure how to regulate HP expression level in PBMCs. We examined HP expression in some cell lines derived from blood cell under various culture conditions and found HP expression was induced under stress condition. Intensive research on HP expression will reveal what is causing the difference in the HP expression level between patients with well or poor outcome and what function HP has in immune systems.

Intense interactions between TNF and glucocorticoids in sepsis

C. Libert
Inflammation Research Center, VIB and Ghent University, Ghent, Belgium

Sepsis hits almost 20 million people yearly. The mortality is very high and there is an urgent need for novel therapeutics and new insights in the disease. Despite sepsis has a clearly inflammatory component, glucocorticoids (GCs) are not helpful in sepsis. The reason for this GC resistance is investigated in our work. We apply several mouse models for sepsis and septic shock and we focus on the mechanism by which GCs protect against TNF-induced acute inflammation and on the impact that TNF has on the anti-inflammatory activities of GCs.

Keywords: glucocorticoid, inflammation, TNF.

Interaction between glycans and the immune system: do glycans play a role in Crohn's disease?

L. Baram[1,2], S. Cohen-Kedar[1,2], L. Spektor[1,2], H. Elad[1,2], H. Tulchinsky[2,3], H. Guzner-Gur[2,4], I. Dotan[1,2]
[1]*Department of Gastroenterology and Liver Diseases and the Research Center for Digestive Tract and Liver Diseases, IBD Center, Tel Aviv Medical Center,* [2]*Sackler Faculty of Medicine, Tel Aviv University,* [3]*Proctology Unit, Division of Surgery,* [4]*Internal Medicine B, Tel Aviv Medical Center, Tel-Aviv, Israel*

Introduction: Crohn's disease (CD) is characterized by loss of tolerance towards intestinal microorganisms, reflected by serologic responses towards fungal-related glycans such as mannan and beta-glucans.
Objective: To explore glycan-induced immune responses and their correlation with intestinal inflammation.
Methods: Peripheral blood mononuclear cells (PBMCs), isolated from CD and normal control patients, were stimulated by glycans or heat killed (HK) yeasts. Mucosal cells were freshly isolated from surgical specimens. Mucosal biopsies were obtained from CD and ulcerative colitis (UC) patients (inflamed/ non-inflamed) and controls. Expression of the beta-glucan receptor-Dectin1, and mannose receptor- MR, cytokine secretion, and signaling pathways were assessed using flow cytometry, immunofluorescence, and ELISA. Dectin-1 (*CLEC7A*) and MR (*MRC1*) mRNA levels were assessed by real time quantitative PCR.
Results: Mannan induced significantly higher pro-inflammatory cytokine secretion by CD versus normal PBMCs ($p \leq 0.05$). Significant inhibition of glycan-induced cytokine secretion was observed using Syk and Src inhibitors (up to 90% inhibition).

HK yeast induced higher TNF-α and lower IL-10 secretion by CD versus normal PBMCs. Dectin-1 is expressed in the lamina propria and by freshly isolated epithelial cells. Mucosal Dectin1 and MR expression was higher in inflamed CD, but not UC versus controls.
Conclusions: Glycans are capable of stimulating innate immune responses. Glycan receptors are expressed by peripheral and mucosal immune cells and are enhanced in intestinal inflammation, specifically in CD. CD is characterized by hyper-responsiveness towards yeast-characteristic glycans. Thus, glycans may have a role in the pathogenesis of CD.

Keywords: beta glucans, Crohn's disease, mannan.

Interactions of Cu(II) and Cu(I) ions with amyloid-β peptides

A. Tiiman[1], J. Luo[2], A. Gräslund[1], S. K. Wärmländer[1]
[1]*Department of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden,* [2]*Institute of Chemistry, Leiden University, Leiden, The Netherlands*

Alzheimer's disease (AD) is a progressive neurodegenerative disease that is characterized by a wide array of pathological features, including amyloid plaque formation, oxidative stress and metal dyshomeostasis. Metal ions have been proposed to be, directly or indirectly, involved in the neurodegenerative mecha-

© 2014 The Authors. FEBS Journal © 2014 FEBS

nisms of AD. In the amyloid plaques, there is colocalization of metal ions such as Zn, Cu, and Fe ions, and the Aβ peptide coordinates the metals with relatively high affinity. However the role of metal ions in AD etiology remains unresolved. Redox-active copper ions have been proposed to contribute to AD neurodegeneration. Copper is over-represented in AD brains, and binding of copper to the amyloid beta (Aβ) peptide modulates the aggregation pathways. The amyloid plaques are present in the extracellular space where the stable form of copper is Cu(II), and therefore Aβ/Cu(II) is the predominant complex outside the cells. But it has been demonstrated that copper is redox active in the amyloid, generating reactive oxygen species by copper redox cycling between the +1 and +2 oxidation states. In addition due to the reducing environment of the cytosol, the Cu(I) form may dominate inside the cells, enabling the Aβ peptides to interact with Cu(I). Therefore studying Aβ interactions with Cu(I) can contribute to the understanding of the molecular mechanisms of AD. While Aβ/Cu(II) binding has received a lot of attention, Aβ/Cu(I) interaction has been less well studied.

Here, we use NMR, circular dichroism and fluorescence spectroscopy to compare the effects of Cu(II) and Cu(I) on the Aβ peptide. Cu(II) results were similar to previous data reported in the literature, showing a realatively strong specific interaction (1–3). All the experimental methods used demonstrate that Cu(I) displays a non-specific weak interaction with the Aβ peptide, and only mildly affects its aggregation. Earlier studies have observed chemical shift changes in histidine NMR signals upon addition of Cu(I), which were interpreted as proof of histidine ligandation. However, as histidine chemical shifts are sensitive to pH changes, such shifts alone should not be taken as proof for specific binding. In this work, no histidine chemical shift changes were observed in the presence of Cu(I).

Acknowledgments: This study was supported by a scholarship to A.T. from the Swedish Institute.

Interleukin-33 promotes intestinal barrier function by direct effects on epithelial proliferation and differentiation

M. Mahapatro, G. He, C. Günther, M. F. Neurath, S. Wirtz, C. Becker
Gastroenterology, Medicine Clinic 1, University of Erlangen, Erlangen, Germany

Background and Aims: The small intestine comprises an array of epithelial cells that serves distinct functions during its time course. Many pathways are known to regulate this programming of intestinal stem cell. The balance between various cells of absorptive lineage and cells of secretory lineage (Goblet, Paneth and Enteroendocrine) is highly necessary to maintain homeostasis. However, under pathological conditions the intestinal epithelium is forced to undergo some changes which is mediated by cells of the immune system. Recently, Innate Lymphoid Cell Type2 family cytokines have been shown to participate in the process where particularly IL-33 is associated with goblet cell hyperplasia. In order to investigate its role in controlling small intestinal epithelium differentiation we used the IL-33 overexpressing transgenic mice.

Methods: We generatedan inducible transgenic mouse expressing IL-33 specifically in gut. For expressionof the cytokine mice were injected intraperitoneallywith Tamoxifen. Cre-mediated recombination was genotyped by PCR on tail DNA.To analyse the role of IL-33 directly on epithelium we used the*in-vitro* cultivation of organoids from C5BL/6mice. Localization of IL-33 was studied in IL-33*LacZ/LacZ*reporter mice.

Results: We observed high expression of IL-33 in the gut of TLR-ligand challenged mice. IL-33 was specifically expressed by cells which are located around the intestinal crypt bottom, where stem cells are located. Overexpression of IL-33 in transgenic mouse led to increased expression of anti-microbial peptides and goblet cell markers. Signaling of IL-33 into intestinal epithelial cells in vivo and in organoid cultures in vitro was associated with altered intracellular signalling governing proliferation and differentiation of intestinal epithelial cells.

Conclusions: Our data demonstrate a novel mechanism of IL-33 signallingand its significant consequences on intestinal epithelial cell function. Therefore it plays a role in maintaining intestinal homeostasis and tackling foreign challenges.

Investigation of tumor necrosis factor-receptor 2 gene polymorphisms in Turkish periodontitis patients

G. Kuyucuklu[1], G. N. Guncu[2], E. Baltacioglu[3], E. Dursun[2], E. Sukuroglu[3], S. Sumer[4], F. A. Akalin[2]
[1]Faculty of Medicine, Trakya University, Edirne, [2]Faculty of Dentistry, Hacettepe University, Ankara, [3]Faculty of Dentistry, Karadeniz Technical University, Trabzon, [4]Biology Department, Hacettepe University, Ankara, Turkey

Periodontitis is a highly complex and multi-factorial disease. With the pooled knowledge about genetic polymorphisms that were claimed to play a role in the predisposition to and the progression of aggressive and chronic periodontitis, it is now possible to identify candidate genes that could act as potential risk or protective factors for the disease. Genetic researches in periodontitis were generally focused on inflammatory cytokines, cell surface receptors and enzymes and related factors. In particular, genetic polymorphisms for cytokines and their receptors have been proposed as potential markers for periodontitis. One of these cytokines Tumor Necrosis Factor-α (TNF-α); mediates its diverse biologic effects by binding two high-affinity, cell surface receptors, TNF receptor 1 (TNF-R1, p55 TNFR) and TNF receptor 2 (TNF-R2, p75 TNFR). TNF-R2 may modulate TNF-α mediated inflammatory responses in periodontal disease. Recent studies have shown that TNF-R2 (+587) T/G gene polymorphism is associated with periodontitis. The aim of this study was to analyze TNF-R2 (+587) T/G polymorphisms in chronic periodontitis (CP) and agressive periodontitis (AP) patients in a Turkish population.

CP ($n = 54$), AP ($n = 47$) and periodontally healthy individuals ($n = 54$) were included in the study. The participants had no systemic diseases. After clinical and radiographic examinations, blood samples were obtained and genomic DNA was extracted from peripheral blood using QIAamp Blood MiniKit according to the manufacturer's instructions. Single nucleotide polymorphisms (SNP) were analyzed by PCR (Polymerase Chain Reaction) and RFLP (Restriction Fragment Length Polymorphism) methods in DNA samples. For TNF-R2 (+587) T/G polymorphism; TT, TG and GG genotype and allele frequencies were analyzed in CP and AP patients and controls.

For TNF-R2 (+587) T/G polymorphism; TT, TG and GG genotype and allele frequencies were analyzed and the differences in genotype and allele frequencies were found significant between the groups ($p < 0.001$). G allele carriage rates were found 66% for AP, 63% for CP and 29.6% for the control group. Further

© 2014 The Authors. FEBS Journal © 2014 FEBS

studies including greater number of subjects and performing linkage analyses may provide more supporting results.

Keywords: genetic polymorphism, Periodontitis, TNF-R2.

In-vitro research of epidermal growth factor on the gene expressions associated with the apoptosis in the gastric epithelial cells of ulcerous patients

F. Söylemez[1], M. E. Erdal[2], Ö. İzci Ay[2]
[1]*Medical Biology and Genetics, Avrasya University, Trabzon,* [2]*Mersin University, Mersin, Turkey*

Epidermal grow factor (EGF) has a major role on recovery process of gastroduodenal ulcers and organization of mucosal cell proliferation. Apoptosis is also an important period taking role in ulcer formation. In this study, EGF application to the biopsy samples of gastric and duodenal ulcer patients and the cells increased from gastric cancer cell line has been carried out in-vitro environment in three different doses (20, 50 and 100 ng/ml). Using the RNAs isolated from these cells, the expression levels of Bax, Fas and Bcl-2 genes have been determined both semi quantitatively and with Real-Time PCR by making 'Comparative C_T Analysis'. In consequence of statistical analyses, the EGF application was found not to change expressions of Bax, Fas and Bcl-2 genes in gastroduodenal ulcerous patients. As a result of statistical evaluation of the data got by making 'Comparative C_T Analysis with Real-Time PCR, separately from the EGF, only the expression level of Bax gene in the control group was determined to be higher in comparison with the patient group (p = 0.001)'. When the gene expression levels in the primer cell culture and gastric cancer line were evaluated in Real Time PCR, it was found that EGF doses had no effect on the expression levels in semi quantitative method; on the other hand, there was a clear increase I n the expression level of Bax gene in the cell line when one dose EGF (20 ng/ml) was applied (p = 0.001) and it was also observed that 2 doses EGF (50 ng/ml) application decreased the expression of Fas gene in the cell line (p = 0.033).Consequently, it was determined that EGF playing a role especially on the ulcer recovery had influence on the expression of Bax and Fas genes which have a function activating apoptosis and the expression of Bcl-2 gene also didn't change with the EGF application. Because this study is the first examining the apoptotic effect of EGF in ulcerous patients, it is thought that it will be a guide for the other studies about this subject.

Is there an impact of von Willebrand factor and claudin-5 for reflecting disease activity in rheumatoid arthritis?

G. Gürol[1], E. Karakeçe[2], I. H. Çiftci[2], H. Harman[3], I. Tekeoğlu[3], **S. Arabacı**[1]
[1]*Department of Physiology,* [2]*Department of Microbiology,* [3]*Department of Rheumatology/Rehabilitation, Sakarya University, Sakarya, Turkey*

Claudin family has an important role for endothelial cell permeability. Previous studies revealed that relationship existed between the vWF and Claudins. However there is no evidence about relationship between vWF and Claudins in patients with Rheumatoid arthritis (RA). The aim of the present study was to investigate possible relationships between von Willebrand factor (vWF) and Claudins with the level of disease activity in patients with RA.

A total of 35 frozen (−20°C) serum samples 25 of them belonged to patients with RA, and 10 sample belonged to healthy people, were enrolled prospectively. We used DAS-28 to evaluate disease activity. The following clinical data gathered from the original patients' charts. Serum VWF and Claudin-5 levels were measured by enzyme-linked immunosorbent assay.

The average DAS-28 score was found 3.43 ± 0.31 for RA patients in this study. The Claudin-5 levels in RA patient and healthy controls were found 44.9 ± 31.9 and 10.2 ± 4.1 respectively. Also the VWF levels in RA patient and healthy controls were found 41.1 ± 0.29 and 9.8 ± 3.9 The increase of VWF and Claudin-5 levels were found in high-level, correlation with disease activity (p = 0.009 and p = 0.011 respectively).

Our prelimenary results show that VWF and Claudin-5 contribute to pathological condition of RA. Thus, we believe that serum endothelial activity marker levels especially VWF and Claudin-5 can be as a marker in patients with RA, too. However other inflammatory diseases should be further investigated

Keywords: Claudin-5, rheumatoid arthritis, von Willebrand factor.

Kyotorphin analgesic derivatives and its anti-inflammatory effects: intravital microscopy and microcalorimetry studies

K. Conceicao[1,2], M. M. Domingues[2], V. G. Ramu[3], M. Heras[3], E. R. Bardaji[3], M. Lopes Ferreira[4], M. A. Castanho[2]
[1]*Departamento de Ciencia e Tecnologia, ICT-UNIFESP, São José dos Campos, Brazil,* [2]*Instituto de Medicina Molecular, Lisboa, Portugal,* [3]*LIPPSO, Girona, Spain,* [4]*LETA, Instituto Butantan, São Paulo, Brazil*

Current pain research has not resulted in an optimal translation to the clinic where all analgesics – opioid agonists, anti-inflammatory steroids and non-steroidal anti-inflammatory drugs (NSAIDs) – have safety issues. In a new strategy we recently designed and tested the efficacy of new class of drugs derived from an endogenous neuropeptide, Kyotorphin (KTP, Tyr-Arg) combining C-terminal amidation and Ibuprofen (Ibp) conjugation. As the main bottleneck in the development of analgesic and anti-inflammatory drugs are the safety concerns, we evaluated the impact of the newly designed drugs on microcirculation and their undesired physiological effects. Their effective in vivo behaviour on microcirculation was studied by intravital microscopy (IVM) in the murine cremasteric muscle. We also evaluated if the conjugated drugs retained anti-inflammatory activity by its effects on LPS-induced leukocyte recruitment in vivo and the mechanisms involved in its anti-inflammatory activity in vitro by isothermal

© 2014 The Authors. FEBS Journal © 2014 FEBS

titration microcalorimetry (ITC). The combination of analgesia and anti-inflammatory activities with absence of toxicity is highly appealing from the clinical point of view and broadens the therapeutic potential and application of kyotorphin peptides. Our data show that KTP and conjugates do not cause damage on microcirculatory environment and efficiently decrease the number of leukocyte rolling induced by LPS challenging. The probable mechanism by which KTP conjugates peptides are able to decrease leukocyte rolling and adherent induced by LPS appeared to be correlated with their ability to bind/or perturb LPS micelles, revealed by ITC experiments. The selected drug leads in this work are expected to overcome the limitations of conventional analgesic peptides, resulting in candidates conjugating analgesic and anti-inflammatory activities, therefore bearing the potential to develop novel medicines.

Keywords: Intravital microscopy, Kyotorphin, microcalorimetry.

Lack of association of apolipoprotein E (Apo E) ε2/ε3/ε4 polymorphisms with depression among Turkish psoriatic patients

M. M. Hiz[1], C. Aki[1], Z. Öğretmen[2], F. Silan[3]
[1]Department of Biology, Faculty of Arts and Science, Çanakkale Onsekiz Mart University,, [2]Department of Dermatology, Faculty of Medicine, Çanakkale Onsekiz Mart University, [3]Department of Medical Genetics, Faculty of Medicine, Çanakkale Onsekiz Mart University, Çanakkale, Turkey

Apolipoprotein E (ApoE) polymorphisms are also known as an important risk factor for several neurological diseases as well as depressive symptoms. Psoriasis is an immune-mediated skin disease with several comorbidities and psoriatic patients increased risk of depression due to the bodily manifestations related appearance. Aside, depression itself is also known as triggering factor for psoriasis development. In this reseach, we hypothesized that, Apolipoprotein E polymorphisms would be common triggering factor and have increased risk for depression among psoriatic patients with apolipoprotein E ε2-ε4 carriers.

Totally 134 psoriatic patients (69 with depression) were enrolled to this research. The genotypes were determined with melting curve analysis by using Real-Time polymerase chain reaction (Roche). Odds ratio were calculated to estimate the risk related to Apolipoprotein E variation and depression risk among psoriatic patients and Fisher's exact test was used to calculate the significance of OR.

The mean age of the cohort was 46.74 ± 16.5 and 59% were women. Psoriatic patients with depression did not shown significantly higher frequency of ApoE2/E3 [OR = 1.73, 95% confidence interval (CI) = 0.66–4.56; P = 0.27] or ApoE4/E3 [OR = 1.42, 95% confidence interval (CI) = 0.46–4.40; P = 0.54] than psoriatic patients without depression. Psoriatic patients who carriers of ApoE epsilon4 allele had not increased depression risk as compared to ApoE epsilon3 allele carriers [OR = 01.21, 95% confidence interval (CI) = 0.44–23.38; P = 0.71]. Also, epsilon2 allele carriers were not increased depression risk when compared with ApoE epsilon3 isoform [OR = 1.21, 95% confidence interval (CI) = 0.52–2.77; P = 0.66].

Neither the ApoE epsilon2 allele nor ApoE epsilon4 are sufficient risk factors for depression among psoriatic patients. The primary results of this study need to be confirmed by extensive study groups.

Leptin-preconditioning induces cardioprotection against myocardial infarction through activation of AMPK and, induction of ROS

K.-S. Kim, Y.-W. Cho, S.-G. Park
Korea Institute of Toxicology, Deajoen, Korea

Introduction: Leptin, a product of the *ob* gene, is a 16-kDa peptide synthesized primarily by white adipose tissue. It is also produced in the heart, suggesting that it has a cardioprotective effect. AMP-activated protein kinase (AMPK) is a serine/threonine protein kinase that plays a key role in cardioprotection in the abnormal heart. However, it is not clear whether AMPK-mediated cardioprotection influences the effects of leptin in cardiac muscle. Here, we investigated the mechanism of cardioprotection in leptin preconditioning and the relationship between leptin preconditioning-induced cardioprotection and the regulation of AMPK.

Methods: A rat ischemia model was constructed using left anterior descending coronary artery occlusion (CAO). Infarct size was measured to evaluate the cardioprotective effect. A rat cardiac myoblast cell line (H9c2) was used to investigate the cardioprotective mechanism of leptin.

Results: Leptin decreased myocardial infarct size in rat cardiac ischemic reperfusion model. The effect of leptin was abolished in combination with compound C, an AMPK inhibitor or NAC, a ROS scavenger. Leptin phosphorylated AMPK dose- and time-dependently in H9c2 cells. Leptin also induced generation of reactive oxygen species (ROS) dose- and time-dependently in H9c2 cells. AMPK phosphorylation by leptin was abolished in combination with NAC, however, leptin-induced ROS generation was not affected by compound C. Therefore, Leptin induced generation of ROS followed by activation of AMPK. Activated AMPK decreased cardiac ischemic damage.

Conclusions: AMPK activation plays a key role in leptin preconditioning-induced cardioprotection. Leptin-induced ROS generation results in AMPK activation.

Keywords: Leptin, cardioprotection, ischemia.

Lipid structures as biomarkers in septic shock: a new road to travel

F. Pinheiro Da Silva[1], T. Cataldi[2], T. M. de Lima[1], P. N. Starzynski[3], H. V. Barbeiro[1], M. V. Labate[2], M. C. C. Machado[1], I. T. Velasco[1], H. P. de Souza[1], C. A. Labate[2]
[1]Emergency Medicine, University of Sao Paulo, São Paulo, [2]Genetics, University of Sao Paulo, Piracicaba, [3]Biosciences Institute, São Paulo, Brazil

Purpose/Objetive: Sepsis is the first cause of death in Intensive Care Units (ICUs) and the molecular mechanisms underlying this disease remain poorly understood. Most of the times, it′s very difficult for the clinician to diagnose sepsis promptly, since many other inflammatory diseases present similar manifestations, while a specific sepsis biomarker is still lacking. The purpose of this study is to investigate lipid structures as potential sepsis biomarkers. These molecules, therefore, would be able to identify sepsis during its early phase, helping in its diagnosis and treatment.

Material and Methods: 11 patients who suffered severe trauma and were admitted in our ICU were included in the study. After 48 hours, their blood was collected and the plasma was sent for metabolomic analysis. At this time, any patient had manifested signs of infection yet. 7 of those patients didn′t infect during their

© 2014 The Authors. FEBS Journal © 2014 FEBS

whole ICU stay. 4 of them did infected early (after 48 hours, but before day 7) and developed septic shock.

Results: Metabolomic analysis identified 7 lipid structures that have the potential to be used as early biomarkers of sepsis. These structures are: homoserine lactone, sorbaldehyde, succinic acid, methylmalonic acid, bromo-decanoic acid, 4-hydroxy-3-methyl-but-2-en-1-yl trihydrogendiphosphate and many others.

Conclusion: Lipid structures may regulate unexpected molecular pathways during sepsis. Their role in inflammation, immunity and infection must be investigated, as well as their potential to help direct clinicians in the treatment of this devastating disease.

Lipopolysaccharide induces pro-inflammatory cytokines and MMP production via TLR4 in nasal polyp-derived fibroblast and organ culture

J.-S. Cho[1], J.-Y. Um[1], J. A. Kim[1], H.-M. Lee[1,2]

[1]Biomedical Science, [2]Department of Otorhinolaryngology-Head and Neck Surgery, College of Medicine, Korea University, Seoul, Korea

Nasal polyposis is characterized by persistent inflammation and remodeling in sinonasal mucosa. Toll-like receptors (TLRs) play a role in the innate immune response to microbes in the sinonasal cavity. The aim of this study was to evaluate whether nasal polyp-derived fibroblasts (NPDFs) and organ-cultured nasal polyps can synthesize pro-inflammatory cytokines and matrix metalloproteinases (MMPs) after exposure to lipopolysaccharide (LPS), a TLR4 agonist. NPDFs and organ-cultured nasal polyps were isolated from nasal polyps of 8 patients and exposed to LPS. The mRNA and protein expression levels of TLRs, cytokines, and MMPs were determined using a gene expression microarray, real-time RT-PCR, western blot analysis, enzyme-linked immunosorbent assay, and immunofluorescence staining. The enzymatic activities of MMPs were analyzed using collagen or gelatin zymography. The protein expression level of MMP-1 increased in nasal polyp tissues compared to inferior turbinate tissues. LPS induced mRNA expression of *TLR4*, *IL-6*, *IL-8*, and *MMP-1* and activated MAPK signaling in NPDFs. LPS promoted the release of interleukin (IL)-6 through extracellular signal-related kinase (ERK) and IL-8 through ERK and c-Jun N-terminal kinases (JNK). Production of IL-6 and IL-8 was induced by PI3K/Akt signaling in LPS-stimulated NPDFs. LPS increased the transcript and protein expression levels of MMP-1 and induced collagenase activity of MMP-1 via ERK and p38, but did not induce gelatinase activity of MMP-2 and MMP-9. LPS from *Rhodobacter sphaeroides* (LPS-RS) inhibited the stimulatory effects of LPS in NPDFs as well as in organ culture of nasal polyp. LPS triggers immune response via TLR 4 and activates MAPK and PI3K/Akt signaling pathway, which is involved in remodeling of nasal polyps.

Keywords: Cytokine, nasal polyp, toll-like receptor.

Liposomes for photodynamic therapy of vitiligo via pilosebaceous route

M. Bhargava[1], S. Bhargava[2], V. Bhargava[3]

[1]ICFAI University, [2]Signa Pharma, [3]KRV Hospitals Pvt. Ltd., Kanpur, India

Vitiligo is an acquired depigmentory skin disorder in which the pigment producing cells (melanocytes) are absent. It affects 0.1–4% of the population worldwide and is emotionally and socially devastating. Well established treatment modalities in today's therapeutic armamentrum have their own side effects and failure. Photodynamic therapy (PDT) an entirely new treatment modality which involves a photosensitizer and light. PUVA therapy used so far has marked failure in many of the clinical trials studies. Since no full therapeutic solution for vitiligo is available, PDT is the ray of hope. The aim of project was to develop and investigate the therapeutic efficacy of liposomes to produce immediate repigmentation (by melanin) along with correcting the cause simultaneously. Topical route has been chosen to directly target the diseased site and to minimize the systemic toxicity. Methoxsalen-melanin loaded liposomes were prepared by a lipid cast film method and were characterized *in-vitro* for their shape, size, percent antigen entrapment, Skin permeation and stability. Fluorescence microscopy was carried out to confirm the uptake of bilosomes. The *in-vivo* part of the study comprised of Induction of vitiligo by mushroom tyrosinase intradermally & photodynamic studies with different formulations. Cosmetic disfiguration and psychological sequel underlines the impact of vitiligo. Immunization with mushroom tyrosinase resulted in discoloration of the areas showing its effectiveness in inducing vitiligo. Sustained pigmentation resulted after application of formulation was suggestive of cure with fast repigmentation. Thus, pilosebaceous route is effective in targeting follicular melanocytes. Toxic manifestations of methoxsalen were also subsided when delivered in liposomes.

Keywords: liposomes, Methoxsalen, vitiligo.

Loading and release efficiencies of Bortezomib on chitosan coated magnetic nanoparticles

G. Unsoy[1], S. Yalcin[2], R. Khodadust[1], P. Mutlu[3], N. Taghavi Pourianazar[1], U. Gunduz[1]

[1]Biotechnology, METU, Ankara, [2]Food Engineering, Ahi Evran University, Kırsehir, [3]Central Laboratory Molecular Biology and Biotechnology R&D, METU, Ankara, Turkey

Conventional chemotherapeutics are unspecifically distributed all over the body and they affect both cancerous and normal cells. This treatment results in excessive toxicities. Targeted drug delivery has emerged to overcome the lack of specificity of conventional chemotherapeutics. Nanotechnology opened a new door to the development of particles with nano sizes that can be fabricated from a multitude of materials in a variety of compositions, including quantum dots, polymeric magnetic nanoparticles, and

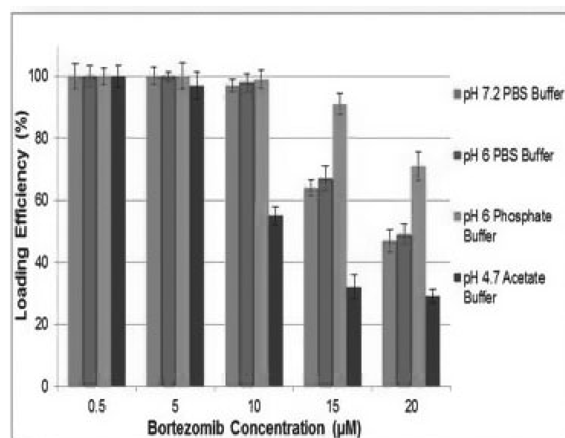

Fig. 1. Effect of initial Bortezomib concentration on loading efficiency in acetate buffer (pH 4.7), phosphate buffer (pH 6.0), phosphate buffered saline (pH 6.0 and pH 7.2).

© 2014 The Authors. FEBS Journal © 2014 FEBS

dendrimeric. Nanoparticles are promising to circumvent these challenges, by enabling high amounts of drugs to be loaded and targeted to the tumor site. Delivery of drugs via nanoparticles increases the half life and reduces toxic side effects of drugs, by improving their pharmacokinetic profile and therapeutic efficacy.

Chitosan magnetic nanoparticles (CS MNPs) were generated for targeting of tumor cells in the presence of magnetic field (Unsoy *et al*., 2012) and loaded with the anti-cancer drug Bortezomib (Velcade®). Bortezomib loading efficiency of CS MNPs was optimized (Figure 2). Highest loading capacity and Drug release characteristics of CS MNPs were identified. Stability of Bortezomib loaded CS MNPs were determined. Bortezomib, a highly potent proteasome inhibitor, was successfully loaded on CS MNPs and their release behavior was pH dependent. Bortezomib loaded pH sensitive CSMNPs were perfectly stable at physiological pH.

As a result, synthesized and Bortezomib loaded CS MNPs can be effectively used in magnetic targeted drug delivery as nanocarrier for the pH dependent release of Bortezomib in cervical cancer cells.

Keywords: Bortezomib, cervical cancer, nanoparticle, targeted drug delivery.

Local inflammatory response induced by CcH1, a P-I metalloproteinase isolated from *Cerastes cerastes* venom

H. Boukhalfa-Abib, F. Laraba-Djebari
Department Cellular and Molecular Biology, USTHB, Faculty of Biological Sciences, Algiers, Algeria

Envenomings induced by snakebite are characterized by local tissue damage, including, necrosis of skeletal muscle, edema, hemorrhage and inflammatory response, as well as by systemic alterations such as hemorrhage, cardiovascular shock, acute renal failure and coagulopathies. Local and systemic effects caused by snake venoms have been associated with diverse components of the venom, such as phospholipases A_2 and metalloproteinases. Snake Venom Metalloproteinases (SVMPs) play a relevant role in the complex multifactorial inflammatory response induced by snakebite. CcH1, an P-I class SVMP isolated from *Cerastes cerastes* snake venom, is a weak hemorrhagic protein, able to induce myonecrosis and to degrade fibrinogen, fibrin, type IV collagen and laminin. In this study, we analyzed the inflammatory reaction induced by CcH1 in gastrocnemius muscle, aiming to identify the cellular components involved in muscular cytokine release.

The inflammatory reaction induced by CcH1 in gastrocnemius muscle was assessed by tissue analysis and the release of pro-inflammatory mediators. Indeed, upon intramuscular injection, CcH1 induces formation of blisters and leukocyte infiltration into dermis, indicating an important pro-inflammatory effect of CcH1. Moreover, the injection of CcH1 in the gastrocnemius muscle, revealed a marked elevation of muscular levels of pro-inflammatory cytokines (TNF-α and IL-6), 50% higher than controls. The muscular concentrations of these cytokines returned to normal levels after 24 h of injection. Muscle injected with CcH1 resulted also the production of pro-inflammatory gelatinases, observed by zymography analysis. Two gelatinolytic bands were detected an apparent molecular weight of approximately 60 kDa and 100 kDa corresponding to latent forms of MMP-2 and MMP-9, respectively. These results suggest that the early production of cytokines induced by CcH1 may stimulate accumulation of leukocytes that will produce MMPs, which will enhance the levels of inflammatory mediators thus potentiating the local response and the tissue damage.

In conclusion, these results indicate that CcH1 is able to induce an inflammatory response characterized by a marked leukocyte infiltrate, MMPs and cytokines production in muscle tissue, indicating that multiple pathways may be involved in muscle inflammatory reaction. The characterization of the cell types and mediators involved with tissue damage and inflammatory response induced by metalloproteinases in snakebite accidents may contribute to the improvement of current therapies, adding to the currently available therapy with antivenoms.

Macrophages engulfing apoptotic cells produce non-classical retinoids to enhance their phagocytic capacity

G. Joós, Z. Sarang, É. Garabuczi, R. Rühl, Z. Szondy
Biochemistry and Molecular Biology, University of Debrecen, Debrecen, Hungary

Previous work in our laboratory has shown that transglutaminase 2 (TG2) acting as a coreceptor for integrin $\beta 3$ is required for proper phagocytosis of apoptotic cells. In the absence of TG2 SLE like autoimmunity develops in mice, similarly to other mice characterized by a deficiency in the clearance of apoptotic cells. In the present study we demonstrate that increasing TG2 expression alone in wild-type macrophages is not sufficient to enhance engulfment. However, during engulfment the lipid content of the apoptotic cells triggers the lipid sensing receptor liver X receptor (LXR), which in response upregulates the expression of the phagocytic receptor Mertk and the phagocytosis related ABCA1, and that of retinaldehyde dehydrogenases leading the synthesis of a non-classical retinoid. Based on our retinoid analysis this compound might be a dihydro-retinoic acid derivative. The novel retinoid then contributes to the upregulation of further phagocytic receptors including TG2 by ligating retinoic acid receptors. Inhibition of retinoid synthesis prevents the enhanced phagocytic uptake induced by LXR ligation. Our data indicate that stimulation of LXR enhances the engulfment of apoptotic cells via regulating directly and indirectly the expression of a range of phagocytosis-related molecules, and its signaling pathway involves the synthesis of a nonclassical retinoid. We propose that retinoids could be used for enhancing the phagocytic capacity of macrophages in diseases such as systemic lupus erythematosus, where impaired phagocytosis of apoptotic cells plays a role in the pathomechanism of the disease.

Fatty acid metabolites – eicosanoids are important signalling molecules and regulate a variety of physiological and pathophysiological processes including inflammation.

The aim of our study was to assess the effect of eicosapentaenoic acid (EPA) supplementation with added Maresin and/or

© 2014 The Authors. FEBS Journal © 2014 FEBS

benzo(a)pyrene (BaP) on A549 human lung carcinoma epithelial cells by using a UHPLC/MS-TOF method. Additionally, we use Western blot technique to visualise the impact of Maresin, EPA and BaP on the enzymatic activity of cyclooxygenase 2 (COX-2) and prostaglandin E synthase (PES) in the A549 cells.

In the cells supplemented with EPA + Maresin + BaP we did not observe the presence of 8-iPGF3α, PGF3α, 8-isoPGF2α and 5-iPF2α in contrast to other treatment groups. Also, less activity of COX-2 and PES were observed in this group compared to the results for cells incubated with BaP. In our work, we have shown for the first time, protective role of EPA and EPA + Maresin in the model of epithelial cells exposed to BaP.

This project was possible through the support given by National Science Centre, Poland DEC-2011/01/B/NZ7/00038.

Mesuagenin C attenuated LPS-stimulated BV-2 and NG108-15 cells by modulating NF-κβ, CCL21 and cytokines through PI3K-Akt/GSK-3β

H. Abdul Kadir[1], M. N. A. Kamarudin[1], G. Chan[2], K. Awang[3]
[1]Biomolecular Research Group, Institute of Biological Sciences, Faculty of Science, [2]Department of Chemistry, Faculty of Science, [3]Department of Chemistry, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia

Background: The aetiology of neurodegenerative diseases remains vague, albeit growing empirical evidences implicate the role of microglial mediated neuroinflammation in the pathogenesis of the diseases. Mesuagenin C (MC) was found to protect NG108-15 cells against neuronal apoptosis which involved the modulation of CCL21. Therefore, we investigated the anti-neuroinflammatory effects of MC in LPS-stimulated BV-2 and NG108-15 cells through the modulation of chemokines and cytokines.

Material and Methods: The nitric oxide and ROS level were determined in the BV-2 cells and the expression of iNOS, COX-1, COX-2, mTORC1/2, PI3K-Akt and GSK-3β were examined. The production of TNF-α, IL-6 and IL-10 was first measured by cytometric cytokines bead array (CBA). The CCL21 gene in NG108-15 cells was silenced by using siRNAs, subjected to LPS and evaluated by chemotaxis and customized cytokines protein array. BV-2 and NG108-15 were co-cultured and stimulated with either LPS or recombinant CCL21 and compared to transfected NG108-15 cells. The translocation of p65NF-κβ was evaluated and its regulation with chemokines and cytokines was also determined.

Results: Pretreatment with MC decreased the iNOS expression which concomitantly attenuated both NO and ROS level. This was followed with the attenuation of COX-2 but not COX-1 expression. CBA revealed that MC significantly suppressed the production of TNF-α and IL-6 and reciprocally augmented the anti-inflammatory cytokines, IL-4 and IL-10. MC was found to activate mTORC1/2 and PI3K-Akt which led to the inactivation of GSK-3β and p65NF-κβ translocation. Furthermore, cytokines array revealed that treatment with MC, lithium chloride and ethyl 3,4-dihydroxychromate abated the production of most pro-inflammatory chemokines and cytokines (CCL21, IFN-γ, IL-1β, IL-2, MIP-1A, MIP-3B, RANTES) which accentuated the involvement of GSK-3β and NF-κβ in modulating LPS-induced neuroinflammation. Moreover, following CCL21 knockdown, both transfected and wild-type NG108-15 co-cultured with BV-2 cells pretreated with MC displayed suppression of microglial chemotactic activity and microgliosis in BV-2 which further proved that modulation of CCL21 was crucial in the initiation of microgliosis and hence, neuroinflammation.

Conclusion: MC suppressed LPS-induced neuroinflammation in BV-2 and NG108-15 by modulating GSK-3β and NF-κβ reciprocal regulation of CCL21, chemokines and cytokines through PI3K/Akt pathway. This finding advocates the MC potential for the treatment of neuroinflammation with a specific role of CCL21 in suppressing initiation of neuroinflammation.

miR-146a deficiency in Ly6Chigh monocytes contributes to pathogenic bone loss during inflammatory arthritis

M. Ammari[1], I. Duroux-Richard[1], **A. Kolandaswamy**[1], J. Presumey[1], G. Roussignol[2], C. Roubert[2], V. Escriou[3], C. Ponsolles[1], K. Toupet[1], A.-L. Bonnefont[1], P. Georgel[4], C. Jorgensen[1], F. Apparailly[1]
[1]Inserm U 844, CHU Saint Eloi, Clinical Unit for Osteoarticular Diseases, University of Medicine, University Hospital of Montpellier, F-34295 Montpellier, [2]Exploratory Unit, Sanofi-Aventis R & D, F-34184 Montpellier, [3]Inserm U 1022, CNRS, UMR8151, UFR des Sciences Pharmaceutiques et Biologiques, F-75006 Paris, [4]INSERM UMR S 1109, Centre de Recherche d'Immunologie et d'Hématologie, University of Strasbourg, F-67085 Strasbourg, France

Monocytes represent a prototypic cell type when investigating the interplay between immune and skeletal systems as they can give rise to different cell types including dendritic cells, macrophages and osteoclasts (OC), which play key roles in immunity and bone homeostasis. Circulating monocytes consist of at least two main functional subsets, Ly6Chigh and Ly6Clow monocytes. It has been suggested that OC might develop preferentially from the Ly6Chigh monocyte subset which excessive and prolonged activation is a hallmark of many inflammatory diseases. Among key molecular rheostats of cell fate, micro(mi) RNAs are a class of regulatory RNAs that control basic biological functions and orchestrate inflammatory responses. Few miRNAs have been involved in osteoclastogenesis. The present study aimed at investigating the role of miRNAs in osteoclastogenesis in the context of monocyte subsets, under steady state and inflammatory conditions.

Genome-wide miRNA expression study identified 8 miRNAs and putative targeted pathways that are differentially expressed between Ly-6Chigh and LyC6low FACS sorted mouse monocytes, and common to their human counter parts CD14+CD16– and CD14dimCD16+ monocytes, respectively. Among these, miR-146a showed higher expression in Ly-6Clow monocytes when compared to Ly6Chigh monocytes. Under inflammatory arthritis conditions, expression of miR-146a in Ly6Chigh monocytes was down regulated as compared to healthy controls. Deficiency for miR-146a increased OC differentiation and bone erosion both in vitro and in vivo, respectively. Enforced expression of miR-146a both in vitro and in vivo led to decreased TRAP positive cells and was associated with decreased RelB expression.

Overall, our results show that specific over-expression of miR-146a in Ly6Chigh monocytes altered OC differentiation and decreased bone erosion in inflammatory arthritis. These data suggest a novel role for miR-146a in controlling osteoclast fate of Ly6Chigh monocytes and that reduced miR-146a expression in Ly6Chigh monocytes under arthritic conditions contributes to pathogenic bone loss.

Keywords: miR-146a, Monocyte subsets, Osteoclasts.

Mitigating the inflammatory response by TiO2 nanotubes

N. Patricia[1], M. Anca[2], P. Jung[3], C. Marieta[1], S. Patrick[2], D. Ioana[4], C. Anisoara[1]
[1]*Departament of Biochemistry and Molecular Biology, University of Bucharest, Bucharest, Romania,* [2]*Departament of Materials Science,* [3]*Department of Pediatrics, University of Erlangen-Nuremberg, Erlangen, Germany,* [4]*Faculty of Applied Chemistry and Materials Science, University Politechnica of Bucharest, Bucharest, Romania*

Introduction: Macrophages (MF) recruited at the biomaterials implantation site are the primary mediators of the non-self response. They play a key role in modulating the tissue healing around the implant and in mediating the foreign body reaction (FBR). FBR is characterized by the accumulation and activation of MF and the formation of foreign body giant cells (FBGCs). Surface nano-topographical cues of the endo-osseous implants proved to positively influence the osteoblasts behavior but little is known about the MF response. Hence, the aim of our study was to evaluate the effects of TiO_2 nanotube modified Ti surface (TNT) on inflammatory activity of MF with regard to cell activation, expression of the pro-inflammatory mediators and FBGCs formation.
Materials and Methods: TNT were elaborated by electrochemical anodization. Cell culture model was represented by murine MF cell line, RAW 264.7. These cells were maintained in contact with the test surfaces up to 7 days, under standard and pro-inflammatory (stimulation with LPS) culture conditions. Cell viability and proliferation were evaluated using MTT and Live/Dead assays and the cell morphology was assessed by fluorescent visualization of actin. The gene expression and protein secretion of the pro-inflammatory cytokines/chemokines were evaluated after 24 h and 48 h using qPCR and ELISA assays. Furthermore, the LPS-mediated induction of multinucleated cells was assessed at 7-days post-seeding by fluorescent labeling of actin and nuclei with FITC-phalloidin and DAPI, respectively. Further, the percentage of MF fusion was estimated by determining a 'multinuclear index'.
Results: The results regarding MF viability and proliferation did not show significant differences between the two analyzed surfaces. Instead, the microscopy studies, as well as the evaluation of gene expression and protein secretion levels exhibited by the pro-inflammatory mediators revealed a mitigation of the MF inflammatory activity on TNT. Thus, on cpTi surface was observed an increased number of modified cells, as a sign of the pronounced initial activation, fact that was also confirmed by low levels of pro-inflammatory factors. Likewise, less FBGCs were noticed on titania nanotubes.
Conclusions: These studies demonstrate a strong correlation between the nanotopography of TNT and MF behavior, nanotube modified surface eliciting a weaker inflammatory response.

Modification of fibrinogen function and structure in post acute myocardial infarction patients

G. Bruschi[1], M. Becatti[1], R. Marcucci[2], N. Taddei[1], D. Bani[2], A. M. Gori[2], B. Giusti[2], G. F. Gensini[2], R. Abbate[2], C. Fiorillo[1]
[1]*Department of Biomedical, Experimental and Clinical Sciences,* [2]*Department of Medical and Surgical Critical Care-AOU Careggi, University of Florence, Florence, Italy*

Cardiovascular diseases are one of the most important causes of death globally and atherothrombosis is the underlying cause of most cardiovascular events. There is widespread evidance that oxidative stress contributes to vascular damage.

Among plasma proteins, fibrinogen represents the major target of oxidative modifications.

In postmyocardial infarction (postAMI) patients (6 months after the acute event) fibrinogen oxidative modification (protein carbonyls) and fibrinogen function were estimated by an in vitro and an ex vivo approach. Fibrinogen structural features and clot architecture were also explored.

In 39 postAMI patients and in 28 controls comparable sex and risk factors, oxidative stress markers (in plasma and in purified fibrinogen fractions), thrombin-catalyzed fibrin polymerization and plasmin-induced fibrin lysis were estimated. Not only the functional aspects were assessed, but also the structural ones. Circular Dichroism (CD) spectra of purified fibrinogen extracts, electron microscopy analysis and differential interference contrast microscopy analysis of fibrin clot were also performed. Differences in terms of oxidative stress were found between plasma of patients and controls ($p < 0.01$ versus Controls). In particular, an increased fibrinogen carbonylation, among patients (3.5 folds over control values), respect controls ($p < 0.01$ versus Controls) was evident.

As regards function, purified fibrinogen fractions from postAMI patients showed significantly reduced clotting ability and less susceptibility to plasmin-induced lysis ($p < 0.01$ versus Controls).

Not only fibrinogen function, but also structure was altered. In fact in patients, both fibrinogen secondary structure as suggested by CD spectroscopy, and fibrin clot architecture analysed by electron and confocal microscopy were modified.

In conclusion, post AMI patients an overall imbalance in redox status and a marked fibrinogen carbonylation associated to altered fibrinogen function are evident. These features occur along with modifications in protein structure and in clot architecture.
Keywords: Fibrinogen, Carbonylation, Fibrin clot.

Modulation of TRPA1/TRPV1-mediated responses in trigeminal sensory neurons by ADM_12

R. Gualdani[1], M. Zanardelli[2], L. di Cesare Mannelli[2], O. Francesconi[1], C. Ghelardini[2], C. Nativi[1], M. R. Moncelli[1]
[1]*Department of Chemistry, University of Florence, Sesto Fiorentino,* [2]*Department of Neuroscience, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence, Firenze, Italy*

The Transient Receptor Potential Vanilloid 1 (TRPV1) and Ankyrin 1 (TRPA1) ion channels belong to the TRP superfamily and are both integrators of a variety of noxious stimuli. Both channels are non selective cation channels which exert pleiotropic functions in a variety of cells; more specifically they colocalize in

© 2014 The Authors. FEBS Journal © 2014 FEBS

primary sensory neurons of the trigeminal, vagal and dorsal root ganglia (DRG). TRPA1 is activated by a number of pungent and irritant reactive chemical compounds including allyl isothiocyanate (AITC, mustard oil), cinnamaldehyde (cinnamon oil), allicin (onions), carvacrol (oregano), polygodial (Tasmanian pepper) and formaldehyde (formalin); all of these molecules elicit a painful burning and a prickling sensation. TRPV1 is activated by noxious stimuli including high temperature, pH, and vanilloid compounds such as capsaicin.

In this context, we describe a new water soluble derivative of lipoic acid [1], ADM_12 (Patent n. PCY/IB2014/059289) which proved to block TRPA1 channels activated by well-known TRPA1 agonists (AITC, Menthol, oxaliplatin); selectivity studies showed no appreciable block by this molecule of TRPM8, hERG and NaV channels.

Moreover we showed that ADM_12 was able to activate TRPV1 channel in TRPV1-expressing cells, whereas it acted as an antagonist of capsaicin- and AITC- induced responses in TRPA1/TRPV1 coexpressing cells.

Similarly we found that ADM_12 elicited ionic current in the TRPV1-positive/TRPA1-negative subset of trigeminal neurons, whereas it was able to block capsaicin- and AITC- induced responses in sensory neurons that express both TRPV1 and TRPA1 channels.

Based upon these findings, we speculated that ADM_12 could act as modulator of the heteromeric complex in sensory neurons between TRPA1 and TRPV1 channels, suggesting an interesting strategy for the design of a novel class of analgesic drugs.

The financial support of Ente Cassa di Risparmio di Firenze and MIUR (PON project 2007–2013, 01_00937) is gratefully acknowledged.

Molecular and cellular responces to titanium dioxide nanoparticles

A. Zhornik, L. Baranova, I. Volotovski
Laboratory of Molecular Biology of Cell, Institute of Biophysics and Cell Engineering of NAS of Belarus, Minsk, Belarus

The increased use of nano-sized materials in the past several years has compelled the scientific community to investigate the potential hazards of these unique and useful materials. One of the most widely used nanoparticles is titanium dioxide. TiO2 is a very versatile compound that has many uses, depending on its particle size.

The objective of the research is to investigate the alterations in molecular and cellular responses in culture of primary lymphocytes to titanium dioxide nanoparticles.

Human lymphocytes isolated from heparinized blood samples of healthy individuals were exposed to TiO2 nanoparticles. Viability, ROS generation, the changes in the expression of genes encoding proinflammatory mediators TNF-α, Il-1β and Il-8 and DNA damage were assessed.

To examine the toxic effects of titanium dioxide nanoparticles, human lymphocytes were incubated with different concentrations of nanoparticles and viability was determined 24 and 48 h after treatment, respectively. Cell viability was decreased by treatment with nanoparticles in both a time- and concentration-dependent manner.

The ability of TiO2 to induce ROS formation in lymphocytes was evaluated using DCF (2',7'-dichlorofluorescin) fluorescence as a reporter of oxidant production. The fluorescence intensity of oxidized DCF was increased in cells when treated with nanoparticles. This means that ROS generation was occurring in response to the treatment with titanium dioxide nanoparticles in a concentration- and time-dependent manner, while fluorescence was insignificant in the control group.

To investigate the expression level of mRNA related to the inflammation responses in human lymphocytes real-time PCR was performed. The expression of interleukin-1β, interleukin-8 and TNF-α genes were increased by the exposure to nanoparticles (10, 20 and 40 μg/ml) for 24–48 h.

TiO2 nanoparticles were shown to induce the dose-dependent fragmentation of DNA strands.

Much evidence of hazardous health effects of nanoparticles has been reported in toxicological studies. In this study, viability was reduced under the exposure to TiO2. Oxidative stress was revealed by the treatment with titanium dioxide nanoparticles. Consequently, cytotoxicity in human lymphocytes seemed to be caused by oxidative stress. Oxidative stress may also trigger inflammation signals. Induced by exposure to nanoparticles it may cause the translocation of transcription factors to the nucleus, which regulate pro-inflammatory genes, such as TNF-α, Il-1β, Il-8. ROS is an important factor in the apoptotic process, and the excess generation of ROS induces mitochondrial membrane permeability and damages the respiratory chain, to trigger the apoptotic process.

Keywords: gene expression, reactive oxigen species, titanium dioxide nanoparticles.

Molecular basis for the heterointeractions between human guanylate-binding proteins (hGBPs)

M. Kutsch, C. Herrmann
Physical Chemistry I, Ruhr-University Bochum, Bochum, Germany

The interferon gamma-induced guanylate-binding proteins (hGBPs) are key players of the cellular response to pathogens like hepatitis C virus, influenca A virus and *Chlamydia trachomatis*. Although the molecular function of the hGBP family is still unknown, guanine nucleotide-dependent homo- and heterointeractions of hGBPs seem crucial for their anti-pathogenic function. Cellular localisation studies revealed a hGBP network in which the translocation of hGBPs is regulated in a GTP-hydrolysis dependent, hierarchical manner (Britzen-Laurent et al., 2010). Nevertheless, quantitative heterointeraction studies characterising the hGBP heterocomplexes are required as the molecular basis for understanding hGBP's cellular, and in particular, anti-pathogenic function. Therefore, we established an assay to investigate the formation of hGBP homo- and heterocomplexes in vitro, which is based on the proteins' GTPase activities. We showed earlier that GTPase activity of hGBP1 as well as hGBP5 is stimulated upon formation of homocomplexes in a protein concentration-dependent manner. Intriguingly, we observed a stimulation of the GTPase activity when combining different hGBP isoforms. For instance, we obtained maximal GTPase activities even for low hGBP5 concentrations, where hGBP5 is monomeric, upon addition of hGBP1 which leads to the formation of a hGBP1/hGBP5 heterocomplex. Beside this stimulating effect, we observed that the heterocomplex is tighter than the homocomplexes. Our studies provide quantitative data for better understanding the networking of hGBPs.

Molecular basis of the digestion-resistant peptides from the major peanut allergen Ara h 2

D. Apostolovic[1], D. Stanic-Vucinic[1], G. A. de Jong[2], J. Nordlee[3], J. Baumert[3], S. Taylor[3], N. Garrido Clua[4], H. H. de Jongh[4], T. Cirkovic Velickovic[1], S. J. Koppelman[3]
[1]Biochemistry, Faculty of Chemistry, University of Belgrade, Belgrade, Serbia, [2]TNO, Zeist, The Netherlands, [3]Food Allergy Research and Resource Program, University of Nebraska, Lincoln, NE, USA, [4]TI Food and Nutrition, Wageningen, The Netherlands

Peanut allergens can trigger a potent and dangerous immune response in an increasing number of people. The molecular structures of these allergens form the basis for understanding this response. Conglutin isoforms Ara h 2 are considered the most relevant peanut allergens, because they are frequently recognized by patient's serum, and highly potent in IgE-binding. This may be explained by the fact that Ara h 2 is highly resistant to digestion. The aim of this work is to investigate the effect of digestion on the structure and immunogenicity of the different Ara h 2 isoforms.

Purified Ara h 2 isoforms Ara h 2.02, Ara h 2.01 were digested with immobilized trypsin. Digestion resistant peptides were analysed by SDS PAGE, Far UV CD spectroscopy, competitive IgE inhibition ELISA and immunoproteomics (2D PAGE, 2D immunoblot, and mass spectrometry).

Prolonged digestion with trypsin resulted of mixture of digestion-resistance peptides (DRPs), with masses close to the masses of the undigested forms. Under reducing conditions these DRPs contains lower masses which is association with arrangement of disulphide bonds. The secondary structure of the DRPs compared to the native counterparts was not changed. DRPs exhibited virtually the same IgE-binding potency as the native protein.

Digestion of separated Ara h 2 isoforms result in digestion-resistant peptides that resemble structure and IgE-binding from the native allergens, even although the peptide backbone is cleaved. The fact that allergic proteins or peptides survived proteolytic treatment and remains allergenic in vitro it's likely that they will be secreted into biological fluids. This indicates that they are most likely the sensitizing or tolerating agents within an allergic food, and may contribute to original development of allergic disease.

Keywords: digestion-resistance peptides, food allergy, immunoproteomics.

Molecular insights into interactions between isoforms of human guanylate-binding proteins – antipathogenic players of the immune systems

S. Ince, M. Kutsch, S. Shydlovskyi, C. Herrmann
Physical Chemistry I, Ruhr-University Bochum, Bochum, Germany

During evolution, human organism has developed a variety of strategies to protect against pathogens. The innate immune system is the first line in defense. Upon infections the innate immune system upregulates a high number of proteins that in turn can eliminate pathogens and, therefore, inhibit disease progression. Several of the seven human guanylate-binding proteins (hGBP1-7), being members of the dynamin-superfamily and strongly upregulated in response to interferon-γ, have been shown to provide anti-pathogenic actions, among others, against Influenza A virus, Hepatitis C virus, and *Chlamydia trachomatis*. Homo- and heterointeractions of isoforms hGBP1-5 were qualitatively shown to define the subcellular localization of the proteins and intracellular hGBP translocation was shown to be regulated in a nucleotide-dependent, hierarchal manner, whereby prenylated hGBPs (hGBP1, 2 and 5) dominates over non-prenylated GBPs (hGBP3, 4, 6 and 7). However, the understanding of hGBPs networking demands quantitative data on the formation of heterocomplexes of the isoforms.

We used recombinant hGBPs to identify their individual biochemical properties. Specific nucleotide binding affinities, GTPase activities as well as the ability to form nucleotide dependent polymers defined a unique pattern for each isoform. Further, we established two different assays employing either GTPase activity or the polymerization of the hGBPs as a measure for heterocomplex formation. All the investigated hGBPs yielded a stimulated GTPase activity upon homointeractions, meaning low GTP turnover at low concentrations where the protein is expected to be monomer, but maximum activity at higher concentrations where the protein is shown to be dimer. When the hGBP isoforms were pairwise combined, remarkable effects on the GTPase activity were obtained. For instance, hGBP1 made hGBP5 to exhibit maximal GTPase activity even at low concentrations indicating that heterocomplex formation is not only tighter but also capable of stimulating the partner. Further quantifications could be made within the absorbance-based polymerization assay. We monitored that GTP-hydrolysis induces polymerization of prenylated hGBPs, which in turn is inhibited by non-prenylated hGBPs in a concentration dependent manner.

Taken together, the hGBPs interact and mutually influence each other in a finely tuned system, which engages on two fundamental molecular mechanisms: firstly, the GTP hydrolysis properties and secondly, the polymerization and depolymerization. Both are involved in defining the subcellular localization and the function of the hGBPs.

Molecular interactions and possible polyfunctionality of serum blood protein which is associated with inflammation, tumors and autoimmune conditions

D. M. Nikulina, T. B. Vorobyeva, Y. A. Kriventsev, A. A. Gavrilenko, R. A. Bisalieva
Department of Biochemistry, Astrakhan State Medical Academy, Astrakhan, Russian Federation

The name of pregnancy associated alpha2-glycoprotein- α2-PAG (also is pregnansi zone protein – PZP) is empirical name evidence only that he was first discovered in this physiological state. Shortly it was found a small concentration in the blood of healthy persons. Next, in a large clinical material we have found that the synthesis of 2-PAG significantly increases not only during pregnancy, but the inflammation and swelling. This phenomenon is definitely associated with its function.

For establishing function of the α2-PAG, we studied its immunomodulatory properties in vivo on mice. His condition in the blood were studied by immunochemical and physico-chemical properties – by biochemical methods.

Had been revealed communication between rising of α2-PAG level and decreasing of IgA, IgG, TNFα, IL4 and lymphocytes in a blood of patients with inflammatory diseases. Were obtained data on affinity of α2-PAG to estrogen. We have also identified a discrepancy physicochemical parameters α2-PAG in the blood to its molecular weight. In chromatography elution volume α2-PAG coincides with a peak output of alpha2-macroglobulin- MG (fraction 'heavy blood proteins'). MG twice as heavy PAG. Use of detergents indirectly confirms the intermolecular interactions between two proteins with different molecular weights.

© 2014 The Authors. FEBS Journal © 2014 FEBS

To justification the interactions α2-PAG and MG we used the database of proteins SwissModel and Swiss PDB Viewer program for forming putative conformations and studying coinciding for interaction positions non polar amino acids (single and multiple), which are responsible for interaction.

Analysis showed that the location of nonpolar amino acids is often the same position in the range of 1–2. It is possible that certain amino acids may remain on the surface of the tertiary structure of the protein and to be a basis of intermolecular interactions due to of hydrophobic bonds. Is possible that these effects can provide intermolecular interactions (or adhesion effect) which determine the function of the protein.

This work was supported by RFFR grant N Nk 14-04-01075/14.

Keywords: 2-PAG or PZP, associated with inflammation protein, molecular interactions.

Molecular modeling and virtual screening to identify new antifungal compounds against the drug target thioredoxin reductase

A. K. Abadio[1], E. S. Kioshima[2], N. Martins[3], B. Maigret[4], M. Felipe[5]

[1]Cellular Biology, University of Brasília, Brasilia, [2]University of Maringá, Maringá, [3]Embrapa – Genetic Resources and Biotechnology, Brasilia, Brazil, [4]University Henri Poincaré-Nancy I, Nancy, France, [5]University of Brasilia, Brasilia, Brazil

The prevalence of invasive fungal infections has increased steadily worldwide in the last few decades. The development of drugs that act selectively in target pathogenic fungi without producing collateral damage to mammalian cells is a daunting pharmacological challenge. Indeed, many of the toxicities and drug interactions observed with contemporary antifungal therapies can be attributed to non selective interactions with homologous enzyme or cell membrane systems found in mammalian host cells. We selected the potential drug target *trr1*, a gene that encodes for thioredoxin reductase and is conserved in eight human fungal pathogens and absent in humans. The recombinant protein Trr1 of *Paracoccidioides lutzii* was produced by heterologous expression in *Escherichia coli* system. The Trr1 recombinant protein was used for enzymatic assay and antifungal activity in vitro. Moreover, we performed the homology modeling of *P. lutzii* Trr1to predict 3D model and the virtual screening in chemical libraries for select the main small molecules that interact with Trr1 model. Initially, compounds from Life Chemicals was docked with the model by virtual screening simulations. The small molecules that interact with the model were ranked and, among the best hits, 12 molecules were finally selected as putative inhibitors of Trr1. These molecules were synthesized for validation and in vitro antifungal activity assays for *Paracoccidioides lutzii*, *P. brasiliensis*, *Candida albicans* and *Cryptococcus neoformans* were performed. From the molecules tested, 3 of which turned out to harbor inhibitory activity against *Paracoccidiodes* spp. Corroborating these findings we have also detected inhibitory activity of those molecules against the purified recombinant enzyme TRR1 in biochemical assays. Therefore, a rational combination of molecular modeling simulations and virtual screening of new drugs has provided a cost-effective solution to an early-stage medicinal chemistry problem. Consequently, news perspectives were generated for technological development and innovation for new antifungal agents against human pathogens. Financial Support: CNPq (*Conselho Nacional de Desenvolvimento Científico e Tecnológico*) and FAP-DF (*Fundação de Apoio a Pesquisa do Distrito Federal*).

Native stability and the pathway of α1-antitrypsin polymerisation

J. A. Irving[1], I. Haq[1], J. A. Dickens[2], S. V. Faull[1], D. A. Lomas[1]

[1]Wolfson Institute for Biomedical Research, University College London, London, [2]Cambridge Institute for Medical Research, University of Cambridge, Cambridge, UK

Serpins are a family of protease inhibitors whose active conformation is a kinetically stabilised folding intermediate, and includes the abundant plasma protein, α_1-antitrypsin. Upon cleavage of an exposed loop on α_1-antitrypsin by elastase, the central five-stranded β-sheet undergoes a transition to an extremely stable six-stranded form. Mutations can promote this transition in the absence of a proteinase; when accompanied by an intermolecular domain swap, the result is a growing polymer chain of inactive molecules. Polymers result in pathologies with various degrees of severity, and can also be generated experimentally under destabilising conditions, such as at elevated temperatures. Various mutations – both naturally-occurring and rationally-designed – have been described that alter the rate of heat-induced polymerisation, and in some studies these data have been used to infer features of the polymerisation mechanism. However, this approach is overly simplistic, as it does not account for general effects on native stability. Here we show that the temperature midpoint of thermal denaturation reflects the transition of α_1-antitrypsin to an intermediate species, and determine the relationship with polymerisation rates in the presence of stabilising additives and mutations at several different temperatures. This study shows that the effects of mutations on polymerisation are primarily manifested through global changes in native state stability, and seldom through specific structural perturbations of the polymerisation mechanism.

Keywords: polymerisation, serpinopathies, stability.

Nesfatin-1 levels in polycystic ovary syndrome

E. Alp[1], U. Gormus[1], N. Guducu[2], O. Timirci Kahraman[3], S. Bozkurt[4]

[1]Biochemistry, [2]Obstetrics and Gynecology, Istanbul Bilim University Medical School, [3]Molecular Medicine, Istanbul University, Istanbul, [4]Biostatistics, Akdeniz University, Antalya, Turkey

Nesfatin-1 is an hormon synthesized mainly in hypothalamus and several other specific organs regulating eating habits, appetite and is thought to be related to ovarian functions. In our study, we aimed to evaluate nesfatin-1 levels with the other metabolic parameters in the polycystic ovary syndrome(PCOS), a condition that is known to be related to both ovarian functions and obesity. Study subjects were chosen from the women who applied to the Obstetrics and Gynecology Department of Istanbul Bilim University Avrupa Florence Nightingale Hospital. Thirty-five healthy control subjects and 55 PCOS patients were included. Blood samples were obtained in the 3rd-4th days of the menstrual cycle. Luteinizing hormone (LH), Follicle-stimulating hormone (FSH), Free testosterone (FT), Dehydroepiandrosterone sulfate (DHEA-S), Insulin, Fasting blood glucose (FBG), High density lipoprotein (HDL), Low density lipoprotein (LDL), Triglycerides (TG), Sex hormone binding globulin (SHBG) levels were measured; homeostatic model assessment – insulin resistance (HOMA- IR) value was calculated. Nesfatin-1 levels were measured by a competetive inhibition ELISA method. Due to our results, PCOS patients were having lower nesfatin- 1 levels compared to the control group. Additionally, the groups were divided into subgroups according to their BMI and the nesfatin-1 results

© 2014 The Authors. FEBS Journal © 2014 FEBS

were found to be independent of the BMI, we emphasize the necessity of further studies with larger groups to be able to understand the mechanism of nesfatin-1 decrease in PCOS cases.

Neuropathy-associated mutations of alpha-crystallin domain affect the structure and properties of human small heat shock protein HspB1

V. Nefedova, M. Sudnitsyna, N. Gusev
Department of Biochemistry, Moscow State University, Moscow, Russian Federation

Charcot-Marie-Tooth disease (CMT) is peripheral distal neuropathy affecting motor and sensory neurons of peripheral nervous system. About twenty mutations of small heat shock (sHsp) protein HspB1 correlate with development of CMT. HspB1 belongs to the large family of sHsp which are able to prevent aggregation of denatured proteins and demonstrate the chaperone-like activity. The small heat shock proteins possess multiple activities; however, molecular mechanisms underlying induction of neuropathy by mutated HspB1 remain obscure. In order to understand effect of HspB1 mutations in the onset of neuropathy we analyzed structure and some properties of four mutants (G84R, L99M, R140G, K141Q) carrying a single point mutation located in the alpha-crystallin domain.

The data of size-exclusion chromatography, analytical ultracentrifugation and dynamic light scattering indicate that the wild type HspB1 and its K141Q mutant form large stable oligomers with apparent molecular weight of ~560 kDa. At the same time G84R, L99M and R140G mutants form much less stable oligomers tending to dissociate at low protein concentration. In addition large oligomers formed by R140G mutant are very unstable and tend to aggregate. In response to different stimuli HspB1 undergoes phosphorylation by MAPKAP 2 kinase inducing dissociation of large oligomers. Mutations G84R and L99M promote phosphorylation-induced dissociation of HspB1 large oligomers. All mutants analyzed possessed lower in vitro chaperone-like activity than the wild type protein with two model protein-substrates (a-lactalbumin and subfragmet-1 of skeletal muscle myosin). Thus, all mutations analyzed significantly modify the structure and properties of HspB1 and this is probably one of the reasons of development of CMT disease. This research was supported by the Russian Foundation for Basic Research (13-04-00015).

Nicolau Institute of Virology,* [3]*Pathophysiology and Immnunology Department,* [4]*Pathophysiology and Immunology Department,* [1] *Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Introduction: Chronic obstructive pulmonary disease (COPD), ischemic stroke (IS) and viral meningitides (M_VIR) have been associated with systemic inflammation. Pro-inflammatory cytokines and neurotrophins have been recognized as mediators of neuroprotective mechanisms or in airway remodeling processes. In the present work we investigated the serum levels of NT-3 and pro-inflammatory cytokines TNFα and IL-6 in order to identify the similarities and particularities of systemic inflammatory response in these human different pathologies.
Patients and Methods: Serum levels of NT-3, TNFα and IL-6 were investigated by ELISA (kits EuroClone) in the three groups of patients: with chronic disease COPD (n = 30) and acute diseases, IS (n = 30) and M_VIR (n = 30), 2–6 days after admission. The study was conducted in three types of comparative clinical courses: favorable (F), medium (M) and severe (S). Data were statistically analyzed by Student t test; the threshold of significance was considered for $p < 0.05$.
Results: The mean level of NT-3 (pg/ml) was increased in COPD compared to the IS and M_VIR in all clinical courses: (F) 19.2 ± 3.5 versus 14.4 ± 4.9 and 8.3 ± 0.8 / (M) 33.7 ± 31.2 (#) versus 21.8 ± 9.9 and 8.8 ± 0.7 ($p < 0.05$) / (S) 44.2 ± 16.1 (#) versus 14.2 ± 3.5 ($p = 0.016$) and 7.9 ± 0.6 ($p = 0.01$). On the contrary, the mean level of IL-6 (pg/ml) was increased in IS compared to COPD and M_VIR in all the clinical courses: (F) 26.9 ± 8.6 versus 9.4 ± 3.5 ($p = 0.001$) and 2.1 ± 0.7 ($p = 0.05$) / (M) 55.5 ± 24.6 (#)versus 15.1 ± 14.4 and 2.2 ± 0.7 / (S) 35.3 ± 24.3 (#) versus 19.5 ± 16.7 (#) and 11.8 ± 0.9 ($p = 0.0038$). The dispersion of NT-3 and IL-6 responses in a large range of values (#) has been accompanied by persistent responses of TNFα [IS: (M) 158.4 ± 76.5 and (S) 103.2 ± 45.6 / COPD (M) 24.5 ± 17.6 and (S) 40 ± 16.8 / M_VIR (S) 58 ± 17].
Conclusion: Although the pathologies investigated by us are different, the increased mean level of NT-3 and IL-6 shows a strong systemic inflammatory response in IS and COPD as opposed to M_VIR where the inflammatory response is mainly locally. The trend of increasing of systemic NT-3 level in COPD is associated with the progression of chronic disease, while the increasing of systemic IL-6 level in IS is accompanied with acute course complicated. The TNFα persistence indicates the worsening clinical condition and imminent death.

SUN-242
Neurotrophin-3 lung synthesis as a possible fibrosis inducing mechanism in chronic obstructive pulmonary disease

M. Gheorghiu[1], D. Pasarica[1], M.-F. Trandafir[2], T. Trandafir[1]
[1]*Pathophysiology and Immunology Department,* [2]*Student, University of Medicine and Pharmacy, Bucharest, Romania*

Introduction: Chronic obstructive pulmonary disease (COPD), estimated to be the 3rd cause of death in 2020, is characterized by an irreversible and progressive airflow limitation, mucus hypersecretion, inflammatory changes and remodeling of the airway wall. Immunocytochemistry and other evidence suggest that both neurotrophins and their receptors are expressed by a wide variety of component lung cells (nerves, immune cells, epithelium, smooth muscle, fibroblasts and endothelium). As with many other diseases, there is limited information on the role of neurotrophins in pulmonary fibrosis. Neurotrophin-3 (NT-3) is elevated during airway inflammation, because alveolar macrophages, mastocytes and eosinophils expresss NT3, as well as NT3-receptor. This work studies the role of NT-3 in inflammation and regeneration modulation in COPD, the purpose being to emphasize the potential of NT-3 in improving our understanding of the pathophysiology of COPD.
Patients and Methods: NT-3 serum and bronchoalveolar lavage levels were determined in 43 patients with COPD using

© 2014 The Authors. FEBS Journal © 2014 FEBS

ELISA. Inflammatory cytokines interleukin-1β (IL-1β), interleukin-6 (IL-6), Tumoral necrosis factor α (TNF-α) and interleukin10 (IL-10) were determined, too.

Results: A significant increase of serum and bronchoalveolar lavage NT-3 and IL-6 levels was obtained, as well as a positive correlation between these two parameters.

Conclusion: Bronchial smooth muscle cells, local macrophages and neutrophils secrete cytokines, chemokines and growth factors. The expression of NT-3 may be regulated by IL-6, suggesting a dynamic interplay that might have a potential role in airway inflammation. Previous in vitro studies found that human pulmonary fibroblasts constitutively secrete nerve growth factor (NGF) and that NGF secretion is enhanced by proinflammatory cytokines (IL-1β and TNF-α). Our in vivo results suggest that IL-6 enhances NT-3 lung synthesis in COPD, which should result in enhanced production of extracellular matrix components, thus contributing to fibrosis. NT-3 could be used to quantify lung fibrosis in COPD.

NFATc1 is required for imiquimod-induced psoriasis-like skin inflammation in mice

H. Alrefai[1,2], A. Kerstan[3], M. Goebeler[3], E. Serfling[1]
[1]Molecular Pathology, Pathology institut, Würzburg, Germany, [2]Medical Biochemistry, Faculty of Medicine, Mansoura, Egypt, [3]Dermatology, Venereology and Allergy, Wuerzburg University, Würzburg, Germany

Psoriasis is a systemic chronic immunological disease characterized primarily by abnormal accelerated proliferation of the keratinocytes in the epidermal layer of the skin. In psoriasis patients, the precipitating event leads to keratinocytes activation followed by immune cell activation. Also, there is recent evidence that in psoriasis the tolerance towards self antigens is defective. The main players investigated in psoriasis are the effector T cells. However, there is recent evidence that B cells play some role in the disease.

Bregs are a special type of B cells that are believed to have a regulating influence on other B cells and T cells, tuning the immunological response through immunomodulatory cytokines. They serve to keep the immune response in check in case of auto immune diseases and in case of fulminate inflammatory conditions. Their effects are reported on Th1, Th17, $CD4^+$ T cells and monocytes.

NFATs are a family of transcription factors that are highly expressed T cell and B cells. The typical NFAT members have different isoforms due to the use of multiple promoters, several polyadenylation sites and alternative splicing events. NFATc1 is part of the signal transduction pathways that regulates B cell activation and function.

We used the mouse model of IMQ-induced psoriasis-like inflammation, which was first reported by Gilliet in 2004. We induced the psoriasis-like inflammation in wild type (WT) mice, mice that lack NFATc1 in their B cells ($NFATc1^{f/f}$ x mb1-cre) and mice that lack B cells (mb1-cre homozygous mice). The $NFATc1^{f/f}$ x mb1-cre mice showed significantly less IMQ-induced psoriasis-like inflammation than the WT mice. This pointed that NFATc1 is needed for the development of psoriasis. The mb1-cre homozygous mice showed a flared up psoriasis-like inflammation in comparison to the WT mice. This suggested an important role of B cell in psoriasis. Analysis of the $NFATc1^{f/f}$ x mb1-cre mice showed that both Bregs and germinal center B cells were affected favoring the dampened clinical picture in case of mice that lack NFATc1 in their B cells. Investigation of in surface expression of B cells showed that IL-10 is highly expressed upon NFATc1 ablation especially with IMQ treatment. This suggested that IL-10 is an important link between NFAT ablation and less aggressive psoriasis-like inflammation in IMQ treatment.

SUN-244
NLRC3 as a novel regulator of the cryopyrin inflammasome

E. Eren, N. Özören
Molecular Biology and Genetics Department, Bogazici University, Istanbul, Turkey

Inflammasomes are protein complexes which recognize pathogens and activate inflammation. Special attention has been attributed to the Cryopyrin inflammasome due to its wide range of activator molecules and its implication in the physiopathology of several auto-inflammatory diseases. To avoid accidental induction of inflammation, the Cryopyrin inflammasome activation is tightly regulated in the cells. Control mechanisms started to be identified but still other Cryopyrin inflammasome modulators remain to be characterized.

NLRC3, another member of the NLR family, was found to be a negative regulator of T-cell activation, NFκB pathway and STING-dependent cytokine secretion. However, the effect of NLRC3 on the Cryopyrin inflammasome or other inflammasomes is still unknown. We propose that NLRC3 could be a novel regulator of the Cryopyrin inflammasome. For this purpose, we tested NLRC3's effect on Cryopyrin inflammasome activation under overexpression and endogenous conditions and in *vivo* systems.

HEK293FT cells were transfected with different components of the Cryopyrin inflammasome and IL-1β secretion was measured. Whereas transfection of Cryopyrin induced IL-1β secretion in a dose-dependent manner, co-transfection of Cryopyrin and NLRC3 resulted in significantly reduced IL-1β release. Similarly, co-transfection of HEK-ASC-GFP cell lines with Cryopyrin and NLRC3 led to a significant decrease in ASC speck formation. These results were further confirmed in THP-1 cells lines, where IL-1β secretion in response to known Cryopyrin inflammasome activators such as MSU, ATP and Imiquimod was significantly higher in NLRC3 KD stable lines compared to control lines. Moreover, injection of NLRC3 protein in rat's eye treated with LPS decreased IL-1β levels compared to the ones only treated with LPS. In conclusion, we have found that NLRC3 interferes with ASC speck formation and inhibits IL-1β secretion in all systems tested. Thus, NLRC3 is a novel negative regulator of the Cryopyrin inflammasome. The exact molecular mechanism of this inhibition is still under investigation.

Keywords: NLRC3, Cryopyrin, Inflammasome.

Novel Kv1.3 blockers for the treatment of autoimmune diseases

K. Kudryashova, A. Kuzmenkov, O. Nekrasova, A. Feofanov, E. Grishin, A. Vassilevski
Institute of Bioorganic Chemistry, Moscow, Russian Federation

The subset of inflammatory T and B cells with elevated expression level of voltage-gated potassium Kv1.3 channel is a functional marker of autoimmune diseases (multiple sclerosis, type 1 diabetes, rheumatoid arthritis). Inhibition of Kv1.3 channel is an attractive strategy for the treatment of autoimmune diseases without generalized immunosuppression. Peptide toxins found in animal venoms are potent inhibitors of Kv1-family channels, and some of them possess high selectivity to Kv1.3 channel.

The original fluorescent analytical systems developed by us were used to search for Kv1.3, Kv1.1 and Kv1.6 channel blockers in arthropod venoms. The analytical systems are based on (i) expression of hybrid potassium channel KcsA-Kv1.x (x = 1,3,6) in the plasma membrane of *E.coli.*, (ii) fluorescently labeled ligand and (iii) confocal microscopy as a measurement technique. New ligands are recognized and characterized a competitive binding assay. Using these analytical systems we studied dozens of spider and scorpions venoms for the presence of peptides possessing affinity to Kv1 channels. We confirmed the presence of active compounds in *Leiurus quinquestriatus* and *Orthochirus scrobiculosus* scorpion venoms. Six new high affinity Kv1.x (1,3,6) blockers were discovered in addition to 3 known ligands in *Mesobuthus eupeus* scorpion venom. Functional studies of novel peptide toxins are in progress now. They are aimed to clarify pharmacological value of the new blockers.

Novel nanoscale carriers as alternative in further cancer therapy

Y. Senkiv[1], N. Boiko[1], A. Riabtseva[2], A. Zaichenko[2], W. Berger[3], R. Stoika[1]
[1]*Departmant of Regulation Cell Proliferation and Apoptosis, Instutute of Cell Biology NAS of Ukraine,* [2]*Department of Organic Chemistry, Polytechnic National University of Lviv, Lviv, Ukraine,* [3]*Departmant of Experimental Cancer Therapy Development, Institute of Cancer Research, Vienna, Austria*

Severe toxic side effects and drug resistance are the major limitations of doxorubicin (Dox), one of the most potent anticancer agents in clinical use. Nanocarrier preparations offer the opportunity to overcome these drawbacks, which is reflected in the clinical approval of two liposomal Dox preparations. Additionally, there are many attempts to enhance the activity of Dox against multidrug resistant (MDR) cancer cells. However, most of these strategies resulted in the increased uptake of Dox in resistant cells, only, while it remained unchanged in chemo-sensitive cells.

Here, we present a new polymeric-phospholipidic hybrid delivery system which distinctly enhanced the accumulation and activity of Dox in all tested cancer cell lines including several MDR cell models. Notably, the resistance levels against Dox were reduced from about 6-fold to about 2-fold. Moreover, the new nanocarriers were shown to rapidly (within 10 min) and effectively transport Dox into resistant as well as sensitive cancer cells. Consequently, treatment with the new Dox-containing nanocarriers resulted in effective cell cycle arrest in G2/M phase and ROS-induced cell death induction.

Finally, the new nanocarriers were tested against NK/Ly lymphoma and L1210 leukemia cells in vivo. Since rather low drug concentrations were used in these tests (0.1 mg/kg), the treatment schemes were well tolerated and the mice did not exhibit any symptoms of toxicity, such as fatigue, or significant weight loss even in the Dox-receiving groups. Treatment with Dox at these concentrations led to transient stop of tumor growth (indicated by increased body weight) and, thus, prolonged the mean survival of NK/Ly bearing mice from 21 to 39 days. The nanocarrier distinctly increased this activity resulting in disease remission and cure, which was indicated by restored body weight of the NK/Ly-bearing mice to the initial levels. Notably, even after end of PC-Dox treatment no increase in body weight was observed. Thus, at day 60 (end of experiment) all of the PC-Dox-treated mice were still alive and, thus, classified as 'cured animals'. Similar results were observed in the L1210 model as depicted in, where a dose of 0.1 mg/kg PC-Dox resulted in complete loss of tumor-mediated animal death. In both cell models, the nanoformulation of Dox resulted in 100% cured animals already at low concentrations (0.1 mg/kg), while free Dox solely extended survival time.

SUN-248
Novel sea anemone peptide inhibitor of acid-sensing ion channel 3 (ASIC3)

D. Osmakov, Y. A. Andreev, S. G. Koshelev, S. A. Kozlov, E. V. Grishin
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

The ASIC3 channel belongs to a family of sodium-selective acid-sensing ion channels (ASIC), activated by a drop of extracellular pH. ASIC3 channels are predominantly expressed in peripheral sensory neurons and play an important role in acidic and inflammatory pain stimuli during pathological conditions. ASIC3 channels generate a transient current followed by a sustained component in response to a drop of extracellular pH. Animal venoms already proved themselves as useful tools for the study of structural and functional features of various ion channels. Only two selective peptide inhibitors of ASICs is known to date. It is Psalmotoxin 1 (PcTx1), a potent and specific inhibitor of homomeric ASIC1a channels from a tarantula venom, and APETx2, an inhibitor of homomeric and heteromeric ASIC3 channels from a sea anemone venom.

Three novel peptides of 29 amino acid, cross-linked by two disulfide bridges, were isolated from the sea anemone *Urticina grebelnyi* venom. The structure of the gene encoding the shared precursor protein of the identified peptides was determined. One peptide, Ugr 9-1, produced a reversible inhibition effect on both the transient and the sustained current of human ASIC3 channels expressed in *Xenopus laevis* oocytes. Recombinant Ugr 9-1 was produced through the prokaryotic expression system with the with the final yield of about 8 mg/liter of cell culture. The identity of the recombinant Ugr 9-1 and the natural peptide was confirmed by the chromatographic as well as the electrophysiological methods. Ugr 9-1 completely blocked the transient component (IC_{50} 10 μM) and partially (~50%) inhibited the amplitude of the sustained component (IC_{50} 1.5 μM) of the ASIC3 current. Also Ugr 9-1 showed no activity on the other ASIC isoforms: ASIC1a, ASIC1b, and ASIC2a Using in vivo tests in mice, Ugr9-1 significantly reversed inflammatory and acid-induced pain. It is *worth noting that* the structure and the mechanism of action of this peptide differ from the well known sea anemone toxin APETx2.

NMR spectroscopy revealed that Ugr 9-1 has an uncommon spatial structure, stabilized by two S-S bridges, with three classical β-turns and twisted β-hairpin without interstrand disulfide bonds. This is a novel peptide spatial structure that we propose to name boundless β-hairpin. *It is interesting to note that* two other peptides, Ugr 9-2 and 9-3, don't modulate ASIC3 activity but have

© 2014 The Authors. FEBS Journal © 2014 FEBS

significant homology with the active Ugr 9-1 peptide and evidently have the same fold type. All together, the three novel peptides are a visual confirmation of the combinatorial biochemistry model, according to which several sequence alterations of peptides with similar folds result in selectivity to different cellular receptors.
Keywords: acid-sensing ion channel, inflammatory pain, peptide structure.

Nutritional modification of endoplasmic reticulum stress and inflammasome activity by a bioactive lipokine prevents atherosclerosis

I. Çimen, **S. Koyuncu**, E. Erbay
Molecular Biology and Genetics, Bilkent University, Ankara, Turkey

The prevalence of obesity has increased epidemically, with little hope for effective treatments on the horizon. Rising along with obesity is an aggregation of co-morbidities including insulin resistance, diabetes, hepatosteatosis, dyslipidemia, hypertension and atherosclerosis, collectively known as the metabolic syndrome. Signaling pathways that lie at the interface of metabolism, inflammation and stress are altered by excessive exposure to lipids and other nutrients and profoundly influence these chronic diseases. Despite intense research into the crosstalk between metabolic, inflammatory and stress pathways, there remains a gap in our knowledge regarding the nutritional modification of such crosstalk. What are the nutritional cues that can beneficially modify this crosstalk? Bioactive lipokines offer tools for nutritional modification of the crosstalk between metabolism, inflammation and stress pathways that are major contributors to the formation of atherosclerosis.

Recent studies showed that bioactive lipid species have profound effects on metabolism. For example, palmitoleate (PAO) can act as a lipokine – a lipid that is generated from the adipose tissue through *de novo* lipogenesis and exert endocrine effects in distant tissues such as the liver and skeletal muscle. PAO can suppress inflammation in the adipose tissue and improve insulin signaling in skeletal muscle and liver. The impact of PAO on atherosclerotic lesions is also highly relevant to cardiovascular diseases; the links between nutrients, stress pathways and inflammation are central to atherogenesis and its complications, but very little is known about nutritional modification of this crosstalk. Our studies show that PAO can inhibit lipid-induced endoplasmic reticulum stress, inflammasome activity, pro-inflammatory cytokine secretion in macrophages and prevent atherosclerosis in mouse models. Our findings have important implications for unraveling the pathogenesis of metabolic and inflammatory diseases and can facilitate generation of novel therapeutic approaches utilizing bioactive lipokines in these diseases.

Obesity protects heart but increases lung injury by endotoxin inflammation

T. M. D. Lima, M. C. Maldonado, R. Petroni, D. Barbeiro, F. G. Soriano, F. Pinheiro da Silva
Emergency Medicine, University of São Paulo, Sao Paulo, Brazil

Purpose/Objective: Sepsis is a severe disease that represents a significant healthcare burden worldwide, while obesity has reached epidemic proportions over the last few decades. Although the mechanism is uncharted, it is known that obesity increases morbidity and mortality in sepsis through its multiple effects on many organ systems, including heart and lungs. Our aim was to investigate the effects of obesity in heart and pulmonary inflammatory process in an experimental model of endotoxemic shock.
Material and Methods: Animals were fed a high fat diet (30% of fat) for 6 weeks and then injected with 15 mg/kg LPS i.p. They were euthanized after 6, 24 and 48 hours. Inflammation was characterized by measurement of plasma and tissue cytokines. Quantification of adipokines and adhesion molecules were performed by ELISA.
Results: Obesity decreased the survival rate of the animals 24 hours after LPS injection. There was higher plasma concentration of IL1-beta, IL-6 and TNF-alpha in these animals. Furthermore, LPS increased resistin plasma levels, and this effect was more evident in obese mice. Adiponectin levels were higher in obese mice, and this difference was abolished by LPS injection. Endotoxemia resulted in increased concentration of IL-6, IL-1beta and MIP2 in obese mouse lungs, but decreased IL-6 and IL-1beta in their heart. The protective effect in the heart may be related to decreased expression of adhesion molecules (ICAM and VCAM). Although lung inflammation was exacerbated in obese mice, no difference was observed in collagen deposition.
Conclusion: Obesity may be an additional complication factor in sepsis induced pulmonary inflammation.

Oligopeptidase B from *Serratia proteamaculans*: structural basis for cold adaptation

A. Nikolaeva[1,2], T. Rakitina[1,3], A. Mikhailova[3], M. Ovchinnikova[3], D. A. Korzhenevskiy[1], D. Karlinsky[3], A. Lipkin[1], L. Rumsh[3]
[1]NBIKS-Center, NRC Kurchatov Institute, [2]A.N. Bach Institute of Biochemistry RAS, [3]Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Oligopeptidase B (opdB) is a ‘processing peptidase’ from the prolyl oligopeptidase family of serine peptidases present in bacteria, protozoa and plants. OpdB is known to be an important virulence factor of bacterial and protozoan pathogens, causing severe diseases that are difficult to diagnose and treat: Chagas disease, sleeping sickness and other trypanosome infections as well as leishmaniasis that make the enzyme a promising therapeutic target.

OpdB from the nonpathogenic, psychrotolerant gram-negative microorganism *Serratia proteamaculans* (PSP) is the first known psychrophilic enzyme of this class. As a result this protein may serve as a model enzyme for the study of the pathogenesis of many infectious diseases or for drug development, since unlike its highly pathogenic mesophilic counterparts PSP poses no danger to researchers due to its thermal inactivation at 37°C.

The aim of the study is to reveal the mechanism of cold adaptation of PSP in the context of its structure-function features. Here we applied experimental and bioinformatic approaches to highlight the different aspects of the PSP structure associated with cold adaptation and studied the impact of different external and internal factors on thermostability and activity of recombinant PSP.

The positive effect of glycerol on PSP thermostabilization was revealed using the Thermofluor Stability Assay, though ionic strength and calcium ions caused the acceleration of PSP unfolding. The findings were in good agreement with the results of high-sensitivity differential scanning calorimetry and the residual enzymatic activity determination following heat treatment at 37°C. The full-sized PSP and its truncated form lacking an N-terminal 100 amino acid loop were produced in *E. coli* and used for crystallization screening and structural studies.

Palmitoylation of proteins in LPS-stimulated cells analyzed by click chemistry

J. Dembinska, P. Roszczenko, K. Borzęcka, A. Pórciennikowska, A. Sobota, K. Kwiatkowska
Cell Biology, Nencki Institute of Experimental Biology, Warsaw, Poland

Lipopolysaccharide (LPS) is a component of the outer membrane of Gram-negative bacteria. During bacterial infection, LPS is bound in the serum by LPS-binding protein (LBP) which delivers LPS to CD14 protein of the plasma membrane in macrophages. CD14 transfers LPS to the TLR4/MD-2 complex which subsequently triggers two signaling pathways, MyD88- and TRIF-dependent one. Production of pro-inflammatory mediators follows. Our previous studies indicated that Lyn kinase is among key factors controlling TLR4-triggered signaling. Taking into account that both CD14 and Lyn kinase are anchored in sphingolipid- and cholesterol-rich rafts of the plasma membrane, these membrane regions are likely to contribute to TLR4 signaling. Among few factors facilitating interaction of proteins with rafts is their acylation with palmitic acid (C:16). Therefore, we aimed to examine whether palmitoylation of Lyn, and possibly other proteins, affects pro-inflammatory responses to LPS.

To examine the importance of protein palmitoylation in LPS-induced signaling, RAW264 cells were incubated with 2-bromopalmitic acid (BPA), an inhibitor of palmitoyl transferase. An exposure of RAW264 cells to 50–250 μM BPA inhibited in a dose dependent manner the production of TNF-α and RANTES in cells stimulated with 100 ng/ml LPS. These two cytokines were chosen for analysis because they are generated in MyD88- and TRIF-dependent manner, respectively. BPA at 250 μM inhibited also significantly activation of NFκB indicated by IκB phosphorylation in LPS-stimulated cells. In an attempt to identify proteins palmitoylated in LPS-stimulated cells, a click chemistry was applied. For this, cell were metabolically labeled with ω-alkynyl-palmitate analog of palmitic acid, and after lysis, subjected to 'click reaction' with azido-azo-biotin. Subsequently, labeled proteins were immunoadsorbed on streptavidin beads, eluted with sodium dithionite which cleaves azido-azo-biotin. Eluted proteins were separated by SDS-PAGE, transferred onto nitrocellulose and probed with antibodies against selected proteins, including Lyn. We detected palmitoylation of Lyn in resting cells which was increased after stimulated with 100 ng/ml LPS for 1 h. LPS-induced palmitoylation of proteins was inhibited in the presence of 125 μM BPA.

Taken together our data indicate that palmitoylation of proteins, including Lyn kinase, can control TLR4-triggered signaling.

Keywords: click chemistry, lipopolysaccharide, protein palmitoylation.

Pancreatic β-cell glycotoxicity: alterations in ERp46 expression and the role of glucagon-like peptide analogues

E. Lampropoulou, A. Lyberopoulou, A. Charonis
Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Background: Diabetes Mellitus is characterized by peripheral insulin resistance, hyperglycaemia and defective insulin secretion. Insulin producing pancreatic beta cells are equipped with a highly developed endoplasmic reticulum (ER) and thus are affected by ER stress under hyperglycaemic conditions. We have previously studied the influence of high glucose on cultured β-cells in vitro. Proteomic analysis revealed a number of proteins involved in glucose toxicity, while further biochemical analysis identified the endoplasmic reticulum protein ERp46 as a molecule with a possible role in insulin production at the post-translational level. In addition, the involvement of incretin hormone glucagon-like peptide 1 (GLP-1) in diabetes proposes that incretin-mimetic compounds may be among the optimal choices in future therapeutic interventions; therefore their effects on various aspects of the pathogenesis of diabetes mellitus should be explored in detail.

Aim: Based on the above, we examined the possible involvement of ERp46 in insulin production and the effect of the GLP-1 analogue liraglutide on the expression of ERp46 in vitro, in β-cells cultured under high glucose conditions and in vivo, in the mouse db/db diabetic model, where pronounced hyperglycemia is a key characteristic.

Results: Confocal microscopy revealed areas of co-localization of ERp46 and pro-insulin in pancreatic islets. In order to explore the possible interaction between ERp46 and insulin immunoprecipitation was used. In extracts from cultured β-cells, antibodies against insulin co-precipitated ERp46 and antibodies against ERp46 co-precipitated insulin, as shown by Western blotting. Furthermore, β-cells cultured in high glucose conditions exhibited a 2-fold decrease in ERp46 expression, while treatment with the GLP-1 analogue liraglutide restored ERp46 levels, leading to a 2.5-fold increase of ERp46. In the diabetic mouse model db^{-}/db^{-}, ERp46 expression was reduced in pancreatic islets, as documented by morphological and biochemical techniques. This decrease was abolished after treatment with the GLP-1 analogue in a dose-dependent manner.

Conclusions: We propose that since ERp46 is a member of the disulfide isomerases family, it is likely to play a key role in insulin biosynthesis and its reduction under high glucose conditions may be a novel contributor to the glycotoxicity of β-cells. In addition, the GLP1 analogue liraglutide seems to interfere in this process and may exert its beneficial effects in diabetes by affecting insulin production via restoration of ERp46 expression.

Paraoxonase activities in depending on the gender and tobacco smoking

M. Ściskalska, H. Milnerowicz
Department of Biomedical and Environmental Analysis, Faculty of Pharmacy, Wroclaw Medical University, Wroclaw, Poland

Paraoxonase (PON) is high density protein-attached (HDL-attached) extracellular esterase, which contributes the protection of HDL against peroxidation. PON is known to have antioxidative and anti-inflammatory properties against oxidative stress from tobacco smoke.

The aim of the study was to investigate a possible association between PON activities and lipids peroxidation in persons exposed to tobacco smoke.

The investigations were performed in the serum of 58 healthy persons, who were in similar age (23.73 ± 4.83 years) and body mass index (21.49 ± 2.87 kg/m^2). Data about smoking were verified by the determination of cotinine concentration – the metabolite of nicotine (ELISA method). The concentrations of total cholesterol, HDL and triglycerides were determined by spectrophotometric methods. Low density protein (LDL) concentration was calculated using Friedewald formula. PON

© 2014 The Authors. FEBS Journal © 2014 FEBS

activity was measured by spectrophotometric method using paraoxon (phosphotriesterase activity, PON-P), phenyl acetate (aryloesterase activity, PON-A) and dihydrocoumarin (lactonase activity, PON-L) as substrates.

It was shown a statistically significant an increase in PON-P activity in the group of non-smoking women compared to non-smoking men (122.5 ± 58.7 and 80.9 ± 41.2 U/l, respectively). An increased PON-A and PON-L activities in men compared to women (PON-A: 200.5 ± 29.2 and 167.1 ± 34.3 U/l, PON-L: 12.7 ± 3.0 and 9.6 ± 2.1 U/l, respectively) in smokers groups were noted. It was shown a decreased PON-P activity in smokers (65.8 ± 21.6 U/l) compared to non-smokers in the groups of women. An increase in PON-A and PON-L activities in smokers compared to non-smokers (PON-A: 164.4 ± 31.3 U/l, PON-L: 10.2 ± 1.8 U/l) in men groups were shown. The links between LDL concentration and PON-P activity (r = 0.8214, p = 0.0234 in the group of non-smoking women) was observed.

PON is a sensitive maker, which activity is dependent on the gender and it can be modulated by oxidative stress resulting from tobacco smoke. Depending on the gender, various activities of PON are engaged in the protection against oxidative stress induced by tobacco smoke.

Keywords: gender, paraoxonase, tobacco smoke.

Pathogenic and non-pathogenic Simian immunodeficiency virus (SIV) infections induce host DNA methylation changes

S. Jochems[1,2], N. Tchitchek[3], N. Huot[3], B. Targat[3], M. Ploquin[3], R. LeGrand[3], J. Tost[4], B. Jacquelin[1], M. Müller-Trutwin[1]
[1]*Unité de Régulation des Infections Rétrovirales, Institut Pasteur,* [2]*University of Paris Diderot, Sorbonne Cité, Paris,* [3]*Division of Immuno-Virology, CEA, Fontenay-Aux-Roses,* [4]*Laboratory for Epigenetics and Environment, CNG, Evry, France*

Introduction: In human immunodeficiency virus (HIV) infection, a chronic state of immune activation leads to a progressive depletion of $CD4^+$ T cells, culminating in AIDS in the absence of treatment. SIV infection in macaques (MAC) leads to a disease profile resembling that of humans, while SIV infection of its natural hosts, such as African green monkeys (AGM), is non-pathogenic. AGM downmodulate the excessive immune activation by the end of acute infection, unlike MAC and humans, and maintain this control their entire lifespan. This control is especially pronounced in lymph nodes and associates with low levels of viral replication locally. Here, we investigated whether DNA methylation is involved in the immune and/or viral control of SIV-infected AGMs.

Materials and Methods: We intravenously infected five AGM and five MAC with SIVagm.sab92018 and SIVmac251, respectively. Before infection and at days 14 and 65 post infection (p.i.), lymph nodes were collected. $CD4^+$ cells were isolated from these lymph nodes, DNA was extracted and a bisulfite-treated DNA library was constructed for each of the 30 samples. Samples were sequenced on a Hiseq2000 (Illumina) and BSMAP was used to align reads to reference genomes and estimate methylation levels. Differentially methylated regions (DMRs) were defined using windows of 20 base pairs, q-value < 0.01 and a methylation difference of at least 40%.

Results: For each sample, 85% of all cytosines were covered. SIV infection induced methylation changes in both species. For AGMs, 84 hyper- and 35 hypo-DMRs (19 and 11 genes affected (DMGs)) were identified at day 14 p.i. At day 65 p.i., 55 hyper- and 111 hypo-DMRs (22 and 23 genes) were identified. For MACs, 411 hyper- and 193 hypo-DMRs (96 and 71 genes) were

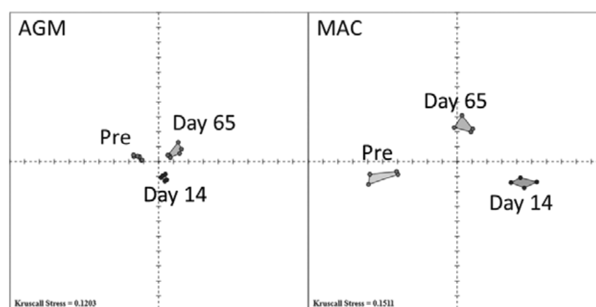

Fig. 1. Multidimensional scaling profiles of the DMRs in AGM and MAC. Each dot is the methylome profile of a biological sample. Panels are scaled to size.

identified at day 14 p.i. and 98 hyper- and 166 hypo-DMRs (42 and 41 genes) at day 65 p.i. The samples segregated per time-point based on the list of DMRs (Fig 1), showing DNA methylation was dynamic during infection. Among the DMGs in MAC were immune genes, e.g. *IRF4*, *RUNX3*, *IL6R* and *NLRP11*, as well as other genes as *MAP4K5*, *IGF2R* and *USP2*. For AGM, *CD37*, *TRAC* and *MAP3K11* were among the DMGs. Proviral genomes were not methylated. We are currently integrating these results with transcriptomic analysis to analyze the effect of these different methylation profiles on gene expression. Concluding, SIV infection modifies the host methylome more deeply in pathogenic than in asymptomatic lentiviral infection.

Pathological changes in hepatic tissue following scorpion envenomation: involvement of oxidative stress and inflammation-related mediators

S. Adi-Bessalem, F. Laraba-Djebari
Department Cellular and Molecular Biology, USTHB, Faculty of Biological Sciences, Algiers, Algeria

Hepatic inflammation is a common finding during liver diseases including scorpion venom-induced liver damage. The inflammatory phenotype can be attributed to the innate and adaptive immune response generated by Kupffer cells, monocytes, neutrophils, and lymphocytes. The exact mechanism of the triggering of the inflammatory response following scorpion envenomation is still not completely understood and several related events have been suggested to be involved.

The purpose of this study is to assess *in-vivo* hepatic inflammatory response and to evaluate organ toxicity and oxidative damage induced by scorpion venom in an experimental model *envenomated* with Algerian scorpion venom *Androctonus australis hector* (Aah).

This study showed that envenoming with Aah venom caused an inflammatory reaction, characterized by vasodilatation and increased the permeability of the hepatic vessels. This event was accompanied by edema-forming as assessed by the increased liver index and also by an increase in cell infiltration, phagocytes including neutrophil and eosinophil cells as indicated by the increase of myeloperoxidase and eosinophil peroxidase activities. Increase of these immune cell levels results in an important release of reactive oxygen intermediates such as H_2O_2 and nitrogen reactive species. The excessive release of nitric oxide and reactive oxygen species, leads to severe imbalanced redox status with altered or insufficient antioxidant systems, demonstrated by

© 2014 The Authors. FEBS Journal © 2014 FEBS

the reduction of the hepatic glutathione level, superoxide dismutase and catalase activities.

Our findings showed also that the immune response induced by scorpion venom is characterized by *increased lymphocyte count* associated with highly production of percentages of Thelper Th1 (IL-2, IFN-γ) and Th2 (IL-4, IL-10) cytokines-in peripheral blood. These results suggest that cytokines produced during the inflammatory process intensify the level of oxidative stress caused by leukocytes, which may have serious consequences for liver membrane integrity.

Envenomed mice displayed also hepatic alterations marked by hemorrhage, edema and inflammatory cell infiltration. These tissue alterations caused by Aah venom are correlated with severe concomitant increase of metabolical enzymes in sera indicated by the increased plasma levels of alanine aminotransferase and aspartate aminotransferase activities which are usually correlated with the intensity of tissue damage.

In conclusion, pathophysiological changes occurring in the liver may be mediated, in part, by cytokines and cytotoxic leukocyte-derived product release and possibly reactive oxygen/nitrogen species.

Peptidome profiling of gingival crevicular fluid by MALDI-TOF/TOF mass spectrometry

D. Falcone, M. Preianò, G. Maggisano, C. Arturi, S. Paduano, R. Savino, R. Terracciano
Health Science, University of Catanzaro 'Magna Graecia', Catanzaro, Italy

Mass spectrometry (MS) represents a promising tool for novel biomarker and eventually new druggable targets discovery [1]. As a part of an ongoing project aimed to the detection of biomarkers in human bodily fluid [2–4], we are now investigating gingival crevicular fluid (GCF), an exudate that can be collected from the gingival sulcus by a minimally invasive procedure. The composition of the GCF is highly diversified and the analysis of its specific constituents provides a quantitative biochemical indicator of the local cellular metabolism that reflects a person's periodontal health status [5]. Because of its sample size, limited to sub-microliter volumes, identification of GCF protein composition by classical biochemical methods has always been limited. To ensure optimized protein extraction from GCF, a novel protocol was developed. After informed consent was obtained, GFC was collected from 5 healthy and 5 gingivitis subjects by paper strips. MALDI-TOF peptidomic profiles of healthy and gingivitis subjects were then compared. Five peptides were found to be significantly more intense in gingival subjects in comparison to healthy individuals.

The pattern of five peptides was identified by both MALDI-TOF/TOF MS and 1-DE followed by MALDI-TOF/TOF MS for molecular weights over 4000 Da. The identified biomarkers included proteins involved in inflammation and immunological processes.

PI3K associated with the IgG mediated phagocytic receptor complex in mouse RAW 264.7 macrophages

T. Thavarajah, J. Marshall
Department of Chemistry and Biology, Faculty of Science, Ryerson University, Toronto, Canada

The circulating blood ligand Immunoglobulin G (IgG) binds to foreign antigens via its variable domain and its Fc domain is recognized by its Fc receptor on macrophages that trigger phagocytosis, which is required for engulfment of bacteria and microscopic particles. The IgG-Fc receptor complex from RAW 264.7 macrophages was analyzed using Live cell Affinity Receptor Chromatography (LARC) that resulted in the detection of phosphoinositide 3-kinase (PI3K) with the activated receptor complex by liquid chromatography and tandem mass spectrometry (LC-ESI-MS/MS). Computation with SQL, statistical analysis with R revealed specific proteins that overlayed the previously existing genetic and biochemical literature using STRING that revealed the network of PI3K associated proteins of the Fc receptor complex. PI3K were shown to be specifically associated with the activated receptor complex and was detected 78 times compared to about three times in the non-specific controls or other ligands such as BSA, and oxLDL that served as controls. The PI3K proteins captured by LARC were compared to immunoaffinity chromatography (IAC) of the Fc receptor complex from crude homogenates that was not as effective. Staining of RAW cells by anti-PI3K antibody resulted in the detection of staining on the plasma membrane during phagocytosis compared to secondary antibody alone as shown with a laser scanning confocal microscope. Western blotting was used to confirm the specificity of the PI3K antibodies. We screened the effect of the receptor specific PI3K isoforms with silencing RNA (siRNA) that was transiently transfected into RAW macrophages alongside scrambled siRNA controls to assay their effect on the phagocytosis of IgG opsonized microbeads. Treatment of RAW cells with range pharmacological inhibitors including wortmannin, LY24002, and ZSTK474 prevented the phagocytosis of IgG microbeads as measured by laser confocal microscope. The dose of inhibitor required to achieve knockdown was consistent with the siRNA data that indicated PI3KC2G is the key isoform for IgG mediated phagocytosis in RAW macrophages.

Plant proteins with medically important properties: structural studies of three members of the β-trefoil family that function as serine protease inhibitors and/or as lectins

A. Wlodawer[1], D. Zhou[1], A. Gustchina[1], R. D. S. Ferreira[2], Y. A. Lobo[2], D. Hansen[2], M. L. V. Oliva[2]
[1]Macromolecular Crystallography Laboratory, National Cancer Institute, Frederick, MD, United States, [2]Departamento de Bioquímica, Universidade Federal de São Paulo, São Paulo, SP, Brazil

Three related plant proteins that belong to the β-trefoil family, which includes Kunitz-type serine protease inhibitors, have been investigated by X-ray crystallography as well as by biochemical and biophysical techniques. Two of them are potent inhibitors

© 2014 The Authors. FEBS Journal © 2014 FEBS

of trypsin-related enzymes. EcTI, isolated from the seeds of *Enterolobium contortisiliquum*, inhibits the invasion of gastric cancer cells through alterations in integrin-dependent cell-signaling pathway. BbKI, found in *Bauhinia bauhinioides* seeds, is a kallikrein inhibitor with a reactive site sequence similar to that of kinins, the vasoactive peptides inserted in kininogen moieties. A much weaker protease inhibitor isolated from the bark of *Crataeva tapia* tree (CrataBL) also functions as a lectin. We determined high-resolution crystal structures of free EcTI and in complex with bovine trypsin, in the process re-determining the amino acid sequence. A comparison of the EcTI-trypsin complex with the complexes of related Kunitz inhibitors has shown that rigid body rotation of the inhibitors by as much as 15° is required for accurate juxtaposition of the reactive loop with the active site while preserving its conformation. Modeling of the putative complexes of EcTI with several serine proteases and a comparison with equivalent models for other Kunitz inhibitors elucidated the structural basis for the fine differences in their specificity, providing tools that might allow modification of their potency towards the individual enzymes. The structure of free BbKI was determined at high resolution, showing that the presence of disulfide bonds is not necessary for stabilization of the fold of the members of this family. We have also determined the high-resolution crystal structures of two different crystal forms of glycosylated CrataBL and identified dimers of the protein forming the crystals. CrataBL shows relatively weak inhibitory activity against trypsin and is more potent against Factor Xa, but not active against a number of other serine proteases. We have shown that, as a lectin, CrataBL binds only sulfated oligosaccharides, most likely heparin and its derivatives. We have observed that addition of CrataBL to DU145 and PC3 prostate cancer cell lines leads to their apoptosis, with release of mitochondrial cytochrome *c* through activation of caspase-3. The viability of these cell lines was also impaired by BbKI. Further studies aimed at more complete elucidation of the structural basis of the anti-cancer activities of these β-trefoil family members are in progress.

Potential novel biomarker from iTRAQ analysis between pre-chemotherapy and post-chemotherapy serum of metastatic osteosarcoma patients

S. Ab-Rahim[1], A. Mansor[2], Z. Roslan[3], E. Omar[1], K. M. Zahari[1], M. Muhamad[1], T. Kamarul[4]
[1]*Faculty of Medicine, Universiti Teknologi MARA, Sungai Buluh,* [2]*NOCERAL, Department of Orthopaedic Surgery, Faculty of Medicine, University of Malaya, Kuala Lumpur,* [3]*Institute of Molecular Medicine and Biotechnology, Faculty of Medicine, Universiti Teknologi MARA, Sungai Buluh,* [4]*NOCERAL, Department of Orthopaedic Surgery, Faculty of Medicine, Universiti Teknologi MARA, Kuala Lumpur, Malaysia*

Osteosarcoma (OS), a malignant bone tumour occurs commonly in children and young adults between the ages of 10–30. Although the standard treatment for OS advances has significantly improved OS patient survival rate, its poor prognosis continues to remain as major problem in managing the disease. In this study, we have conducted a series of systematic analysis to identify the novel proteins associated with the metastatic progression of human OS using a 4-plex iTRAQ analysis. Pooled serum samples were collected from patients diagnosed with metastatic osteosarcoma at two stages (pre- and post-chemotherapy) and they were actively monitored for at least 5 years. Approximately 217 proteins with 104214 spectra were analysed. The PANTHER analysis revealed presence of many plasma proteins involved in biological processes such as cellular component organization or biogenesis (39.4%), cellular process (35.4%), biological regulation (20.0%) and immune system process (29.3%). In addition, these proteins have also shown to be significantly altered in their expression at pre- and post-chemotherapy patients as compared to the control such as C-reactive proteins, vascular adhesion molecule-1 (VCAM-1) and gelsolin. To date, this study is the first differential protein expression study on metastatic osteosarcoma patients' serum at different stages for proteome comparison. We have successfully generated a comprehensive data on the differentially expressed protein. The comparative study results showed a significant amount of proteins expression that has been altered. The results could provide a new insight in the OS biological processes and can be used to identify potential biomarkers for better OS prognosis.

Prevalence of HCV infection among Thalassemia patients; a perspective from a multi-ethnic population of Islamabad region

J. I. Dasti[1], S. G. Uddin[1], M. S. Malik[2]
[1]*Microbiology,* [2]*Animal sciences, Qauid-i-Azam University, Islamabad, Pakistan*

In Pakistan consanguineous marriages, high birth rates, and large population result in high number of thalassemic patients and according to an estimate, each year approximately 5000 newborns are affected due to this genetic disorder. Management of thalassemia is primarily based on regular blood transfusions that results in iron overload and transfusion transmitted infectious diseases. Presented here is a study based on 95 thalassemic cases, a formal consent of the patients was obtained and necessary data was collected including demographic location, clinical representation and family history of these individuals. Altogether, 96% of these patients were of beta thalassemia major, based on serological findings 49% were confirmed as anti-HCV positive. Upon dividing data into two groups, thalassemic only and thalassemic with HCV infection, mean ferritin levels were calculated for both groups, statistical analysis showed a random distribution of ferritin levels, though gender wise analysis showed female patients have relatively higher ferritin levels in comparison to male patents however, the differences were not statistically significant (t-test = 1.203; $p = 0.2319$). Similarly, a random distribution of Hepatitis C was observed regarding ethnic background, demography, socioeconomic status and ABO blood grouping of these patients. Prevalence of HCV was found more common among males 53% in comparison to females 45% and a direct association of age, number of blood transfusion and the prevalence of HCV among these patients was confirmed. Overall, associated clinical complications in these patients included hepatomegaly, splenomegaly and splenectomy. Despite the fact that in many countries standardized screening procedures for the blood related products were already outlined in 1990s higher prevalence rates of HCV among thalassemic patients requires greater attention.

Preventing pathogenic ordered aggregation of α1-antitrypsin using an engineered single chain antibody fragment

N. Motamedi Shad[1], M. Liedtke[1], S. V. Faull[1], J. Perez[2], E. Miranda[3], I. Haq[1], J. A. Irving[1], D. Lomas[1]
[1]Internal Medicine, University College London, London, UK, [2]University of Malaga, Malaga, Spain, [3]University of Rome, La Sapienza, Rome, Italy

Alpha-1-antitrypsin (AAT) is a protease inhibitor that is mainly produced by hepatocytes and secreted into the circulation. It prevents excessive proteolytic damage by the enzyme neutrophil elastase in the lung. Most individuals have a normal 'M' allele of the SERPINA1 gene that encodes AAT. The Glu342Lys (Z) mutation is the most common severe deficiency allele in Europe and causes the synthesized AAT to self-associate into ordered polymers. These polymers are sequestered within the endoplasmic reticulum of hepatocytes and are associated with liver disease. Nearly half of AAT-deficient adults over 50 have pathological features of liver cirrhosis and occasionally hepatocellular carcinoma. The concomitant lack of circulating AAT predisposes to early onset emphysema. Severe cases of emphysema are treated with AAT replacement therapy where purified AAT is given as a weekly intravenous infusion. No other therapies or alternatives to this costly and partly controversial approach are currently available. In seeking new therapeutic strategies to prevent AAT caused pathologies, we recently developed a monoclonal antibody (4B12) that blocks polymer formation in cell models and *in vitro*. In order to characterise the structural basis for this activity, we have mapped the epitope of the 4B12 antibody. This was done by creating various single cysteine mutants that were conjugated to a 5 kDa PEG molecule. Impaired 4B12 binding to these modified AAT variants was assessed by ELISA and gel shift assays, and three critical positions were identified that are involved in 4B12 binding. Characterisation of the binding site and the definition of a binding pocket will form the basis for subsequent screening of small molecules with similar activity that could be further developed into drugs.

Production of IL-33 and Galectin-3 by primary glial cells in response to myelin basic protein charge isomers

L. V. Shanshiashvili[1,2], I. V. Kalandadze[2], E. Tsitsilashvili[1], T. Oniani[1], D. G. Mikeladze[1]
[1]Institute of Chemical Biology, Ilia State University, [2]Department of Biochemistry, I. Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia

Myelin basic protein (MBP) is one of the candidate autoantigens of the human inflammatory demyelinating disease – multiple sclerosis (MS), which is characterized by the active degradation of the myelin sheath. By a wealth of post-translational modifications MBP is presented as different charge isomers. The charge effects modulate MBP functions and may play an important role in pathogenesis of MS. The functions of IL-33 and its producing cells in the CNS are still uncertain.

In this study, we investigate the production of IL-33 and Galectin-3 in response of MBP Charge isomers by primary glial cells. We have found that primary astroglia release IL-33 in response to myelin basic protein charge isomers. The continuous exposure (12, 24, 72 h) of primary glial cells to 0.5 mM MBP C8 (the most modified, citrullinated form) and C1 isomers (the most cationic form) differently induce the release of IL-33 protein.

Besides we have shown that MBP charge isomers induce the secretion Galectin-3 from primary glia. Remarkable effects were seen for C1 isomer. As galectin-3 acts as a specific binding partner of activated k-Ras and that this interaction promotes strong k-Ras activation, we have investigated k-Ras activation in the lysate of the same cells. C1 isomer effect on the Galectin-3 secretion was correlated with the elevation of cytoplasmic k-Ras content. Our results suggest that myelin basic protein charge isomers have immunomodulatory properties and besides effects on Galectin-3 and IL-33 production, can change intracellular signaling through k-Ras translocation.

Keywords: IL-33, inflammation, myelin basic protein.

Prognostic value of IFN-γ, IL-6 and TNF-α in the radiation response of patients diagnosed with local advanced nonsmall cell lung canser and glioblastoma multiforme

C. D. Cetinkaya[1], on behalf of Clinical Chemistry, M. Gurbilek[1], on behalf of Clinical Chemistry, M. Koc[2], on behalf of Oncology
[1]Medical Biochemistry, [2]Radiation Oncology, Faculty of Medicine, Konya, Turkey

Objective: To investigate the effect of radiotherapy (RT) on plasma levels of Interferon gamma (IFN-γ), Interleukin 6 (IL-6) ve tumor necrosis factor alpha (TNF-α) which are critical for the clinical radiation response of patients with local advanced non-small cell lung cancer (NSCLC) and Glioblastoma multiforme (GBM).
Material and Methods: This study was performed 20 patients with NSCLC, 10 patients with GBM, all of whom was treated with RT and 30 healthy controls. Heparinised blood samples were taken from the control group for once and from the patients for twice before RT and after the completion of RT.Circulating cytokine levels were measured in patients.IFN-γ, IL-6 and TNF-α plasma levels were measured by ELISA prosedures.Post-RT and pre-RT levels compared.
Results: Post-RT TNF-α levels in NSCLC and IFN-γ levels in GBM were significantly lower compared to the pre-RT levels. Statistical analysis did not show any significant difference in IL-6 levels between post-RT and pre-RT. But pre-RT IL-6 levels in GBM, post-RT IL-6 levels in NSCLC were significantly higher compared with control group.
Conclusion: We observed that TNF-α levels in NSCLC and IFN-γ levels in GBM associated with RT.TNF-α levels in NSCLC and IFN-γ levels in GBM were significantly decreased after radiation exposure.

One question arising from our results is why we did not observe the same changes of cytokine for patients with GBM and NSCLC.The total volume of irradiated tissue usually is assumed to have an influence on the development of tissue injury. In our study, IL-6 levels were higher in post-RT NSCLC group versus the post-RT GBM group.

Interleukin-6 expression is linked to irradiation and radiation resistance, as demonstrated by in vitro and in vivo experiments. Interleukin-6-silencing vectors induces more tumor inhibition and DNA damage after irradiation. IL-6 can be important in determining the radiation response of tumor cells. Irradiation-induced IL-6 can be responsible for tumor regrowth. Therefore, treatment with concurrent IL-6 inhibition could be a potential therapeutic strategy for sensitizing nonsmall cell lung tumors to irradiation in the clinic.

Pro-inflammatory cytokines TNF-α, IL-6 and IL-1β exhibit differential effects on the expression and transcriptional activity of HIFs in human liver cancer cells

E. Pangou, G. Simos, P. Liakos
School of Medicine, University of Thessaly, Larissa, Greece

During inflammation, the tissue microenvironment is characterized by high levels of inflammatory cytokines and chemokines, but also by decreased levels of O_2. Adaptive responses to this hypoxic microenvironment are mediated by the family of Hypoxia Inducible Factors (HIFs). It has been found that HIFs mediate the growth of tumors that are initiated by inflammation. Moreover, it has been proposed that HIFs, in addition to hypoxia, are also induced by inflammatory mediators. A complicated relationship exists between chronic inflammation and cancer, since inflammatory cytokines that induce chronic inflammation also play significant roles in oncogenesis. However, the precise mechanisms that mediate activation of HIF1 and HIF2 and the signaling pathways initiated by the inflammatory cytokines are elucidated neither under normoxia nor hypoxia. Here, we investigate the expression and transcriptional activity of HIF-1 and HIF-2 in response to the pro-inflammatory cytokines TNF-α, IL-6 and IL-1β in a human hepatoma cell line (Huh7) expressing both HIF-α isoforms. The expression of the hypoxia target genes PGK and EPO as well as plasmids expressing *PGK* or *SOD2* promoter constructs were used to specifically monitor HIF-1 or HIF-2 transcriptional activity, respectively. Our results show that HIF-2α protein levels are not affected by any of the pro-inflammatory cytokines tested, while HIF-1α protein levels are decreased by TNF-α and increased by IL-6 or IL-1β under hypoxia. While no effect on the HIF-1 transcriptional activity could be observed when cells were treated with TNF-α, IL-6 or IL-1β, HIF-2 transcriptional activity was significantly reduced only by TNF-α under hypoxia. In support of this result, we also observed that TNF-α reduced both the mRNA levels of EPO, a HIF-2 specific target gene, and EPO secretion under hypoxia. Our findings show that the expression and transcriptional activity of HIFs are differentially modulated by the pro-inflammatory cytokines TNF-α, IL-6 and IL-1β in human liver cancer cells. We are currently investigating the underlying molecular mechanisms, clarification of which will improve our knowledge on carcinogenesis and contribute to better therapeutic strategies.

The project '3129 Pro-inflammatory cytokines TNF-α, IL-6 and IL-1β exhibit differential effects on the expression and transcriptional activity of HIFs in human liver cancer cells'. Is implemented under the 'ARISTEIA II' Action of the 'OPERATIONAL PROGRAMME EDUCATION AND LIFELONG LEARNING' and is co-funded by the European Social Fund (ESF) and National Resourses.

Protease inhibitors and lectins from mushrooms accentuate the plasticity of the β-trefoil fold

J. Sabotič[1], M. Renko[2], J. Pohleven[1], P. Avanzo Caglič[1], S. Žurga[1], D. Turk[2], J. Kos[1,3]
[1]Department of Biotechnology, [2]Department of Biochemistry, Molecular and Structural Biology, Jožef Stefan Institute, [3]Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia

Mushrooms are a source of proteins that show unique characteristics and are exclusive to basidiomycetes (1,2). We have characterized several protease inhibitors and lectins with the β-trefoil fold that affords them resistance to proteolytic degradation and tolerance to extreme pH and high temperatures (3). Two families of cysteine protease inhibitors, mycocypins, including clitocypin from *Clitocybe nebularis* (family I48) and macrocypins from *Macrolepiota procera* (family I85), displayed a distinct mechanism of cysteine protease inhibition, and showed inhibitory profiles differing from those of protease inhibitors from other sources. Two representatives of trypsin specific protease inhibitors (family I66), cnispin from *C. nebularis* and cospin from *Coprinopsis cinerea* (4), further showed that different loops of the β-trefoil fold can be recruited for inhibition of the same protease and the same loop can be recruited for inhibition of different proteases. Antiproliferative activity specific to human leukemic T cells was demonstrated for a *N,N'*-diacetyllactoseamine (GalNAcβ1-4GlcNAc)-specific lectin, CNL, from *C. nebularis* (5). Another ricin B-like lectin that specifically binds *N*-acetyllactoseamine (Galβ1-4GlcNAc), MpL, was isolated and thoroughly characterized from *M. procera* fruiting bodies. These protease inhibitors and lectins were suggested to have a defensive role in basidiomycetes, protecting spore-bearing fruiting bodies against parasites and predators that cause tissue damage, such as insect larvae and nematodes. In addition to a stable molecular scaffold, specific features of defensive β-trefoil proteins include lack of endogenous targets, cytoplasmic localization and genetic heterogeneity. These features can also be exploited for numerous potential applications of these proteins in biomedicine, biotechnology and agriculture. They could find use in drug development and design as well as in research leading to understanding of the role of individual proteases or glycoreceptors in cancer, neurodegenerative, cardiovascular and autoimmune diseases.

Protective effect of lidocaine against glycocalyx damage secondary to lung ischemia reperfusion

L. Rancan[1], K. Aymonnier[1], S. D. Paredes[2], E. Marchal-Duval[1], J. Casanova[3], I. Garutti[3], C. Simon[4], E. Vara[1]
[1]Biochemistry and Molecular Biolgy III, School of Medicine, [2]Physiology, Universidad Complutense de Madrid, [3]Anesthesiology, [4]Thoracic Surgery, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Increased vascular permeability is a characteristic feature of ischemia reperfusion injury (IRI) that has been ascribed to a malfunction of endothelial cells. Recently it has become evident that the endothelial glycocalyx (EGX) is of considerable importance concerning various aspects of vascular physiology. It is involved in inflammatory and immune reactions and it mediates the release of vascular regulatory agents such as nitric oxide. Another important biological property of the EGX is the ability to create a barrier between the endothelium and the blood cells to prevent cell adhesion. The degradation of the EGX is associated with increased circulating levels of the major EGX components heparan sulfate (HS) and syndecan-1 (Synd-1). Lidocaine is a commonly used local anesthetic agent which has also been found to possess anti-inflammatory activity in several tissues including lung. However, the influence of lidocaine on glycocalyx structure has not been investigated.
Aim: To investigate a possible protective effect of lidocaine on lung glycocalyx injury secondary to IRI.
Animals and Methods: 2 groups (control and lidocaine) of 6 large-white pigs were submitted to left lung auto-transplant. Both groups received the same anesthetic induction (fentanyl 3 μg/kg, propofol 3 mg/kg, atracurium 0.5 mg/kg). In addition animals of lidocaine group received a continuous IV of lidocaine 1.5 mg/kg/h during surgery. Blood samples were taken in four different moments, 1) pre-pneumonectomy (PPn) (5 min before pulmonary artery clamp), 2) pre-reperfusion (PRp) (5 min before reperfusion), 3) 30 min post-reperfusion (PR30) and 4) 60 min post-reperfusion (PR60), in order to measure the levels of glycocalyx markers Synd-1, HS and Cathepsin B. Intercellular adhesion molecule-1 (ICAM-1) was also measured.
Results: Levels of Synd-1 were markedly higher ($p < 0.05$) at PR30 compared to PPn and PRp values. The increase was even higher at PR60. IRI also increased HS and ICAM-1 concentrations in plasma ($p < 0.05$). On the contrary, decreased syndecan-1 levels were observed in the lung ($p < 0.05$) after reperfusion. All these effects were partially blocked by lidocaine.
Conclusions: Our findings demonstrate the contribution of the endothelial glycocalyx to the lung IRI. Lidocaine prevented the deleterious effect on glycocalyx markers suggesting that lidocaine administration may aid to protect the glycocalyx.
Keywords: glycocalyx, ischemia reperfusion injury, lung.

Protective effects of (R)-(+)-α-lipoic acid against MPP+-stimulated microglia cells and toxicity in dopaminergic SH-SY5Y cells through PI3K-Akt/GSK-3β pathway

M. N. A. Kamarudin, H. Abdul Kadir, N. A. Mohd Raflee
Biomolecular Research Group, Institute of Biological Sciences, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia

Microglia are primary immune cells of the brain whose uncontrolled activation can lead to aberrant production of inflammatory factors that contribute to neuronal injury and progressive degeneration of neurons. Numerous empirical evidences have supported the use of LA as anti-inflammatory nutraceutical since it evokes an exclusive array of cellular and molecular mechanisms, albeit its conclusive molecular mechanisms in Parkinson's disease are still not completely understood. We investigated the neuroprotective effects of (R)-(+)-α-Lipoic Acid(R-LA) on 1-methyl-4-phenylpyridinium (MPP^+)-induced activation of microglia BV-2 and neurotoxicity on dopaminergic SH-SY5Y cells. We then investigated the protective effects of R-LA in co-cultured BV-2 and dopaminergic SH-SY5Y cells stimulated with MPP^+. R-LA mitigated MPP^+-induced cell death in both dopaminergic SH-SY5Y and activated BV-2 cells. Pretreatment with R-LA significantly attenuated MPP^+-induced overexpression of inducible nitric oxide synthase (iNOS) and subsequent production of nitric oxide in BV-2 cells. R-LA treatment induced the activation of PI3K-Akt which then reduced the cyclooxygenase (COX)-2 expression, inactivated GSK-3β(Ser9) and supressed the p65NF-κβ translocation in BV-2 cells. Following this, R-LA aggrandized the level of anti-inflammatory cytokine IL-10 which concomitant diminution of pro-inflammatory cytokines TNF-α, IL-Iβ, IL-2 and IL-6. Furthermore, R-LA independently decreased MPP^+-induced oxidative stress in SH-SY5Y by reducing intracellular ROS level, aggrandizing the GSH level and the expression of heme oxygenase-1. Following co-culture of BV-2 and SH-SY5Y cells, neuronal cell death was inhibited where nuclear condensation and apoptotic bodies was abated with intact mitochondrial membrane potential which led to the suppression of caspase-dependent apoptosis as compared to MPP^+-treated co-cultured cells. Moreover, the addition of lithium chloride and triciribine hydrate (API-2) resulted in the prolonged BV-2 activation, elevation of pro-inflammatory cytokines which led to neuronal cell death in SH-SY5Y cells. This further confirmed R-LA protected the BV-2 and dopaminergic SH-SY5Y against MPP^+ through PI3K-Akt/GSK-3β pathway. In conclusion, neuroprotective effects of R-LA against MPP^+ are mediated, at least in part, through suppression of neuroinflammation and oxidative stress-associated factors in BV-2 cells. This further justifies the rational use of R-LA as nutraceutical for neurodegenerative diseases.

Protective effects of 2-benzoxazolinone derivatives with anti-oxidant and anti-inflammatory activities on experimental acute pancreatitis in rats

B. I. Ucar[1], S. Yabanoglu-Ciftci[2], U. Salgın-Goksen[3], N. Gokhan-Kelekci[3], A. B. İskit[4], G. Ucar[2]
[1]Department of General Surgery, Faculty of Medicine,, Dumlupinar University, Evliya Celebi Training and Research Hospital, Turkey, Kütahya, [2]Department of Biochemistry, [3]Department of Pharmaceutical Chemistry, Faculty of Pharmacy, Hacettepe University, Ankara 06100, Turkey, [4]Department of Medical Pharmacology, Faculty of Medicine, Hacettepe University, Ankara 06100, Turkey

New derivatives designed and synthesized by molecular hybridization of benzoxazolinone, triazole and thiadiazole have been previously reported as novel compounds with potent anti-inflammatory and analgesic activity and with no ulserogenic risk (1). Acute pancreatitis is a disease with high morbidity and mortality, but its complete mechanism has not been established. Present study was designed to evaluate the protective effect of the two new anti-inflammatory agents, substituted hydrazide (**4**) and 4-methoxybenzylidenehydrazine (**8e**), on experimental acute pancreatitis in a rat model of cerulein-induced acute pancreatitis.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Male Wistar rats were randomly divided into control group, pancreatitis group and study groups. In the control group, normal saline was replaced by cerulein. Pancreatitis was induced using four i.p. injections of cerulein (50 μg/kg) in 1 ml of saline at 1-h intervals within 4 h. In the study groups, rats were pretreated orally with compounds 4 and 8e (100 mg/kg in 0.5% sodium carboxymethyl cellulose) 12 hours before cerulein induction. Twelve hours after cerulein or saline injections, the animals were killed by decapitation. Blood samples were collected to analyze serum levels of LDH, transaminases, amylase, lipase, and proinflammatory cytokines (TNF-α, IL-1ß and IL-6). Reduced and oxidized GSH, lipid peroxidation level and myeloperoxidase activity were determined in pacreatic tissues. Tissue samples were also examined histologically. Acute pancreatitis markedly increased serum LDH, AST, ALT, amylase and lipase activities as well as serum TNF-a, IL-1ß, and IL-6 levels. Acute pancreatitis caused a significant decrease in tissue reduced GSH levels, increase in oxidized GSH levels while pancreatic MDA level and MPO activity were also increased. On the other hand, pretreatment with the novel compounds reserved all these biochemical parameters as well as histopathologic alterations that were induced by cerulein. According to the results, newly synthesized compounds protected the pancreatic tissues from inflammation and oxidative damage induced by cerulein, and this effect possibly involves the inhibition of neutrophil infiltration and lipid peroxidation. However, more detailed in vivo studies are needed to clarify whether these prodrugs could provide a therapy of pancreatitis.

Protective effects of vitamin U on amiodarone-induced liver injury of rats

S. Sancar-Bas[1], I. B. Turkyilmaz[2], S. Bolkent[1], R. Yanardag[2]

[1]*Department of Biology, Faculty of Science, Istanbul University,* [2]*Department of Chemistry, Faculty of Engineering, Istanbul University, Istanbul, Turkey*

Amiodarone is a currently used drug for the treatment acute life-threatening arrhythmias and for chronic suppression of arrhythmias. Beside beneficial effects, it has several side effects in organs such as lung, thyroid, kidney, liver, eye, brain and skin. S-methionine sulphonium, which is a derivative of the methionine amino acid, defined mostly as vitamin U (Vit U) and antiulcer properties, antiinflammatory action, wound-healing and cell protective effects of Vit U have been demonstrated. The present study was undertaken to determine whether the vitamin U exhibits preventive effects on amiodarone-induced liver toxicity. Male Sprague-Dawley rats were randomly divided into four groups. Group I; control animals receiving corn oil. Group II; control animals receiving Vit U (50 mg/kg) for 7 days orally. Group III; animals receiving 100 mg/kg amiodarone for 7 days orally. Group IV; animals receiving Vit U orally for 7 days (in the same dose and time) 1 h prior to the administration of amiodarone. On the 8th day, all the animals were sacrificed. Liver tissue was taken from animals for histopathological and biochemical studies. Pretreatment with Vit U particularly regressed mild degenerative morphological changes such as picnotic nucleus in hepatocytes, sinusoidal dilatation, hyperemia, dark eosinophilic cells, rupturings in endothelium of central vein seen in amiodarone treated rats. On the other hand, liver aspartate transaminase, alanine transaminase and alkaline phosphatase activities were increased, catalase, superoxide dismutase, glutathione peroxidase, glutathione-S-transferase activities were decreased in amiodarone group. Administration of Vit U reversed these effects in amiodarone group. In conclusion, pretreatment with Vit U may decreases liver injury induced with amiodarone treatment.

Protein phosphatase 2A in lipopolysaccharide-induced cyclooxygenase-2 expression in murine lymphatic endothelial cells

Y.-F. Chuang, M.-J. Hsu

Graduate Institute of Medical Sciences, Taipei Medical University, Taipei, Taiwan

The lymphatic endothelium plays a crucial role not only in maintaining interstitial fluid balance, but also in modulating immune response. Many lines of evidence demonstrated that alterations in lymphatic functions are associated with edema and inflammation. However, the underlying mechanisms by which lymphatic endothelium responses to inflammatory stimuli remain poorly understood. In addition, cyclooxygenase (COX)-2 plays a major role in inflammatory processes, and its expression has been linked with several diseases associated with inflammation. We thus interested to investigate the signaling cascade involved in inducing COX-2 expression in murine lymphatic endothelial cells (LECs) exposed to proinflammatory stimuli, lipopolysaccharide (LPS). The COX-2 mRNA and protein levels were increased in LECs exposed to LPS. LPS time-dependently induced phosphorylation of JNK1/2 and p38MAPK. Treatment of cells with a p38MAPK inhibitor (p38MAPK inhibitor III) and a JNK signaling inhibitor (JNK inhibitor II) significantly inhibited LPS-induced COX-2 expression in LECs. In addition, okadaic acid, a protein phosphatase 2A (PP2A) inhibitor, abrogated LPS's effects on JNK1/2 and p38MAPK phosphorylation. LPS exposure also led to increases in COX-2 promoter-luciferase activity as well as C/EBPβ- and κB-luciferase activities. COX-2 promoter luciferase activity induced by LPS was attenuated in cells transfected with the COX-2 reporter construct possessing the C/EBP- or κB-binding site mutation. C/EBPβ- and κB-luciferase activities were suppressed by okadaic acid despite presence of LPS. LPS-increased p65 and C/EBPβ binding to the COX-2 promoter region was attenuated in the presence of okadaic acid. LPS also caused an increase in PP2A phosphatase activity in LECs. In conclusion, we demonstrated in this study that PP2A may contribute to LPS-induced p38MAPK and JNK1/2 activation, leading to increase in p65 and C/EBPβ binding to the *cox-2* promoter region and subsequent COX-2 up-regulation in LECs.

Keywords: lymphatic endothelial cells, cyclooxygenase-2 (COX-2), protein phosphatase 2A (PP2A).

P-selectin functionalized lipid nanoparticles specifficaly target activated endothelium in acute and chronic inflammation mice models

V. Simion, D. Stan, C. Constantinescu, M. Pirvulescu, A. Gan, E. Dragomir, I. Manduteanu, M. Simionescu, M. Calin

Institute of Cellular Biology and Pathology 'Nicolae Simionescu', Bucharest, Romania

Background: Inflammation is a common occurrence associated, involved and/or responsible for many pathologies. P-selectin is a

© 2014 The Authors. FEBS Journal © 2014 FEBS

cell adhesion molecule highly expressed by endothelium in inflammation, and therefore a potential target for nanotherapy. We hypothesize that functionalization of nanoparticles with P-selectin high affinity peptide will increase their binding to activated endothelium in inflamed tissues. Thus, the aim of this study was to develop nanoparticles loaded with curcumin (Cm, a hydrophobic anti-inflammatory polyphenol) that are able to target the inflammatory process in both, acute and chronic inflammation.

Materials and Methods: Curcumin-loaded lipid nanoparticles (CmLN) functionalized with a P-selectin affinity peptide (P-sel_CmLN) have been developed. The CmLN were characterized for size and structure (by DLS and TEM), entrapment efficiency and curcumin release capacity (by HPLC). In vitro studies using human endothelial cells (HEC) were performed to investigate the cytotoxicity of CmLN (by MTT), their cell binding and internalization (by flow cytometry and confocal microscopy), the signaling pathways involved (Western Blot) and the effect on monocytes adhesion to HEC (fluorescence microscopy). In vivo studies were performed using IVIS Caliper live imaging system on an acute [C57BL mice injected with lipopolysaccharide (LPS) for 5 h] and chronic inflammation mice models [atherosclerotic ApoE-/- mice fed a high cholesterol diet for 4 months].

Results: In vitro studies on HEC revealed that CmLN have: (1) low cytotoxicity; (2) anti-inflammatory effect by down-regulating ERK1/2 and p38 MAPK signaling pathways and (3) impaired adhesion of monocytes to activated endothelial cells. Functionalization of CmLN with P-sel peptide induced (4) an increased binding to activated HEC. In vivo studies (after 1 h of nanoparticles administration) revealed (6) an increased accumulation of Psel_CmLN in the lungs of LPS-injected C57BL mice compared to controls (i.e. non-targeted CmLN and PBS-injected C57BL mice) and (7) an increased binding of Psel-CmLN to the aorta (in atherosclerotic plaque-prone areas) of ApoE-/- mice, compared to non-targeted CmLN binding.

Conclusion: P-selectin coupled CmLN efficiently bind to activated endothelial cells in vitro and in vivo in acute and chronic experimental inflammation. Therefore, P-selectin exposed on activated HEC surface represent a reliable target for delivery of nanoparticles-carrying drugs.

Purification and characterization of a fibrinolytic metalloprotease from exiguobacterium indicum isolated from tapioca flour waste

Y. Yanti[1], A. Widya[1], B. W. Lay[1], M. T. Suhartono[2]

[1]Biotechnology, Atma Jaya Catholic University, Jakarta, [2]Food Science and Technology, Bogor Agricultural University, Bogor, Indonesia

Cardiovascular diseases as the leading cause of death in the world can be triggered by thrombosis. Discovery of novel fibrinolytic enzymes as potential therapeutic agents for thrombosis becomes the focus of research investigation. Tapioca flour waste is a potential source to isolate protease-producing microbe because the use of cassava, which contains >1% of crude proteins. In addition, microbes that isolated from waste may produce novel enzymes since they have to survive in extreme conditions during the process of tapioca flour production. The aim of this study was to purify and characterize a fibrinolytic enzyme from selected tropical microbe isolated from tapioca flour waste. Isolate Tap 3.1 was identified through biochemical and molecular screening as *Exiguobacterium indicum*. Crude enzyme was produced by *E. indicum*. The enzyme was purified through several steps of purification, including ammonium sulphate precipitation, dialysis, concentration, and ion exchange using FPLC. Fibrinolytic activity was characterized by fibrin zymography. The apparent molecular mass of the purified enzyme was estimated to be 66.5 kDa by SDS-PAGE. The precipitation with 50% ammonium sulphate resulted in a 2.6-fold purification of the enzyme. The optimal temperature for fibrinolytic enzyme was 37°C, and its activity was still observable at extreme temperatures (4 and 70°C). Interestingly, the optimal pH for fibrinolytic enzyme was reached at broad ranges of pH (4–10). The enzyme effectively hydrolyzed fibrinogen as well as gelatin, elastin, and casein, suggesting its catalytic specificity in broad protein substrates. Fibrinolytic activity was potently inhibited by EDTA, indicating that the enzyme is a metalloprotease. In summary, a fibrinolytic enzyme from *E. indicum* isolated from tapioca flour waste may have potential to be developed as an alternative therapeutic agent for thrombosis.

SUN-276
Raft-located Lyn kinase serves as a negative regulator of TLR4 signlaing triggered by LPS

K. Borzęcka, K. Kwiatkowska, A. Sobota

Nencki Institute of Experimental Biology Polish Academy of Sciences, Warsaw, Poland

Toll-like receptor 4 (TLR4) is localized in the plasma membrane of macrophages and is activated by lipopolysaccharide (LPS) of Gram-negative bacteria. Activation of TLR4 involves a sequential engagement of serum LPS-binding protein (LBP), plasma membrane CD14 and the TLR4/MD2 signaling complex. CD14 is a GPI-anchored protein enriched in sphingolipid- and cholesterol-rich microdomains of the plasma membrane, rafts, and associates with Lyn kinase, a member of the Src tyrosine kinase family in macrophages. As protein tyrosine phosphorylation controls pro-inflammatory signaling of TLR4, we undertook studies to address an engagement of Lyn kinase in these events. In RAW264 macrophage-like cells LPS induced activation of Lyn in a dose- and time-dependent manner, as indicated by phosphorylation of tyrosine residue 396 of the catalytic domain of Lyn and simultaneous dephosphorylation of inhibitory tyrosine residue 507. Activated Lyn was enriched in the raft fraction of the plasma membrane and the integrity of rafts was crucial for the enzyme activity. Inhibition of protein palmitoylation under the influence of 2-bromoplmitic acid also reduced the amounts and activity of Lyn kinase found in the raft fraction. These data indicate that raft-anchored Lyn is involved in LPS-induced signaling pathways. We undertook studies to reveal the role of Lyn in two signaling pathways of TLR4 which depend on the engagement of either MyD88 or TRIF adaptor proteins. For this, we obtained a series of Lyn constructs fused with GFP at the C-terminus: wild type Lyn, constitutively active Y507F, so-called up/up Lyn, kinase-dead K275R Lyn and Lyn with point mutations in either SH2 (R155A) or SH3 (W98A) domains. The proteins were overexpressed in RAW264 macrophage-like cells with transfection efficiency reaching 40% of cell population. The Lyn-GFP construct were anchored in the plasma membrane as shown by confocal microscopy. Overexpression of the wild type and constitutively active forms of Lyn inhibited NFκB activation, reduced TNFα and MIP-2 production and nearly abolished RANTES generation induced by 100 ng/ml LPS, thus affected

© 2014 The Authors. FEBS Journal © 2014 FEBS

both signaling pathways of TLR4. The wild-type and constitutively active Lyn became enriched in the raft fraction under the influence of LPS. In contrast, an expression of kinase-dead Lyn (K275R) increased TRIF-dependent production of RANTES by 50%, moderately up-regulated NFκB activation and increased MyD88-dependent production of TNFα and MIP-2 both at mRNA and protein levels. Similar effects were exerted by overexpression of R155A and W98A Lyn kinase mutated in its SH2 and SH3 domains, respectively. Taken together, our results indicate that raft-anchored Lyn functions as a negative regulator of TLR4 signaling pathway in macrophages.

SUN-277
Recognition of tumor cells by Dectin-1 orchestrates innate immune cells for anti-tumor responses

H. Ikushima, H. Ueki, S. Chiba, H. Yanai, T. Taniguchi
Department of Molecular Immunology, Institute of Industrial Science, Max Planck-The University of Tokyo Center for Integrative Inflammology, University of Tokyo, Tokyo, Japan

The eradication of cancer cells requires communication between cells which constitute the complex immune system. Natural killer (NK) cells are essential tumor-killing effector cells of the innate arm of the immune system; however, little is known about whether or how other immune cells recognize tumor cells to assist NK cells. In addition, although signal-transducing pattern recognition receptors are known to play important roles in innate immune responses against invading pathogens through recognition of pathogen-associated molecular patterns (PAMPs), it is still enigmatic whether and how these receptors contribute to anti-tumor immune responses. In this study, we show that the innate immune pattern recognition receptor Dectin-1 expressed on dendritic cells (DCs) and macrophages is critical to NK-mediated killing of tumor cells. We also show that tumor cell-mediated Dectin-1 signaling is instigated by the receptor recognition of N-glycan structures on tumor cells, which we term tumor-associated molecular patterns (TAMPs). As such, the TAMP-Dectin-1 signaling causes activation of the Interferon Regulatory Factor 5 (IRF5) transcription factor and subsequent induction of genes required for the full-blown killing activity of NK cells. The importance of these events is underscored by the observation of massive tumor metastasis in mice genetically deficient in either Dectin-1 or IRF5. Thus, these results reveal a hitherto unrecognized facet of pattern recognition receptors in the orchestration of anti-tumor innate immune responses; recognition of TAMPs. This study is the first demonstration that an innate immune pattern recognition receptor potentiates anti-tumor immune responses, offering new insight into anti-tumor activity of the innate immune system with implications for anti-tumor immunotherapy.

Recombinant TMV-based virus carrying hydrophobic hemagglutinin influenza fusion peptide moves via plant vascular system and forms stable particles

N. Petukhova, T. Gasanova, T. Erokhina, P. Ivanov
Lomonosov Moscow State University, Moscow, Russian Federation

Influenza is one of the world's most common and deadly viruses. The inherent disadvantages associated with the preparation of conventional vaccines suggest discovering of the universal Influenza vaccine. Given the importance of neutralizing antibodies against hemagglutinin (HA) in controlling Influenza infection, the conserved regions in the HA proteins have received great attention in recent years. The HA2 N-terminal amino acids (aa) are conserved among all Influenza subtypes. This highly hydrophobic peptide serves for fusion of viral and endosomal membranes inside an infected cell. Recently it was shown that monoclonal antibodies against this so-called fusion peptide (fp) are capable of reacting with all types of Influenza HA proteins; therefore, it might be a perspective candidate for production of the broad-spectrum vaccine. Lately a new approach for plant super-expression of another conservative Influenza epitope M2e has been developed in our research group. Chimeric TMV-M2e particles based on *Tobacco mosaic virus* (TMV-U1, wt) genome proved high-level protective efficacy against lethal homologous and heterologous challenge (Petukhova *et al*., 2013, *Curr. Pharm. Des*., 19, 5587–5600). Similarly, we constructed TMV-fp vector designed for *Agrobacterium*-mediated delivery into the plant cell nucleus. TMV coat protein (CP) contained 14 aa of fusion peptide (GLFGAIAGFIEGGW). The codon usage of foreign antigen was optimized for expression in plants. Infection of *Nicotiana benthamiana* with TMV-fp vector caused systemic symptoms on 11th day post inoculation differing from symptoms caused by TMV-wt and TMV-M2e viruses. We observed severe necrosis and deformation of upper leaves and necrotic fracture of the stem. Western blot analysis of plant extracts revealed the protein (22–23 kDa) that coincided with the predicted molecular weight of CP-fp, reacted with antiserum (AS) against TMV CP and was not found in negative control. One may conclude that recombinant virus TMV-fp is able to replicate and systemically transport in *N. bentamiana* plants. Following the purification, we found two proteins in viral preparation corresponding to CP-fp and CP without epitope (approximate ratio 30:70). Electron microscopy of TMV-fp preparation represented the rod-shaped particles similar in morphology to TMV-wt virions. RT-PCR analysis of total RNA fraction from infected plants and genomic RNA from purified viral preparation showed the presence of fp-sequence in the CP gene. Direct sequencing of PCR product did not reveal any mutation thus confirming genetic stability of TMV-fp vector. Thereby, this is the first report of hydrophobic Influenza fusion peptide expression using plant viral particles expected as a carrier.

Relation of protein oxidation parameters in patients with Behçet's disease

S. Özyazgan[1,1,], G. Andican[2], H. Erman[2], A. Tuzcu[2], H. Uzun[2], Y. Ozyazgan[3], B. Onal[1]
[1]Pharmacology, [2]Biochemistry, [3]Ophtalmology, İstanbul University, Cerrahpasa medical faculty, Istanbul, Turkey

Background: Behçet's disease (BD) is a chronic inflammatory vasculitis characterized by endothelial dysfunction, elevated reactive oxygen species (ROS), and neutrophil hyperfunction production including acute attacks and remission periods. Ischemia modified albumin (IMA), advanced oxidation protein products (AOPP), prooxidants-antioxidants balance (PAB), and ferric reducing antioxidant power (FRAP) were evaluated in regard to their role in the pathogenesis of BD as well as their relation to clinical presentation, uveitis attacks and remission periods, and healthy volunteers.
Methods: The study included 28 BD cases and 27 healthy volunteers as the control group. Blood samples were taken twice from each patient; first during an attack and second about three months after an attack, during remission period.
Results: AOPP, IMA and PAB levels were significantly increased in active periods of patients with BD compared with healthy control and remission periods of patients with BD ($p < 0.0001$, $p < 0.0001$, $p < 0.0001$, respectively). FRABP levels were found to be lower in active periods of patients with than healthy controls and remission periods of patients with BD ($p < 0.001$, $p < 0.05$, respectively). The AOPP levels were negatively correlated with the levels of FRAB in patients ($r = -0.468$, $p = 0.012$; $r = -0.394$, $p = 0.038$, respectively). The PAB levels were positively correlated with the levels of CRP in patients ($r = -0.606$, $p = 0.001$).
Conclusions: Our results show that these parameters play a major role in the inflammatory reactions observed in BD. Increased levels of IMA and PAB are likely to be a result of inflammation-induced oxidative stress and hence its potential significance as a new marker of oxidative stress in BD.
Keywords: Behçet's disease, AOPP, IMA.

Relationship between C-reactive protein, glucose, HbA1c and age

C. Topcu[1], C. D. Cetinkaya[2], M. Gurbilek[1]
[1]Biochemistry, Necmettin Erbakan University, Konya,
[2]Biochemistry, Public Health Laboratory, Van, Turkey

Objective: After understanding the importance of inflammation in the pathogenesis of Cardiovascular diseases (CVD), CRP usage has been increased for the determination of cardiovascular risk. As an inflammation marker, the relationship between CRP levels and CVD risk and age has already been shown. In this study our purpose is to investigate the relationships between CRP, glucose, Haemoglobin A_{1c} (HbA1c) and age.
Materials and Methods: CRP, HbA1c, glucose levels and ages were analysed retrospectively in subjects admitted to the laboratory in 2013. Correlations were examined between CRP, HbA1c, glucose levels and ages. In the present study no patient had CRP value higher than 10 mg/dL.
Results: CRP, HbA1c, glucose levels and ages of 53 females, 67 males, overall 120 cases were 3.26 ± 2.59 mg/dL (mean $\pm$ SEM), 7.07 ± 1.818, 153.18 ± 83.54 and 55.66 ± 15.33 respectively. Positive correlation was found between CRP and HbA1c in whole group ($r = 0.250$, $p < 0.05$). Cases were divided into two groups, according to their HbA1c values (Group A: HbA1c ≥ 6.5, Group B: HbA1c < 6.5). Glucose and HbA1c levels were found to be significantly higher in group A ($p < 0.05$). In group B, significant positive correlations were determined between age and HbA1c; and glucose and age ($r = 0.366$, $p < 0.05$ and $r = 0.269$, $p < 0.05$, respectively). In group A, significant negative correlation between age and HbA1c and positive correlation between glucose and HbA1c were determined ($r = -0.337$, $p < 0.05$ and $r = 0.796$, $p < 0.05$, respectively).
Conclusion: In patients with CVD, Diabetes mellitus (DM) leads to functional and structural vascular alterations of the peripheral vasculature which are determined by the control of the disease underlining the relevance of a strict control of the DM to prevent accelerated atherosclerosis. CRP is also associated with macrovascular events in patients with DM. In our study, positive correlation was found between HbA1c and CRP. It showed that a higher level of circulating HbA1c was related to elevate inflammatory markers such as CRP. We conclude CRP levels, add significantly to the prediction of macrovascular events and mortality in individuals with DM who have baseline CVD or risk factors.

In this retrospective study significant negative correlation in Group A and positive correlation in Group B were found between HbA1c and age. HbA_{1c} levels in Group B increase with age. Therefore, see a need for age-specific reference ranges for HbA_{1c} in normal subjects.
Keywords: C-reactive protein, glucose, Haemoglobin A1c.

Resistance mechanisms in silver-citrate nanoparticles treated colon cancer cells

D. Kovács[1], N. Igaz[1], C. Keskeny[1], T. Tóth[2], G. Spengler[3], Z. Kónya[2], I. M. Boros[1,4], **M. Kiricsi**[1]

Despite the significant progress in cancer treatment over the last decades, multidrug resistance (MDR) continues to be the biggest challenge in tumor therapy. The various resistance mechanisms and their combinations represent the adaptation capacity of MDR cancer cells to toxic insults when structurally and functionally unrelated chemotherapeutic agents are applied. Induction of drug efflux pumps, overexpression of P-glycoprotein encoding MDR1 gene, all contribute to the development of a resistant phenotype, since through these membrane proteins cytotoxic drugs are exported from the cells.

Recently, novel nanotechnology-based therapeutic strategies gathered grounds because they target different biochemical pathways and provide the potential to overcome MDR. Silver nanoparticles (AgNPs) are broadly used nanomaterials in medicine due to their unique chemical, physical properties and their outstanding antiviral and antibacterial features. Our recent results indicate that AgNPs induce apoptosis in various cancer cells but their effect on MDR cells is still unknown. The potential application of AgNPs in cancer therapies, as single agents or in combination with targeted and conventional drugs, has raised our interest to investigate their activity on MDR cancer.

In this study we used sodium-citrate coated ~35 nm sized quasi-spherical AgNPs for treating drug-sensitive (Colo 205) and MDR1 overexpressing drug-resistant (Colo 320) colon adenocarcinoma cells. We found that AgNPs killed cancer cells in a concentration dependent manner, however drug resistant Colo 320 cells showed higher viability compared to drug sensitive Colo 205 cells. Cleaved caspase 3 staining indicated apoptosis during AgNP mediated cell death which proved to be more prominent

© 2014 The Authors. FEBS Journal © 2014 FEBS

in drug sensitive cells. We detected elevated levels of reactive oxygen species in nanoparticle treated MDR cells compared to control suggesting the induction of the mitochondrial apoptosis pathway. Immunofluorescent staining revealed the disappearance of mitotic cells after AgNP treatment, indicating a cell cycle arrest. Examination of mRNA levels of apoptotic and stress markers verified programmed cell death in Colo 205 cells however elevated expression of the antiapoptotic survivin was observed in Colo320 cells.

Our results show that although AgNPs kill both drug resistant and sensitive cells, MDR Colo 320 cells manifest several resistance mechanisms to fight the applied stressor and survive.

Keywords: nanoparticles, inflammation, cell death.

Reversing effect of vitamin U on valproic acid-induced renal damage through its anti-oxidant, anti-inflammatory and anti-fibrotic properties

S. Gezginci-Oktayoglu[1], I. B. Turkyilmaz[2], M. Ercin[1], R. Yanardag[2], S. Bolkent[1]
[1]Biology, [2]Chemistry, Istanbul University, Istanbul, Turkey

Valproic acid (VPA) is extensively used as anti-epileptic drug for decades. However, it has many side effects such as renal damage. It has recently become prominent with its inhibiting effect of histone deacetylases. Several reports have indicated that anti-epileptic drugs affect the oxidant/antioxidant status, immune system and fibrosis, but the mechanism is not clear. Vitamin U (Vit U), S-methyl methionine sulfonium chloride, is a water soluble vitamin. The aim of the present study was to investigate the effect of Vit U on the oxidative stress, inflammation and fibrosis within the context of VPA-induced renal damage.

In this study, female Sprague Dawley rats were randomly divided into four groups. Group I was intact control animals. Group II was control rats given Vit U (50 mg/kg/day, by gavage). Group III was given only VPA (500 mg/kg/day, intraperitonally). Group IV was given VPA+ Vit U. The animals were treated by Vit U one hour prior to treatment with VPA every day. On the 16th day of experiment, animals were sacrificed under anesthesia. Kidney tissue was taken from animals for biochemical and microscopic analysis.

The following results were obtained in Vit U + VPA-treated rats; *i.* The reversing effect of Vitamin U on renal damage was showed by decreased histopathological changes and increased activity of Na^+/K^+-ATPase *ii.* Antioxidant property of Vit U was determined by decreased malondialdehyde level; increased glutathione level and activities of catalase and superoxide dismutase. *iii.* Anti-inflammatory property of Vit U was determined by decreased TNF-α, IL-1β, MCP-1 levels and activities of adenosine deaminase and xanthine oxidase in Vit U+VPA-treated rats. *iv.* Anti-fibrotic effect of Vit U was showed by decreased TGF-β1, Collagen-1 and activity of arginase.

Collectively, these data show that VPA is a promoter of inflammation, oxidative stress, and fibrosis which resulted in renal damage. Vit U can be proposed as a potential candidate for reversing renal damage which arose during the therapeutic usage of VPA.

Keywords: Renal Damage, Valproic acid, Vitamin U.

Role of adipokines in insulin synthesis and secretion

D. Lixandru[1], P. Alexandru[2], A. Rosca[1], I. Stoian[1], B. Smeu[3], C. Copaescu[3], V. Atanasiu[1], C. Ionescu-Tirgoviste[4]

Introduction: The adipose tissue has become a central player in the pathogenesis of metabolic disease. The aim of this study was to evaluate whether preadipocytes from different depots, could change differently synthesis and secretion of insulin in beta-pancreatic cells.

Methods: We performed isolation, cultivation and differentiation of human preadipocytes using either abdominal subcutaneous or mesenteric adipose tissue obtained from bariatric interventions. Oil Red O staining was used as marker of differentiation. The media from day 0, 4, 7, 10, 15 and 20 was added over PANC-1 cells ($2X10^4$ cells) and the insulin and proinsulin levels were measured by ELISA. We also used a transwell system in which the PANC-1 beta-pancreatic cells grown in the lower well of the 6-well culture plate were co-cultured for 24 hours with differentiated adipocytes (day 0, 4, 7, 10, 15 and 20) in the transwell inserts (with 0.4 μm porous membrane). The leptin, adiponectin, insulin and proinsulin levels in co-cultured PANC-1 cells (media and cell lysates) were determined by ELISA as well. The experiments were done in duplicate and repeated four times.

Results: Intracellular proinsulin level was higher then in the media while insulin was lower in the cell lysates and these was maintained with preadipocytes differentiation. The expresion level of leptin increases steadily with the degree of differentiation only intracelular while levels of adiponectin dit not differed. When the two types of cells were cocultured in the transwell system except for proinsulin all parameter did not differ from those obtained in experiment 1. Adiposse tissue origin does not influence neither synthesis nor secretion of insulin.

Conclusion: Our results suggest that the ratio between pro/anti-inflamatory adipokines during adipocytes differentiation has an important rol in both production and secretion of insulin in beta-pancreatic cells.

Role of an aspartic acid cluster within the internal cavity of endoplasmic reticulum aminopeptidase 1 in regulating enzyme activity and substrate specificity

D. Koumantou, I. Evnouchidou, E. Stratikos
N.C.S.R. 'Demokritos', Athens, Greece

Endoplasmic reticulum aminopeptidase 1 (ERAP1) trims N-terminally extended peptide antigenic precursors to produce mature epitopes that are presented by major histocompatibility complex

© 2014 The Authors. FEBS Journal © 2014 FEBS

class I molecules. The internal sequence of peptide precursors highly affects the N-terminal trimming rates by ERAP1. Specifically, ERAP1 shows preferences towards peptides that contain positively charged aminoacid residues. In an effort to understand the atomic determinants of this preference we investigated the contribution of an aspartic acid cluster located within the enzyme's extended substrate binding cavity. We produced recombinant ERAP1 in which aspartic acids at positions 406, 435 and 439 are replaced by alanine and we compared enzymatic activity with the wild-type enzyme. The mutant enzyme was found to be more active than the wild-type using model fluorigenic substrates. Arginine scanning using the model antigenic epitope LSIINFEKL revealed that this cluster can affect substrate trimming rates but this was highly dependent on the position of the Arginine residue in the substrate. Surprisingly, the mutant was much more efficient in further trimming the LSIINFEKL epitope to smaller peptides that would not be expected to bind onto MHC class I, suggesting that the aspartate cluster may be important for length selection. This phenomenon was however, sequence-dependent since the length selection properties of ERAP1 versus a series of poly-Glycine peptides remained unaltered.

Role of antoxidants on RANKL and OPG production in apoptotic osteocytes

F. Fontani[1], G. Marcucci[2], T. Iantomasi[1], M. L. Brandi[2], M. T. Vincenzini[1]
[1]*Department of Experimental and Clinical Biomedical Sciences,*
[2]*Department of Surgery and Translational Medicine, University of Florence, Florence, Italy*

Osteocytes are the major mechanosensory cells in bone, and their apoptosis due to microdamage is related to increased local bone turnover and resorption observed in various bone diseases. Previously, we showed in a osteocyte-like cell line, MLO-Y4, that the starvation-induced-apoptosis, that mimics the apoptosis due to microdamage, is an redox-regulated process related to JNK activation. The aim of this study was to investigate in starvation-induced-apoptosis in osteocytes the role of antioxidants, such as glutathione (GSH), NAC and lipoic acid (LA), on cytokines, such as the receptor activator kB ligand (RANKL) and osteoprotegerin (OPG), involved in bone remodelling. These factors are produced by osteoblasts and osteocytes, RANKL increases bone resorption, whereas OPG inhibits osteoclastogenesis activating bone formation. These events are maintained in equilibrium by the regulation of RANKL/OPG ratio. The involvement of the redox-regulated kinases, ERK1/2 and JNK, on the production of these cytokines was also studied.

The results show that in MLO-Y4 all antioxidants inhibited RANKL expression and release which increased in apoptotic cells, in particular, RANKL levels returned to the control values after treatment with all antioxidants. Whereas, OPG expression remarkably decreased in apoptotic cells, and only NAC and LA were able to significantly increase the OPG levels. No OPG release has been detected in our experimental conditions. Therefore, RANKL/OPG ratio, measured by using expression values, significantly enhanced in apoptotic cells as compared with controls, whereas the ratio decreased in cells treated with the antioxidans. The results show that JNK and ERK1/2 were activated in apoptotic osteocytes but all antioxidants inhibited their activation. Experiments performed with SP600125 and U0126, specific inhibitors of JNK and ERK1/2 respectively, show that the activation of both kinases up-regulated RANKL expression and release. On the contrary, only JNK activation down-regulated OPG expression. However, RANKL/OPG ratio decreased in SP600125 or U0126 treated apoptotic cells indicating the involvement of both kinases on the ratio regulation.

These results suggest that the osteocytes, JNK and ERK1/2 may be potential therapeutic targets for treatments of bone diseases related to oxidative stress. It should be also interesting to evaluate the association of these antioxidants and/or JNK and ERK1/2 antibodies with anti-resorptive drugs to enhance the therapeutic efficacy and/or to decrease toxic effects.

Keywords: antioxidant activity, Osteocytes, redox homeostasis.

Role of EGF and TGF beta in modulating the expression of the stearoyl CoA desaturase 1 in association with metastatic breast cancer development

F. Bouazizi, C. Mounier[1], M. Cartier-Millon, C. Mounier
Biologie, UQAM, Montreal, QC, Canada

Despite significant scientific progress in prevention, detection and treatment of breast cancer, it remains the leading cause of women cancer deaths in the world. The percentage of mortality significantly increases when the cancerous cells acquire a metastatic potential. We previously showed that high stearoyl CoA desaturase 1 (SCD1) expression, a key lipogenic enzyme, was associated with increased metastatic potential of breast cancer cells. SCD1 desaturated long chain fatty acids forming monounsaturated fatty acids. EGF (Epidermal Growth Factor) and TGFβ (Transforming Growth Factor -beta) are also associated with the acquisition of a metastatic potential. In breast cancer cells, EGF activates JAK / STAT, PI3K, Src kinase, PLCγ, ERK dependent signaling pathways while pathways activated by TGFβ involved the Smad proteins.

Project's Objectives: The aim of our study was to analyze the role of EGF and TGFβ in SCD1 expression and to characterize the signaling pathways induced by the two hormones using the MDA-MB 231 breast cancer cells.

Methodology: MDA-MB 231 cells were treated with or without EGF (10 ng/ml) or TGFβ (0.2 nM) and cytosolic proteins were analyzed by Western blotting. The same hormonal treatment was made on cells transfected with a construct containing 3.7 kb of the SCD1 promoter cloned upstream of the luciferase reporter gene. Finally, specific inhibitors of kinases involved in signaling pathways induced by EGF or TGFβ, were added for 1 h before addition of the hormones. 24 h latter, the effect of each inhibitor on SCD1 expression was evaluated by RT -PCR.

Results and Conclusion: Our results showed that both EGF and TGFb increased SCD1 protein expression in MDA-MB-231 cells. This hormonal effect is probably due to a regulation at the transcriptional level as both hormones increased SCD1 promoter activity by more than 3 fold. In addition, the use of specific inhibitors allowed us to determine the pathways involved in SCD1 regulation by both EGF and TGFb. Our study describes for the first time a new link between EGF and TGFb with SCD1 expression associating lipid metabolism with metastasis development in breast cancer cells.

Role of interleukin-1β in antifungal immunity – differential host responses induced by *Candida albicans* and *Candida parapsilosis*

A. Tóth[1], K. Csonka[1], M. G. Netea[2], A. Gacser[1]
[1]*Department of Microbiology, University of Szeged, Szeged, Hungary,* [2]*Department of Medicine, Nijmegen Institute for Infection, Inflammation, and Immunity, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands*

Candida parapsilosis is an emerging fungal species causing invasive candidiasis worldwide. However, little is known about the molecular background of immune responses induced by this pathogen. In this study, our aim was to investigate the host responses induced by *C. albicans* and *C. parapsilosis* using human peripheral blood mononuclear cells (PBMCs) and PMA-induced THP-1 monocytes. We have previously shown that heat killed *C. parapsilosis* induces similar Tumor necrosis factor α (TNFα) and Interleukin-6 (IL-6), but slightly lower Interleukin-1β (IL-1β) production in human PBMCs compared to *C. albicans*. Furthermore, we have shown that *C. parapsilosis* induces significantly lower T helper 17 (Th17) differentiation in comparison to *C. albicans*. In this study, we found that PBMCs stimulated with live *C. parapsilosis* produced similar quantities of TNFα and IL-6, and much lower amounts of IL-1β, compared to *C. albicans*-stimulated cells. As IL-1β has been shown to be important for Th17 differentiation, we further examined the details of IL-1β production upon *C. albicans* and *C. parapsilosis* infection using PMA-induced THP-1 monocytes (the prototypic cell line for IL-1β production and inflammasome activation studies). We found that while *C. albicans* induced the release of IL-1β after 24 hours already at an MOI of 1:100 (*Candida:* THP-1), a 100-times higher dose of *C. parapsilosis* cells (MOI 1:1) was needed for the induction of IL-1β secretion. Moreover, using different isolates of *C. albicans* and *C. parapsilosis*, we proved that this difference was species rather than strain specific. Furthermore, our data strongly suggest that the difference in secreted IL-1β levels originates from the differential processing of IL-1β protein rather than from different transcriptional or translational regulation of IL-1β synthesis. Additionally, we found that the production of IL-1β in response to both *C. albicans* and *C. parapsilosis* is dependent on Caspase-1, Caspase-8 and Syk. In conclusion, our results show that there is a marked difference in the production of IL-1β induced by *C. albicans* and *C. parapsilosis*, possibly contributing to the differential Th-responses induced by the two species. Importantly, these results implicate that the activation of inflammasome, the protein complex responsible for IL-1β processing, may be less effective upon infection with *C. parapsilosis*. Our findings highlight the importance of studies focusing on different *Candida* species rather than *C. albicans* alone when investigating the immunity against these pathogens.

Keywords: candida, inflammasome, inflammation.

SAG-dependent UPS regulates macrophage death or survival and immune response

S.-C. Chang, J.-L. Ding
Department of Biological Sciences, National University of Singapore, Singapore, Singapore

Macrophages, at the frontline of immune defense, undergo apoptosis as an optimal strategy against a severe microbial infection. However, the mechanism on how the immune cell shifts between apoptosis and immune response is under-explored. Here, we show that ubiquitination by SAG-UPS (sensitive to apoptosis gene ubiquitin-proteasome system) confers survival advantage to the macrophages during early infection. We demonstrated that SAG plays a key regulatory role in balancing the ratio of pro- and anti-apoptotic factors in the infected macrophages. *SAG*-knockdown significantly reduced the ubiquitination of Bax and SARM (sterile alpha and HEAT/armadillo-motif-containing protein), stabilizing these pro-apoptotic factors and leading to intrinsic apoptosis. In contrast, under chronic infection-inflammation condition, macrophages overexpress *SAG*, leading to upregulation of pro-tumorigenic cytokines (IL-1β, IL-6 and TNF-α), and downregulation of anti-tumorigenic IL-12p40 and anti-inflammatory IL-10. Altogether, our findings identified SAG as a survival determinant for macrophages, as well as a modulator in manipulating timely immune response. This work provides a novel mechanistic perspective into how SAG-UPS acts as a functional link between immune defense and apoptosis or immune-overactivation and tumorigenesis. The potency of SAG-UPS suggests it to be a poten-

Search and identification of peptide biomarkers of colorectal cancer in sera

I. Azarkin[1], R. Ziganshin[1], S. Kovalchuk[1,2], G. P. Arapidi[1], N. Anikanov[1], O. Ivanova[1], V. Shender[1], V. Govorun[1,2], V. Ivanov[1]
[1]IBCH RAS, [2]NII FHM FMBA, Moscow, Russian Federation

Colorectal cancer (CRC) is a common and deadly disease in the world. The average lifetime risk to develop nonhereditary, sporadic CRC is approximately 5%. Each year more than one million people are diagnosed with CRC and about half of them die from this malignancy.Stage of the disease, is an important prognostic factor, with five year survival rates of more than 90% for localized CRC (stage I) and only about 10% for CRC that metastasized to distant organs(stage IV). The aim of the present work was a search and identification of peptide markers of CRC in sera using modern mass spectrometry techniques.

Blood sera obtained from 50 patients with CRC and 50 healthy donors (control) were used for isolation and identification of peptides.Serum samples of each analyzed groups were fractionated using magnetic beads with weak cation exchange surfaces, obtained eluates were analyzed by nanoLC-MS/MS using ABSciexTripleTOF 5600. All samples were analyzed by DDA (identification of serum peptides) and by SWATH (for label-free relative quantitative mass spectrometry analyses) approaches.

As a result of LC-MS/MS analysis of sera more than 6000 unique peptides originated from the almost 1000 unique proteins were identified. Among identified peptides 786 were unique for CRC samples, and 125 of those were originated from the proteins unidentified in the control samples. For the control group there were 1075 unique peptides, 259 of which were originated from the proteins unidentified in CRC samples. We believe that the presented data set contains valuable information which will enable interested researchers to identify of new potential biomarkers for colorectal cancer.

Keywords: Biomarkers.

Search for TRPA1 modulators

Y. A. Shapranova[1], Y. A. Andreev[1], K. Stensvåg[2], I. V. Mosharova[1], Y. V. Korolkova[1], E. V. Grishin[1]
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation, [2]Norwegian College of Fishery Science, University of Tromsø, Tromsø, Norway

TRPA1 receptors play significant role in neurogenic inflammatory pain. These receptors are expressed in mammalian somatic and visceral sensory neurons and they co-localize with TRPV1 in a subset of small diameter, unmyelinated, peptidergic neurons. Activators of TRPA1 are exogenous and endogenous irritants and mechanical stimuli. TRPA1 agonists from cigarette smoke and smog trigger eye irritation, cough and neurogenic inflammation of the airways. Endogenous agonists are compounds generated during tissue inflammation, asthma, chemical hypersensitivity, chronic cough, chronic obstructive pulmonary disease and stress. Thus, the TRPA1 is an important target for design of novel drugs.

The DNA encoding TRPA1 receptor was constructed on the base of cDNA from rat brain tissue using the PCR technique. The gene was cloned into the expression vector pcDNA4/TO, which allows provide inducible expression in mammalian cell lines. Sea anemone venoms were separated by HPLC method. Individual chromatography peaks were analyzed by MALDI-TOF (matrix-assisted laser desorption ionization, time-of-flight mass spectrometry). Activities of separated compounds were tested on cell line with inducible expression of TRPA1 by fluorescence spectroscopy method. Using genetic engineering approaches we produced recombinant analogues of individual compounds.

On the base of cells of the CHO line with inducible expression of TRPA1 was developed test-system for screening biological samples (natural venoms and individual compounds). From sea anemones venoms of *Urticina eques* and *Metridium senile* we isolated peptides modulating TRPA1 activity by HPLC separation. Recombinant peptides from *U. eques* and *M. senile* were produced in *E. coli* expression system.

As the result, we isolated novel peptide modulators of TRPA1 from sea anemone venoms. Peptides modulating TRPA1 activity are valuable biological tools in receptor research work.

Keywords: inflammatory pain, sea anemone venom, TRPA1 receptor.

Searching for novel peptide-based antimicrobials applicable in treatment of wounds

P. Kosikowska[1], A. Lesner[1], P. Langa[2], M. Pikua[2], P. Trzonskowski[2], M. Obuchowski[3]
[1]Bioorganic Chemistry, University of Gdańsk, [2]Clinical Immunology and Transplantology, Gdansk Medical University, [3]Department of Medical Biotechnology, Intercollegiate Faculty of Biotechnology, Medical University of Gdansk, Gdańsk, Poland

Despite the significant achievements in the field of medicinal chemistry of antibiotics, the rising level of drug resistant pathogens emphasizes the need for novel compounds with an alternative mode of action. This problem becomes more and more evident in the medical treatment and managing of chronic wounds. This type of wounds are usually seen in diabetic feet and legs, radiation-induced skin damage, non-healing traumatic wounds etc [1]. In this case clinicians usually have to deal not only with the impaired mechanisms of natural skin regeneration, but also with bacterial and fungi infections on a wound site, causing either a delay in wound healing or its deterioration.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Trying to find a solution to this particular problem, we designed, synthesized and evaluated biological properties of several simple bifunctional peptide conjugates, that are composed of two different peptides bind to each other through the PEG molecule (8-Amino-3,6-dioxaoctanoic acid). The first fragment of the conjugate responsible for its antimicrobial activity is formed by selected cationic antimicrobial peptide (AMP) [2,3], while the second one is represented by the peptides able to stimulate natural reparative processes in the skin, like fibroblasts and keratinocytes proliferation /migration [4] or antioxidant activity [5] .

All sequences of the native peptides used in the design of the conjugates were retrieved from the available literature data and synthesized by means of the solid-phase synthesis applying Fmoc chemistry. Their bactericidal and fungicidal activity was evaluated by means of well-established procedure of MIC (minimal inhibitory concentration) determination, while pro-proliferative activity was analyzed using standardized MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay using human keratinocyte cell line (HACAT) and fibroblasts obtained from human skin biopsies.

The preliminary results suggest that α-helical structure of tested conjugates as well as their native AMPs components is crucial to maintain their antimicrobial activity. In contrast to appreciable bactericidal and fungicidal properties of PEG-conjugates, their pro-proliferative effect on the keratinocyte and fibroblast cell line was not so pronounced.

Sensitization of bacteria to antibiotics by combined antibiotic-photodynamic treatment

M. Gutterman, A. Valkov, **M. Nisnevitch**
Chemical Engineering, Biotechnology and Materials, Ariel University, Ariel, Israel

The emergence of bacterial resistance to antibiotics raised the need to develop alternative technologies for eradication of pathogenic bacteria. One such technology is photodynamic antimicrobial chemotherapy (PACT), which is based on photosensitizers (dyes which are either non-toxic or with low toxicity) and visible light. Another technique, reported in this work, is based on the combined application of antibiotics and photosensitizers. Both methicillin-sensitive (MSSA) and methicillin-resistant (MRSA) strains of *S. aureus* treated with sub-MIC (minimal inhibitory concentration) concentrations of Rose Bengal and sub-MIC concentrations of the antibiotics methicillin, kanamycin A and ampicillin exhibited sensitization to the antibiotic treatment and were inhibited by 3–15 times lower doses of the antibiotics. The MIC value of Rose Bengal was 5 times lower for MRSA than for MSSA. *P. aeruginosa* treated with Rose Bengal combined with methicillin or fucidin exhibited the same trend and the MIC values of the antibiotics were reduced 4–6 fold. Immobilization of Rose Bengal and ampicillin in polystyrene led to an increased inhibition zone relative to the activity of each component immobilized separately. Combined antibiotic-photosensitizer application showed good antibacterial activity against Gram-positive and Gram-negative bacteria at reduced antibiotic doses. It can be assumed that the antibiotics and Bengal Rose acted synergistically against both types of bacteria.

Serum cytokines and growth factors modulation on pituitary adenomas

E. Codrici, D. I. Popescu, S. Mihai, A. Nita, R. Albulescu, C. Tanase
Biochemistry Proteomics, Victor Babes National Institute of Pathology, Bucharest, Romania

Background: Serum cytokine and growth factors levels have been investigated in relationship with invasiveness in pituitary adenomas in order to evaluate the involvement of these potential biomarkers in pituitary tumor cell proliferation.

The aim of this study was to evaluate the cytokine and growth factors profile in pituitary adenomas in order to establish a panel of biomarkers useful in early detection of this pathology.

Methods: We determined cytokine levels in sera from 22 patients (15 non-invasive; 7 invasive adenomas), angiogenic factors in sera from 66 patients (23 non-invasive; 43 invasive adenomas) and 33 healthy controls. Using MilliplexTM MAP Human Cytokine/Chemokine Panel (Millipore, MA, US) on a Luminex® 200TM system, we analyzed 12 analyte-specific bead sets: proinflammatory IL-1β, IL-2, IL-6, IL-8, IL-12, TNFα, GM-CSF, INFγ, anti-inflammatory IL-4, IL-10, and angiogenic factors VEGF and FGF-2. Multiplex data acquisition and analysis were performed using STarStation 2.3 (Applied Cytometry Systems, Sheffield, UK).

Results: Increased levels of IL-1β, IL-6 and TNFα were found in 27%, 32% and 41% of pituitary adenomas patients. Cytokines expression was significantly higher in invasive pituitary adenomas 86% compared to non-invasive ones 7%. IL-6 and IL-1β levels were 4, and respectively 4.7 fold higher than controls, while TNFα level was up to 1.8 fold higher. We have noticed a positive correlation between the cytokines level and the tumoral invasiveness. TNFα, IL-6 and IL-1β mean values were 2.2, 1.8 and respectively 2.8 fold higher in invasive adenomas compared to non-invasive ones.

Growth factors analysis also revealed an increase of their mean values in patients versus control: 1.6 fold higher for VEGF and 1.2 fold higher for bFGF. Growth factors values obtained by xMAP array were comparable with the outline obtained by ELISA tests.

Conclusions: Our findings demonstrate that cytokines and angiogenic factors levels are closely linked to pituitary tumoral behaviour. Expression of cytokines and angiogenic factors are strongly related to tumor invasion and in this way may act as supporting factors of pituitary tumour expansion. Luminex xMAP might be a suitable tool to evaluate tumoral development.

Serum from patients with familial Mediterranean fever does not induce apoptosis

G. Manukyan[1], Z. Khachatryan[2], A. Hyusyan[3], S. Margaryan[1], A. Martirosyan[1], K. Ghazaryan[1]
[1]Molecular and Cellular Immunology Group, [2]Laboratory of Ethnogenomics, Institute of Molecular Biology, National Academy of Sciences, Yerevan, Armenia, [3]EFI Accredited HLA Typing Laboratory, Armenian Bone Marrow Donor Registry Charitable Trust, Yerevan, Armenia

Pyrin, the protein product of the familial Mediterranean fever (FMF) gene *MEFV*, plays regulatory role in inflammation and apoptosis. Pyrin mutation may lead to dysregulated apoptotic processes in FMF. However, the molecular mechanisms of neutrophil apoptosis have not been fully investigated. We have previously shown that spontaneous apoptosis of the neutrophils from FMF patients is accelerated. We aimed to determine if soluble factors in the serum of FMF patients are responsible for the accelerated neutrophil apoptosis and able to induce apoptosis in vitro. Isolated neutrophils from FMF patients and healthy subjects were analyzed immediately or incubated with 10% autologous or heterologous pooled serum for 18 h. Diseased and healthy neutrophils were investigated for apoptosis by flow cytometry with Annexin V/PI staining, as well as for Fas (CD95) expression with PE anti-human CD95 antibody at 0 time and after 18 h cultivation. FMF neutrophils displayed a higher rate of spontaneous apoptosis compared to healthy cells (1.8-fold, $p < 0.05$), while spontaneous Fas expression did not differ between the studied groups. Apoptotic rate and Fas expression of cultured FMF and healthy cells was not affected by autologous or heterologous sera, and was not significantly different between both studied groups ($p > 0.05$). Taken together, our results show that the serum from FMF patients does not directly modulate the rate of neutrophil apoptosis. Having observed no differences in Fas expression with increased apoptotic rate of diseased neutrophils at basal level and no differences at the values measured after the cultivation, we can assume that the elevated susceptibility of FMF neutrophils to undergo apoptosis spontaneously is due to in vitro manipulations. This is indicative of increased sensitivity of the cells towards stress conditions.

Keywords: apoptosis, familial Mediterranean fever, Fas.

Significance of serum 25-hydroxy vitamin D levels in Bulgarian patients with prostate cancer

D. Gerova[1], B. Galunska[2], **P. Kosev**[3], D. Anakievski[3], A. Hinev[3]
[1]Department of General medicine and Clinical laboratory, [2]Pharmaceutical Sciences, [3]Department of Surgery, Clinic of Urology, Medical University of Varna, Varna, Bulgaria

Aim: To investigate the relationship between the circulating vitamin D levels and various prognostic variables, associated with the severity and progression of prostate cancer (PCa) in Bulgarian patients.

Patients and Methods: 53 male patients (mean age 67.0 ± 7.1) with clinical suspicion for PCa (elevated prostate specific antigen, PSA and/or abnormal digital rectal examination) were enrolled in the study. All they were subjected to systemic transrectal ultrasound-guided tru-cut prostate biopsies (10 cores at least) and processed for standard histological and immunohistochemical examination. All malignant tumors detected were divided into two subgroups according to the tumor grade (Gleason score < 7 and 3 7). Serum 25-hydroxy vitamin D levels were assayed by HPLC tandem MS. PSA levels were evaluated immunochemically. Statistical analysis was performed by commercial software, using one-way ANOVA non-parametric and correlation analysis. Statistical significance was detected at $p < 0.05$.

Results: PCa was detected in 25 patients (mean age 68.0 ± 7.0), while in 28 patients (mean age 66.0 ± 7.2) benign prostate hyperplasia (BPH) was histologically proved. Significantly lower 25-hydroxy vitamin D levels were detected in PCa patients, compared to those with BPH ($p < 0.05$). There was a significant decrease in the 25-hydroxy vitamin D levels among patients with the most aggressive PCa – those with high grade tumors (Gleason score >7) ($p < 0.05$). With the increase of the Gleason score among patients, the 25-hydroxy vitamin D levels significantly decreased (Pearson $r = -0.39$). Surprisingly, higher 25-hydroxy vitamin D levels were found in PCa patients with a high (> 6) number of positive cores, but the difference was not statistically significant ($p < 0.089$). Other examined covariates, such as: PSA level, age and BMI, did not show any difference between the PCa and BPH patients. Significant seasonal variations in 25-hydroxy vitamin D levels, both for PCa and BPH patients, were detected ($p < 0.05$). During summer, the 25-hydroxy vitamin D levels for both groups reached values, close to the reference range (80–200 nmol/L), while during spring, the PCa group was 25-hydroxy vitamin D deficient (54.01 ± 3.331).

Conclusions: Our results suggest a potential beneficial role of vitamin D in PCa patients. Further studies are needed to strengthen the interrelationships between 25-hydroxy vitamin D levels and various laboratory and clinical parameters, used for diagnosis and prognosis of PCa.

Keywords: 25-hydroxy vitamin D3, prostate cancer.

SUN-299
Silencing of ARTD1 enhances RANKL-induced osteoclast formation by up-regulating IL1beta gene expression

A. Robaszkiewicz[1,2], M. Hottiger[1]
[1]Institute of Veterinary Biochemistry and Molecular Biology, University of Zurich, Zurich, Switzerland, [2]Department of Environmental Pollution Biophysics, University of Lodz, Lodz, Poland

Bone homeostasis, remodeling and healing after fracture are governed by bone-forming osteoblasts and bone-resorbing osteoclasts. The differentiation of pre-osteoclasts during osteoclastogenesis is associated with the activation of the transcription factor nuclear factor-kappaB (NF-kappaB) by the receptor activator of NF-kappaB ligand (RANKL). Upon activation, NF-kappaB induces the expression of pro-inflammatory cytokines and osteoclastogenic factors, which all combined affect the differentiation process in an autocrine and paracrine fashion. ADP-ribosyltransferase Diphtheria toxin-like 1 (ARTD1), the most abundant poly(ADP-ribosyl) polymerase, is involved in the DNA damage response and in intracellular signaling, but has also been demonstrated to be a cofactor of NF-kappaB-dependent transcription. Using RAW 264.7 macrophages treated with RANKL, we show that ARTD1 silencing as well as inhibition of ADP-ribosylation enhance the formation of functionally active osteoclasts, as demonstrated by increased multinucleation, mineral matrix resorption activity, activity of tartrate-resistant acid phosphatase and expression of osteoclastogenic markers such as NFATc1, c-fos and cathepsin K. Interestingly, inhibition or knock-down of ARTD1 resulted in complete inhibition of IL6 transcription, but augmented transcription of IL1beta, two genes regulated by NF-kappaB and IL1beta was found to repress expression of IL6, indicating that IL1beta act as the main

© 2014 The Authors. FEBS Journal © 2014 FEBS

driver of ARTD1-regulated osteoclast maturation. These results provide strong evidence that ARTD1 is important for osteoclastogenesis and might alter bone formation and/or remodeling.

Keywords: inflammatory cytokines, osteoclast differentiation, transcriptional regulation.

Silent entry of mycobacteria into macrophages via Dectin-1?

A. Decout[1,2], G. Tiraby[2], J. Nigou[1]
[1]Tuberculosis and Infection Biology, Institute of Pharmacology and Structural Biology, [2]InvivoGen, Toulouse, France

Innate immunity is the first line of host defense against invading microorganisms. It is based on the detection of invariant molecular signatures that are unique to microorganisms, referred to as pathogens-associated molecular patterns (PAMPs), by a limited number of pattern recognition receptors (PRRs). The latter include Toll-like receptors (TLRs), NOD-like receptors (NLRs) or C-type lectin receptors (CLRs).

Dectin-1 is a CLR that recognizes 1,3-β-glucans from yeast and fungi cell walls and that triggers innate immune responses through an NF-kB-dependent signaling pathway. Several reports indicate that Dectin-1 is involved in mycobacteria uptake by different cell types and in the subsequent cytokine production. However, the underlying mechanisms are still poorly understood and no mycobacterial ligands of this receptor have been identified so far.

Using a soluble form of human Dectin-1 (hDectin-1-Fc), we have shown that the receptor can indeed recognize mycobacterial cell wall components. However, we have found that mycobacteria do not induce the Dectin-1-mediated intracellular signaling pathway, suggesting that Dectin-1 may constitute for *Mycobacterium tuberculosis* a silent entry gate into phagocytic cells.

Keywords: Dectin-1, innate immunity, Mycobacteria.

Silica nanoparticles induce inflammatory response in human fibroblast cells

S. N. Petrache Voicu[1], C. Sima[2], A. Hermenean[3], A. Ardelean[3], A. Dinischiotu[1]
[1]Department of Biochemistry and Molecular Biology, University of Bucharest, Faculty of Biology, [2]Laser Department, National Institute of Laser, Plasma and Radiation Physics, Bucharest, [3]Department of Histology, Faculty of Medicine, Pharmacy and Dentistry, Vasile Goldis Western University of Arad, Arad, Romania

The study of silica nanoparticles has attracted considerable attention in recent years, but there are some concerns about their toxicity.

Our objective was to assess the effect of silica nanoparticles to induce an inflammatory response in human lung fibroblasts (MRC-5 cell line) in order to expand the limited information known in this field.

The primary nanoparticle size distribution was a lognormal function, in the range 3–14 nm, most of them being of 5–8 nm. MTT and LDH tests were used in order to evaluate MRC5 cell viability after treatment with 6.3×10^5 particle SiO_2 for 24, 48 and 72 hours.We have also investigated the protein expression of interleukin 6 (IL-6) and interleukin 8 (IL-8), human prostaglandin E_2 (PGE_2), reactive oxigen species (ROS) and nitric oxide (NO) production.

The viability of the treated MRC5 cells decreased in a time dependent manner compared to control. Cell membrane damage was indicated by the increase in LDH by 3%, 14% and 22% after 24, 48 respectively 72 hours.

The level of ROS increased by 16%, 34 and 39%, whereas that of nitric oxide grew by 62%, 32%, 24% after 24 h, 48 h and 72 of exposure. A very significant increase of IL-6 and IL-8 expression time-dependent accompanied by a similar increase in PGE_2 productionin was registered.

All these data suggest that nanoparticles trigger an inflammatory response in MRC-5 cells.

Keywords: nanoparticles, inflammation, cytokines.

SUN-302
Silicon-based quantum dots induce inflammation in human lung cells and disrupt extracellular matrix homeostasis

M. S. Stan[1], I. Memet[1], S. Badea[1], C. Sima[2], O. Cinteza[3], A. Dinischiotu[1]
[1]Department of Biochemistry and Molecular Biology, University of Bucharest, Bucharest, [2]National Institute for Laser, Plasma and Radiation Physics, Bucharest-Magurele, [3]Faculty of Chemistry, University of Bucharest, Bucharest, Romania

Quantum dots (QDs) are nanocrystalline semiconductor materials that have been recently tested for biological applications such as cancer therapy, cellular imaging and drug delivery, despite the serious lack of information of their effects on mammalian cells. Our aim was to evaluate the potential of Si/SiO_2 quantum dots to induce an inflammatory response in human lung fibroblasts (MRC-5 cell line).

The characterization of hydrodynamic size and zeta potential of Si/SiO_2 QDs dispersed in various solutions was performed using dynamic light scattering and laser Doppler velocimetry, respectively. MRC-5 cells were exposed to different concentrations of Si/SiO_2 QDs (25–200 μg/ml) for 24, 48, 72 and 120 hours. QDs internalization was observed due to their self-fluorescence and protein corona was established by SDS-PAGE. The QDs' effect on cell membrane integrity was evaluated by measuring the LDH release in the media. Lysosomes distribution was visualized after LysoTracker Green DND26 labeling. In order to assess inflammatory potential, enzymatic activity of matrix metalloproteases (MMPs) was investigated by gelatin and casein zymography. The protein expression level of MMPs and cytokines were quantified by Western blotting.

Our results showed that QDs uptake was dependent on biocorona formation and nanoparticles' stability in various biological media (Minimum Essential Medium without or with 10% FBS). The cell membrane damage indicated by the increase in LDH release after exposure to QDs was dose and time-dependent. The level of lysosomes increased proportionally with the concentration of QDs, while an accumulation of autophagosomes was also observed. Cellular morphology was affected, as shown by the disruption of actin filaments. The enhanced NO production and the increase in IL-6 and IL-8 protein expression suggested that nanoparticles triggered an inflammatory response in MRC-5 cells. QDs decreased the protein expression and enzymatic activity of gelatinases (MMP-2 and MMP-9) and MMP-1 caseinase activity, while the protein levels of MMP-1 and TIMP-1 increased.

This study reveals for the first time that silicon-based QDs are able to generate inflammation in lung cells and cause an imbalance in extracellular matrix turnover through a differential regulation of MMP and TIMP protein expression and enzymatic activity.

Smad-dependent regulation of Cx43 expression during TGF-β1-induced activation of fibroblast-to-myofibroblast transition in primary human bronchial fibroblasts

M. Kosińska[1], I. Borek[1], D. Ryszawy[1], K. A. Wójcik[1,2], K. Piwowarczyk[1], M. Michalik[1], J. Czyż[1]
[1]Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, [2]Department of Medicine, Jagiellonian University Medical School, Kraków, Poland

Fibroblast-to-myofibroblast transition (FMT) is induced in bronchial fibroblasts by TGF-β_1. It plays a pivotal role in the induction of airway wall remodeling during bronchial asthma [1]. FMT is regulated by the activation of Smad signaling and accompanied by up-regulation of α-SMA expression – a marker of myofibroblasts [2]. The involvement of connexin (Cx)43, a protein which constitutes gap junctional channels, in the regulation of FMT has been recently reported in cardiac tissue [3]. It prompted us to estimate the role of Cx43 in TGF-β_1-induced FMT undergone by primary human bronchial fibroblasts propagated from bronchial biopsies derived from asthmatic patients (AS HBFs). Up-regulation of Cx43 levels accompanied FMT and α-SMA accumulation upon prolonged exposure of AS HBFs to TGF-β_1 as was demonstrated by immunofluorescence, immunoblotting and flow cytometry analyses. This effect was correlated with the induction of Smad signaling, illustrated by nuclear translocation and accumulation of p-Smad2 in TGFβ_1-treated AS HBFs. Inhibition of gap junctional intercellular coupling by 18-α-glycyrrhetinic acid considerably reduced the efficiency of FMT. However, it had no effect on TGF-β_1-induced nuclear translocation of p-Smad2 and Cx43 expression levels in AS HBFs. On the other hand, transient inhibition of Cx43 expression by siRNA attenuated both the α-SMA transcript quantity and FMT, and Smad signaling activity in AS HBFs. These observations indicate the overlapping gap junctional channel-dependent/independent effects of Cx43 on the efficiency of FMT during airway wall remodeling. Gap junctional coupling may participate in FMT of AS HBFs through mediating by-stander effects in a Smad2-independent manner. On the other hand, Cx43 affects Smad activity in these cells in a channel-independent fashion.

Smart inflammation sensitive self-reporting theragnosis

H. Patra[1,2], A. Tiwari[1], A. Turner[1]
[1]Biosensor and Bioelectronics Center, IFM, [2]Integrative Regenerative Medicine (IGEN) Center, Linköping University, Linköping, Sweden

We have designed and develop a novel class of nanocomposites for inflammation based hallmark functions using biocompatible metallic nano-objects (SPION, nanorod) assembled with a pH sensitive amphiphilic azide terminated block polymer, polystyrene-b-poly (acrylic acid) and temperature-responsive polymer Poly (N-isopropylacrylamide) (PNIPAAm) in a single nanoscopic platform. The nano-architecture is a uniform core-shell micellar assembly of polymer around the biocompatible metallic core. Doxorubicin and methotrexate are loaded within the architecture as the model therapeutic module. The drugs are linked through pH and enzyme sensitive bonds. The complete nano-architecture and linkages are characterized by electron microscopy, NMR and Photon Correlation Spectroscopy. The drug release response has been optimized with different cell line in vitro. The model suggest that change/increase in temperature, reduction of pH and the redox enzymatic activities are increased at the localized inflammatory sites, can be addressed by the developed module and the drug will be released at the inflammation sites only due to their specific linkage to the module. Again we have explored order–disorder micellar structures dependent T_1 & T_2 MRI properties of the module. This results indicate that the fabricated module can also be useful not only probing the inflammation site non invasively through MRI but also will give us idea on the extent of release of drugs at the inflammation sites. The outcomes of these results elucidate the potential of this fabricated nano-architecture for smart theranostics through physicochemical and microenvironment feature based drug delivery, site-specific therapy, real-time probing and non-invasive monitoring of the drug action course for personalized therapy.

Steroids inhibit VEGF expression via TLR4/Akt/NF-κB pathway in chronic rhinosinusitis with nasal polyp

J.-H. Kang[1], J.-S. Cho[1], J.-Y. Um[1], J. A. Kim[1], H.-M. Lee[1,2]
[1]*Biomedical Science,* [2]*Department of Otorhinolaryngology-Head and Neck Surgery, Korea University, College of Medicine, Seoul, Korea*

Vascular endothelial growth factor (VEGF) is elevated in chronic rhinosinusitis with nasal polyps. Steroids have anti-inflammatory properties and are ideal candidates for treating chronic inflammatory airways. The aims of this study were to identify the inhibitory effects and mechanisms of steroids on lipopolysaccharide (LPS)-induced VEGF expression in nasal polyps. Nasal polyp-derived fibroblasts (NPDFs) were stimulated with LPS alone or with both LPS and steroids were used to determine the expression levels of toll-like receptor (TLR)-4, myeloid differentiation primary response gene 88 (MyD88), and VEGF by using RT-PCR. VEGF protein level was analyzed by immunocytochemical staining and ELISA. Small interfering RNA (*si*RNA) for TLR4 was transfected to downregulate TLR4 expression. Activation of Akt and NF-κB pathway on VEGF expression were determined by western blot analysis, immunocytochemical staining and ELISA. Nasal polyp organ cultures were stimulated with LPS alone or in conjunction with steroids or LPS-RS (TLR4 inhibitor) and accessed the expression of VEGF. Steroids decreased the expressions of *TLR4*, *MyD88*, and *VEGF* mRNA and VEGF protein in LPS-stimulated NPDFs. Steroids inhibited LPS-induced VEGF expression levels in dose-dependent manner. The suppression of TLR4 transcription by *si*RNA treatment reduced LPS-induced expression of both TLR4 and VEGF in NPDFs. Furthermore, steroids inhibited the production of VEGF by blocking Akt and NF-κB activation and preventing with NF-κB translocation. Also, steroid and TLR4 inhibitor decreased VEGF expression in nasal polyp organ cultures. These results indicate that steroids inhibit LPS-induced VEGF expression through the TLR4/Akt/NFκB signaling pathway in chronic rhinosinusitis with nasal polyp.

Keywords: steroid, Toll-like receptor 4, vascular endothelial growth factor.

Structural bases for the antigenicity of peptide-MHC complexes

J.-B. Reiser[1], F. Legoux[2], S. Gras[1], A. Chouquet[1], A. Leger[2], M. Bonneville[2], X. Saulquin[2], **D. Housset**[1]
[1]*Insitut de Biologie Structurale, UMR 5075, CEA, CNRS, Université J. Fourier, Grenoble,* [2]*Centre de Recherche en Cancérologie Nantes Angers, INSERM, Université de Nantes, Nantes, France*

We aim at understanding the structural bases for the recognition by T cell receptors of tumoral antigens presented by MHC molecules. We are investigating possible links between intermolecular interactions at the TCR-peptide-MHC interface characterized by crystallographic and surface plasmon resonance (SPR) techniques [1] and the ability of these peptide-MHC complexes to mount an efficient T cell immune response. Any advance in this direction would be extremely valuable for the development of anti-tumoral immunotherapy. By combining structural studies of several peptide-MHC complexes and analysis of the frequency of naive T cells that are specific for these peptide-MHC complexes [2], we have highlighted a few principles and have shown that several parameters should be taken into account. An optimum bulginess of the peptide out of the MHC groove seems to correspond to the highest frequency observed. The analysis of several different TCR specific for the same tumoral antigen, Melan-A [3], by SPR shows a good correlation between affinity at the molecular level and functional avidity at the cellular level. A in depth investigation of the contribution of both the α and the β chains will help us to understand the reasons underlying the biased usage of a specific TRAV encoded germline segment for the α chain and the structural rational supporting the difference in affinity and functional avidity for these TCR.

Structural similarity between the N-terminal domain of LonA proteases and the highly conserved RNA-binding PUA domains

A. Gustchina[1], A. Wlodawer[1], T. Rotanova[2]
[1]*Macromolecular Crystallography Laboratory, National Cancer Institute, Frederick, MD, USA,* [2]*Shemyakin-Ovchinnikov Institute, Moscow, Russian Federation*

Homooligomeric LonA proteases are the key components of the protein quality control system in bacteria and eukaryotes. Proteolytic activity of LonA is coupled to ATP hydrolysis. Pioneering studies in the 1980s have shown that members of this family of proteases/ATPases are also nucleic acid-binding proteins, and their proteolytic and ATPase activities are stimulated by DNA binding. Such studies indicated that a number of different DNA species increased the rate of degradation of target proteins by the protease, and suggested that association with DNA might be involved in regulation of protein breakdown in cells. In particular, studies of the mitochondrial LonA demonstrated that this enzyme binds to DNA and RNA, and that the binding affinity is affected by the presence of a nucleotide and a protein substrate.

Structural data for the individual domains and/or their combinations have recently become available for several representative LonA proteins. Crystal structure of the N-terminal fragment of *E. coli* LonA comprising residues 1–117 revealed structural similarity to the PUA domain, a highly conserved RNA-binding motif found in a wide range of archaeal, bacterial, and eukaryotic proteins. Here we compare the structure of the N-terminal domain of LonA to the structures of the PUA domains from several protein complexes with RNA, with the aim to reveal possible epitopes for the interactions with nucleic acids.

Keywords: ATPase activity, Protein structure, Proteolysis.

Structure based virtual screening of MDPI database: discovery of structurally diverse and novel DPP-IV inhibitors

O. Tanwar, M. Akhter, M. M. Alam
Pharmaceutical Chemistry, Jamia Hamdard (Hamdard University), New Delhi, New Delhi, India

Inhibition of dipeptidyl peptidase IV (DPP-IV) has been emerged as a promising approach for the treatment of type 2 diabetes (T2D). Structure based virtual screening (SBVS) of Molecular Diversity Preservation International (MDPI) database was performed using Glide and Gold against DPP-IV enzyme. Six promising hits were identified and tested for DPP-IV inhibition. Three compounds were found to be active at low micromolar concentration. The 3-(1-hydrazinyl-1-(phenylamino)ethyl)-4-hydroxy-1-methylquinolin-2 (1H)-one (Compound A) was found to be the most potent hit with an IC_{50} of 0.73 μM. These three compounds (A, B and D) were then assessed for their glucose lowering effects in glucose fed hyperglycemic female wistar rats. The glucose lowering effects of compounds also confirms their potential as anti-diabetic agents. The present study demonstrates a successful utilization of *in-silico* SBVS tools in identification of novel and potential DPP-IV inhibitor

Studies on the immunogenicity of amyloid beta oligomers and their role in macrophage-mediated inflammation

I. Dalgediene[1], R. Lasickiene[1], R. Budvytyte[2], R. Morkuniene[3], V. Borutaite[3], G. Valincius[2], A. Zvirbliene[1]
[1]*Department of Immunology and Cell Biology, Vilnius University Institute of Biotechnology,* [2]*Department of Bioelectrochemistry and Biospectroscopy, Vilnius University Institute of Biochemistry, Vilnius,* [3]*Laboratory of Biochemistry, Lithuanian University of Health Sciences Neuroscience Institute, Kaunas, Lithuania*

The central molecule in the pathogenesis of Alzheimer's disease (AD) is believed to be a small-sized polypeptide – beta amyloid (Aβ) which has an ability to assemble spontaneously into oligomers. Various studies concerning therapeutic and prophylactic approaches for AD are based on the immunotherapy using antibodies against Aβ which in some cases of clinical trials led to neuroinflammation. However, knowledge on the mechanisms of Aβ-induced immune responses is rather limited. Previous research on Aβ1-42 oligomers in rat brain cultures showed that the toxicity of these oligomers considerably depends on their size. In the current study, we evaluated the dependence of immunogenicity of Aβ1-42 oligomers on the size of oligomeric particles and identified the immunodominant epitopes of the oligomers. Moreover, we demonstrated that Aβ1-42 immune complexes increase the neurotoxicity of the Aβ1-42 oligomers.

Results: The analysis of mice serum antibodies revealed that 1–2 nm Aβ1-42 oligomers are highly immunogenic. In contrast, larger Aβ1-42 oligomers and monomers induced a weak IgG response in immunized mice. Monoclonal antibody against 1–2 nm Aβ1-42 oligomers was generated and used for the antigenic characterization of Aβ1-42 oligomers. Epitope mapping of both monoclonal and polyclonal antibodies demonstrated that the main immunodominant region of the 1–2 nm Aβ1-42 oligomers is located at its aminoterminus, between amino acids 1 and 19. This enabled us to use antibody in rat brain cultures (primary neurons with microglia) to investigate how antibodies can shape neurotoxicity of the Aβ1-42 oligomers. We have determined that not only antibody interacts with Aβ1-42 oligomers and forms immune complexes but also increases neurotoxicity of Aβ1-42 oligomers. We were able to confirm that this effect might be due interaction between antibodies and Fc receptors which are found on microglia cells.

Conclusions: Small Aβ1- 42 oligomers of size 1–2 nm induce the strongest immune response in mice. The amino-terminus of Aβ1-42 oligomers represents an immunodominant epitope which indicates its surface localization. The data demonstrate that Aβ1-42 oligomeric antigens in complex with specific antibodies can increase neurotoxic effects on primary neurons by Fc-dependent microglia activation. The results of the current study may be important for further development of Aβ-based vaccination and immunotherapy strategies.

Acknowledgments: This research was funded by a grant (No. LIG-04/2012) from the Research Council of Lithuania.

Study of catalytic antibodies and their implication in autoimmune disease

M. A. Shahsavarian, A. Friboulet, B. Avalle, S. Padiolleau Lefèvre
Cellular and Enzymatic Engineering, Universite de Technologie de Compiegne, Compiegne, France

Catalytic antibodies (or abzymes) are immunoglobulins capable of catalyzing an enzymatic reaction. In the late 1980s and the early 1990s, many abzymes were observed on the background of autoimmune disease (reviewed in [1]). This suggested the existence of a link between autoimmunity and the formation of natural catalytic antibodies. Abzymes have also been discovered in normal physiological states [2]. Despite advances in the study of catalytic antibodies, there are many questions yet to be answered about the nature of these molecules and their role in the immune system. To address these questions, a statistical analysis was performed on the genetic sequences of 40 abzymes [3]. We analyzed the gene subgroups, catalytic residues, and somatic mutations responsible for the catalytic function of these catalytic antibodies. It was shown that they display a high conservation degree with their germline counterparts, significant modification of the physico-chemical

© 2014 The Authors. FEBS Journal © 2014 FEBS

properties of their mutated amino acids, and a more frequent expression by rare gene subgroups. This suggests that there is a difference between the maturation process of abzymes and binding antibodies and can possibly explain their high occurrence in autoimmune disease. Following a new methodology [4] and using newly designed primers, we have constructed 4 phage displayed combinatorial libraries of single-chain antibody fragments (scFv) representing different immune repertoires: healthy or autoimmune, naive or immunized. The 4 libraries have been independently tagged and pooled together resulting in a single library of size 10^9, allowing us to perform a unique selection process. We select for catalytic antibodies in this pooled library by exploiting a suicide substrate used for immunization as the trapping agent. Here, we investigate the gene subgroup representation profiles among the 4 repertoires focusing on a window of 100 sequences per library. These results together will lead to a better understanding of the characteristics of catalytic antibodies and their link to autoimmune disease.

The anti-inflammation effects of water extract of curcumae radix and cortex *Magnolia officinalis* for prevention of gastric ulcer in vitro and in vivo

H.-C. Chaung[1], M.-L. Wu[2], M.-H. Hsieh[3], Y.-L. Tsai[1], Y.-Y. Lien[1]
[1]*Veterinary Medicine,* [2]*Food Science,* [3]*Biotechnology, National Pingtung Univeristy of Science & Tech, Pingtung, Taiwan*

Tranditional Chinese medicines play an important role in the health care for Chinese people for several thousands years. Many herbs have been used on protecting gastric mucosa against chronic or acute inflammation. This study investigated the anti-inflammation effects of water extracts of Curcumae Radix and Cortex Magnoliae Officinalis, for prevention of gastric ulcer in vitro and in vivo. Our in vitro results showed that water extracts of Curcumae Radix and Cortex Magnoliae Officinalis specifically promoted the cell viability and decreased the production of reactive oxygen species (ROS) of the gastric epithelial cells in the acidic medium as compared with those of control cells. The results from the animal model of Shey's ulcer ligation suggested that the water extract of Cortex Magnoliae Officinalis decreased the productions of tumor necrosis factor-alpha (TNF-alpha) and interleukin 6 (IL-6) of gastric tissue and thus significantly decreased the gastric ulcer index in vivo. In conclusion, the water extract of Cortex Magnoliae Officinalis may protect the gastric mucosal tissue from the acidified injury by enhancing gastric epithelial cell survival rates and decreasing ROS, TNF-alpha and IL-6 productions in the injured gastric tissue.

The determination of serum and urinary endothelial cell-specific molecul-1 (endocan, ESM-1) levels in patients with bladder cancer

E. Laloğlu[1], **H. Aksoy**[1], Y. Aksoy[2], F. Özkaya[2], F. Akçay[1]
[1]*Medical Biochemistry,* [2]*Urology, Medical school, Ataturk University, Erzurum, Turkey*

Bladder cancer is one of the most common malignancies in men. Endothelial cell-specific molecul-1 (endocan, ESM-1) is a proteoglycan and plays an important role in angiogenesis and inflammation. The aim of this study was to evaluate the diagnostic value of serum and urinary levels of ESM-1 in bladder cancer. The study included 50 bladder cancer patients, 50 with urinary tract infection (UTI) and 51 healthy volunteers. Serum and urinary ESM-1 levels were measured with enzyme linked immunosorbent assay (ELISA).

In bladder cancer group, serum and urinary ESM-1 levels were significantly higher than in the healthy subjects ($p = 0.003$ and $p < 0.0001$). Urinary ESM-1 levels in cases with UTI were also higher than in healthy volunteers ($p = 0.002$). There were no significant differences between bladder cancer and UTI groups in terms of serum and urinary ESM-1 concentrations.

In the three groups, urinary ESM-1 concentrations were higher than those of corresponding serum ESM-1 concentrations ($p < 0.0001$ for bladder cancer and UTI groups, $p = 0.002$ for healthy subjects). In bladder cancer group, there was a statistically positive correlation between serum ESM-1 and urinary ESM-1 concentrations ($r = 0.32$, $p = 0.002$). We determined the ability of serum ESM-1 levels to differentiate between bladder cancer patients and healthy subjects. The sensitivity and specificity were 50%, and 77%, respectively, with a 'cut off' point of 630 pg/mL. The sensitivity and specificity of urinary ESM-1 levels were 62%, and 71%, respectively, with a 'cut off' point of 1100 pg/mL.

When bladder cancer cases were divided according to pathological stages, there was no significant difference between invasive bladder cancer and non-invasive bladder cancer groups in terms of serum and urinary ESM-1 concentrations.

As a conclusion, serum and urinary ESM-1 concentrations increase in bladder cancer. This parameter also increases in serum and urine of cases with UTI. That urinary ESM-1 values were higher than serum ESM-1 values in all groups may be attributed to direct exfoliation of epithelial cells in bladder to urine.This condition must be taken into consideration when evaluating ESM-1 in bladder cancer.

The determination of the angiogenesis and apoptosis markers role on the prognosis of acute myocardial infarction

Z. Gokcen, on behalf of Medical Biochemistry, **M. Gurbilek**, on behalf of Medical Biochemistry, C. D. Cetinkaya, on behalf of Medical Biochemistry
Medical Biochemistry, Faculty of Medicine, Necmettin Erbakan University, Konya, Turkey

Introduction: Acute coronary syndromes are a leading cause of mortality, morbidity, and health care cost. Innate and acquired immune responses influence the extent of atherothrombosis and the vulnerability of single lesions. Complement activation, interleukins and acute-phase proteins modulate the extent of myocardial damage, aggravating the prognosis. In this study, cells after ischemic injury in acute myocardial infarction (AMI), is developing angiogenesis or apoptosis, we aimed to learn, which way the cells prefer.

Materials and Methods: Our study was performed on 42 patients diagnosed with AMI (26 men, 16 women), 42 healthy controls (23 men, 19 women). We have tried tumor necrosis factor-α (TNF-α), Caspase-9, insulin-like growth factor 1 (IGF-1) and interleukin-8 (IL-8) in blood that collected by grouping. In our study, patients in the initial emergency contact, 24 per hour

© 2014 The Authors. FEBS Journal © 2014 FEBS

and a month later (30th day of) blood samples were taken during the controls.

Results: The differences were found for IL-8 between the value of the control-24.hours and control-30.day. Significant differences were found in IL-8 levels comparison in patients group. IGF-1 levels were not significantly different in comparison. TNF-α values for the intertemporal comparison with the control group; significant differences were found between the control-24.hours and the control-0.hours. There were differences in TNF-α between the 24.hours-30.day and 0.hours-30.day in patients according to the time value comparison. Value comparison of Caspase-9 did not differ significantly. Significant positive corelation was found between IL-8 and TNF-α.

Conclusion: After undergoing myocardial infarction, TNF-α levels were increased, Caspase-9, IGF-1 and IL-8 levels were decreased. One month later, measurement of TNF-α has also started to decline while other parameters have showed increase. These data will provide new meanings to myocardial infarction. For further studies of myocardial infarction patients should be monitored for a longer period.

The effect of dipeptidyl peptidase-IV inhibition on the immune functions in patients with type 2 diabetes

L. Sromova[1], P. Busek[1], H. Mareckova[2], J. Potockova[3], M. Andel[3], A. Sedo[1]

[1]Laboratory of Cancer Cell Biology, Institute of Biochemsitry and Experimental Oncology, [2]Institute of Immunology and Microbiology, 1st Faculty of Medicine, Charles University, [3]2nd Department of Internal Medicine, 3rd Faculty of Medicine, Charles University in Prague and Faculty Hospital Královské Vinohrady, Prague, Czech Republic

Dipeptidyl peptidase-IV (DPP-IV) is a membrane bound multifunctional serine protease identical with the marker of activated lymphocytes CD26 and its soluble form can be found in blood plasma. Recently, specific DPP-IV inhibitors (the gliptins, e.g. sitagliptin) that improve insulin secretion by preventing the DPP-IV mediated degradation of incretins were introduced for the treatment of type 2 diabetes. In addition to the breakdown of incretins, DPP-IV however proteolytically modifies several other biologically active peptides such as neuropeptides and chemokines and its long-term inhibition could therefore lead to unfavorable effects including immune dysregulation.

The aim of this study is to assess the effects of DPP-IV inhibition by sitagliptin on the immune system in patients with type 2 diabetes.

Patients with type 2 diabetes were examined before the initiation of sitagliptin treatment and 4 weeks and 12 months thereafter, the results were compared intraindividually as well as with the control group of type 2 diabetic patients treated with other oral antidiabetic drugs. Immunophenotyping of Treg and T cells (CD4+, CD8+) was performed in freshly collected peripheral blood, the proportion of Th1 population and the presence and activation of NK cells were analyzed after in vitro stimulation with phytohemaglutinine, phorbol myristate 13-acetate and ionomycine in the presence of brefeldin A. DPP-IV enzymatic activity was determined in heparinized blood plasma and isolated blood mononuclear cell.

Compared to patients treated with other hypoglycemic drugs, plasmatic DPP-IV enzymatic activity was inhibited by 76.4 ± 15.5 and 60.5 ± 27.5% (mean ± SD) at 4 weeks and 12 months of sitagliptin treatment, suggesting long term systemic inhibition of DPP-IV in our patient cohort. After 4 weeks, the proportions of Treg and NK cells significantly decreased, whereas Th1 increased, but the changes normalized in the majority of patients after 12 months of treatment.

Our data show that sitagliptin treatment may lead to transient changes in the proportion of various lymphocyte populations in type 2 diabetes patients.

SUN-319
The effect of epigallocatechin-3–gallate on major peanut allergens' structure

J. Vesic, D. Apostolovic, M. Milcic, T. Cirkovic Velickovic

Faculty of Chemistry, University of Belgrade, Belgrade, Serbia

Epigallocatechin-3-gallate (EGCG) is the most abundant catechin in green tea. EGCG possesses anti-allergic properties due to its inhibitory effect on mast cells degranulation and histamine release. Peanuts are widely used for the preparation of a variety of foods, while being important elicitors of food allergy and the predominant source of ingested allergens worldwide. Homologs Ara h 2 and Ara h 6 are major peanut allergens known for their cross reactivity.

Covalent and non-covalent interactions of EGCG with proteins have been reported. However, the mechanisms of EGCG binding to allergens remain poorly understood and biological effects of these interactions have not been investigated so far. EGCG-allergen interaction could alter IgE epitopes and influence allergenic potential.

The main goal of this study was elucidation of EGCG effect on major peanut allergens', Ara h 2 and Ara h 6 structure by studying the interactions between EGCG and said proteins.

CD spectroscopy results revealed both Ara h 2 and Ara h 6 structure relaxation upon incubation with increasing amounts of EGCG. Increase in β-sheet content, at the expense of α-helix occurs at the EGCG concentrations around or above the K_d in case of both proteins.

Ara h 2 has a Trp-residue, a strong fluorophore whose fluorescence quenching (FQ) analysis could provide protein structural information. Ara h 6 only has Tyr-residues, so no such data could be obtained by FQ. In order to establish the strength and nature of the putative Ara h 2/EGCG interaction in solution, we employed various mathematical models – Stern-Volmer, Lehrer, Double logarithm and Langmoir analysis. Association constants were in the range of $2–4 \times 10^4$ M^{-1}, while the number of binding sites was determined to be 0.92 EGCG molecules/protein. Computational and docking analysis of binding affinity revealed most probable binding sites of EGCG on Ara h 6. The calculated free energy of binding of −7.9 kcal indicates stable complex formation between EGCG and Ara h 6.

Our results provide better understanding of physiologically significant effects which EGCG exhibits in presence of allergenic proteins. CD spectroscopy confirmed the same EGCG effect on both proteins' conformation. Ara h 2 FQ analysis results could indicate the strength and nature of EGCG interactions with Ara h 6 as well. Docking studies performed on Ara h 6 could also provide insight into EGCG binding sites of Ara h 2. These results show promise on revealing the potential contributing mechanism of anti-allergic properties of EGCG.

Thermal skin burn is one of the most common problems in the world. It induces the activation of an inflammatory process resulting in local and distant tissue damage. Leaves of the *Myrtus communis* subsp. *communis* (Myrtaceae) are used in the treatment of wounds and burns in traditional medicine. It was shown that the topical applications of the compound with free-radical-scavenging properties in patients significantly improved wound healing and protected tissues from oxidative damage. In the present study, we investigated the putative antioxidant effect of local *Myrtus* L.(Myrtaceae) treatment on burn-induced oxidative tissue injury. Under ether anaesthesia, Wistar albino rats (200–250 g) were exposed to a 90°C (burn) or 25°C (sham) water bath for 10 s. Leaves of *Myrtus communis* subsp. *communis* were collected from the Turgutlu region of Denizli and were dried in the shade at room temperature. Powdered leave samples (100 g) was extracted with ethanol in a Soxhlet aparatus, filtered and dried under vacuum and stored under refrigeration. *Myrtus* L.(Myrtaceae) was locally (100 mg/kg) applied on 4 cm^2 area after the burn and this was repeated twice a day. Rats were decapitated 48 h after burn injury. Skin tissue samples were taken from animals and homogenized in saline. Oxidant-antioxidant biochemical parameters were determined in homogenized skin samples. Results were evaluated statistically and discussed.

The effect of resistin and fractalkine on macrophage-smooth muscle cells cross-talk

M. Pirvulescu, E. Butoi, A.-M. Gan, D. Stan, V. Simion, M. Calin, I. Manduteanu
Biopathology and Pharmacology of Inflammation, Insitute of Cellular Biology and Pathology 'Nicolae Simionescu', Bucharest, Romania

Resistin was found in human atherosclerotic lesions and was suggested to be an inflammatory marker of atherosclerosis and to promote atherogenesis. Fractalkine (FKN) has dual function acting as a cell adhesion molecule and chemokine mediating direct capture, firm adhesion and transmigration of leukocytes and its expression is enhanced in human atherosclerotic plaques. Both resistin and fractalkine were found at increased levels in the human atherosclerotic lesions, resistin being associated with CD68 monocytes/macrophages in carotid arteries and aortic aneurisms, and fractalkine predominantly associated with intimal smooth muscle cells (SMC) and with monocytes/macrophages but their role in this location is not very clear yet. Our recent data showed that resistin has pro-inflammatory effects on SMC and that fractalkine has proatherogenic effects in human monocytes/SMC cross-talk. The objective of this study was to explore the role of resistin and FKN in macrophage-SMC cross-talk and to uncover the molecular mechanisms involved. THP-1 cells (a monocytic cell line) were differentiated to macrophages with phorbol myristate acetate (PMA) and then interacted with SMC cultured on membrane inserts in the presence or absence of resistin or FKN. After 24 hours, the gene and protein expression of inflammatory mediators induced in macrophages by macrophages-SMC cross-talk was determined by Q-PCR and Proteome ProfilerTM Array (R&D Systems). Macrophages alone or macrophages activated with resistin or FKN were used as controls. Protein array experiments revealed that macrophages exhibit after their interaction with SMC an increased expression of chemokines (CCL1, CCL4, CCL5, CCL19, CXCL1, CXCL5, CXCL7) and cytokines (IFNγ, TNFα, IL-1α, IL-10, IL-2, IL-23, IL-27, IL-5, IL-6 and IL-8) and PAI-1 (plasminogen activator inhibitor-1). Moreover, resistin enhanced the inflammatory macrophage phenotype induced by their interaction with SMC, by increasing the level of the chemokines CCL1, CCL4, CCL5, CXCL1 and of the cytokines: IFNγ, IL-1α, IL-5, IL-6, IL-23, IL-27, IL-8 and PAI-1. In addition, resistin induced in macrophages interacted with SMC an increased expression of the chemokines: CCL10, CCL17, CCL3, CXCL11 and cytokines IL-13, IL-17, IL-17E, IL-ra, IL-1β and ICAM-1, MIF (Macrophage migration inhibitory factor), CD40L. Our preliminary data indicate that FKN also modulate macrophage-SMC interaction by increasing the expression of mediators involved in inflammation and fibrosis. Our results suggest that resistin and fractalkine may exert pro-inflammatory effects in macrophages-SMC cross-talk and the molecular mechanisms involved may reveal targets for novel anti-inflammatory therapies.

Keywords: fractalkine, macrophage-smc cross-talk, resistin.

The evaluation of serum amylase and lipase in the diabetic patients with chronic pancreatitis with a possible correlation with the pancreatic functions

M. Sliwinska-Mosson[1], S. Milnerowicz[2], H. Milnerowicz[1]
[1]Department of Biomedical and Environmental Analyses, [2]Department of Gastrointestinal and General Surgery, University of Medicine Wroclaw, Wroclaw, Poland

Diabetes mellitus is a chronic metabolic disorder which is associated with hyperglycaemia. It is caused by a derangement in the secretion or function of the endocrinal portion of the pancreas. There is a close anatomical and functional relationship between its exocrine and endocrine parts. The current study was designed to evaluate the blood glucose, insulin levels and the amylase, lipase activities of diabetic patients as representatives of the two parts of the pancreas respectively.

We were investigated exocrine function by assaying both amylase and lipase activity in 24 diabetic patients with chronic exacerbate and chronic pancreatitis (CEP, CP) and 50 healthy persons. Endocrine function in patients was analyzed based on the glucose and insulin concentrations in plasma. In addition, the analysis also age, BMI and smoking factor. Patients and healthy persons were separated into two groups according to whether smoked, or non-smoked cigarettes.

Significantly high serum amylase and lipase activities were found in the smoking diabetic patients with CEP (339.1 $\pm$ 38.9 [U/L]; 212.4 $\pm$ 41.7 [U/L]) and CP (52.5 $\pm$ 2.8 [U/L]; 79.7 $\pm$ 42.7 [U/L]) as compared to those in the non-smoking healthy controls (40.2 $\pm$ 13.4 [U/L]; 26.3 $\pm$ 10.7 [U/L]; $p < 0.001$ respectively). It is interesting that the enzymes activities were 8-fold higher in smoking patients with CEP compared to control. Also, the levels of fasting serum glucose were significantly higher in the smoking patients with CEP (177.6 $\pm$ 32.8 [mg/dL]) and CP (154.5 $\pm$ 28.6 [mg/dL] as compared to those in the non-smoking patients (142.6 $\pm$ 15.8 [mg/dL], $p < 0.001$; 136.2 $\pm$ 8.9 [mg/dL], $p < 0.05$, respectively) and controls (74.4 $\pm$ 15.7 [mg/dL], $p < 0.001$ and <0.01). The insulin level was found lower in the smoking diabetic

© 2014 The Authors. FEBS Journal © 2014 FEBS

patients (CEP: 1.4 ± 0.6 [μU/mL] and CP: 1.4 ± 0.8 [μU/mL] as compared to non-smoking patients and control (2.1 ± 0.4 [μU/mL]; 2.8 ± 0.6 [μU/mL] and 10.7 ± 2.9 [μU/mL], $p < 0.001$; respectively). In smoking patients with diabetes differed with regard to BMI as compared with non-smoking.

In patients with CP and diabetes, association of decreased pancreatic exocrine function with BMI and vascular disease suggests a role of pancreatic arteriopathy. The increase enzymes activities and a decrease in insulin level in patients with CEP and diabetes probably was associated with the exacerbation of pancreatitis due to smoking cigarettes.

Keywords: Diabetes, enzyme activity, pancreatitis.

The fatty acid composition of type 1 diabetic patients in Turkish population and its relation with glycosylated hemoglobin

E. Kaya, F. Bakar, S. Nebioğlu
Biochemistry, Ankara University, School of Pharmacy, Ankara, Turkey

Background: Type 1 diabetes mellitus is a disease characterized by pancreatic B-cell destruction and insulin deficiency. The studies have long-standing continued on the relation between diabetes and atherosclerosis and there are also studies suggesting that HbA1c, glycosylated form of hemoglobin, may be associated with atherosclerosis in diabetic patients. The aim of this study is to evaluate the relation between fatty acid alteration and HbA1c levels of type 1 diabetic patients in Turkish population.

Material and Method: The study was performed with 59 type 1 diabetic patients, who were admitted to the Endocrinology and Metabolism outpatient clinic, and 42 healthy volunteers. The fatty acid composition, including was performed on gas chromatography and the fatty acid levels were calculated as % amounts by use of standard methyl ester mixtures. HbA1c levels were analyzed in an A1c HA-8160 analyzer by HPLC.

Results: The levels of stearic acid (C18:0) in type 1 diabetic group were significantly higher (0.45 ± 0.042 μg/μl) when compared to control (0.11 ± 0.027 μg/μl, $p = 0.000$). The results showed that the levels of unsaturated fatty acids, C18:1, C18:2, C18:3 and C22:4 were significantly lower in type 1 diabetic group, when compared to control ($p < 0.001$). The average HbA1c levels of type 1 diabetic group was 9.86% and the higher C18:0 levels were positively correlated with HbA1c levels ($r = 0.067$).

Conclusion: We found decreased unsaturated fatty acid composition and increased stearic acid levels in type 1 diabetic group, sustaining the hypothesis that type 1 diabetes is prone to atherosclerotic disease development. The positive correlation of HbA1c with C18:0 is also a supporting issue whereas need to be clarified with further studies.

Keywords: type 1 diabetes mellitus, fatty acid, HbA1c.

In the recent studies have shown that glial cells are involved in the pathophysiology of epilepsy. Activated glial cells produce cytokines. It is known that the neuroinflammation process contribute to the pathogenesis of epilepsy. However there is an age-related early impairment of the neuron–glia interactions in rats with genetic absence epilepsy. IL-33 has immunomodulatory functions in the brain. It's role in absence epilepsy had never been studied before. In the preliminary findings of our study, 16 male rats, aged 2 months were used. Rats were divided into 2 groups as follows; WAG/Rij rat group and Wistar control rat group. All rats were decapited after that cortex and thalamus were dissected. Protein expression level was assessed with Western blot. Western blots were performed using standard techniques. IL-33 expression level was statistically increased in both cortex and thalamus as compared with control group. Our results suggest that IL-33 may play a role in pathogenesis of absence epilepsy. For further studies we aim to study IL-33 at 6 months age. In this respect the role of IL-33 in the pathophysiology of absence epilepsy are thought to be enlightened.

Keywords: Epilepsy, IL-33, WAG/Rij.

The impact of silymarin nano-formulation on experimental liver damage in Balbc mice

M. Cengiz[1], H. M. Kutlu[1], D. Vejselova[1], A. Ayhancı[2]
[1]*Biology, Anadolu University,* [2]*Biology, Eskisehir Osmangazi University, Eskisehir, Turkey*

Hepatoprotectivity, anti-oxidative, anti-inflammatory and anticancer effects are known to be showed by silymarin as flavonolignan with above mentioned characteristics. Clinically applied silymarin in high doses was found to be biologically safe. But, pharmacocinetic studies have shown the biopharmaceutical imitations of this agent as improper diffusion in the tissue, poor solubility in water, and decomposition in the intestine. For this reason in this study we aimed to formulate silymarin nanoparticles and to investigate the hepatoprotective effects of this particles on experimentally damaged liver tissue by TNF-alpha/D-Galactosamine application. For detecting the ultrastructural changes the liver tissues on silymarin administered and control animals were fixed with 2.5% glutaraldehyde in 0.1 M phosphate buffer at pH 7.4 and and left in buffer overnight at +4°C. The tissue sample were post fixed in %2 osmium tetroxide and dehydrated in graded alcohol: 70, 90, 96 and 100%, then embedded in EPON 812 epoxy and sectioned on ultramicrotome (LEICA UC6). After staining the tissues were observed on transmission electron microscope (FEI Tecnai BioTWIN). Our results show that the ultrastructure of the liver cells of silymarin nano-particle administered animals are more similar to the control animal cells than the TNF-alpha/D-Galactosamine administered animal cells. Our results show the hepatoprotective effect of silymarin nanoparticles in experimental liver damage in Balbc mice.

Keywords: Balbc mice, Hepatoprotective, Silymarin.

SUN-326
The impact of thrombospondin-1 in pathophysiology of absence epilepsy

G. Gürol[1], Z. Seçkin Akkilik[2], **S. Arabacı**[1], S. Sarı[1], Y. Yükselten[3], A. E. Yeni[2], D. Güneri[2], F. Ekici[2], K. Demircan[4]

Thrombospondins (TSPs) are glycoproteins. TSP-1 has identified as an astrocyte-secreted protein and regulate synaptogenesis. It's

© 2014 The Authors. FEBS Journal © 2014 FEBS

role in absence epilepsy had never been studied before. The aim of this study is to investigate the neural mechanism underlying absence epileptic seizure in WAG/Rij rats.1, 3 and 6-months-old female WAG/Rij (n = 21) rats were used in our study. All animals were decapitated using transcardiac perfusion. The cortex was dissected from brains of WAG/Rij rats in all group. TSP-1 protein expression levels were assessed with Western blot. Western blots were performed using standard techniques at 1 months old WAG/Rij rats, 3 and 6, respectively. p values <0.05 accepted as statistically significant. Compared with our preliminary results from WAG/Rij rats groups, 3 months age group showed significantly higher TSP-1 protein expression level. However 6 months age group also showed significantly lower TSP-1 protein expression level in cortex. TSP-1 protein expression levels in 1 months age group were found to be increased compared to 6 months age group. But this alteration in 1 months age group was not statistically significant. The differences of expression level and other TSP variants within groups and other brain region will be subjected to further analysis by us for confirmation. Our results suggest that TSP-1 is possibly involved in absence epileptic seizure maturation in cortex. This alteration should lead to maturation of synapses and contribute to the pathophysiology of absence epilepsy.

The in vivo effects of chronic cadmium toxicity in the liver

N. Yazihan[1], M. Kacar[2], E. Akcil[1], A. Sayal[3], O. Erdem[3], O. Uzunalimoglu[4]

[1]Pathophysiology, Ankara University Faculty of Medicine, Ankara, [2]Physiology, Yeditepe University, Istanbul, [3]Department of PharmaceuticalToxicology, y, Gulhane Military Medical Academ, [4]Turkish Hepatology Foundation, TurkishHepatology Foundation, Ankara, Turkey

Accumulation of the widespread environmental toxin cadmium (Cd) in tissues results intoxicity. Liver is one of the most effected tissues. Cd exposure induces inflammation in effected tissues. Galectin-3 is inflammation related molecule, which takes part in cell survival, apoptosis, and migration.The present study was focused to evaluate role of TNF-α and IL-6 during Cd toxicity and their relationships with galectin-3 levels. Male Wistar rats were exposed to Cd at the dose of 15 parts per million (ppm) for 8 weeks. Inflammatory status in liver was evaluated with measurement of tissue TNF-α and IL-6 levels. Liver tissue caspase-3 level was used to identify apoptosis. Tissue galectin-3, TNF-α and IL-6 levels were evaluated by ELISA. A significant increase in galectin-3 tissue level was seen after Cd toxicity, this was accompanied with a significant increase in the TNF-α and IL-6 levels. Increased caspase-3 levels were measured after Cd toxicity. Chronic Cd toxicity induces inflammation and apoptosis in rat livers. Cd causes increased galectin-3 production in liver tissue. The formation of TNF-α due to Cd exposure may likely trigger this mechanism.

Keywords: cadmium, galectin-3, inflammation.

The inflammatory mediator tumor necrosis factor α (TNFα) has cell type-dependent effects on hypoxia-inducible factor 1 (HIF-1)

E.-A. Triantafyllou[1], S. Tsapournioti[1], I. Mylonis[2], G. Simos[2], P.-A. Molyvdas[1], **E. Paraskeva**[1]

[1]Laboratory of Physiology, Faculty of Medicine, [2]Laboratory of Biochemistry, Faculty of Medicine, University of Thessaly, Larissa, Greece

Inflammation is often accompanied by hypoxia due to high cellular metabolic activity and accumulation of immune system cells at the sites of inflammation. The key mediators of the cellular response to hypoxia are the Hypoxia-Inducible Factors (HIFs) (1). HIF-1α, the regulatory subunit of HIF-1, can be induced by cytokines, mainly in cells of the immune system (2). In order to investigate the induction and function of HIF-1 under inflammatory conditions in cells of non-immune origin, we analyzed the effect of tumor necrosis factor α (TNFα) on human epithelial cancer H1299 and A549 cells, hepatocarcinoma Huh7 cells, as well as in primary bronchial airway smooth muscle cells (HBSMCs), under normoxia or hypoxia. Treatment of the cancer cells with TNFα did not affect the expression of HIF-1α, although mRNA expression levels of the inflammation markers RANTES, ICAM and VCAM were increased significantly. In contrast, TNFα up-regulated HIF-1α protein and mRNA levels, under both normoxia and hypoxia, in non-cancer primary HBSMCs, through an NF-kB-depended pathway. However, despite the induction of HIF-1α protein in HBSMCs, the transcriptional activity of HIF-1 was reduced by TNFα, due to inhibition of the interaction between HIF-1α and ARNT and subsequent blocking of HIF-1 binding to target gene DNA (3). Our results show that in contrast to cells of the immune system, TNFα is not an inducer of HIF-1α in lung and liver cancer cells and is a negative regulator of HIF-1 activity in primary smooth muscle cells. These suggest that cross talk between hypoxia and inflammation is highly complex and cell-type or tissue specific.

Supported by the 'ARISTEIA II' Action of the 'Operational Programme Education and Lifelong Learning' and co-funded by the European Social Fund (ESF) and Greek national resources.

The influence of tobacco smoke and occupational exposure in copper foundry on the antioxidants status of MT and PON in blood

H. Milnerowicz, M. Zalewska, A. Bizon

Department of Biomedical and Environmental Analyses, Wroclaw Medical University, Wroclaw, Poland

Metallotionein (MT) and paraoxonase (PON) are proteins both involved in protection against xenobiotics and free radicals. MT plays important role in protecting against a number of xenobiotics such as: heavy metals, carbon tetrachloride, chemiotherapy and UV radiation. MT also scavenges hydroxyl radical, superoxide anion radicals and hydrogen peroxide.

PON are a family of three enzymes called PON-1, PON-2 and PON-3. PON-1 is the most studied enzyme and hydrolyses the active metabolites of several organophosphorus insecticides (phosphotriesterase activity, PON-P) as well as protects against

© 2014 The Authors. FEBS Journal © 2014 FEBS

LDL oxidation. PON-1 has also antioxidant function and is involved in defense against hydrogen peroxide.

The aim of present study was to analyze MT concentration and PON-P activity in the blood of smoking and non-smoking smelters as well as investigate the relationship between these markers.

The concentration of MT in plasma was measured by enzyme-linked immunosorbent assay elaborated in our laboratory using a commercial antibody and own standard MT (isoforms MT-I and MT-II) isolated from human liver (1). PON-P activity in serum was measured spectrophotometrically at $\lambda = 405$ nm using paraoxon as a substrate (2).

The highest concentration of MT was observed in the plasma of smoking smelters (6.09 ± 3.76 μg/l), whereas in these group the lowest PON-P activity was observed (100.70 ± 54.24 U/l).

No statistically differences were found between the concentration of MT in the plasma of smoking (4.15 ± 1.84 μg/l) and non-smoking control group (4.07 ± 2.21 μg/l) as well as between non-smoking smelters (4.67 ± 2.61 μg/l) and smoking and non-smoking control groups.

The activity of PON-P was lower in serum of non-smoking smelters (110.72 ± 59.23 U/l) when compared to non-smoking (133.63 ± 66.21 U/l) and smoking control group (156.27 ± 57.62 U/l).

We have observed a negative correlation between MT concentration and PON-P activity in the blood of non-smoking smelters ($r = -0.84$, $p = 0.0024$) and non-smoking control group ($r = -0.47$, $p = 0.045$).

Tobacco smoke disturbs status of these antioxidants and their interacts, both in control and smelters groups.

The influence of β-glucans intake on activity of antioxidant enzymes

K. Bukowska, S. Gudej, D. Suchecka, J. Wilczak, J. Harasym, J. Gromadzka-Ostrowska
Department of Dietetics, Warsaw University of Life Sciences, Warsaw, Poland

β-glucans are polysaccharides, found in the cell walls of bacteria, fungi, and plants such as oat or barley. It is known that physicochemical properties of β-glucans vary between β-glucans of different source. Moreover, the physiological effects (i.e. antioxidant potential) of various β-glucan forms are correlated with their molecular weight, intrinsic viscosity, composition and chemical structure (Zhao et al., 2014). β-glucan possesses free radical scavenging activity and the ability to alleviate inflammatory conditions. What is more, β-glucan demonstrates significant protective properties against the severe oxidant induced lipid peroxidation in blood or plasma (Saluk-Juszczak, 2011). Inflammation is undoubtedly a major driving force for the stride of major chronic diseases (Poli et al., 2013). Therefore, the attention is concentrated on the role of natural antioxidants which are able to protect living organisms against the action of reactive oxygen species and in this way decrease the risk of various diseases.

The aim of the present study was to examine the antioxidant activity of two forms of oat β-glucans (low and high molecular weight) in laboratory animal model of enteritis.

The study was performed on mature Sprague Dawley male rats (n = 48), divided into 3 groups (fed control diet (K) and diet supplemented with small molecular wieght (G1) and large molecular wieght (G2) oat β-glucans. Within groups animals were divided into healthy individuals (K, G1, G2) and individuals with experimentally induced (intravenously injection of E. coli lipopolysaccharides) intestinal inflammation (Kz, G1z, G2z). The activity of superoxide dismutase (SOD), glutathione peroxidase (GPx) and reductase (GR) was determined using commercially available assays.

Enteritis was confirmed histologically. Injection with E. coli LPS resulted in a significant increase of activity of SOD, GPx and GR in Kz group. Addition of β-glucans to the feed in groups G1 and G2 significantly reduced SOD, GPx and GR activity. A decrease in GR, GPx and SOD activity was observed in G1z and G2z groups compared to Kz. The decrease in SOD and GR activity was larger in G2z than in G1z but the decrease in GPx activity was larger in G1z than in G2z.

In conclusion, B-glucan possesses antioxidant properties as manifested by a reduction in superoxide dismutase, glutathione peroxidase and reductase activity.

The research has been supported by grant NN312427440.
Keywords: β-glucan, rat, enteritis.

SUN-331
The interplay between MT1-MMP and ADAMs

H. L. X. Wong, K. M. Chan, Z. Zhou
Department of Biochemistry, The University of Hong Kong, Hong Kong, Hong Kong

Membrane Type I-Matrix Metalloproteinase (MT1-MMP/MMP14), a membrane anchored enzyme, is essential for diverse physiological and pathological processes through extracellular matrix remodeling and pericellular proteolysis. Mutation in MT1-MMP causes Winchester Syndome characterized by the multicentric osteolysis and arthritis. Deficiency in MT1-MMP leads to severe growth retardation, craniofacial deformities, angiogenic defects and premature death in mouse.

Previously, most works involving MT1-MMP have solely related those developmental defects to the defective collagen remodeling, which cannot provide a precise molecular mechanistic explanation for those defects. We found that defective calvarial osteogenesis in *Mmp14*$^{-/-}$ mice is a consequence of compromised Fibroblast Growth Factor (FGF) signaling. In calvarial osteoblasts, the loss of MT1-MMP reduces cell surface presentation of FGFR2 in conjunction with formation of truncated FGFR2 fragments. The increased ectodomain shedding of FGFR2, mainly mediated by ADAM9, subsequently compromises FGF signal perception on cell surface and results in defective FGF-induced proliferation and downstream MAPK signaling. Furthermore, MT1-MMP can form a tertiary complex with FGFR2 and ADAM9, in which MT1-MMP proteolytically inactivates ADAM9 to protect FGFR2 from shedding mediated by ADAM9. Interestingly, targeted deletion of *Adam9* completely restores the defective FGF signaling and largely rescues the calvarial bone defects in *Mmp14*$^{-/-}$ embryos. These results suggest that MT1-MMP inactivates ADAM9 to maintain optimal FGF signaling for calvarial development, revealing a novel regulatory mechanism for FGF signaling (Figure A) (*Developmental Cell*, 2012). However, this ADAM9/MT1-MMP dependent regulatory loop for FGF signaling is tissue-specific as depletion of ADAM9 fails to rescue defective FGF-2 induced corneal angiogenesis in *Mmp14*$^{-/-}$ mice, suggesting that other proteins apart from ADAM9 may be involved in MT1-MMP dependent vascular development (*Cell Cycle*, 2012).

© 2014 The Authors. FEBS Journal © 2014 FEBS

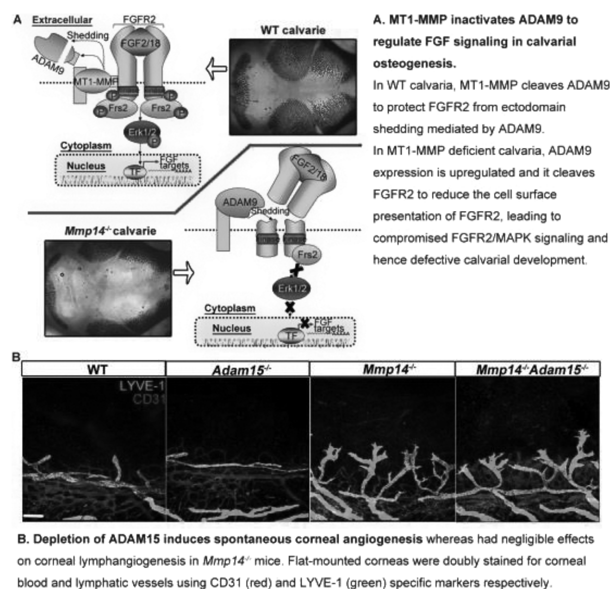

Fig. 1. (A) MT1-MMP inactivates ADAM9 to regulate FGF signaling in calvarial osteogenesis. In WT calvaria, MT1-MMP cleaves ADAM9 to protect FGFR2 from ectodomain shedding mediated by ADAM9. In MT1-MMP deficient calvaria, ADAM9 expression is upregulated and it cleaves FGFR2 to reduce the cell surface presentation of FGFR2, leading to compromised FGFR2/MAPK signaling and hence defective calvarial development. (B) Depletion of ADAM15 induces spontaneous corneal angiogenesis whereas had negligible effects on corneal lymphangiogenesis in *Mmp14*$^{-/-}$ mice. Flat-mounted corneas were doubly stained foi corneal blood and lymphatic vessels using CD31 (red) and LYVE-1 (green) specific markers respectively.

Besides the MT1-MMP and ADAM9 interaction, we also found that MT1-MMP also cleaves and inactivates ADAM15. Indeed, loss of ADAM15 leads to aberrant spontaneous angiogenesis in *Mmp14*$^{-/-}$ corneas (Figure B), indicating that the defects in corneal angiogenesis in *Mmp14*$^{-/-}$ mice are likely attributable to the deregulated activity of ADAM15. Therefore, the interplay between ADAM15 and MT1-MMP is essential for the maintenance of vascular homeostasis.

This work for the first time provides a new molecular explanation for the critical roles of MT1-MMP in the intramembranous ossification and vascular development. These findings raises a new research interest in which the interplay among MT1-MMP, ADAMs and FGFR2 signaling may be important for regulating multiple developmental processes.

The method of immunoassay for detection of antibodies against oxidized LDL using colloidal gold nanoparticles

H. Yeritsyan, S. Marukhyan
Laboratory of Medical Biotechnology, Buniatian Institute of Biochemistry, NAS RA, Yerevan, Armenia

Atherosclerosis has increasing trend, so the sensitive and specific laboratory methods for early detection are of great importance. Atherosclerosis is *characterized* by the development of an arterial occlusion containing lipids and cellular deposits. In the recent years the autoimmune character of atherosclerosis was shown. The severity of this disease directly linked to activation of immune system. The cause of atherosclerosis is the oxidative modification of low density lipoproteins (LDL), which brings to the development of many pathological processes promoting both cellular and humoral immunity. Oxidized LDL (ox-LDL) appears in blood flow and binds to some plasma proteins: β_2-glycoprotein, C-reactiv protein. With these proteins ox-LDL initiates forming of highly immunogenic complexes. As a result antibodies against ox-LDL are developed in the blood of patients. The role of these antibodies is not clear. On the one hand, the detection of anti-ox-LDL antibodies in the serum of patients indicates atherosclerosis. On the other hand, there are several data reporting the presence of minor amounts of such antibodies in serum of healthy subjects too. Nevertheless, these antibodies can be accepted as diagnostic markers for detection of atherosclerotical processes and may be applied for evaluation of the severity of the disease.

The purpose of the presented work was the development of simple and accurate method for detection of anti-ox-LDL antibodies based on colloidal gold nanoparticles. The reason for the use of nanoparticles in immunoassays is those unique optical properties. Gold nanoparticles are colored in solution due to the surface plasmon resonance. In our study immunoassay using gold nanoparticles was developed to determine the anti-ox-LDL antibodies. 20 nm gold nanoparticles were prepared by the method of Frens. Ox-LDL was conjugated to these nanoparticles. Ox-LDL extracted from the atherosclerotic lesions has similar properties to ox-LDL induced in vitro by Cu^{2+}. The oxidation level of ox-LDL was determined by quantifying MDA (in the reaction with TBA) and protein carbonyl content (in the reaction with 2,4-DNPH).

The conjugation conditions were optimized at different pH values. The stabilization point of ox-LDL was determined. The conjugates were analyzed with serum of patients suffered with atherosclerosis, as well as with anti-human rabbit ox-LDL antibodies. The presented system will give a possibility to determine rapidly anti-ox-LDL antibodies both in serum of atherosclerosis patients and healthy donors. The results of our investigations in all probability will allow us to clarify the diagnostic role of anti-ox-LDL antibodies, about which currently there are different opinions.

Keywords: atherosclerosis, colloidal gold, low density lipoproteins.

The novel collagen peptide reduced the photo-aging induced by UVA irradiation

Y. Maehata, K. Kobayashi, C. Miyamoto, S.-S. Takahashi, F. Yoshino, S. Wada-Takahashi, A. Yoshida, M. C.-I. Lee
Kanagawa Dental University, Yokosuka, Japan

Ultraviolet ray (UV) irradiation from the sun has deleterious effects on human skin, including sunburn, photo-aging. Skin photo-aging may occur due to the generation of reactive oxygen species (ROS) such as hydroxyl radical (HO·), superoxide anion radical ($O_2^{\cdot -}$), singlet oxygen ($^1O_2$) induced by UV irradiation. The chronic injury induced by ROS may damage fibroblasts in the dermal layer.

We have developed the pepsin-treated novel collagen peptide (P-NCP), which has a low allergenic potential over conventional products. Although P-NCP is used in cosmetics for excellent moisture retention and water-holding capacity, the purpose of using P-NCP except for these advantages has not been investigated. In the present study, we set out to examine the direct antioxidant effects of P-NCP on ROS generation using electron spin

© 2014 The Authors. FEBS Journal © 2014 FEBS

resonance (ESR), and to determine the effect of P-NCP on cell viability after UVA irradiation of human fibroblasts.

We investigated the antioxidant effects of P-NCP on ROS by ESR spin trapping with 5,5-dimethyl-1-pyrroline-*N*-oxide or 2,2,6,6-Tetramethyl-4-piperidinol and the effects on cell viability after UVA irradiation of human fibroblasts. P-NCP was fractionated into 19 fractions by gel filtration chromatography and the antioxidant effects of each fraction on $^1O_2$ were measured using ESR.

We confirmed that P-NCP directly inhibited $HO^•$ and $^1O_2$. Furthermore, addition of P-NCP to fibroblasts inhibited cell death induced by UVA irradiation in a dose-dependent manner. In addition, the antioxidant effect on $^1O_2$ was observed in the peptide fractions rich in Gly, Pro, Hyp, Glu, Ala, and Arg. Although Gly, Pro, Hyp, Glu, and Ala directly inhibited $^1O_2$, we found that together with these five kinds of amino acids, Gly-X-Y, which composed a repeating sequence of collagen, plays a key role in scavenging $^1O_2$. These results suggested that P-NCP can inhibit photo-aging related to ROS generation due to its antioxidant effects.

Keywords: Collagen peptide, ROS, UVA.

The nuclear receptor Nor1/Nr4a3, a novel regulator of beta-cell mass

A.-F. Close[1,2], B. Villela[1,2], C. Rouillard[3,4], J. Buteau[1,2]
[1]Alberta Diabetes Institute, [2]AFNS, University of Alberta, Edmonton, [3]Psychiatry and neurosciences, University Laval, [4]Centre de recherche du CHU de Québec, Québec, Canada

Background: The insulin-secreting pancreatic beta-cell plays a central role in the maintenance of glucose homeostasis and in the pathogenesis of both type 1 and type 2 diabetes mellitus. In both cases, production of pro-inflammatory cytokines causes beta-cell apoptosis, which results in the progressive deterioration of beta-cell mass and function. Thus, it is important to understand the molecular mechanisms underlying the regulation of beta-cell 'life and death' as this could lead to the development of new therapeutic options.

Our previous studies have identified *Nor1* as a potentially important gene in beta-cells. The *Nor1* gene encodes a nuclear receptor of the Nr4a family. Whereas Nor1 has been extensively studied in other tissues, its biological roles in the beta-cell remain relatively unexplored.

Aim: We therefore sought to investigate the expression, activity and potential role of Nor1 in the regulation of pancreatic beta-cell mass.

Results: Pro-inflammatory cytokines produced a significant up-regulation of Nor1 mRNA and protein levels in beta-cells. Interestingly, this effect seemed specific to Nor1, as other members of the *Nr4a* family were less affected by cytokines. Cytokines induced the translocation of Nor1 to the mitochondria, where it has been previously shown to exert pro-apoptotic actions. Over-expression of Nor1 induced beta-cell apoptosis but did not significantly impact proliferation. Conversely, siRNA-mediated silencing of *Nor1* abolished cytokine-induced apoptosis. Nor1-Knockout (KO) mice presented an increased beta-cell mass compared to wild type animals. Consistently, Nor1-KO animals displayed better glucose tolerance after injection of a glucose bolus.

Conclusion: Our study characterizes Nor1 as a mediator of cytokine-induced beta-cell death. We thereby demonstrate a critical role for Nor1 in the regulation of beta-cell mass and identify Nor1 as a new molecular target for the treatment of diabetes.

SUN-335
The production of interleukins 8 and 10 are changed through modulation of NMDA receptor in lymphocytes

N. Natsvlishvili[1,2], E. Zhuravliova[1,2], D. Mikeladze[1,2]
[1]I. Beritashvili Center of Experimental Biomedicine, [2]Ilia State University, Tbilisi, Georgia

Human T lymphocytes express ionotropic and metabotropic glutamate receptors which control immune responses, cell activation and death. Long-term circulation of T lymphocytes in blood may lead to downregulation/desensitization of glutamate receptors. This downregulation can change the intracellular signaling specificities and functional activities of lymphocytes. σ-ligands, like pentazocine and dextrorphan, have specificity and bind to NMDA glutamate receptors. Taking into account that during neuroinflammation, peripheral infiltrated leukocytes activate and release inflammatory molecules, including IL-8 and IL-10, we have examined the effects of NMDA and σ1-receptor ligands on IL-8 and IL-10 secretion by human lymphoid cells.

To evaluate the glutamate- and σ-mediated production of cytokines, we examined the action of noncompetitive NMDA receptor antagonist MK-801, ligand with certain σ-activities – dextrorphan and σ-agonist-pentazocine on the synthesis of IL-10, IL-8 in the Jurkat cell line. We have found that σ-ligands decreased the NMDA-stimulated synthesis of IL-8 and enhanced the production of IL-10. Since glutamate receptors are active in the control of T cell activation, we have studied the responses of peripheral blood lymphocytes (PBL) to various concentrations of glutamate and found that glutamate concentrations within normal plasma levels modulate the secretion of IL-10 positively, whereas the synthesis of IL-8 is not changed significantly. Since chronic activation of glutamate receptors by plasma glutamate in PBLs could induce receptor down-regulation, we examined the effect of high and low glutamate concentrations on the internalization of NMDA receptor subunits in PBLs. Our results have shown that long-term treatment of PBLs with glutamate at concentrations within normal plasma levels, in contrast to low concentrations, down-regulates the NR2A subunit. All together suggest the involvement of NMDA glutamate and σ1-receptors in the production of IL-8 and IL-10 by T lymphocytes.

SUN-336
The protective role of autophagy in RAW 264.7 cells exposed to Si/SiO2 QDs is inhibited or augmented by oxidative stress?

L. Stanca[1,2], A. I. Serban[2], A. Dinischiotu[1]
[1]Department of Biochemistry and Molecular Biology, Faculty of Biology, University of Bucharest, [2]Preclinical Sciences, Faculty of Veterinary Medicine, University of Agronomical Sciences and Veterinary Medicine Bucharest, Bucharest, Romania

The persistent and intense fluorescent emission of quantum dots (QDs) makes them ideal for monitoring of biological processes at cellular level. However, QDs exposure is potentially cytotoxic and can induce cell death. There are several types of programmed cell death, one of them being autophagy. There is much debate whether nanoparticle induced autophagy is a toxic effect or a protective response to cell stress. For a better understanding of its function we tried to identify the cellular context accompanying autophagy.

The fluorescent Si/SiO_2 QDs were synthesized by laser ablation and had an average diameter of 5 nm, with a crystalline Si core. The 24 h half maximal inhibitory QDs concentration in

© 2014 The Authors. FEBS Journal © 2014 FEBS

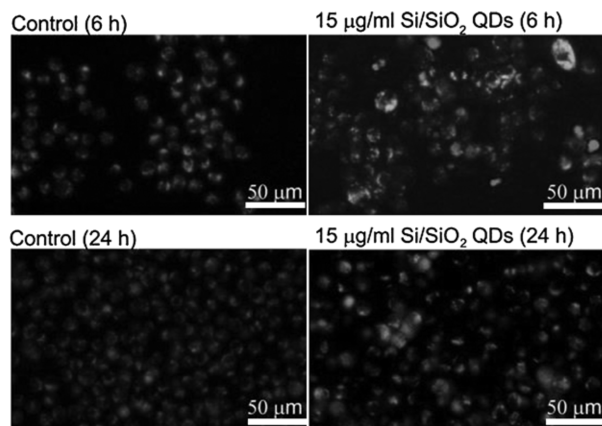

Fig. 1.

RAW 264.7 macrophages was 15.26 μg/ml and corresponded to a 45% decrease in live cell counts and a 38% decrease in viability by MTT assay. All further investigations were done on 15 μg/ml Si/SiO_2 QDs treated cells for 6, 12 and 24 h. Live cell numbers were reduced by 26% and 39% after 6 respectively 12 h, while MTT indicated 22% and 30% viability decreases.

Monodansylcadaverine stained authophagic vacuoles (light blue) and propidium iodide (red) stained dead cells observed by fluorescence microscopy (see figure) indicated that the autophagic process was most intense after 6 h. Microtubule-associated protein light chain 3 – II (LC3-II) immunobloting confirmed a maximal 4.6 fold expression increase after 6 h and a decrease thereafter. Longer QDs exposure increased dead cells number. Beclin 1 protein expression was decreased by 20 and 43% after 12 and 24 h, enforcing the autophagy inhibition.

Reactive nitrogen and oxygen species generation are central mechanisms of QDs toxicity. In moderate quantity, they are involved in cell signaling, being known inducers of autophagy. After the 24 h exposure, nitric oxide levels increased by 1.74 fold, while reactive oxygen species (ROS) rose by 1.8 fold. Lactate dehydrogenase levels in culture media were 1.6, 1.3 and 2.8 fold higher compared to control after 6, 12 respectively 24 h, emphasizing the process of necrotic cell death (also observed by bright field microscopy). Also, the levels of prostaglandin E2 in culture media of QDs exposed cells increased by 5.6, 4.3 and 4.7 fold after 6, 12 respectively 24 h.

Our data suggest an inverse relationship between autophagy and necrosis in the RAW 264.7 cells exposed to Si/SiO_2 QDs which is time dependent. Autophagy had a protective role in moderate oxidative stress, but at higher levels of nitric oxide and ROS it was inhibited and inflammation, followed by necrosis occurred.

The role of adiponectin in dexamethasone-induced intrauterin growth restricted rat placental development

D. Kipmen-Korgun[1], A. Erdogan[1], Z. Avcil[1], G. Unek[2], A. Ozmen[2], E. T. Korgun[2]

[1]Department of Medical Biochemistry, [2]Department of Histology and Embryology, Akdeniz University, Antalya, Turkey

Placenta is an organ which acts as a barrier between maternal and fetal circulation during pregnancy and plays an important role in fetal development and growth. A healthy pregnancy is closely associated with normal placental development. Overexposure to maternal glucose and glucocorticoids causes several placental and fetal pathologies. Placenta tissue is a target for circulating adiponectin. It is not clear how adiponectin affects placenta and fetus in preeclampsia, diabetes and intrauterine growth restriction (IUGR). The aim of this study was to investigate the effect of adiponectin on placental growth in rats with intrauterine growth restriction.

IUGR was provided by injection of dexamethasone. Adiponectin and its receptors (AdipoR1 and AdipoR2) were detected in the control and IUGR rats placentas on day 14, 16, 18, and 20 of pregnancy using Western Blot and RT-PCR techniques. For adiponectin signal transduction, AMPK and eNOS proteins were measured by Western Blot technique. Serum concentrations of adiponectin were assessed by ELISA method.

There was a weight loss in dexamethasone injected rat placenta and embryo. We showed that adiponectin, AdipoR1 and AdipoR2 protein and mRNA expressions were increased in the IUGR group compared to the control group. We found that maternal dexamethasone treatment led to a decrease in AMPK and eNOS phosphorylation during rat placental development. Serum adiponectin levels were significantly lower in the IUGR group.

The reason of weight loss in dexamethasone injected rat placenta and embryo can be related to AdipoR1 and AdipoR2 proteins which are members of AMPK signal pathway. Our data indicated the increased AdipoR1, AdipoR2 protein and mRNA levels in the IUGR rat placentas on day 14, 16, 18, and 20 of pregnancy. We conclude that upregulation of adiponectin and its receptors provide normal placental growth in the IUGR placentas in contrast to glucocorticoids. Our study emphasizes the role of adiponectin to eradicate the glucocorticoids's adverse effects.

The role of ADP dependent glucokinase in the peroxide production of HL-60 cells

R. Pittner, T. Kardon

Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University, Budapest, Hungary

ADP dependent glucokinase (ADPGK) catalyses glucose phosphorilation using ADP as a phophoryl donor thus saving ATP. ADPGK is highly expressed in leukocytes and has a possible role in the antibacterial defense mechanism. The glucose-6-phosphate produced by this enzyme metabolised through various pathways e.g. the pentose-phosphate pathway thus contributing to NADPH production. Among the effector functions of neutrophile granulocytes the reactive oxid species produced by NADPH oxidases has a large significance. We examined various aspects of ADPGK in undifferentiated and neutrophile-like, differentiated HL-60 cells. For the latter we used dimethyl-sulfoxide. Using qPCR we found that differentiated cells has a three-fold higher ADPGK expression than the undifferentiated cells. This difference was confirmed by Western-blot experiments as well. After transfection of both cell types with ADPGK siRNA, we measured peroxide production by Amplex Red method and found, that ADPGK silencing reduced peroxide production in the differentiated cells. These results indicate the ADPGK has a potential role in the bactericidal properties of neutrophil granulocytes by infulencing the peroxide production of these cells.

The role of exogenous Hsp70 in ROS production in monocytes cell lines

N. Troianova, A. Sapozhnikov
Cell Interaction, Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Reactive oxygen species (ROS) play an essential role in the organism functioning. One of the most important aspects of the ROS biological activity is associated with their damaging effect on tissue. And D. Harman hypothesis about an important role of the ROS damaging effects in the process of aging is well known. However, many aspects of ROS production regulation in cells remain unclear.

We have shown previously that one of the endogenous factors that cause suppression of the excessive ROS production by human phagocytes may be the heat shock protein 70 kDa (Hsp70) extracellular form.

To study the mechanisms of respiratory burst amplitude reducing in presence of Hsp70 we studied this process on THP-1, RAW 264.7 and J774 cell lines. ROS detection was carried out using the luminol-dependent chemiluminescence method and cells were activated by phorbol 12-myristate 13-acetate (PMA) in concentration 25 ng/ml to 2 μg/ml.

We have shown that PMA in concentration 2 μg/ml causes snowballing increasing of ROS level in THP-1 cells up to ten-fold comparing with control level. Activating cells by less PMA concentration resulted weak response. 30 min preincubating with 5 μg/ml Hsp70 resulted significant decrease of both background ROS production level and oxidative burst amplitude.

Snowballing ROS production was detected in RAW 264.7 and J774 cell lines after stimulation with PMA in concentration 500 and 100 ng/ml respectively. Significant PMA-induced ROS production decreasing effect of Hsp70 was also detected in this models. Additionally background ROS level suppressing effect of Hsp70 was confirmed on J774 cell line.

So, the antioxidant effect of exogenously supplied Hsp70 on spontaneous and induced ROS production was shown using different cell models.

The role of macrophage inositol requiring enzyme-1 in lipid-induced inflammation

O. Tufanli, I. Şimşek, S. Koyuncu, E. Erbay
Moleculer Biology and Genetics, Bilkent University, Ankara, Turkey

The epidemic increase in obesity constitutes a serious global health threat. Obesity increases the risk of many metabolic diseases such as insulin resistance, diabetes, fatty liver disease, and atherosclerosis. Metabolic overloading in obesity leads to a low grade, chronic inflammation in metabolically active tissues, known as metaflammation and causal to these pathologies that cluster around obesity. However, the underlying mechanism in the development of metaflammation remains largely unknown.

Metabolic overloading leads to stress in catabolic and anabolic organelles. Under metabolic stress conditions, such as excessive exposure to fatty acids and cholesterol, endoplasmic reticulum (ER) activates its unique membrane bound stress response system known as the unfolded protein response (UPR) to recover cellular homeostasis. ER has a crucial role in both metabolic stress-sensing and the initiation of inflammatory signaling pathways. However, the molecular mechanisms that link the ER stress response to inflammation under metabolic stress conditions is not well understood largely because specific tools to modulate the activities of the different UPR branches have been lacking. In this study, we specifically modulated the IRE1 branch to determine its contribution to lipid-induced inflammation in macrophages.

The classic UPR signaling is coordinated by three ER membrane-bound proteins; inositol-requiring enzyme 1 (IRE-1), PKR-like endoplasmic-reticulum kinase (PERK) and activating transcription factor 6 (ATF-6). The most evolutionary conserved arm of UPR involves the IRE1, which oligomerizes and autophosphorylates to activate its dual kinase and endoribonuclease activities under ER stress conditions. Here, by using specific IRE1 endoribonuclease inhibitors and RNAi-based knock-down we aimed to delineate the differential role of IRE1's kinase and endoribonuclease activities in translating metabolic stress into inflammatory response. We show that IRE1, in particular its endoribonuclease domain, regulates both the induction of the inflammasome and the production of pro-inflammatory cytokines in response to lipid stress in primary bone marrow derived mouse macrophages. Previous studies have shown mitochondrial reactive oxygen species (ROS) production plays a crucial role in bridging saturated fatty acids to inflammasome activation. Indeed, fatty acid induced mitochondrial ROS production is markedly suppressed in the IRE-1-deficient mouse embryonic fibroblasts. Taken together, our results demonstrate lipid-induced ER stress can activate inflammation through IRE1, in particular through its endoribonuclease domain. Specific endoribonuclease inhibitors for IRE-1 may present a novel potential therapeutic approach to metabolic disorders.

SUN-341
The role of Nox4 in oxidative stress underlying psoriasis pathology proved by in vitro fibroblasts-keratinocytes co-culture model

V. V. Barygina[1], M. Becatti[1], T. Lotti[2], N. Taddei[1], C. Fiorillo[1]
[1]*Department of Biomedical, Experimental and Clinical Sciences, University of Florence, Florence,* [2]*Dermatology, University 'G.Marconi', Rome, Italy*

The reductive-oxidative (redox) imbalance in the blood and skin of patients affected by psoriasis vulgaris was previously highlighted. In the present study, we established human primary fibroblasts cultures from the skin of 6 psoriatic patients and of 5 healthy subjects (controls). First, the redox profile of these fibroblasts was investigated by luminometric and fluorometric methods, flow cytometry, confocal microscopy and commercially available kits. We found significantly increased levels of total intra- and extra-cellular ROS production, lipoperoxidation, TBARS concentrations, and intracellular Ca^{2+}; decreased total antioxidant capacity in psoriatic fibroblasts with respect to control ones. The activation of MAPK pathways and increased expression of NFkB were also shown in psoriatic fibroblasts. Further, we showed highly increased superoxide production by mitochondrial electron transport chain and NADPH oxidase 4 (Nox4) expression in psoriatic fibroblasts. Second, to investigate whether the psoriatic fibroblasts can affect the redox profile of normal keratinocytes, in vitro fibroblasts-keratinocytes co-culture model was created. The main advantages of this in vitro model is its prevention of mixing keratinocytes with fibroblasts, allowing to study the effects of co-culture for each cell types separately. The co-incubation of human keratinocyte permanent cell line HACAT with psoriatic fibroblasts leaded to a significant increase in intra-cellular ROS production levels and to the activation of

© 2014 The Authors. FEBS Journal © 2014 FEBS

MAPK pathways in these cells with respect to the ones co-incubated with control fibroblasts. The knockdown of Nox4 with siRNA in psoriatic fibroblasts abolished these effects in keratinocytes co-incubated with silenced psoriatic fibroblasts.

Our results demonstrated the notable redox imbalance in dermal fibroblasts of psoriatic patients, which can be due to the increased activity of NADPH oxidase and mitochondrial electron transport chain. The proposed in vitro fibroblasts-keratinocytes co-culture turn to an easy-to-manage model for studying cellular pathology and interaction in the skin of psoriatic patients. Finally, the NADPH oxidase isoform 4 can be proposed as a potential target for adjuvant local therapy of psoriasis.

The role of oxidative stress and serum lipid levels in stable chronic obstructive pulmonary disease

Ü. Can[1], F. H. Yerlikaya[2], S. Yosunkaya[3]
[1]Department of Biochemistry, Konya Education and Research Hospital, [2]Department of Biochemistry, Meram Faculty of Medicine, University of Necmettin Erbakan, [3]Department of Chest Diseases, Meram Faculty of Medicine, University of Necmettin Erbakan, Konya, Turkey

Objective: Chronic obstructive pulmonary disease (COPD) is has been associated with increased oxidative stress or reduced antioxidant resources. The main goal of this study was to evaluate serum ıschemia modified albumin (IMA), total oxidant status (TOS) levels and total antioxidant status (TAS) in stable COPD patients compared with the control group.
Methods: The study was performed on 51 stable COPD patients and 45 healthy controls. Serum lipids, IMA, TAS and TOS levels of the subjects were measured.
Results: Serum IMA levels and TOS levels of the COPD patients were significantly higher than those of control subjects. There was no difference between serum TAS, triglycerides, total cholesterol, LDL-C levels of the COPD patients and those of the control subjects. Serum HDL-C levels of the COPD patients were significantly lower than the corresponding levels of control subjects.
Conclusions: Our study indicates that serum IMA and TOS may play an important role in oxidative stress in COPD. The measurement of serum IMA and TOS levels may be useful for the evaluation of stable COPD.

Keywords: Chronic obstructive pulmonary disease, IMA, TOS and TAS, oxidative stress.

The role of PAI-2 in NLRP3 inflammasome activation and endotoxin-induced sepsis

L.-C. Hsu, S.-Y. Chuang, C.-H. Yang
Institute of Molecular Medicine, National Taiwan University, Taipei, Taiwan

The NLRP3 inflammasome, a multiprotein complex, triggers caspase-1 activation and maturation of proinflammatory cytokines IL-1β and IL-18 upon sensing a wide range of pathogen- and damage-associated molecules. Dysregulation of NLRP3 inflammasome activity contributes to the pathogenesis of many diseases including cancer and metabolic disease, but its regulation remains poorly defined. Plasminogen activator inhibitor 2 (PAI-2), a member of a large group of proteins that inhibit serine proteases, is regulated by IKKβ-dependent activation of the transcription factor NF-κB. Previous studies demonstrated that mice with *Ikk*β deletion in myeloid cells are hypersusceptible to endotoxin (LPS)-induced septic shock, and increased LPS susceptibility is associated with elevated plasma IL-1β. Reconstitution of *Ikk*β-deficient macrophages with PAI-2 blocks IL-1β release after LPS stimulation. To further elucidate the physiological role of PAI-2 in LPS-induced septic shock, we generated transgenic mice that specifically express PAI-2 in myeloid cells, and then crossed this transgenic mice with myeloid-deleted *Ikk*β mice. PAI-2 expression decreased plasma IL-1β in myeloid-deleted *Ikk*β mic after LPS challenge. In addition, PAI-2 transgenic mice showed a decrease in circulating IL-1β level upon *Escherichia coli* infection. We also demonstrated that depletion of PAI-2 in macrophages resulted in NLRP3- and ASC-dependent caspase-1 activation and IL-1β secretion in macrophages in response to TLR activators and *E. coli* infection with no need of a second stimulus. Together, our data identify a new tier of TLR signaling in controlling NLRP3 inflammasome activation.

This work was supported by grants from National Science Council, Taiwan (NSC100-2320-B-002-096-MY3).

The role of PON1 and CC16 protein as antioxidant in young persons exposed to tobacco smoke

H. Milnerowicz[1], S. Milnerowicz[2], K. A. Sobiech[3], M. Ściskalska[1]
[1]Department of Biomedical and Environmental Analyses, [2]Department and Clinic of Gastrointestinal and General Surgery, Wroclaw Medical University, [3]Department of Human Biology, University School of Physical Education, Wroclaw, Poland

Clara cells secretory protein (CC16) is produced by bronchiolar club cells. Its secretion can be modulate by cigarette smoking. Low concentration of CC16 in blood is typical for injury due to cigarette smoking. It is known that CC16 serum concentration is related to lipids system. Paraoxonase 1 (PON-1) is HDL-attached extracellular esterase, which contributes to protection of HDL against peroxidation. Both CC16 and PON-1 have antioxidative and anti-inflammatory properties against oxidative stress from tobacco smoke.

The aim of the study was to investigate a possible association between CC16 concentration and PON-1 activity in the individuals exposed to tobacco smoke.

The investigations were performed in the serum of 27 healthy persons. Data about smoking were obtained from direct personal interview and were verified by the determination of cotinine concentration – the metabolite of nicotine (ELISA method).The study population was in similar age (23.73 ± 4.83 years) and similar BMI (21.49 ± 2.87 kg/m^2). CC16 concentration was determined by ELISA kit. PON-1 activity was measured spectrophotometric method using paraoxon as substrate. BMI was calculated as weight/hight square [kg/m^2].

It was shown a significant decrease in PON1 activity in smokers (61.40 ± 32.12 IU/l) compared to non-smokers (117.54 ± 56.04 IU/l) ($p = 0.0071$). However, the difference in CC16 concentration between examined groups was not observed (28.99 ± 11.57 ng/ml for smokers and 28.11 ± 10.60 ng/ml for non-smokers). It was shown a correlation between CC16 concentration and PON1 activity ($r = 0.6573$, $p = 0.0202$) in non-smokers. The link between CC16 concentration and BMI in smokers was also shown ($r = 0.6703$, $p = 0.0122$).

PON1 is a very sensitive maker, which activity can be easy modulated by oxidative stress resulting from tobacco smoke. Decreased PON1 activity can induce the secretion of CC16 protein, which concentration is increased proportionally to BMI of

© 2014 The Authors. FEBS Journal © 2014 FEBS

persons exposed to tobacco smoke. Probably, both PON1 and CC16 protein play an important role as antioxidants against oxidative stress from tobacco smoke.

Keywords: CC16 protein, paraoxonase, tobacco smoke.

SUN-345
The role of TNF-α in the development and function of dendritic cells activated by collagen I

B. Poudel[1,2], H.-H. Ki[1], Y.-M. Lee[2], D.-K. Kim[1]
[1]Department of Immunology, Chonbuk National University, Jeonju, [2]Wonkwang-Oriental Medicines Research Institute, Wonkwang University, Iksan, Korea

Previous reports have demonstrated that dendritic cells (DCs) maturation and function can be regulated by collagen I, a major extracellular matrix (ECM) component. DCs interact with collagen present at the inflammatory sites and regulate the function of DCs. This interaction is known to enhance the expression of co-stimulatory molecules expression and secretion of cytokines such as interleukin (IL)-12 and tumor necrosis factor (TNF)-α. However, the understanding of the role of these cytokines in DCs maturation and function remains incomplete.

We studied the role of TNF-α in the development and function of DCs activated by collagen I. Upon inhibition of TNF-α (TNFn), collagen I-induced IL-12 secretion, expression of DCs maturation markers and genes associated with DCs activation pathway were suppressed. Additionally, we examined if TNFn exhibited any effect on expression of interferon regulatory factor 4 (*IRF4*), a transcription factor of IRF family which is expressed by DCs and is known to have a role in DCs development. Our data demonstrate that collagen I-activated DCs exhibited reduced *IRF4* expression whereas opposite effect was observed when TNF-α was neutralized.

To sum up, our data suggest that collagen I-induced DCs maturation and function is regulated by TNF-α production through down-regulation of *IRF4*. These data may implicate an importance in development of anti-TNF-α therapeutics for the various inflammatory disorders.

Keywords: anti-TNF-α, collagen I, dendritic cells.

The substrate length selectivity of aminopeptidases that generate antigenic peptides

A. Stamogiannos, A. Mpakali, D. Koumantou, E. Zervoudi, I. Evnouchidou, E. Stratikos
NCSR Demokritos, Athens, Greece

Endoplasmic Reticulum aminopeptidases (ERAP) 1 and 2, as well as the Insulin-Regulated Aminopeptidase (IRAP), are integral components of the adaptive immune system, due to their active participation in the antigen processing and presentation pathways. ERAP1 and ERAP2 reside in the lumen of the endoplasmic reticulum and trim antigenic peptide precursors to produce mature antigenic epitopes, which associate with Major Histocompatibility Complex class I (MHC-I) molecules that are then transferred to the cell surface for recognition by cytotoxic T-lymphocytes. That recognition allows the organism to constantly monitor for aberrant or infected cells and eradicate them. IRAP resides in specialized intracellular vesicles and participates in a different antigen presentation pathway, called cross-presentation. Previous studies have shown that ERAP1 exhibits a molecular ruler behavior, preferentially trimming longer peptides (9–16 residues), but sparing shorter ones (<8–9 residues), thus generating peptides with optimal length for MHC-I loading. It has also been shown that single nucleotide polymorphisms in these enzymes are associated with predisposition to autoimmune diseases such as Ankylosing Spondylitis, Behcet's disease and Psoriasis, and it has been hypothesized that this is due to altered antigenic peptide generation. In this study we investigated the substrate length specificity of ERAP2 and IRAP as well as a series of disease-linked ERAP1 alleles, using a model peptide-substrate series that carry a polyglycine motif of varying length, designed to probe the length selection preferences of each enzyme. Our results indicate that all ERAP1 alleles, are much more active in trimming peptides of 10 residues or larger, compared to smaller peptides. ERAP2 and IRAP were found to be more permissive in terms of substrate length, processing most effectively peptides of intermediate length. These results are in sharp contrast to the complete lack of length selection by Leucine aminopeptidase, a dominant cytosolic aminopeptidase that does not however participate in antigenic peptide generation. Detailed comparison of the ERAP1 alleles indicated that the polymorphisms have subtle but clearly distinct effects on ERAP1 activity and length specificity, suggesting that the polymorphisms employ at least two different mechanisms to affect enzyme function. Overall, these results indicate that each enzyme exhibits different substrate length specificity and this specificity can be influenced by allelic variation, something that may underlie the mechanisms behind disease predisposition.

TIMP-1 loaded nanoparticles: a therapeutic strategy for neuroprotection

M. Chaturvedi[1], Y. Molino[2], S. Bojja[3], M. Khrestchatisky[4], L. Kaczmarek[1]
[1]Laboratory of Neurobiology, Nencki Institute, Warsaw, Poland, [2]Vect-Horus S.A.S, Marseille, France, [3]Indian Institute of Chemichal Technology, Hyderabad, India, [4]UMR 7259, CNRS – Aix-Marseille Université, Marseille, France

Introduction: There is a marked, deleterious increase in expression of Matrix Metalloproteinase-9 (MMP-9) during numerous pathologic conditions such as ischemic stroke, epilepsy and various excitotoxic/neuroinflammatory processes. Therefore, inhibition of MMP-9 is considered as a potential therapeutic target for neuroprotection. Currently available chemical inhibitors of MMP-9 are poorly specific and have many off-targets leading to unanticipated side effects. As development of specific inhibitors is always a challenging task therefore, we planned to evaluate neuroprotective effects of an endogenous inhibitor of MMP-9, Tissue Inhibitor of Matrix Metalloproteinase-1 (TIMP-1), which is a 28 KDa protein. However, the major obstacles of using TIMP-1 as a neuroprotective agent are its in vivo short half-life and low brain permeability. Hence, we planned to explore a nanotechnological approach for delivery of TIMP-1, by using poly lactic-co-glycolic acid (PLGA) based Nanoparticles (NPs), so in the future it can be developed as a neuroprotective agent.

Results: Here, we have developed TIMP-1 loaded PLGA NPs which can deliver TIMP-1 in a sustained release manner and can cross the blood brain barrier (BBB). These NPs were coated with polysorbate 80 (Ps80) to improve their BBB penetration. We evaluated these NPs for their in vitro and in vivo BBB penetration by using primary rat brain endothelial cell model and by tail vein injection in mice respectively. The in vitro and in vivo results have shown that NPs are non-toxic to endothelial cells and they have BBB penetration. Finally, we evaluated their neuroprotective effects on organotypic hippocampal slice culture using propidium iodide staining and LDH assay which have shown that TIMP-1 and TIMP-1 loaded have neuroprotective

© 2014 The Authors. FEBS Journal © 2014 FEBS

effects against Kainic Acid (KA) induced excitotoxicity. Moreover, we have shown through gelatinase assay that these effects are mediated through MMP-9 inhibition. Currently, we are exploring in vivo neuroprotective effects of TIMP-1 NPs.

An in vitro study on the risk of non-allergic type-I like hypersensitivity to *Momordica charantia*

R. Ilikci Sagkan
Immunology and Allergy Diseases, Gulhane Military Medical Academy, Ankara, Turkey

Background: *Momordica charantia* (MC) is a tropical plant that is extensively used in folk medicine. However, the knowledge about side effects of this plant is relatively little according to knowledge about its therapeutic effects. The aim of this study is to reveal the effects of non-allergic type-I like hypersensitivity to MC by an experiment which was designed in vitro.
Methods: In the present study, the expression of CD63 and CD203c on peripheral blood basophils against different dilutions of MC extracts was measured using flow cytometry and compared with one another. In addition to this, intra-assay CV's of testing extracts were calculated for precision on reproducibility of test results.
Results: It was observed that the fruit extract of MC at 1/100 and 1/1000 dilutions significantly increased active basophils compared to same extract at 1/10 000 dilution.
Conclusion: In conclusion, *Momordica charantia* may elicit a non-allergic type-I like hypersensitivity reaction in especially susceptible individuals.

Toxic molecular mechanisms induced by magnetite nanoparticles in human pulmonary fibroblasts

M. Radu[1], A. Hermenean[2], A. Ardelean[2], A. Dinischiotu[1]
[1]*Department of Biochemistry and Molecular Biology, Faculty of Biology, University of Bucharest, Bucharest,* [2]*Department of Experimental and Applied Biology, Institute of Life Sciences, Vasile Goldis Western University of Arad, Arad, Romania*

The control of biomolecules-nanoparticles interaction from molecular to cellular levels is crucial for potential risks of adverse effects on human health.

The aim of our study was to investigate the molecular mechanisms involved in the inflammatory and cell death processes in human pulmonary fibroblasts (MRC-5 cell line) after magnetite nanoparticles (MNP) exposure.

In order to accomplish these, MRC-5 cells were exposed to 12.5 μg/mL MNP for 24, 48 and 72 hours. As inflammatory markers, the level of prostaglandin-E2 (PGE_2), nitric oxide (NO) and the production of interleukin (IL)-6 and -8 were assessed using biochemical analyses. MNP potential to induce cell death in MRC-5 cells was evaluated by quantifying caspases activity and apoptotic cells through Annexin V/PI staining.

Results have shown a significant stimulation of NO and PGE_2 synthesis after 72 hours by 81% and 82% respectively, compared to control. A slight increase in IL-6 production occurred starting after 48 hours but no significant changes were observed in IL-8 levels. MNP caused no apoptotic events in pulmonary fibroblasts during the analyzed period but an increase of the caspase-1 activity by 35%, 21%, 25% after 24 h, 48 and 72 h compared to controls was noticed. It may be that activated caspase-1 regulated the release of pro-inflammatory cytokine as IL-1β generating the release of NO and PGE_2 into the extracellular milieu. The synthesis of PGE_2 could also be caused by IL-6.

Our findings suggest that human pulmonary fibroblasts exposed to MNP generates an inflammatory response through activation of caspase-1 and release of NO and PGE_2.

Keywords: nanoparticles, inflammation, cell death.

Toxicogenomic analysis of *Capparis ovata* water extract (MSCov)

G. Celik, O. Ozgun, S. Arslan, A. Sen
Biology, Pamukkale University, Denizli, Turkey

Capparis ovata water extract (*MSCov*) has been used for the treatment of multiple sclerosis and other immune diseases. However, its potential toxicity has not been completely investigated. The aim of the study was to determine the toxicology of *MSCov* in C57BL/6 mice and to investigate the underlying cellular mechanism further by microarray analysis. For this purpose, *MSCov* was prepared by using the plant's fruit, bud and flower parts (Turkish Patent Institute, PT 2012/04 093). Doses of *MSCov* at 500 mg/kg for 21 days were administered by oral gavage for subchronic toxicity in C57BL/6 mice. At the end of the experimental period, the animals were sacrificed, the liver tissues were isolated. Changes in the hepatic gene expression were identified with toxicology pathway PCR arrays to study the hepatotoxic mechanism of *MSCov*. A number of changes in the body weight and food consumption, absolute and relative liver weight, biochemical analysis were not observed after the subacute exposure to *MSCov*. A total 384 genes were screened which 14 genes were found to be significantly altered (2-fold, $P < 0.05$), including 14 up-regulated genes and no down-regulated genes. According to our biological pathway analysis, the *MSCov* resulted in aberrant gene expression in metabolic pathways such as phospholipids, cholesterol and asis and fatty acids. Real-time PCR analyses of several genes verified these results. Consequently, our gene expression microarray study will be useful for future *MSCov* toxicity studies. These results strongly suggest that *MSCov* has no or very very of low potenctial of toxicity and considered to be safe as an alternative or complementary therapeutics in MS treatment at the studied dose regime.

Transcription factor hypoxia-inducible factor (HIF)-1alpha is relevant for necrosis of *Mycobacterium avium*-induced granulomas

M. Cardoso[1], T. Silva[1], R. Appelberg[1,2], M. Borges[1,3]
[1]*Laboratory of Microbiology and Immunology of Infection, Institute for Molecular and Cell Biology, University of Porto,* [2]*Instituto de Ciências Biomédicas de Abel Salazar, University of Porto,* [3]*Biological Sciences Department, Faculty of Pharmacy, University of Porto, Porto, Portugal*

Mycobacterial infections are characterized by the formation of granulomas. Granulomas are well-organized aggregates of immune cells, namely infected macrophages. The granuloma's main function is to constrain and prevent dissemination of the mycobacteria while concentrating the immune response to a limited area. In some cases these granulomas undergo central necro-

© 2014 The Authors. FEBS Journal © 2014 FEBS

sis leading to their caseation although the underlying mechanisms are still poorly understood. It has been reported that reduced vascularization of granulomas may be one essential mechanism for caseation and some studies have demonstrated severely hypoxic regions at the center of the granuloma. The hypoxia-inducible factor – 1alpha (HIF-1α) has been shown to be important in some diseases, such as cancer and infections. HIF-1α is able under hypoxic conditions to transcriptionally regulate gene expression, allowing macrophage adaptation to hypoxia [1]. The Appelberg laboratory has developed a granuloma necrosis model that mimics the human pathology of *Mycobacterium tuberculosis,* using C57BL/6 (WT) mice infected intravenously with a low dose of a highly virulent strain of *Mycobacterium avium* (ATCC 25291). Such mice develop granulomas that, at 4 months of infection, exhibit central necrosis [2]. To determine the relevance of HIF-1α during *M. avium* infection we used a mouse strain deleted of HIF-1α under Cre-lox system in the myeloid cell lineage (HIF1αKO). Infected mice were euthanized at different times during the infection and the lungs, liver and spleen were aseptically collected. Bacterial loads were determined in the organs of infected animals. Morphometric analysis of granulomas was performed in haematoxylin-eosin stained liver sections. The localization of macrophages in the livers from infected mice was studied by immunohistochemistry by evaluating the expression of F4/80. The analysis of liver and spleen cell populations were determined by flow cytometric analysis. IFN-gamma and HIF-1α production has been evaluated *ex-vivo* by ELISA. The results obtained indicate that HIF1α KO mice are more susceptible to the infection and the onset of necrotic granulomas is faster.

Urinary hydroxyproline levels in prediabetic patients

I. Kilinc[1], S. Uysal[1], A. Toker[1], H. R. Gokce[2], M. Akcay[2]
[1]Department of Medical Biochemistry, [2]Third Year Students, Meram Faculty of Medicine, Necmettin Erbakan University, Konya, Turkey

Objective: The metabolic stage between normal glucose homeostasis and diabetes mellitus (DM) is called prediabetes. Prediabetes is categorized as impaired glucose tolerance (IGT) and increased fasting glucose (IFG), both established risk factors for DM. Although the relationship between type 2 DM (T2DM) and bone metabolism has been widely investigated, study results have been contradictory. But it is clear that fracture risk is higher in these patients. Recently, it was reported that urinary hydroxyproline increased markedly in diabetic patients. We investigated the urinary hydroxyproline concentrations in patients with prediabetes and T2DM and compared the results to those of normoglycemic individuals at baseline and 2 hours after glucose loading.

Material and Methods: The ADA 2013 criteria were used to identify subjects. These persons were defined as having IFG (100–125 mg/dL) or IGT (2-h values in the oral glucose tolerance test (OGTT) of 140–199 mg/dL) as prediabetes. Based on a 75 g OGTT, subjects were divided into a group with normal glucose tolerance (NGT; n = 28), prediabetes (n = 29) or T2DM (n = 24). Urine concentrations of hydroxyproline were measured by spectrophotometric assay. The hydroxyproline results were expressed as mg/g creatinine. Creatinine in urine samples was determined by Jaffe′s method.

Results: Urinary hydroxyproline levels in patients with T2DM were found to be significantly higher compared with NGT ($p < 0.05$). Urinary hydroxyproline levels in prediabetic patients were higher than NGT group. But it was not found statistically differences ($p > 0.05$).

Conclusion: We suggest that urinary hydroxyproline could be an useful biochemical markers for monitoring possible bone mineral metabolism disorder in T2DM patients. Larger investigations are needed to understand the urinary hydroxyproline levels and bone metabolism in prediabetic patients.

Keywords: diabetes mellitus, hydroxyproline, prediabetes.

Variation within the CASP3 gene and the risk of Achilles teninopathy in a British case-control cohort

R. Rickaby, L. El Khoury, W. J. Ribbans, S. M. Raleigh
The Centre for Physical Activity and Chronic Disease, The Institute of Health and Wellbeing, University of Northampton, Northampton, UK

Achilles tendon pathology (ATP) is a degenerative condition with known genetic risk factors[1]. Excessive tenocyte apoptosis has been observed in tendinopathy and components of the apoptosis pathway have previously been implicated in the aetiology of ATP[2]. Caspases play a key role in the execution and regulation of apoptosis, with caspase-3 being an important mediator of apoptosis[3]. Our aim was to determine whether a single nucleotide polymorphism (SNP) within the *CASP3* gene (rs1049253) was associated with ATP in a British cohort. We recruited 264 (133 ATP cases and 131 asymptomatic controls) British Caucasian participants for this genetic association study. ATP cases were clinically diagnosed with insertional tendinopathy, noninsertional tendinopathy, Achilles tendon rupture, or more than one pathology. TaqMan assay technology was used to genotype all participants using real-time PCR. A Pearson's chi-squared (χ^2) test was used to analyse for differences in genotype and allele frequency for the rs1049253 variant. We compared the collective ATP group against controls. We also conducted several sub-analyses taking into account the different types of tendinopathy. We found no significant difference in genotype ($p = 0.643$) or allele ($p = 0.635$) frequencies between the ATP group and controls. However, we did find a tentative genotypic association ($p = 0.025$) between male insertional tendinopathy cases and male controls. These data must be viewed with caution due to the relatively small sample size and replication in a larger cohort would be necessary to increase confidence. In conclusion, our preliminary data infer a possible role for the rs1049253 variant as a risk factor for insertional tendinopathy in British males. These results could further implicate the involvement of the apoptosis pathway in the development of ATP.

Vitamin D association with immune response in inflammatory bowel disease

K. Soltys[1], M. Stuchlikova[1,2], H. Drahovska[1], S. Stuchlik[1], A. Krajcovicova[3], T. Szemes[1], D. Kuba[2], Z. Zelinkova[3], T. Hlavaty[3]
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Commenius University,* [2]*National Transplant Organization,* [3]*5th Internal Medicine Department, Faculty of Medicine, Commenius University, Bratislava, Slovakia*

Inflammatory bowel disease is a group of chronic inflammatory conditions of the colon and small intestine. Crohn′s disease (CD) and ulcerative colitis (UC) are two main clinicopathological subtypes of IBD. Complex interactions between the immune system, environmental factors, gut microflora and host genotype are considered to underlie the pathogenic process. Vitamin D deficiency has emerged as one of the leading environmental candidates; its causal agency has yet to be fully demonstrated by an adequately powered study. Currently it is suggested that local activation of vitamin D co-regulates activity of the innate and adaptive immunity, mainly through inhibition of the action of pro-inflammatory transcription factor NF-kB and the production of different cytokines. Vitamin D receptor is highly expressed by various cells of the immune system. The panel of 18 genes for gene expression study linked to microbial response in IBD was designed and season-dependent differencies of expression levels were established. A set of 105 samples was analysed for immune profile determination. To investigate the role of genetic background considering vitamin D, we determined allele frequency distribution and genotypes of 4 VDR gene polymorphisms Apa-I, Taq-I, Fok-I and Bsm-I in UC, CD and healthy subjects and analysed their correlation to the immune panel parameters.

WMJ-S-001, a novel aliphatic hydroxamate derivative, exhibits anti-inflammatory properties via MKP-1 in lipopolysaccharide-stimulated RAW264.7 macrophages

W.-C. Chen[1], W.-J. Huang[2], M.-J. Hsu[3]
[1]*Taipei Medical University, Taipei, Taiwan,* [2]*Graduate Institute of Pharmacognosy,* [3]*Department of Pharmacology, Taipei Medical University, Taipei, Taiwan*

Hydroxamate derivatives have been widely investigated and attracted considerable attention, due to their broad pharmacological properties. Recent studies reported their potential use in the treatment of cancer, cardiovascular diseases, arthritis or infectious diseases. However, the inhibitory mechanisms of hydroxamate derivatives in inflammation remain to be elucidated. In an effort to develop a novel pharmacological agent that could suppress abnormally activated macrophages, we investigated the anti-inflammatory effects and the underlying molecular mechanisms of WMJ-S-001, a novel aliphatic hydroxamate derivative, WMJ-S-001, in lipopolysaccharide (LPS)-stimulated RAW264.7 macrophages. The LPS-induced increases in *cox-2 mRNA* and protein levels and COX-2 promoter-luciferase activity were suppressed by WMJ-S-001. WMJ-S-001 inhibited p38MAPK, NF-κB subunit p65 and C/EBPβ phosphorylation in cells exposed to LPS. Treatment of cells with a p38MAPK inhibitor (p38MAPK inhibitor III) markedly inhibited LPS-induced p65 and C/EBPβ phosphorylation and COX-2 expression. LPS-increased p65 and C/EBPβ binding to the COX-2 promoter region was suppressed in the presence of WMJ-S-001. In addition, WMJ-S-001 suppression of p38MAPK and p65 phosphorylation, and subsequent COX-2 expression were restored in cells transfected with mitogen-activated protein kinase phosphatase-1 (MKP-1) dominant negative (DN) mutant. WMJ-S-001 also caused an increase in MKP-1 phosphatase activity in RAW264.7 macrophages. Furthermore, WMJ-S-001 increased survival rate in LPS-induced endotoxaemic mice. In conclusion, WMJ-S-001 may cause MKP-1 activation to dephosphorylate p38MAPK, resulting in the decrease in p65 and C/EBPβ binding to the COX-2 promoter region and COX-2 down-regulation in LPS-stimulated RAW264.7 macrophages. The present study therefore suggests that WMJ-S-001 may be a potential drug candidate in alleviating LPS-associated inflammatory diseases.

Keywords: hydroxamate, inflammation, mitogen-activated protein kinase phosphatase-1.

A facile in vitro assay using engineered yeast vacuoles for measuring membrane fusion driven by neuronal SNAREs

M. Lee, Y.-J. Ko, M. Han, Y. Jun
Life Science, Gwangju Institute of Science and Technology, Gwangju, Korea

Neurotransmission is mediated by membrane fusion between synaptic vesicles carrying neurotransmitters and the presynaptic plasma membrane. This fusion, known as synaptic vesicle fusion, is mediated by a variety of proteins, including SNARE proteins. Because of the critical role of synaptic vesicle fusion in neuronal communications, it has been thought that control of synaptic vesicle fusion can be used to regulate various neuronal activities and to develop cures to neuronal disorders. One such example is the clinical application of botulinum neurotoxins. Botulinum neurotoxins (BoNTs) are zinc-dependent metalloproteases that specifically cleave one or two of the neuronal SNARE proteins, blocking synaptic vesicle fusion, in a serotype-dependent manner. BoNTs are currently used to treat a wide variety of disorders, such as various neuromuscular diseases, myofascial pain and migraine, and multiple sclerosis. Thus, synaptic vesicle fusion and the synaptic SNARE proteins that mediate the process could be attractive therapeutic targets for various neuro-muscular diseases. To date, however, a facile assay, with high-throughput applicability, assessing synaptic vesicle fusion has been limited. Here, we took a synthetic biology approach and engineered the budding yeast *Saccharomyces cerevisiae* to express neuronal SNARE proteins in the vacuole, the yeast equivalent of human lysosomes. Using engineered yeast vacuoles, we established a facile in vitro assay for measuring yeast vacuole fusion driven by neuronal SNAREs.

Keywords: SNARE, synaptic vesicle fusion, yeast vacuole.

SUN-359
A high content screening microscopy approach to dissect the mechanism of Golgi-to-ER retrograde traffic

G. Galea, M. G. Bexiga, A. Panarella, J. C. Simpson
School of Biology and Environmental Science, University College Dublin, Dublin, Ireland

In mammalian cells the biosynthetic pathway delivers newly synthesised molecules to intracellular compartments and the cell surface. At each transport step, forward traffic is counterbalanced by retrograde membrane flow, thereby ensuring organelle homeostasis. Although much is known about the machinery regulating the biosynthetic pathway, comparatively little is known about the retrograde route.

Brefeldin A (BFA) is a fungal metabolite that causes the disassembly of the Golgi complex and the redistribution of resident Golgi markers into the endoplasmic reticulum (ER). BFA treatment of cells results in the redistribution of resident Golgi constituents to the ER, via a process that can be visualised by microscopy in real time. This observation forms the basis of a very powerful morphological assay to assess Golgi-to-ER traffic. Using a cell line stably expressing a GFP-tagged Golgi enzyme, we have carried out two genome-wide gene depletion screens to systematically elucidate this pathway. These results provide the first systematic assessment of proteins associated with Golgi morphology and Golgi-to-endoplasmic reticulum (ER) transport in mammalian cells. Together our data reveal the high complexity and diversity of proteins associated with trafficking between these compartments, and also provides important insight into how the endomembrane system is organised in mammalian cells.

This work is significant on several levels. Firstly, our screens use a novel image analysis approach, incorporating texture feature analysis and machine learning, never before utilised on this scale. Secondly, the systems-wide information that has been gathered may be useful for the design of next generation drug delivery vehicles, allowing targeting of not only certain cell types with appropriate therapeutics, but also specific organelles within the early secretory pathway.

Keywords: high content screening microscopy, membrane trafficking, RNA interference.

A study of the supramolecular structure of K^+ channel clusters

E. van der Cruijsen, K. Visscher, J. Rodrigues, A. Bonvin, M. Baldus, M. Weingarth
Bijvoet Center for Biomolecular Research, Utrecht University, Utrecht, The Netherlands

Multiple lines of experimental evidence highlight the lateral patchiness of bacterial and eukaryotic cellular surfaces, suggesting membranes in which proteins and lipids are organized in heterogeneous domains. This corroborates the notion that membrane signaling proteins like ion channels are assembled in supramolecular clusters, in which channel gating is coupled, possibly to achieve an optimal response to a single stimulus. How clustering occurs, the composition of clusters and how the stimulus may be transferred between channels remains largely unknown, let alone at atomic resolution. Here, using a combination of solid-state NMR experiments, biochemical methods and an extensive set of large-scale MD simulations, we report on the supramolecular structure of clusters of K^+ channel KcsA in complex *E. coli* membranes at unprecedented detail.

We present structural elements of the channel – channel interface, together with a comprehensive study of the membrane micro-environment of KcsA clusters that shows that clustering is accompanied by a stark enrichment of anionic lipids at the channel – channel interface. From the total of our data we infer influences of clustering on KcsA gating. Together with the pronounced influence of buried water[1,2] and specific lipids,[3,4] this study is another step towards the supramolecular structure of K^+ channels in complex physiological environments.[5]

Antagonistic role of Eps15 and Eps15L1 in synaptic vesicle recycling

P. Alberici[1], G. Beznusenko[1], A. Oldani[1], A. Raimondi[2], C. Tacchetti[2], A. Mironov[1], P. P. Di Fiore[1], **N. Offenhaeuser**[1]
[1]*IFOM Foundation,* [2]*Ospedale San Raffaele, Milano, Italy*

Synaptic vesicle recycling (SVR) is a fundamental process for the recovery of proteins and lipids after neurotransmitter release. Different modes of SVR have been described, ranging from ultra-fast, fast and to slow. Their prevalence appears to be cell type and stimulus specific, adapted to the specific needs of a particular neuron. The molecular complexity of these different retrieval pathways just starts to be elucidated. Eps15 is an endocytic adaptor protein, which in *D. melanogaster* and *C. elegans* is involved in SVR.

In these animal models the reduction in synaptic efficacy is accompanied by a reduction at the protein level of the key endocytic players, making it difficult to judge whether Eps15 is primarily involved in SVR or merely in the stabilization of proteins relevant to SVR. In mammals two homologs exist, Eps15 and Eps15L1 and we investigated their role in SVR using knockout (KO) mice. Normal levels of endocytic proteins are maintained in brain extract from both Eps15- and Eps15L1-KO mice. Dye uptake experiments revealed that SVR is reduced in Eps15L1- but normal in Eps15-KO neurons. Additionally, synaptic vesicle number is reduced in Eps15L-KO neurons. By immunofluorescence analysis we detect increased clustering of the endocytic proteins AP2, CHC and Dynamin at synapses in Eps15L1-KO neurons compared to either wildtype or Eps15-KO neurons suggesting that clathrin/AP2 activity is impaired in Eps15L1-KO neurons. Consistently, upon stimulation we observed an increased number of large >80 nm vesicles in Eps15L1-KO neurons respect to wildtype controls suggesting increased formation of endosome like vesicles or a reduced resolution of such structures.

Surprisingly, in double-knockout neurons deficient for both Eps15 and Eps15L1 these phenotypes were reverted. This suggests that neither Eps15L1 nor Eps15 are strictly required for SVR. Rather, in the absence of Eps15L1, Eps15 serves as an 'inefficient' interaction partner that sequesters natural Eps15L1 interactors rendering them less active. In support of this hypothesis we found a shift in Eps15/Eps15L1 interactome and relocalization of the two proteins in the respective KO.

Keywords: endocytosis, synapse, synpatic vesicle recycling.

Assessing the conformation changes of pb5, the receptor binding protein of phage T5, upon binding to its *E. coli* membrane receptor FhuA

C. Ebel[1], F. Gabel[1], A. Flayhan[1], M. Lethier[1], G. Durand[2], P. Boulanger[3], M. Chami[4], C. Breyton[1]
[1]*Institut de Biologie Structurale, CEA-CNRS-Univ. Grenoble Alpes, Grenoble,* [2]*ECBSA, University of Avignon, Avignon,* [3]*IBBMC, Université Paris-Sud, Orsay, France,* [4]*Biozentrum, University Basel, Basel, Switzerland*

Bacteriophages, viruses that infect bacteria, are the most abundant and diverse organisms on Earth. They play a crucial role in the ecology, evolution and pathogenicity of bacterial populations. Within tailed bacteriophages, interaction of the receptor binding protein (RBP) with the target cell triggers viral DNA ejection into the host cytoplasm. In the case of phage T5, the RBP pb5 and the receptor FhuA, an outer-membrane protein of *Escherichia coli*, have been identified. Here, we use small angle neutron scattering (SANS) and electron microscopy (EM) to investigate the FhuA-pb5 complex. Specific deuteration of one of the partners allows the complete masking in SANS of the surfactant and unlabelled proteins when the complex is solubilised in the fluorinated surfactant F_6-DigluM. Thus, individual structures within a membrane protein complex can be described. The solution structure of FhuA agrees with its crystal structure; that of pb5 shows an elongated shape. Neither display significant conformational changes upon interaction (Fig. 1). The mechanism of signal transduction within phage T5 thus appears different to that of phages binding cell wall saccharides for which structural information is available.

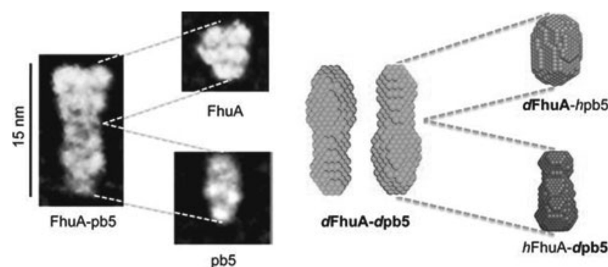

Fig. 1. Comparison of the EM and SANS projections. EM (left), SANS (right). Two SANS projections are presented, rotated by 180° since the relative position of FhuA and pb5 is not determined at this resolution. Projections are drawn to scale.

Assimisome – ammonia assimilating machine of the wheat grain

M. K. Gilmanov, A. A. Yesmambetov, O. Filimonova
Kazakh National University, Scinitific Research Institute of the Problems of Ecology, Almaty, Kazakhstan

It is well known that wheat storage proteins are composed of more than 66% of glutamate. This suggests that there is a huge synthesis of glutamate in ripened wheat seeds. However, the biochemical mechanism of this phenomenon has not yet been studied. Therefore, we paid the attention to this mechanism. By gel chromatography on sepharose 4 B and by isopicnic ultracentrifugation we isolated from ripened wheat seeds the spherical structures in diameter 1.8 μm and buoyant density 1.1 g per cm^3. It was established that this structure has phosphatidylnositol (PI) to which are attached numerous molecular of NADPH- glutamate dehydrogenase (GDh) via own covalently bound Pi-anchors. We studied the kinetic properties of isolated structures. The value of Michael's constant to ammonia ions of the NADPH-Gdh speaks about an extremely high affinity of this enzyme to this substrate. This value is two orders better than with Km to ammonia ions of glutamine synthetase. All this results proved that our structures play a key role in ammonia assimilation in ripened wheat seeds. Thus, the discovered structure works as ammonia assimilating machine in the ripened wheat seeds. In this reason, we named this structure as *Assimisome*.

Keywords: Assimisome, phosphatidylnositol, NADPH- glutamate dehydrogenase.

Boric acid supplementation can prevent oxidative damage caused by prenatal alcohol exposure in rat cerebral cortex

M. Savasan Sogut[1], I. Sogut[2], A. Oglakci[3], K. Kartkaya[3], K. Kusat Ol[3], G. Kanbak[3], M. Erden Inal[3]
[1]*Department of Genetics and Bioengineering, Yeditepe University,* [2]*Department of Medical Services and Techniques, Vocational School of Health Services, Istanbul Bilim University, Istanbul,* [3]*Department of Biochemistry, Faculty of Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey*

In this study, the aim was to investigate the prenatal alcohol-induced oxidative stress on rat cerebral cortex of newborn pups and assess the protective and beneficial effects of Boric acid (BA) supplementation on rats with Fetal alcohol syndrome (FAS). Pregnant rats were divided into three groups as control group, alcohol group and alcohol + boric acid group. As markers of alcohol-induced oxidative stress in newborn pups' cerebral cortex, malondialdehyde (MDA), superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) levels were measured. Although MDA levels in alcohol-administered group was significantly increased compared to control group ($p < 0.05$), its level in the alcohol + boric acid group was shown to significantly decrease compared to alcohol group ($p < 0.01$). CAT activity of alcohol + boric acid group was found statistically higher than the alcohol group ($p < 0.05$). GPx activity in the alcohol group was decreased compared to control group ($p < 0.05$). As a result, we found that alcohol was capable of triggering damage to membranes on cerebral cortex of rat pups and BA could be influential on antioxidant mechanisms resulting from prenatal alcohol.

Keywords: antioxidant activity, boric acid, fetal alcohol syndrome (FAS).

Caenorhabditis elegans P granule liquid phase separation resemble a collapse of the droplet phase at high ecological thermal ranges

A. F. Diaz Delgadillo[1], M. Begasse[1], A. Zinke[1], A. Hyman[1], on behalf of Anthony Hyman Lab, C. Weber[2], Hyman Lab CBG-Dresden
[1]*Hyman Lab, Max Planck Institute CBG,* [2]*Soft Matter Physics, Max Planck for Physics of Complex Systems, Dresden, Germany*

In contrast to endotherms, ectotherms are animals whose temperature varies with the environment. Soil nematodes like *Caenorhabditis elegans* do not regulate their body temperature through metabolic activity and depend upon of physiological strategies to bypass any ecological constraints. How organisms adapt to these conditions and what are the physico-chemical principles that shape the limits of evolution is a field largely unexplored. Here we study the temperature dependence of the cytoplasmic phase separation of liquid-like organelles called P granules that emerge as liquid condensates in the gonadal syncytium of the nematode that segregate to the embryonic cytoplasm of the P cell during embryogenesis. PGL-1 condensates are involved in the development of the germ line and nematode fertility together with GLH helicases and other RNA binding proteins. We discovered that the liquid droplet phase of PGL-1 dissolve as a function of temperature in a reversible manner with a critical point of 27°C and a volume fraction $\Phi = 0.002$ coinciding with the maximum fertile temperature of the nematode but not its maximum survival range. Our results suggest that P granule phase sepsaration process is tuned for mesothermic environments indicating that the volume fraction should be higher than $\Phi > 0.002$ with a P granule puncta count $N > 40$ in order to upkeep fertility at limiting temperatures.

Keywords: Liquid Phase Separation, Mesothermic, P granules.

Cancer cell tropism of glioblastoma-derived exosomes regulated by their lipid components

Y. Toda[1], K. Takata[2], Y. Nakagawa[1], H. Kawakami[2], S. Fujioka[2], K. Kobayashi[1], Y. Hattori[1], Y. Kitamura[2], K. Akaji[1], E. Ashihara[2]
[1]*Department of Medicinal Chemistry,* [2]*Department of Clinical and Translational Physiology, Kyoto Pharmaceutical University, Kyoto, Japan*

Cell-to-cell communication is an important hallmark of multicellular organisms and expressed in the form of direct intercellular contact or transfer of secreted molecules. In the last two decades, extracellular vesicles (EVs) have been recognized as a novel intercellular communication tool. Exosomes with a diameter of 50–100 nm, are formed by inward budding into multivesicular bodies (MVBs). The fusion of these MVB with cell membrane causes the extracellular secretion of exosomes. Exosomes containing mRNA, microRNA, proteins, and lipids are transported into the target cells to be involved in various physiological/pathological phenomena. Despite of the accumulating evidence about biological functions of exosomes, 'exosomal principle', especially about their cellular incorporation, is not yet clear. We hypothesized that exosomes will be received a certain cellular tropism for effective intercellular communication, and the parent cells will regulate the exosomal direction by tuning their constituent molecules. In this study, we investigated whether cancer-derived exosomes were more taken into cancer cells than into normal ones. Exosomes derived from the human glioblastoma cells line U251-MG (U251) were highly purified by density gradient centrifugation. The exosomes ($U251_{exo}$) were hollow particles expressed CD63, and almost of them had a diameter of about 100 nm. $U251_{exo}$ were more taken up by U251 than by normal human astrocytes (Ast). In contrast, Ast-derived exosomes (Ast_{exo}) showed equal translocation into cancer/normal cells. Disrupting the ligand-receptor interaction on cells by enzymatic treatment against $U251_{exo}$ did not affected in their cancer-directional capability. To the end, we focused on the membrane lipid components as a crucial factor of the cellular tropism of the exosomes. In thin-layer chromatography analysis, lipid raft-related lipids (cholesterol and sphingomyelin; SM) accounted for a half of the total lipids of EVs, and the ratio of SM was different in their cell origins. Phosphatidylethanolamine was simultaneously enriched not only in cellular plasma membrane of U251 but also in U251-derived EVs, compared with Ast or Ast-derived EVs. The difference of exosomal lipid raft profiling and partial reflection of cellular lipid components to exosomal ones may alter the membrane affinity for cell-exosome interaction linking to exosomal interanalizing efficiency. These results could provide a novel cell targeting strategy for drug delivery as well as clues to understand the mechanisms of cell-to-cell communication via EVs in our body. Thus, the exosomal lipid components could be one of the important factors for their cell tropisms.

Keywords: cell tropism, exosome, lipid components.

Cell free expression, purification and solubilization of amyloid precursor protein's transmembrane domain with familial mutations V717I/G and L723P

K. Nadezhdin[1,2], A. Urban[2], I. Chaplygin[2], O. Bocharova[1], E. Bocharov[1], A. Arseniev[1]
[1]Department of structural biology, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, [2]Department of Biological and Medical Physics, Moscow Institute of Physics and Technology (State University), Dolgoprudny, Russian Federation

Alzheimer's disease (AD) is the most prevailing neurodegenerative disorder that affects elderly population all over the world. The hallmarks of AD are amyloid plaques and neurofibrillary tangles which were found in brains of patients. Plaques are made of beta-amyloid peptide – a product of sequential regulated intramembrane proteolysis of amyloid precursor protein (APP) by gamma-secretase complex. Many mutations found in APP transmembrane domain are associated with early onset of AD. Although these pathogenic (or familial) mutations are believed to influence the structure of APP, its dimerization capability and/or cleavage by gamma-secretase, the exact molecular mechanisms involved in these processes remain elusive. In this study we describe a highly efficient cell-free expression protocol for APP transmembrane domain with pathogenic mutations: V717I (also known as 'London' mutation), V717G and L723P (referred to as 'Australian' mutation). This method allows in short time to acquire milligram quantities of pure isotope-labeled peptides for high-resolution NMR spectroscopy.

Keywords: Alzheimer's disease, APP, familial mutations.

Cellular response of intestinal epithelial cells exposed to inorganic mercury and methylmercury

M. Vázquez, D. Vélez, V. Devesa
Food Preservation and Quality, Institute of Agrochemistry and Food Technology, Paterna, Spain

The mercurial forms [Hg(II) and methylmercury, CH_3Hg] produce neurological and immune effects as well as hematological and renal alterations. The main route of exposure to these Hg species in humans is through the diet. Consequently, the gastrointestinal mucosa is exposed to these mercurial forms, though the potential toxic effects upon the mucosa are not clear. The present study evaluates the toxicity of Hg(II) and CH_3Hg (0.1–2 mg/L) in intestinal epithelial cells using the differentiated and undifferentiated human Caco-2 cell line.

The experiments made show the mercurial forms to reduce cell viability at high concentrations (≥1 mg/L), with cell death occurring mainly in the form of apoptosis. Exposure also produces the generation of reactive oxygen and/or nitrogen species and a significant decrease in glutathione content at the highest concentrations (≥1 mg/L). This redox imbalance could be the cause of the lipid peroxidation observed after short exposure times (30 min). Such conditions of stress lead to modulation of stress proteins and of tumor necrosis factor-alpha expression. In general, toxicity does not appear to be dependent upon the cell differentiation state. The abovementioned effects may be the cause of the increase in permeability observed in the differentiated cell monolayers, where redistribution of F-actin and ZO-1 protein and dowregulations of proteins of the intercellular junctions are observed after the treatments with mercury.

Keywords: Mercury; intestinal epithelium; intercellular junctions.

SUN-370
Clathrin- and dynamin-independent internalization of PDGF via Rho GTPases

K. Jastrzebski[1], L. Sadowski[1], Y. Kalaidzidis[2], N. Hotchin[3], C. Hellberg[3], M. Miaczynska[1]
[1]Laboratory of Cell Biology, International Institute of Molecular and Cell Biology, Warsaw, Poland, [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, [3]University of Birmingham, School of Biosciences, Birmingham, UK

Platelet-derived growth factors (PDGFs) belong to the family of disulphide-linked dimer ligands which act via transmembrane receptors with tyrosine kinase activity. Activation of the PDGF receptor (PDGFR) regulates major cellular processes like proliferation and migration. In parallel to evoking signaling responses, PDGF binding to the PDGFR induces endocytosis of ligand-receptor complexes which decreases a number of available PDGFR on the plasma membrane. We recently showed that in human fibroblasts PDGF can be internalized in the presence of dynamin inhibitors, arguing that both dynamin-dependent and dynamin-independent pathways can mediate PDGF uptake.

In light of these findings we are currently investigating dynamin-independent internalization of PDGF, which requires the activity of proteins from the Rho family of GTPases. We analyzed endocytic transport of PDGF-PDGFR complexes under overexpression of active or inactive mutants of Rac1, RhoA and Cdc42. We also employed chemical inhibitors directly blocking Rho GTPases or interfering with downstream components of their signaling pathways. Overexpression of Rac1 mutants or acute block of its function with Rac1 inhibitor (NSC 23766) did not affect internalization of PDGFR. The overexpression of active Cdc42 caused formation of enlarged PDGF-positive endosomes. Such accumulation of PDGFR on endosomes may in turn lead to its prolonged signaling. Moreover, overexpression of inactive Cdc42 or blocking its function with a chemical inhibitor (ML 141) decreased the internalization rate of PDGFR. Finally, in cells overexpressing an active form of RhoA, PDGF-containing endosomes were trapped near the plasma membrane, whereas inactive RhoA mutant reduced uptake of PDGFR. This effect was mimicked by blocking RhoA activity using C3 transferase from Clostridium botulinum. Furthermore, interfering with Rho-associated protein kinase (ROCK), which is a major downstream effector of the RhoA, also led to a partial inhibition of PDGFR endocytosis. Currently, we are testing how the above described changes affect signaling induced by PDGF, as we previously showed that acute inhibition of dynamin activity only moderately affected PDGF endocytosis, but it specifically decreased downstream signaling of PDGF via Stat3 transcription factor.

More generally, in this project we expect to verify a hypothesis that the components governing endocytic trafficking, such as dynamin or Rho GTPases, may selectively regulate certain signaling effectors activated by a growth factor, like PDGF.

Keywords: Clathrin- and dynamin-independent endocytosis, PDGF receptor, Rho GTPases.

Coagulation factors X and Xa bind to phospholipid membranes in a hysteresis manner which allows them to be retained in thrombi under flow conditions

N. Podoplelova[1,2], A. Sveshnikova[2], F. Ataullakhanov[2], M. Panteleev[2]
[1]*National Research Centre for Hematology,* [2]*Federal Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*

Introduction: Many regulatory processes in biology involve reversible association of proteins with membranes. Proteins that bind to phosphatidylserine are implicated in diverse processes such as intracellular signal transduction cascades, plasma membrane-cytoskeleton interactions, phagocytosis of apoptotic cells, and blood clotting.

Binding to phosphatidylserine-containing membranes is the first step in the all membrane-dependent reactions and its understanding is a prerequisite for the analysis of their mechanisms. Clotting proteins bind to phosphatidylserine-containing membranes, but clear picture of this interaction has yet to emerge.

Therefore, we show the binding of factors X and Xa to negatively charged phospholipid membranes.

Methods: The binding of coagulation factors to negatively-charged phospholipid membranes was studied with an Accuri C6 cytometer (BD Biosciences, USA) and an Axio Observer Z1 confocal microscope (Carl Zeiss, Jena, Germany) using fluorescein-labeled FX or FXa. Fluorescence intensity was converted to a mean number of molecules per platelet or per phospholipid vesicle using special calibration beads. Computer simulations of fXa binding to a single platelet or to platelet aggregate were carried out using the Virtual Cell environment (http://vcell.org).

Results: Apparent equilibrium binding of fX and fXa to synthetic PS:PC (25:75) was saturable and specific, with 7991 ± 847 binding sites per vesicle and apparent k_d of 435 ± 75 nM for FX, 11 920 ± 1882 binding sites per vesicle with an apparent k_d of 747 ± 57 nM for FXa.

The association data were fitted to a exponential decay model with rates of $k_+ = 0.022 \pm 0.007\ nM^{-1}s^{-1}$ and $0.578 \pm 0.038\ nM^{-1}s^{-1}$ for fX and fXa respectively. However, data from dissociation experiments showed that the binding was not actually reversible: after a 20-fold dilution, the concentration of the bound factor Xa decreases to a value much higher than the equilibrium one. The initial apparent dissociation constant, k_- was of $2.29 \pm 0.26\ s^{-1}$ and $2.41 \pm 0.08\ s^{-1}$ for fX and fXa respectively.

Thus the process of binding and dissociation has been a hysteresis-like one, posing a kind of 'memory'. By mathematical modeling, we have shown that this behavior can only be explained by trimerization of factors.

Our model predicted that the phenomenon of oligomerization may be important for to keep factors on the surface thrombi. Our experiments confirmed the prediction model. Thus, we can assume that the trimerization factors ensures their fixing to the surface of a thrombus under the flow.

The study was supported by the Russian Foundation for Basic Research grants 13-04-00401.

Comparative analysis of growth, UV- resistance and cell wall structure of *Salmonella enterica* serovar Derby ('*S. derby*') cells

A. Z. Pepoyan[1], M. Balayan[1], A. Manvelyan[1], V. Tsaturyan[2]
[1]*Food Safety and Biotechnology, Armenian National Agrarian University,* [2]*Yerevan State Medical University, Yerevan, Armenia*

The association between the form and function of microorganisms is one of the frequently discussed questions in biological investigations.

The *aim* of current investigations was the comparative analysis of growth, UV-resistance and cell wall structure of S. *derby* strain and its plasmid curried derivative.

The following *S. derby* strains were used in this study: *i.* wild conditional pathogenic strain of *K89*, having a R-factor (100 thousand bpn) and giving to bacterial cells multiple resistance to following antibiotics: chloramphenicol, penicillin and tetracycline; *ii. K82,* the plasmid-curried derivative of *K89*; and *iii. K134*, the UV- sustainable mutant of *K89*.

Bacteria were grown in LB medium, pH 7.5, under aerobic conditions. The duration of lag phase and specific growth rate were determined as described previously (1–3).

X-ray diffraction method under the small and large angles was used to investigate the cell walls' structure and its intramembrane organization. Samples were prepared according to investigations described previously (4).

The differences in growth of *K89* cells and its plasmid curried variants were described, and the role of intercellular interactions on growth of K82 UV- resistant cells were shown by us. The changes in the form and size of the *S. derby* cells after the plasmid elimination were detected. It was established the liquid-crystal structure of cell walls for all of investigated bacterial strains. The cell walls from the curried from plasmid K82 strains are more hydrophobic, than the cell walls of K89 and K134 strains. At the same time the association between UV- resistance and qualitative and quantitative composition of phospholipids in *S. derby* cell walls was established. In particular, the increase of contents of acidic phospholipids in K82 strains was shown.

We assume that the structural changes in cell walls of *S. derby* play a key role in bacterial growth and UV- resistance.

Comparison of the effects of some antipsychotics on lipid bilayer

P. Skrobecki[1,2], A. Chmielinska[3], A. Polit[3], M. Dziedzicka-Wasylewska[2,3], M. Nowakowska[1]
[1]Department of Physical Chemistry and Electrochemistry, Faculty of Chemistry, Jagiellonian University, [2]Laboratory of Biochemical Pharmacology, Institute of Pharmacology, Polish Academy of Sciences, [3]Department of Physical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Antipsychotics, which are used in therapy of schizophrenia, are compounds classified as the ligands of membrane G protein-coupled receptors (GPCRs). Especially most of them are considered to be the antagonists of dopamine receptors. However, the accurate mechanism of action of these drugs, which is responsible for their therapeutic effects, is not explained sufficiently. Besides the interaction with receptors (specific activity), neuroleptics exhibit also a nonspecific activity – i.e. the interaction with cell membranes.

The present study were designed to evaluate interactions of some antipsychotic drugs with lipid bilayers. The study was performed for: amisulpride (AMS), sulpiride (SU), thioridazine (TH) and olanzapine (OLP). The monolayer liposomes made of POPC (neutral charge) as well as of POPC/POPG (3:1 molar ratio) (negative charge) have been used as the model of biological membranes. The isothermal titration calorimetry (ITC) has been employed to obtain thermodynamic parameters of the interactions. Additiolnally, the influence of neuroleptics on the permeability of a bilayer in terms of water (dynamic light scattering measurement DLS) was studied as well as the influence on a surface charge of liposomes (zeta potential measurement).

The obtained results indicate the strongest effect of interaction with lipid bilayer for thioridazine and olanzapine. Amisulpride seems to exhibit a weak interaction. No effect for sulpiride was observed.

These results show differences in effects induced by antipsychotic drugs, what indicates that these drugs are not neutral for cell membranes. In this context the obtained results point to the necessity of further research of the influence of neuroleptics on biological membranes with the use of more complicated liposomal systems or membrane fraction of cell lines.

Conformational changes in an aquaporin-nanodisc system modeled with SAXS/SANS

M. Järvå[1], S. Kynde[2], S. Törnroth-Horsefield[3], L. Arleth[2]
[1]Department of Chemistry and Molecular Biology, Institution of natural sciences, Gothenburg, Sweden, [2]Structural Biophysics Group, Niels Bohr Institute, Copenhagen, Denmark, [3]Department of Biochemistry and Structural Biology, Inst. of Natural Sciences, Lund, Sweden

Structural information about macromolecular bio-molecules is crucial for understanding their function. Small angle X-ray/neutron scattering (SAXS/SANS) can be used as either a complementary method to X-ray crystallography and NMR, or as a main tool when the preferred methods are unavailable. SAXS/SANS requires homogeneous samples for proper modeling but for membrane proteins the detergent micelles are heterogeneous, thus making the method problematic. The problem can be circumvented by incorporating the target membrane protein into nanodiscs. They consist of a disc formed bilayer enveloped by two copies of a modified apolipoprotein. The nanodiscs intrinsic homogeneity and reproducibility makes them ideal for SAXS/SANS.

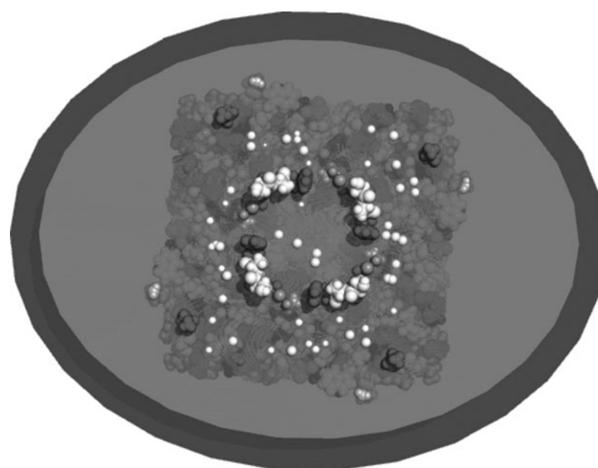

Fig. 1.

Here we have used an water channel as a model system to test the limitations of this method. The spinach leaf aquaporin SoPIP2;1 was reconstituted into nanodiscs and with data from SAXS measurements and subsequent SANS measurements we could model the aquaporin into a nanodisc.

In good agreement with previous studies, SoPIP2;1 had to be modeled as a tetramer. The intracellular loops had to be included in the model to fit the data and the lateral location of these loops was just as important. Furthermore, the number of lipids in the model correlates well with the amount measured in the phosphate assay.

Since SoPIP2;1 is a gated protein and a crystal structure exists of both the open and closed state, a comparison of fits between the two states was made. A slight preference towards the open conformation was seen. The results strongly indicates that the method described here is viable for probing conformational properties in membrane proteins in an environment that is both more native and less heterogeneous than detergent micelles.

The intestinal villous epithelial layer undergoes permanent renewal, suggesting the existence of mechanisms regulating the maintenance of the polarized epithelial monolayer. While intensive research is focusing on crypt cells and cell fate determination, mechanisms underlying the maintenance of the villous homeostasis are largely unknown.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Congenital Tufting Enteropathy (CTE) (MIM #613217) constitutes an interesting working model. This rare human disorder, responsible for intestinal failure, is characterized by abnormal morphology of the intestinal villi, with aberrant focal stacks of multiple layers of enterocytes, named 'tufts'. Mutations in the *EPCAM* and *SPINT2* genes have recently been correlated with CTE in 94% of cases. Here we aimed at understanding the cellular functions of EpCAM and Spint2 in enterocytes, and characterizing the impact of their mutations on villous morphogenesis. We addressed these questions by developing integrated approaches at the cell biological, biophysical, and physiopathological levels.

We show that endogenous EPCAM and SPINT2 are located at the lateral membranes and the terminal web. We analyzed either duodenal biopsies of CTE patients, or stable Caco2 clones depleted for EPCAM or SPINT2. Ultrastructural analyses were performed using transmission electron microscopy, and immunohistological analyses for cell organization, cell differentiation and polarity markers. Our results clearly show specific defects in enterocyte cell polarity and adhesion in the mutant enterocytes: microvillus atrophy, mislocalization of brush border components, and weakened cell-cell junctions. Although Caco2-depleted cells display a large panel of cell organization abnormalities, they still formed epithelial monolayers in 2D cultures. We thus generated 3D culture supports that recapitulate villus topology and constraints. Placing mutant human enterocytes on synthetic villus cultures revealed strong perturbations in the maintenance and dynamics of the epitelial monolayer, mimicking the tufts observed in CTE patient mucosa.

We demonstrated that the CTE disorder is characterized by the loss of enterocyte polarity and differentiation. As a consequence, correct cell dynamics along the villous architecture is impaired in mutant enterocytes.

Detachment of key adhesive proteins from the membrane skeleton is observed in phosphatidylserine-positive platelets

E. Artemenko, F. Ataullakhanov, M. Panteleev
Center For Theoretical Problems Of Physicochemical Pharmacology, Moscow, Russian Federation

Background: The attachment of membrane glycoproteins to the cytoskeleton in activated platelet subpopulations has been poorly studied. In the resting platelets, adhesive membrane proteins are attached to the cytoskeleton with special proteins, and their degradation is supposedly controlled by calpain, a calcium-dependent protease. Upon strong physiological activation, two platelet subpopulations (PS (phosphatidylserine)-positive and PS-negative) are formed, which have different functions in hemostasis and thrombosis. We developed a new flow cytometry-based single-cell approach to investigate the attachment of membrane glycoproteins to the membrane skeleton in platelet subpopulations.

Methods: Platelets were isolated from whole blood by centrifugation and gel-filtration. Then they were activated with physiological agonists such as thrombin and collagen-related peptide. Subpopulations of PS-positive and PS-negative platelets, were separated by flow cytometry due to their different PAC-1 binding. The attachment of membrane glycoproteins (integrin $\alpha_{IIb}\beta_3$, GpIb and P-selectin) to the cytoskeleton was estimated by fixing the platelets with paraformaldehyde after activation in the presence of fluorescently-labeled antibody (CD61, CD42b or CD62P) to surface glycoproteins and treating fixed platelets with detergent. Additionally the status of cytoskeletal proteins was evaluated by electrophoresis.

Results: We observed a release of membrane surface glycoproteins in only the PS-positive platelets (fixed platelets after detergent treatment), but not in the PS-negative activated platelets and resting platelets. This effect was prevented by calpain inhibitors (calpeptin and MDL28170). These results suggest that the degradation of cytoskeletal proteins that provide attachment of the membrane surface glycoproteins to the platelet cytoskeleton occurred only in PS-positive platelets. This effect correlated with the degradation of talin and filamin as detected by protein electrophoresis.

Conclusions: The inhibition of calpain resulted in a significant decrease in the proteolytic degradation of cytoskeletal proteins, suggesting that calpain is involved in the regulation of the attachment of integrin $\alpha_{IIb}\beta_3$, GpIb and P-selectin to the cytoskeleton of platelets. Our data suggest that this detachment of membrane glycoproteins may play a role in the regulation of the adhesive properties of platelet subpopulations.

Development of live cell PALM imaging approaches to studying GM-CSF receptor endocytosis and JAK2 activation on the cell surface

F.-C. Chien[1], C.-S. Liu[2], W.-C. Chang[2], H.-F. Yang-Yen[3], J. J.-Y. Yen[2]
[1]*Department of Optics and Photonics, National Central University, Chung-Li,* [2]*Institute of Biomedical Sciences,* [3]*Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan*

JAK2 kinase plays a very important role in transducing proliferative and survival signals for many cytokines and is involved in regulating the vital function of numerous special tissues. Recently the importance of JAK2 was further emphasized since specific JAK2 mutations were identified in many tumorous and non-tumorous hematopoietic diseases. Various pharmacological inhibitors of JAK2 kinase are also currently under clinical trials, underscoring the importance of JAK2 function in human diseases. We here report the controlling mechanism of JAK2 activation by cytokine GM-CSF and oncogenic JAK2 V617F mutation and proposes a comprehensive hypothetical model for JAK2 kinase activation and oncogenesis based upon biochemical and molecular biology analyses and fixed cell-superresolution microscopic images. In this model endocytotic clathrin-coated pits are proposed to serve as a signaling platform for GM-CSF receptor and JAK2 is activated by the clathrin-coated pit-localized CK2 after JAK2 acquired a liganded-receptor-induced conformational change. Furthermore, we aimed to establish the live cell-Forster resonance energy transfer (FRET) and -photoactivated localization microscopy (PALM) technologies to visualize and analyze the JAK2 activation by cytokines and the interaction of GM-CSF receptor with endocytotic machinery components. To achieve this goal, we used the complementary metal oxide semiconductor (CMOS) camera to achieve the frame rate of 556 frames per second with the pixel number of 256 x 256 and high sensitivity, and used the switchable and bright fluorescence probe such as reversible photoactivatable fluorescence protein, dronpa, (in PALM) and photoswitchable labeling dye (in STORM) to reduce the acquisition time with the larger numbers of photon. By improving the acquisition time of live cell super-resolution fluorescence localization imaging, the behavior of clathrin-coated pit and JAK2 at the plasma membrane in live cell was recorded and studied with temporal resolution of 0.5 second and spatial

Development of the cellular model to study on TrkC- dependent neuritogenesis

P. W. Krawczyk[1], E. Twarog[1], E. Kurowska[1], D. Klopotowska[2], J. Matuszyk[1]

[1]*Department of Microbiology Laboratory of Signaling Protein,* [2]*Laboratory of Experimental Anticancer Therapy 'Neolek', Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland*

PC12 cell line has become a widely used research tool for many aspects of neurobiology. By means of genetic engineering a subset of PC12 cells was engineered to drive doxycycline (Dox) -induced expression of gene encoding TrkC (receptor of neurotrophin 3, NT- 3) in the Tet-On system. In our study we have used second- generation Tet promoter (P_{tight}) which contains both shortened minimal CMV promoter sequences and tetO elements positioned in an optimized manner. P_{tight} promoter provides low basal expression in the absence of Dox. We have developed the cellular model to study on TrkC- dependent neuritogenesis, where *trkC* expression is controlled by tetracycline promoter. In this particular model *trkc* expression is regulated by Dox in a concentration- dependent manner. NT-3 treatment and subsequent activation of TrkC results in ERK1/2 kinases phosphorylation leading to neurite outgrowth.

Keywords: neuritogenesis, PC12-Tet-On, TrkC.

Different regulation of store-operated calcium channels by calcium sensors Stim1 and Stim2 proteins

A. Shalygin, V. Kamaletdinova, A. Skopin, O.Zimina, L. Glushankova, G. N. Mozhayeva, E. Kaznacheyeva

Institute of Cytology Russian Academy of Sciences, St-Petersburg, Russian Federation

Store-operated channels are the major calcium entry pathway in nonexitable cells. Stim proteins are Ca^{2+} sensors of endoplasmic reticulum. Stim proteins are essential for activation of store-operated Ca^{2+} entry. After store depletion Stim proteins change their conformation and activate store operated calcium channels of plasma membrane. On one hand different store-operated channels could coexists in one cell, on the other hand in mammals there are two homologues of Stim proteins.

The goal of this study was to compare regulation of different store-operated channel types by Stim1 and Stim2 proteins.

To evaluate the role of Stim calcium sensors in activating endogenous store-operated channels we use HEK293 cell line. Electrophysiological properties of calcium channels are well described in this cell line, what make it useful model to study store-operated channels. There are three types of Ca^{2+} channels in cell-attached patches from HEK293 cells: I_{max}, I_{NS} and I_{min} (Bugai et al., 2005, JBC).

To separate Stim1- and Stim2-operated channels we used knockdown – overexpression strategy and partial depletion of calcium stores for selective activation of Stim2.

In single-channel patch–clamp experiments with Stim1 or Stim2 overexpression (knockdown) we discovered that I_{NS} channels are activated by Stim1, I_{min} channels are activated by Stim2 and I_{max} channels are regulated by both Stim homologues upon store-depletion.

There is big difference in calcium sensitivity between Stim1 and Stim2 proteins. Stim1 proteins are activated only by strong store depletion, which is evoked by micromolar concentrations of thapsigargin. Stim2 proteins are activated even by small changes in Ca^{2+} store, which do not activate Stim1. In further experiments we induce partial store depletion for specific activation of Stim2 proteins. Partial store depletion lead to Imin channel activation.

We hypothesized that difference in regulation of various store-operated channels by Stim1 and Stim2 proteins define intracellular calcium signaling.

The study was supported by the program of 'Molecular and Cellular Biology' RAS, research grants from the Russian Basic Research Foundation, Dynasty Foundation and the Russian Scientific Foundation 14-14-00720.

Keywords: Patch-clamp, Stim proteins, Store-operated calcium entry.

Dimeric spatial structure of HER2 transmembrane domain in junction to the juxtamembrane regions corresponding to the receptor inactive state

P. Bragin, K. S. Mineev, O. Bocharova, E. Bocharov, A. Arseniev

Laboratory of Biomolecular NMR Spectroscopy, Shemyakin-Ovchinnicov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Receptor tyrosine kinases, such as the members of human epidermal growth factor receptor (HER) family, play critical role in regulating cell metabolism, growth and differentiation. It was shown, that HER members are active in dimeric state and the ligand binding causes rearrangement of transmembrane and intracellular domains of the receptor. Activation of the catalytic domain of the HER receptors is controlled primarily by an allosteric interaction between two protein kinase domains in an asymmetric dimer. Several studies of HER activation led to the conclusion that cytoplasmic juxtamembrane regions of these receptors are essentially important for the HER signaling. Upon ligand binding, juxtamembrane regions in preformed dimer of the HER on the cell surface are supposed to change their conformation from parallel, corresponding to inactive state, to antiparallel, which is proposed to be active. It is also assumed that different functional states of the receptor correspond to different dimerization interfaces on the transmembrane domain. Thus, understanding the principles, lying in the basis of intermolecular interactions of transmembrane and juxtamembrane regions in such receptors is essential for detailed description of the activation mechanism and is necessary for rational design of new drugs, targeting directly the transmembrane and juxtamembrane domains.

Here we investigate the spatial structure and backbone mobility of the HER2 transmembrane domain homodimer in junction to the cytoplasmic juxtamembrane region in membrane-like environment using solution NMR spectroscopy. Our data reveal the parallel orientation of the juxtamembrane regions in the dimer that allows to assign the obtained structure to the inactive state of the full-size receptor. The transmembrane domains interact via a non-standard motif located at the N-terminal part of the transmembrane helix. The interaction is driven mainly by apolar contacts of bulky side chains. The measured parameters of NMR relaxation reveal that the mobility of transmembrane and juxtamembrane regions is quite similar, suggesting that the juxtamembrane regions are buried in the micelle. This conclusion is confirmed by the

© 2014 The Authors. FEBS Journal © 2014 FEBS

observed intermolecular contacts between amino acid residues and lipid molecules of the micelle. The obtained spatial structure is the evidence in favor of the 'ligand-induced rotation' mechanism, suggested for HER receptors, and provides an insight into the structural basis of signal transduction by HERs.

This work is supported by Russian Academy of Sciences (program 'Molecular and Cellular Biology').

Keywords: activation mechanisms of transmembrane receptors, human epidermal growth factor receptors, spatial structure of HER2 transmembrane domain.

Dissecting the retrograde membrane trafficking pathway using bacterial toxins and nanoparticles: A tale of two genome-wide RNAi screens

M. G. Bexiga[1,2], A. Panarella[1,2], G. Galea[1,2], J. C. Simpson[1,2]

[1]School of Biology and Environmental Science, [2]Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland

Newly synthesised molecules are delivered to the plasma membrane, the extracellular space and other intracellular compartments by the biosynthetic pathway. At each transport step, organelle homeostasis is maintained by a retrograde membrane flow which counterbalances forward traffic.

Despite our considerable knowledge of the molecular machinery associated with forward trafficking pathways, much less is known about retrograde transport pathways linking the cell surface and endosomes with early secretory pathway organelles such as the Golgi complex and endoplasmic reticulum. Nevertheless, these routes are important, as they are known to be exploited by a number of viruses and protein toxins as part of their mechanism of action. This retrograde route also holds promise for the delivery of therapeutic agents, and as such it is essential that we understand its regulatory machinery.

In order to identify the proteins that regulate internalisation and retrograde transport pathways two independent genome-wide RNAi screens coupled to high-content image analysis were performed in HeLa cells. Nanoparticles were used to study endocytosis and endosomal-lysosomal delivery pathways, while Shiga-like toxin was the probe to understand transport from the cell surface to the Golgi complex. These studies revealed roles for members of the Rab family of GTPases and components of the cytoskeleton not previously described to be involved in either process, in addition to various other classes of molecule, as key regulators of these pathways.

The results from these screens not only contribute to our general knowledge of the mechanisms of retrograde traffic, but are also valuable in the development of more efficient drug delivery strategies to cells.

Keywords: Genome-ride RNA screening, Membrane traffic, Retrograde trafficking.

Effect of gender and chronological age on erythrocyte membrane quality in blood bank storage condition

U. Aksu[1], H. Erman[2], P. Atukeren[3], D. D. Uzun[4], R. Gelişgen[3], A. Belce[5], E. Uslu[3], **U. Çakatay**[6]

[1]Departmant of Biology, Faculty of Science, Istanbul University, [2]Medical Biochemistry, Medical School, Medeniyet University, [3]Medical Biochemistry, Cerrahpasa Medical Faculty, Istanbul University, [4]Medical Faculty, İatanbul University, [5]Bezmialem Vakıf University, [6]Medical Biochemistry, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Despite the use of various storage solutions, a series of changes in erythrocytes have been occurring and number of functional red blood cells has been decreased. It is known that both in vivo and in vitro, storage lesions caused membrane dysfunction by interfering redox balance and transport function. In our study, the erythrocytes with different ages in Citrate phosphate dextrose-adenine-1 (CPDA-1) storage solution were used to investigate the contribution of gender difference on both radical and non-radical mediated damage. For this purpose, whole bloods from both genders were fractionated with 'Percoll density gradient' method. Fractions were stored in CPDA-1 solution which used as preservative and Oxidative biomarkers in membranes such as ferric reducing antioxidant power (FRAP), pro-oxidant-antioxidant balance (PAB), and advance glycation end products (AGE) were analysed at the end of 7 day storage period. Middle age erythrocytes of male rats showed a significant increase in FRAP activities ($p < 0.05$ versus respective female group), whereas PAB levels were increased in aged fraction of male rats ($p < 0.01$ versus young and middle age). Additionally, aged fraction of male rats was found to be increased in PAB levels compared to aged fraction of female rats ($p < 0.01$). Lastly, middle age fraction of female rats was found to be increased in AGE levels compared to respective male group ($p < 0.01$). This study reveals that changes in erythrocyte membrane redox status during blood bank storage depends unequivocally on gender dependent redox homeostasis. During storage period, male erythrocyte is exposed to free radical mediated oxidative stress but female erythrocyte is under non-radical glycative stress. However male donors could be better choice. The gender-dependent action in storage period needs further investigations.

Keywords: aging, blood storage, erythrocyte.

Effect of low molecular antioxidants on functionality RLIP76 and MRP1 in human erythrocytes

J. Kanash[1], T. Alexander[1], G. Natalia[2]

[1]Institute of Biophysics and Cell Engineering of NASB, [2]The Republic Research & Production Center for Transfusiology and Medical Biotechnologies, Minsk, Belarus

RLIP76 was found in almost all tissues, including human erythrocytes. Protein's nature determines its active participation in the cell signaling processes and membrane regulation. To date, cell detoxification mechanisms by RLIP76 when appeared of redox imbalance is almost unknown. In this context, aim of this study was to evaluate expression level and functional activity of RLIP76 in human red blood cells (RBC) under the influence of α-tocopherol, ascorbic acid (AA) and N-acetylcysteine (NAC).

It was found that fluorescence intensity of RLIP76-positive red blood cells (RBC) after 24 h loading therapeutic concentrations of NAC and α-tocopherol increased on average by 25–35% relative to control, for AA statistically significant differences

© 2014 The Authors. FEBS Journal © 2014 FEBS

compared with control (control was a fluorescence intensity RLIP76-positive cells untreated with investigated antioxidants) had not been established.

After treatment of RBC by NAC export 2,4-dinitrophenyl-S-glutathione (DNP-SG) – conjugates increased on average by 20% compared to untreated cells. At the same time, 24 h (and 1 h) effects of α-tocopherol and AA on human RBC had no effect on transport DNP-SG-conjugates from the cells. It is known that besides RLIP76 in glutathione-mediated detoxification of RBC also involved MRP1 protein.

To clarify the contribution of MRP1 in this process it was determined the residual retention of its substrate calcein under the action of the studied antioxidants. We found that for α-tocopherol and NAC fluorescence intensity of calcein didn't change relative to untreated cells, whereas effect of the AA was reduced on average by 20%, which indicates about an increase in functional activity of MRP1.

Thus, intracellular imbalance of 'antioxidant-prooxidant' in favor of the antioxidants can alternately result in both MRP1 activation (in the case with AA), and changing functionality RLIP76 (under the NAC action) involved in maintaining the redox homeostasis in human erythrocytes.

Human endothelin receptor B (EDNRB) is a member of class A (rhodopsin-like) G protein-coupled receptor (GPCR) family. Its dysfunction leads to many severe diseases such as hypertension, atherosclerosis, heart failure, renal disease and various forms of cancer. Several drug candidates targeting endothelin receptors have failed clinical trials, while only few that have been approved carry undesirable side-effects. Despite the high importance of these receptors, no structural information for them is available, mainly because of challenges related to heterologous expression, purification and crystallization of human membrane proteins. We have engineered a stabilized version of ENDRB by fusing a small soluble protein apocytochrome b562 in the intracellular loop 3, expressed the modified construct in baculovirus infected sf9 insect cells, and purified it to homogeneity by metal affinity chromatography. The purified protein displays an increase in thermostability upon addition of different antagonists, and shows promising behavior in pre-crystallization LCP-FRAP diffusion assays in lipidic cubic phase (LCP). LCP crystallization trials with this ENDRB construct bound to several different antagonists are currently underway.

Among wide range of human membrane proteins (MPs) the hyperpolarization-activated cyclic nucleotide-gated channels (HCNs) mediate functioning of heart and nervous system. Although these channels have crucial importance for pharmacology and medicine, their exact structure and molecular mechanisms of functioning still remain unknown.

The studies of HCNs are hampered by low expression level in host-based systems. To solve this problem we used cell-free expression (CFE) system based on *E. coli* extract. Such CFE systems have shown their efficacy for the production of MPs of different classes. The main advantage of these systems over host-based systems is that the yield of target protein achieves several mg/ml and allows to carry out further structural and functional studies. Also the so-called open nature of CFE systems makes it possible to add ligands and membrane-mimicking environments (micelles, bicelles, etc) directly into a reaction mixture and stabilize the target MP in a soluble and properly folded state.

In this work we used the CFE systems based on S30 extract from *E. coli* for the production of several variants of the transmembrane (TM) and cyclic nucleotide-binding (CNB) domains of the human HCN1 channel. We developed protocols for TM-HCN1 and CNBD-HCN1 expression either in a form of a precipitate or in a soluble form. Also the refolding protocols were developed. Yields of the TM-HCN1 and CNBD-HCN1 in optimal conditions were 1.2 –1.5 mg per 1 ml of the reaction mixture.

This work is crucially important for pharmacology and medicine and opens new horizons in structural and functional studies of human HCN1.

Acknowledgments: This work was supported by the ONEX-IM-group, the Ministry of Education and Science of the Russian Federation, the Russian Foundation For Basic Research (Project 14-04-32313) and 5TOP100 Program.

Expression, purification and functional analyses of human CysLT1 and GPR17 proteins

A. Luginina[1], M. Alexey[1], A. Gusach[1], V. Cherezov[1,2], V. Borshchevskiy[1]

[1]*The Laboratory for Advanced Studies of Membrane Proteins, Moscow Institute of Physics and Technology, Dolgoprudniy, Russian Federation,* [2]*TSRI, San Diego, CA, USA*

Leukotrienes are important inflammatory mediators that are produced from arachidonic acid through its oxidation. Their release in organism leads to bronchial smooth muscle constriction, arise blood vessel permeability, stimulate mucus secretion and attract immune cells. Leukotriene effects are realized via interaction with specific receptors, belonging to a superfamily of G-protein coupled receptors.

© 2014 The Authors. FEBS Journal © 2014 FEBS

CysLT1 is a cysteinyl leukotriene receptor activated mostly by leukotriene D4. It is shown that this protein is involved in inflammatory disorders such as asthma, allergic rhinitis, urticaria, rheumatoid arthritis at al. CysLT1 antagonists zafirlukast, montelukast etc are popular antiasthmatic medicaments but those drugs have considerable shortcomings.

GPR17 is an orphan receptor although its interaction with LTC4, LTD4 as well as purines was proved. This protein is involved in multiple sclerosis, ischemia and leukemia diseases. Thus CysLT1 and GPR17 are important drug targets.

The knowledge of CysLT1 and GPR17 structures could become a key to a specific drug-design. This can be achieved by means of X-ray crystallography method. To obtain protein crystals one needs high amounts of pure and stable protein with crystal contacts.

In this work for CysLT1 and GPR17 mutant constructions with fusion partner BRIL were created, expressed by means of baculovirus expression system, purified, solubilized from membranes. Purity, stability and aggregation level were analyzed by western-blotting, size-exclusion chromatography and thermal shift assay methods. The yield of proteins after purification was 1 mg from 1 liter of cell culture.

This work was supported by the 5top100-program of the Ministry for science and education of Russia.

FERM and PDZ domain containing protein 2 regulates epithelial cell polariZation

A. Skowronek[1], N. Hagemann[2], K. S. Erdmann[1]

[1]TRANSPOL Department of Biomedical Science, University of Sheffield, Sheffield, UK, [2]Department of Biochemistry II, Ruhr-University Bochum, Bochum, Germany

Epithelial cell polarization is characterized by an asymmetric distribution of proteins and lipids between apical and basolateral membranes. Establishment and maintenance of cell polarization involves many biological processes including membrane trafficking, signal transduction and cytoskeletal dynamics. FRMPD2 is a novel multi-PDZ domain protein implicated in cell polarization. FRMPD2 consists of an N-terminal KIND-domain, followed by a FERM domain and three PDZ domains. Thus FRMPD2 likely serves as a scaffolding protein for a larger protein complex. We have shown that FRMPD2 localizes at the basolateral membrane of polarized epithelial cells colocalizing with adherens- and tight junction markers. Decreased expression level of FRMPD2 lead to impairment of tight junction formation accompanied with loss of cell polarity. We find that basolateral targeting of FRMPD2 depends on its FERM domain and is mediated by PtdIns(3,4)P2. Interactions with p0071, ARVCF and δ-catenin – members of the catenin family suggest that FRMPD2 localizes at the basolateral membrane in an E-cadherin dependent manner. Recent studies have shown that FRMPD2 interacts with NOD2 and acts as a scaffold protein that localizes NOD2 to the basolateral membrane of epithelial cells and provides spatial specificity to NOD2-mediated immune responses. NOD2 is an important part of the innate immune system of intestinal epithelia and its recruitment to the plasma membrane is essential for NF-κB activation. In addition, genetic studies have revealed that mutations of NOD2 are closely associated with Crohn's disease. Using the yeast two hybrid system we have identified several new interaction partners for FRMPD2, among these interaction partners are candidates associated with immune-mediated diseases like systemic lupus erythematosus (SLE) and psoriasis (also associated with Crohn's disease). Our results highlight novel insights into molecular function of FRMPD2 in epithelial cell polarization and a potential role of FRMPD2 in immune-mediated inflammatory diseases.

Functionality of integral membrane proteins MRP-family under changing of zinc homeostasis in human erythrocytes

Y. Harmaza[1], A. Tamashevski[1], E. Slobozhanina[1], A. Ciana[2], G. Minetti[2]

[1]Institute of Biophysics and Cell Engineering of NASB, Minsk, Belarus, [2]Department of Biochemistry, University of Pavia, Pavia, Italy

Nowadays there is a hypothesis that Zn^{2+} may be used in cancer therapy jointly with anticancer drugs because have both DNA-protective for normal and DNA-destabilizing effects for tumor cells.

So, the goal of work – to clear the influence of zinc homeostasis in human erythrocytes on the functionality of the integral membrane protein-transporters ABCC (MRP)-family, which are involved in multidrug resistance phenotype and play a key role in the pharmokinetics a wide number of the anticancer drugs.

Results: Incubation erythrocytes with $ZnSO_4$ in vitro in pharmacological or toxic concentrations (50–500 μM) results in rise of intracellular level of labile Zn^{2+} in nanomolar range and accumulation of ROS but doesn't change GSH level. It is established MRP-proteins functionality activation in these conditions. We show that important role in such changing plays modification of phospholipids physical state and membrane cholesterol lateral distribution. Further we proved that one of the possible mechanisms of Zn-induced MRP-proteins activation in erythrocyte membranes is the derangement of structure and function of lipid rafts which have a central role in cell signaling.

Conclusion: The results testify about existence of link between rise of cytosolic concentration of labile Zn^{2+} and functioning of protein-transporters MRP-family in human erythrocytes where modification of lipid rafts structure and function play a key role. Moreover one of the trigger of such changes is disbalance of 'prooxidant/antioxidant' in cells.

This work was partly supported by grant of the Cariplo Foundation organized by the Landau Network-Centro Volta.

Gene-engineering and expression of the human endothelin A receptor' modifications

A. Potapenko[1], A. Mishin[1], V. Borshchevskiy[1], V. Cherezov[1,2], V. Gordeliy[1]

[1]Moscow Institute of Physics and Technology, Dolgoprudny, Moscow Region, Russian Federation, [2]Integrative Structural and Computational Biology, The Scripps Research Institute, La Jolla, CA, USA

Endothelin system is generally responsible for regulation of vascular tissue tension, also it is responsible for cell proliferation stimulation, regulation of cytokines and growth factors ejection into the cardio-vascular system with the participation of endothelins – group of paracrine local peptide (approximately 21 a.r.) hormones. Two (ET-1 and ET-2) of them (ET-1, 2, 3, 4) cooperate with ETA-receptors. ET-1 is prevailing type in cardio-vascular system. Its overexpression in blood plasma and tissues is a marker of

© 2014 The Authors. FEBS Journal © 2014 FEBS

different diseases. Also, cancer cells express endothelins which, in turn, stimulate cancer cell growth.

ETA-receptor is the one of two types G protein-coupled receptor (GPCR) family in human endothelin system. It's present in smooth muscle tissues, vascular fibroblasts, cardiomyocytes, neurons, osteoblasts, adipocytes, reproductive system, melanocytes.

The blockade of the ETA-receptor has a huge therapeutical potential. Some clinic research has led to the success in the treatment of atherosclerosis, heart attacks, hypertension, pulmonary dysfunction, nephritic injuries. Endothelins are the reasons of several types of inflammation and autoimmune reactions. So, the ability of this receptors activity regulation leads to important achievements in fundamental science and medicine.

This report describes the results of gene-engineering of different human ETA-receptor modifications' and their expression with the help of the baculovirus expression system in sf9 insect cells. Further we plan to prepare (purify and stabilize) this protein for the crystallization and further structure determination.

Glycocalyx alterations at apoptosis and its role in immune response and host-pathogen interactions: sweet taste of cell death

R. Bilyy[1,2], T. Dumych[1], R. Stoika[1], J. Bouckaert[3], M. Herrmann[4]
[1]Department of Regulation of Cell Proliferation and Apoptosis, Institute of Cell Biology, NAS of Ukraine, [2]Department of Histology, Cytology, Embriology, Danylo Halytskyy Lviv National Medical University, Lviv, Ukraine, [3]Unité de Glycobiologie Structurale et Fonctionnelle (UGSF), Université Lille 1, Lille, France, [4]Department for Internal Medicine 3, University Hospital Erlangen, Erlangen, Germany

Current report describes the role of two types of apoptotic cell-derived membranous vesicles (ACMV), each bearing distinct glycosylation patterns, in the immune response and host-pathogen interactions. Dying cells possess two active pathways of modification of glycocalyx: a) caspase-dependent activation of plasma membrane-assosiated neuraminidases leads to the formation of desialylated glycoepitopes on ACMV originating from plasma membrane (PM); b) with the aim to compensate membrane surface loss due to apoptotic blebbing dying cells expose on their surface immature membranes of endoplasmic reticulum (ER), bearing a moiety of oligomannosidic glycans. PM-derived ACMV are usually big (>3 μm) and contain nuclear material (histone and DNA), which actively translocates into the ACMV at the late stages of formation. ER-derived ACMV possess oligomannnosidic glycans, attributable to ER, that represent immunologically novel epitopes rapidly cleared by macrophages. Exposure of ACMV-contained nuclear material may support the formation of anti-nuclear (anti-histone and anti-DNA) antibodies in disorders, associated with impaired clearance, like SLE. At the same time adherent-invasive *Escherichia coli* (AIEC) cells, causing uropthatogenic infections and Crohn's disease, are known to utilize oligomannose-specific lectin FimH at the tip of their fimbriae to adhere to the host cells. We demonstrated that AIEC induce formation of ER-derived ACMV and attach to them. This process fosters bacterial infection and host cell colonization.

[1]TRANSPOL U1143 INSERM-UMR3666 CNRS, Institut Curie, Paris, France, [2]TRANSPOL Memphys, University of Southern Denmark, Odense M, Denmark, [3]U1143 INSERM-UMR3666 CNRS, Institut Curie, Paris, France, [4]TRANSPOL, École Polytechnique Federale de Lausanne, Lausanne, Switzerland

Shiga toxin entry into cells occurs by a clathrin-independent pathway in which the first step is the aggregation of initially-separated membrane-bound toxin particles. The molecular driving force of this aggregation is not yet understood, but it is known that toxin particles bind to the membrane via specific interactions with glycosphingolipid Gb3 headgroups. We demonstrate here using computer simulations that when rigid planar nanoparticles adsorb to a lipid bilayer, there is a regime in which they perturb the thermally-excited membrane shape fluctuations sufficiently to drive them together. We derive a theory of this fluctuation-induced aggregation as a form of Casimir force. The simulations predict that the nanoparticles will not aggregate if they are bound to the membrane by flexible linkers that remove the particles from direct contact with the membrane. To test this prediction, we have synthesized Gb3 analogues whose sugar headgroups are separated from their ceramide backbone by short PEG linkers, and we find that Shiga toxin particles do not aggregate although they bind normally to the membrane surface. We conclude that the non-specific interactions of the Shiga toxin particle with the membrane surface are necessary for their aggregation.

Golgi-to-ER recycling regulates the transport rate of membrane cargoes along the secretory pathway

M. Fossati[1,2], S. F. Colombo[2], N. Borgese[2,3]
[1]Institut de Biologie de l'Ecole Normale Superieure, Ecole Normale Superieure, Paris, France, [2]Institute for Neuroscience, CNR-National Research Council, Milan, [3]Department of Health Science, University of Catanzaro, Catanzaro, Italy

The Endoplasmic Reticulum (ER) and the Golgi complex are dynamically connected by both anterograde and retrograde vesicular transport pathways. Although the molecular mechanisms underlying the retrograde pathway have been extensively characterized, whether and to what extent plasma membrane-directed cargoes escape from this recycling has been poorly analyzed. To investigate this problem, we compared the transport of a set of membrane cargoes at the ER-Golgi interface by a combination of live cell imaging and temperature blocks. When the transport between the *trans*-Golgi network (TGN) and the plasma membrane is blocked by incubation at 20°C, VSVG (Vesicular Stomatitis Virus Glycoprotein) is exported from the ER and accumulates in the Golgi; in contrast, a mutant form of VSVG lacking its di-acidic-based ER export signal (VSVG AxA) attains a steady state distribution between the ER and the Golgi, suggesting that a Golgi-to-ER retrograde pathway, in combination with a slow rate of exit from the ER, determines this intermediate localization. iFRAP analysis, as well as treatment with H89, which blocks COPII-dependent export, revealed indeed that VSVG AxA, at variance with the wild-type protein, is recycled

© 2014 The Authors. FEBS Journal © 2014 FEBS

from the Golgi to the ER. Our analysis was then extended to other outward-directed membrane cargoes that lack any known export signal: a tail-anchored construct (FP-22) and the EGF Receptor (EGFR). We found that both these cargoes are included into an energy-dependent Golgi-to-ER recycling pathway with similar first order rate constants of Golgi-to-ER transport. To explore which retrograde route is involved in the recycling phenomenon, we used dominant negative mutants of the two Golgi-to-ER pathways (Arf1/COPI- and Rab6-dependent). In cells overexpressing inactive Rab6, VSVG AxA was more concentrated in the Golgi apparatus at 20°C, and the rate of its retrograde transport from the Golgi to the ER was slowed. The weight of Rab6-dependent recycling in delaying transport of membrane cargoes to their final destination was evaluated by comparing the effect of dominant negative Rab6 on the transport of wt and AxA-VSVG to the cell surface; at variance with wt-VSVG, we found that dominant negative Rab6 stimulated VSVG-AxA's transport to the cell surface. In conclusion, our results identify recycling as a novel limiting step in the transport of membrane cargoes along the secretory pathway, and indicate that a positive signal is required to avoid cargo recruitment into the retrograde Golgi-to-ER pathway.

The Crystal Structure of the Phosphatidyl Inositol 4- kinase IIα

E. Boura
Biochemistry, IOCB, Prague, Czech Republic

Phosphoinositides are a class of phospholipids generated by the action of phosphoinositide kinases with key regulatory functions in eukaryotic cells. Here we present the first atomic structure of a phosphatidylinositol 4-kinase type IIα (PI4K IIα), in complex with ATP solved by X-ray crystallography at 2.8 Å resolution. The structure revealed a rather non-typical kinase fold that could be divided into N- and C-lobes with the ATP binding groove located in between. Surprisingly, a second ATP was found in a lateral hydrophobic pocket of the C-lobe. Monte Carlo simulations revealed two membrane binding modes and the putative function of the hydrophobic pocket. Taken together our results suggest a mechanism of PI4K IIα recruitment, regulation and function on the membrane.

Human guanylate-binding protein 1 tethers giant unilamellar vesicles in a nucleotide-dependent manner

S. Shydlovskyi[1], A. Hohendahl[2], A. Roux[2], C. Herrmann[1]
[1]TRANSPOL Physical Chemistry I, Ruhr University Bochum, Bochum, Germany, [2]TRANSPOL Biochemistry Department, University of Geneva, Geneva, Switzerland

Human guanylate-binding protein 1 (hGBP1) is the most studied protein within the family of guanylate binding proteins (GBPs). GBPs belong to the dynamin superfamily of large GTPases and have seven isoforms in humans. Different dynamins are shown to be involved in the processes of membrane deformation, but so far for hGBP1 this feature was not reported. HGBP1 is expressed to high levels after treatment of the cells with interferons with the highest expression for interferon γ and it was reported to be involved in different antipathogenic responses. However, the molecular mechanism of antipathogenic activity of hGBP1 is poorly understood.

HGBP1 shares common features with other members of dynamin superfamily and shows nucleotide-dependent self-activation and oligomerisation of the protein. In contrast to dynamins, the protein established a different way for membrane association. In the course of the posttranslational modification, the protein is coupled to a lipid anchor (isoprenoid). Although hGBP1 was intensively investigated, almost all studies were performed using the soluble protein without farnesyl anchor.

Previous studies indicated the requirement of GTPase activity of the protein for binding of farnesylated hGBP1 to the liposomes. In contrast, we show that GTP-binding is sufficient for association of the protein to the surface of liposomes and GTPase activity is not necessary required. Moreover, GTP turnover of the enzyme orchestrates dissociation of farnesylated hGBP1 from the surface of the liposomes. By video recording, we demonstrate the farnesylation-dependent ability of hGBP1 to mediate tethering of liposomes in a nucleotide-dependent manner, which is reversible for GTP and non-reversible for its non-hydrolysable analog.

Keywords: GTPase, membrane tethering.

Identification of bacterial sphingophospholipids and their activation of murine macrophages via Toll-like receptor 4

N. Fujiwara[1], T. Naka[2], H. Kuwata[3], S. Maeda[4]
[1]Department of Food and Nutrition, Faculty of Contemporary Human Life Science, Tezukayama University, Nara, [2]MBR Co., Ltd., Osaka, [3]Department of Oral Microbiology and Immunology, Showa University School of Dentistry, [4]Molecular Epidemiology Division, Department of Mycobacterium Reference and Research, The Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Tokyo, Japan

Sphingobacterium spiritivorum has five unusual sphingophospholipids (SPLs). We determined the complete chemical structures of these SPLs. The compositions of the long-chain bases/fatty acids in the ceramide portion, isoheptadecasphingosine/isopentadecanoate or isoheptadecasphingosine/2-hydroxy isopentadecanoate, are characteristic. It is reported that several bacterial sphingoli-

© 2014 The Authors. FEBS Journal © 2014 FEBS

pids composed of ceramide are recognized by CD1-restricted T and NKT cells and that a non-peptide antigen is recognized by γδT cells. The mechanisms of host immune responses against these SPLs remain unknown. The immune response against bacterial lipid components is considered to play important roles in microbial infections. We demonstrated that these bacterial SPLs activated murine bone marrow macrophages (BMMs) via Toll-like receptor (TLR) 4 but not TLR2, although they slightly activated CD1d-restricted NKT and γδT cells. Interestingly, this TLR 4-recognition pathway of bacterial SPLs involves the fatty acid composition of ceramide in addition to the sugar moiety. A non-hydroxy fatty acid composed of ceramide was necessary to activate murine BMMs. The bacterial survival was significantly higher in TLR4-/- mice than in TLR2-/- and wild-type mice. The results indicate that activation of the TLR4-dependent pathway of BMMs by SPLs induced an innate immune response and contributed to bacterial clearance. In this study, we clarified the immune recognition of bacterial SPLs, identified structure/function relationships in this recognition, and assess the impact of SPLs on bacterial burdens.

In vivo studies of aquaporin 0 interaction with calmodulin using bimolecular fluorescence complementation

J. Sjöhamn, P. Båth, K. Hedfalk, R. Neutze

Department of Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden

Protein-protein interactions (PPIs) are important in close to all vital processes in the cell. Ranging from stable protein complexes to transient interactions the studies of PPIs is not only critical in the understanding of protein functions but also difficult to monitor. Bimolecular fluorescence complementation (BiFC) allows PPIs to be studied by analyzing fluorescence as a result of an interaction. Non fluorescent fragments of YFP is fused to the protein targets and upon assembly into a complex fluorescence is emitted.

We show that the BiFC method in *S. cerevisiae* can be used to confirm the tetramerization of human aquaporin0 (hAQP0) which was used as a positive control for the assay. Also, no tetramerization is observed between hAQP0 and hAQP2, acting as a negative control.

The method was then applied to the the well-known interaction between aquaporin 0 and calmodulin (CaM). Whereas previous studies have an in vitro approach, we can show the complex formation of hAQP0-CaM in vivo. By truncating the C-terminal of hAQP0 just before the putative CaM interaction site the fluorescence is drastically decreased as expected when the interaction site is removed.

S. cerevisiae is an excellent system for PPI studies and in the case of hAQP0-CaM it has been shown to also work for interactions between a membrane protein and a soluble protein. This particular complex can now be studied more easily compared to the mammalian cell systems used previously and the consequence of minor changes in either protein can be quantitated and related to differences in the affinity of the complex.

Keywords: bimolecular fluorescence complementation, membrane proteins, protein-protein interactions.

Intramembrane helix–helix interactions of receptor tirosine kinases: structural biology and implications for signaling and human pathologies

M. V. Goncharuk[1,2], S. A. Goncharuk[1,2], D. M. Lesovoy[2], E. V. Bocharov[2], A. Arseniev[2], M. P. Kirpichnikov[1]

[1]Bioengineering, Faculty of Biology, Lomonosov Moscow State University, [2]Structural Biology Department, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation

Cell membrane is important part of living cell. Receptor tyrosine kinases play a key role in biological processes occurring within the membrane. However detailed mechanism of their functioning has not been completely understood yet as there are no structures of full-length receptor tyrosine kinases. Fibroblast growth factor receptor 3 (FGFR3) transduces biochemical signals via lateral dimerization in the plasma membrane, and plays an important role in human development and disease. The most frequent pathogenic mutations G380R and A391E in the transmembrane (TM) region of FGFR3 are associated both with cancer and with disorders in skeletal development. Relatively small size of complexes of TM fragments of FGFR3 (with membrane adjacent regions, tmFGFR3) with detergents or lipids allows one to study their detailed spatial structure using three-dimensional heteronuclear high-resolution NMR spectroscopy. An effective expression system and purification procedure for preparative-scale production of tmFGFR3 in norma and with point mutations for structural and functional studies were developed. The purified peptides were reconstituted in lipid/detergent DPC/SDS (9/1) micelles and characterized using dynamic light scattering, CD and NMR spectroscopy. In the solved NMR structure, the two transmembrane helices pack into a symmetric left-handed dimer, with intermolecular stacking interactions occurring in the dimer central region. Some pathogenic mutations fall within the helix-helix interface, whereas others are located within a putative alternative interface. This implies that although the observed dimer structure is important for FGFR3 signaling, the mechanism of FGFR3-mediated transduction across the membrane is complex. We propose an FGFR3 signaling mechanism that is based on the solved structure, available structures of isolated soluble FGFR domains, and published biochemical and biophysical data.

Isolation of mycobacterial mutants that disrupted the phospholipid synthetase gene, and their properties

S. Maeda[1], N. Nakata[2], T. Naka[3], N. Fujiwara[4]

[1]The Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Kiyose, Tokyo, [2]Leprosy Research Center, National Institute of Infectious Diseases, Tokyo, [3]MBR Co. Ltd., Osaka, [4]Tezukayama University, Nara, Japan

In pathogenic bacteria, cell envelopes are essential in evading various attacks on the host defense system. The membranes of the gram-positive bacteria are overlaid cell walls consisting of a thick layer of peptidoglycans. Phospholipids are one of the indispensable components for formation of bacterial membranes. The synthesis of phospholipids is thus important in mycobacteria.

© 2014 The Authors. FEBS Journal © 2014 FEBS

However, little is known about the effects of various phospholipid compositions on bacterial growth or survival in macrophages. We constructed mutants that disrupted a phosphatidylserine synthetase (PSS) gene and investigated their properties. PSS gene knockout mutants (KO strains) were constructed from *Mycobacterium smegmatis* mc^2 155 and *Mycobacterium bovis* BCG. Also, the compensated strains (Comp) were prepared from KO strains by transformation with the plasmid DNA including the lost gene. The phospholipid compositions, growth rates, and drug susceptibilities were compared among wild type (WT), KO, and Comp strains and the survival rates of the WT strain and mutants in bone-marrow macrophages (BMM) were determined. The growth rates of the WT, KO, and Comp strains were similar to each other. PSS generally produces phosphatidylserine (PS) from cytidine diphosphate diacylglycerol (CDP-diacylglycerol) and serine in bacteria. And phosphatidylethanolamine (PE) is synthesized from PS by phospatidylserine decarboxylase. The composition of phospholipids in these strains on thin layer chromatography (TLC) revealed that the amounts of PS and PE were low, but detectable in WT and Comp strains of both *M. smegmatis* and *M. bovis* BCG, whereas in the PSS-KO strain, neither PS nor PE were detected on TLC. The survival rate of the KO strain in BMM was lower than those of the WT and Comp strains. We found that PSS was not an essential enzyme in mycobacteria. PS and PE were dispensable for their growth. However, composition of bacterial phospholipids had an effect on survival of mycobacteria in macrophages. Drug susceptibility of PSS-KO mutants was also altered.

Keywords: phospholipids, gene, knock-out.

LAPTM4B regulates ceramide clearance from late endosomes

T. Blom[1,2], S. Li[1,2], N. Bäck[1], Y. A. Kim[3], U. Loizides-Mangold[4], H. Riezman[4], R. Bittman[3], E. Ikonen[1,2]
[1]Institute of Biomedicine, University of Helsinki, [2]Minerva Foundation Institute for Medical Research, Helsinki, Finland, [3]Department of Chemistry and Biochemistry, City University of New York, New York, NY, USA, [4]Department of Biochemistry, University of Geneva, Geneva, Switzerland

The late endosomal organelles (LE) have a central role in the degradation and recycling of sphingolipids, but the mechanisms by which sphingolipid catabolites exit LE are not well understood. In order to identify novel regulators of sphingolipid transport, we applied a siRNA screen of lysosomal transmembrane proteins and identified the Lysosome Associated Protein TransMembrane 4B (LAPTM4B) as a facilitator of ceramide exit from LE.

LAPTM4B interacts directly with ceramide based on its high affinity for a cross-linkable ceramide, and cells depleted of LAPTM4B display markedly increased ceramide levels. Knockdown of acid ceramidase (ASAH1) in LAPTM4B-depleted cells aggravates the ceramide storage observed by LAPTM4B silencing alone. Conversely, LAPTM4B overexpression suppresses the ceramide accumulation of ASAH1-deficient cells, suggesting that LAPTM4B and ASAH1 provide alternative means for decreasing LE ceramide. Moreover, LAPTM4B-depleted cells display increased amounts of active cathepsin D, and are sensitized to lysosomal membrane permeabilization as a consequence of the sphingolipid accumulation. Together, these data reveal a novel route for ceramide exit from LE facilitated by LAPTM4B, and pinpoint a role for LAPTM4B in regulating sphingolipid- and lysosome-mediated cell death. This identifies sphingolipid metabolism as a potential target for treating LAPTM4B overexpressing tumors.

Lipidomic profiling of anandamide effects on decidual metabolic pathways

M. Almada[1], R. Domingues[2], L. Dória[2], B. Fonseca[1], N. Teixeira[1], G. Correia da Silva[1]
[1]Laboratory of Biochemistry, Department of Biological Sciences, Faculty Pharmacy University Porto, Porto, [2]Department of Organic Chemistry and Natural Products, University of Aveiro, Aveiro, Portugal

In rodents, in response to blastocyst implantation, endometrial stromal cells proliferate and differentiate. Later, decidual cells undergo a cycle of regression, which occurs mainly by apoptosis [1]. This process is essential to support placental development and conceptus growth. In humans, abnormal decidualization has been linked with unexplained infertility, miscarriage and endometrial pathologies. However, the exact mechanisms controlling decidual regression are not fully understood. Recently, the role of endocannabinoid system in reproductive health has evolved [2]. We have previously shown that endocannabinoid machinery operates on decidual cells and that anandamide (AEA), the main endocannabinoid, induced apoptosis of decidual cells through cannabinoid receptor 1 (CB1) [3]. Also, disruption of endocannabinoid signaling lead to deferred implantation/decidualization and compromises pregnancy outcome [2]. In this study, we intended to analyze by lipidomic analysis possible changes in phospholid (PL) membrane profile of rat primary decidual cells triggered by AEA-induced apoptosis. In brief, PLs were extracted and classes separated by thin layer chromatography with subsequent analysis by mass spectrometry and by direct analysis of the total lipid extract by liquid chromatography-mass spectrometry. Fatty acid quantification was studied by gas chromatography with flame induction detection. Relevant data obtained were: an increase in phosphatidylserine and a decrease of cardiolipin and phophatidylinositol content, as well as an increase in hydroperoxides radicals in treated cells. It was also observed an increase in the content of a particular class of PL, plasmalogens, and in the content of long chain fatty acids specially with high degree of unsaturation. These data will be useful as a starting point to disclose metabolic pathways within decidualization process disruption.

Membrane-active peptides (MP) play important role in the life of various organisms and their communities. Membrane-lytic antimicrobial peptides of eukaryotic origin act as a natural antibiotic component in the “innate” immune system. Some peptide neurotransmitters and hormones, as well as neurotoxins acting on the

© 2014 The Authors. FEBS Journal © 2014 FEBS

membrane receptors, have intrinsic membrane activity. The function of such peptides could involve two steps: the initial binding to the membrane surrounding the receptor, and subsequent formation of the ligand-receptor complex. The biological membrane or suitable membrane mimicking environment is required for the structure-functional studies of membrane-active peptides. Lipid-protein nanodiscs (LPNs) represent one of the most versatile membrane mimicking system. Each nanodisc encloses nanoscaled fragment of flat lipid bilayer stabilized in solution by the apolipoprotein or special membrane scaffold protein (MSP).

The applicability of LPNs for investigation of water-soluble MPs had not been studied previously. This question is not trivial, because LPNs involve additional anionic protein component (MSP, charge -6), while majority of antimicrobial peptides and membrane-active neurotoxins are positively charged. Here we investigated this question on the example of the three cationic water-soluble MPs of different origin. It was shown that pore-forming antimicrobial peptide arenicin-2 from marine lugworm (charge +6) disintegrates LPNs containing zwitterionic phosphatidylcholine (PC) or anionic phosphatidylglycerol (PG) lipids. In contrast to that spider toxin VSTx1 (charge +3), a modifier of Kv channel gating, weakly interacts with the MSP, effectively binds to the LPNs containing anionic lipids (POPC/DOPG 3:1), and has lower affinity to the LPNs composed from zwitterionic lipids (POPC). Snake neurotoxin II (NTII, charge +4), an inhibitor of nicotinic acetylcholine receptor, possesses affinity to the LPNs containing anionic lipids (POPC/DOPG 3:1, or POPC/DOPS 4:1) and does not bind to the LPNs/POPC. NMR study revealed that NTII interacts with the LPN/POPC/DOPS surface in several orientations. One of possible NTII orientations permits the early proposed specific interaction between toxin and the polar head group of phosphatidylserine from the receptor environment. Thus, LPNs could be used for structural studies of water-soluble membrane-active neurotoxins and their interaction with a membrane.

Localization and dynamics study of mouse Klrb1 protein isoforms in mammalian cells

L. Ivanova[1,2], M. Cebecauer[3], P. Novak[1]
[1]Department of Immunology, Institute of Microbiology, AS CR, Prague 4, [2]Department of Cell Biology, Faculty of Science, Charles University Prague, Prague 2, [3]Department of Biophysical Chemistry, J. Heyrovsky Institute of Physical Chemistry, AS CR, Prague 8, Czech Republic

Although natural killer (NK) cells have been known for almost forty years, characterization of their surface receptors still uncovers novel functional issues. Proteins Klrb1A and C are members of a type II family of transmembrane lectin-like receptors on the surface of NK cells important for their activation. They are involved in the protection of the organism against tumors and virally-infected cells. Recently, a new isoform of mouse protein Klrb1A which is missing a transmembrane domain was found as mRNA transcript. The examination of its expression and localization in the cell is a subject of our research. Since there are only limited molecular data on the rest of the family, it is necessary to study these proteins as well and correlate our results to proteins having transmembrane region.

A recent development in microscopic techniques allows a detailed study of Klrb1 proteins in their physiological environment – living cells. Klrb1x-GFP/mCherry fusion proteins were generated to investigate their stoichiometry and dynamics and verified by transient transfection, confocal microscopy and immunoblotting. Also, all proteins were expressed heterologously in *Escherichia coli* and using biochemical methods, they were structurally characterized. For identification of monomer and dimer forms in living cells, Klrb1 receptors were expressed in COS-7 cells, separated on SDS-PAGE under reducing and non-reducing conditions, and immunoblotted using anti-GFP antibody. The results showed the existence of monomer (A, C2) and dimer (C1) isoforms of Klrb1 receptors in living cells. Also the live cell imaging of Klrb1 activating receptors is presented and the data are correlated with these from the structural characterization. Our outcomes shed a light on molecular dynamics of each isoform in cell membrane and demonstrate the subcellular localization of the truncated Klrb1A isoform which is mainly retained in the cell cytoplasm with significant diffusion character.

Loss of association of REEP2 with membranes is responsible for a hereditary motor neuron disease

F. Darios[1], T. Esteves[1], A. Durr[1], M. Boutry[1], M.-P. Muriel[1], J. Branchu[1], G. Rouleau[2], S. Zuchner[3], A. Brice[1], G. Stevanin[1]
[1]ICM, INSERM U1127, Paris, France, [2]Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada, [3]Department of Human Genetics and Hussman, Institute for Human Genomics, University of Miami, Miami, FL, USA

Hereditary spastic paraplegias (HSP) are clinically and genetically heterogeneous neurological conditions affecting cortical motor neurons. Their main pathogenic mechanisms are thought to involve alterations in endomembrane trafficking, mitochondrial function and lipid metabolism. With a combination of whole genome mapping and exome sequencing, we identified three mutations in *REEP2* in two families with HSP: a missense variant (c.107T>A, p.Val36Glu) that segregated in the heterozygous state in a family with autosomal dominant inheritance and a missense change (c.215T>A, p.Phe72Tyr) that segregated *in trans* with a splice site mutation (c.105 + 3G>T) in a family with autosomal recessive transmission. REEP2 belongs to a family of proteins that shape the endoplasmic reticulum, a continuous network of membranous sheets and tubules. *In vitro,* the p.Val36Glu variant in the autosomal dominant family had a dominant negative effect; it inhibited the normal binding of wild-type REEP2 to membranes. The missense substitution p.Phe72Tyr, in the recessive family, decreased the affinity of the mutant protein for membranes that, together with the splice site mutation, is expected to cause complete loss of REEP2 function. REEP2 binds directly to membranes, probably by the insertion of its hydrophobic domains into the phospholipid bilayer. As shown for other members of this family of proteins, this property might regulate the curvature of endoplasmic reticulum membranes where the protein resides. Loss of this function would lead to decrease in endoplasmic reticulum membrane curvature, explaining the expansion of endoplasmic reticulum sheets and endoplasmic reticulum swelling observed in fibroblasts from an affected individual. The altered

© 2014 The Authors. FEBS Journal © 2014 FEBS

morphology of endoplasmic reticulum caused by the loss of REEP2 function also altered the interaction between endoplasmic reticulum and mitochondria. The consequences of mutations in *REEP2* on the mitochondrial functions currently are under investigations.

MAIDEN: model quality assessment for intramembrane domains using an energy criterion

G. Postic[1,2,3,4], Y. Ghouzam[1,2,3,4], J.-C. Gelly[1,2,3,4]
[1]Inserm U1134, [2]University Paris Diderot, Sorbonne Paris Cité, UMR_S 1134, [3]Institut National de la Transfusion Sanguine, [4]Laboratory of Excellence GR-Ex, Paris, France

Membrane proteins represent 25% of all human proteins and nearly 50% of them are drug targets. Knowing the structure of a membrane protein is helpful to characterize its function and mechanism at the molecular level. Despite major advances in solving structures experimentally, most membrane protein structures remain unknown. This lack of available structures, along with the physical constraints imposed by the anisotropic environment of the lipid bilayer, constitutes a difficulty for membrane proteins modelling. Assessing the quality of membrane protein model is therefore critical.

In this study, we have developed a knowledge-based scoring function to distinguish between native (or near-native) structures and non-native ones, using a non-redundant set of 66 membrane proteins sharing no more than 30% of sequence identity. This distance-dependent statistical potential called MAIDEN is specific of the location in the lipid bilayer of each interacting residue. Deriving an accurate statistical potential from such a small data sets is challenging. To overcome that difficulty, we have based the construction of our potential on a kernel density estimation of distances distributions. By a jackknife cross-validation procedure, we show that our potential outperforms a potential optimized on globular proteins (DOPE) in discriminating native membrane protein structures from random sequence decoys. MAIDEN scoring function is also more efficient than DOPE in separating accurate membrane protein models from inaccurate ones. These results suggest that MAIDEN statistical potential will be useful for the modeling of membrane protein structure.

Membrane trans fatty acids in human testicular cancer cell membranes: the signal transduction pathways and effects of chemotherapeutics and antioxidants

T. Ozben[1], A. Cort[1], M. Melchiorre[2], C. Chatgilialoglu[2], C. Ferreri[2]
[1]Biochemistry, Akdeniz University Medical Faculty, Antalya, Turkey, [2]Institute for the Organic Synthesis and Photoreactivity, Consiglio Nazionale delle Ricerche, Bologna, Italy

Testicular germ cell tumors (TGCTs) represent the most frequent malignancy in young males. The number of diagnosed cases has gradually increased, and the current frequency of tumor incidence is 50% higher than it was 30 years ago. However, the causes of this increase remain unclear. Bleomycin is used in chemotherapy regimens in the treatment of patients having TGCT. Mitogen activated protein kinases (MAPKs) are important mediators involved in the intracellular network of interacting proteins that transduce extracellular signals to intracellular responses. There is no study in the literature investigating the effects of Bleomycin, N-Acetyl-L-Cysteine (NAC), and Curcumin on membrane fatty acid changes and the underlying mechanisms related to MAPK pathway in the testicular cancer NTera-2 cells. To establish a causative relation between the cell membrane fatty acid changes and the signal transduction pathways among MAPK kinase family, we incubated Ntera-2 cells for 24 h with Bleomycin, NAC, Curcumin, Bleomycin+NAC or Bleomycin+Curcumin. Membrane fatty acids in the NTera-2 cells were isolated, derivatized and analysed by gas chromatography. We determined the levels of MAPK pathway members; p44/42-MAPK, p38-MAPK, MEK, p-MEK, JNK and pJNK. Bleomycin and curcumin increased the saturated fatty acid percentage of membrane lipids, whereas decreased the percentage of monounsaturated and polyunsaturated fatty acid. Bleomycin and curcumin led to a significant increase in trans lipid isomers of oleic and arachidonic acids, while N-Acetyl-L-Cysteine had no such an effects. 24 h incubation of NTera-2 cells with Bleomycin, Curcumin or their combination resulted in a strong activation of two MAPKs (pJNK, and p38-MAPK) and inactivation of p-MEK and p-ERK. Incubation with NAC alone did not cause any change in p38-MAPK and pJNK levels. Coincubation of NAC with Bleomycin attenuated the activation of p38-MAPK and pJNK which were upregulated by Bleomycin and caused an enhancement in p-MEK and p-ERK levels. Bleomycin, curcumin or their combination reduced the level of EGFR. Our results indicate that Bleomycin has an essential role in the regulation of membrane fatty acid profile alterations in human testicular cancer cell line. These results highlight the role of the membrane asset for fatty acid remodeling and suggest the potential of lipid-based strategies for influencing cell response and fate in testicular germ cell tumors.

Keywords: Bleomycin, Curcumin, N-Acetyl-L-Cysteine.

SUN-407
Modulation of cholesterol level and glutamate transport in brain nerve terminals by polymers of cyclodextrines

O. Voronova, T. Borisova, N. Krisanova, R. Sivko, A. Borysov
Department of Neurochemistry, Palladin Institute of Biochemistry NAS of Ukraine, Kyiv, Ukraine

Introduction: Recently, we demonstrated that a decrease in the level of membrane cholesterol may be used for neuroprotection under pathological conditions including stroke, cerebral hypoxia/ischemia, traumatic brain injury that were associated with an increase in glutamate uptake reversal. Visa versa in norm, a decrease in the concentration of membrane cholesterol may cause neurotoxic consequences resulted from the enhancement of the extracellular glutamate level because of a decrease in glutamate uptake. Also, novel acute effects of cholesterol acceptor methyl-beta-cyclodextrin (MCD) on glutamate transport in rat brain nerve terminals was demonstrated. However, these effects may be associated with ability of MCD to penetrate the plasma membrane of nerve terminals.

Methods: Planar Lipid *Bilayer* technique, spectrofluorimetry, radiolabeled assay.

Results: Several polymers of MCD was synthesized in Institute of Macromolecular Chemistry NAS of Ukraine. Comparative analysis of the effects of MCD and MCD polymers on cholesterol level, as well as uptake and ambient level L-[^{14}C]glutamate in nerve terminals and synaptic vesicle acidification was performed It was shown that MCD polymers in comparison with single molecule of MCD are able to decrease uptake and increase

© 2014 The Authors. FEBS Journal © 2014 FEBS

the ambient level of L-[^{14}C]glutamate in a narrow concentration range. Also, MCD polymers similarly with MCD molecule are able to dissipate the proton gradient of synaptic vesicles.

Discussion: This data create background for usage of MCD polymers in nanoneurotechnology.

Conclusion: Synthesized MCD polymers demonstrated similar effects with MCD monomer in modulation of transport of neurotransmitter and cholesterol level in nerve terminals underlying their high potential for usage in nanoneurotechnology.

Keywords: glutamate uptake, methyl-beta-cyclodextrin polymers, synaptic vesicle acidification.

SUN-408
Molecular dynamics study of human erythrocyte cell membrane

P. Hakobyan, A. Poghosyan, A. Shahinyan
Bioinformatics Group, International Scientific Educational Center NAS RA, Yerevan, Armenia

We have performed 100 ns molecular dynamics (MD) simulation of human erythrocyte asymmetric membrane and investigated its molecular and structural properties.

We have created a phospholipid bilayer, using the phospholipid composition of human red blood erythrocyte membrane. The model also consists of cholesterol molecules and the transmembrane part of Glycophorin A (GpA) protein. The final system was solvated in water with 33 molecules per head group to reach fully hydrated crystalline state of the system. At the starting point of MD simulation, the phospholipid bilayer size was 10.5 x 9 x 9 nm^3 with 57640 atoms. Further, the system was minimized and subjected to a short MD simulation in NVT ensemble to avoid bad Van der Waals contacts. Finally, 100 ns MD simulation was carried out in NPT ensemble. The pressure and the temperature of the system were maintained to 1 atm and 310 K correspondingly. Particle Mesh Ewalds (PME) method was used for electrostatic interactions and for Van der Waals interactions cutoff radius was 14 Å. MD simulation was carried out by NAMD code using CHARMM27 force field, parallel on a Linux cluster with 64 processors.

The thickness of the membrane in equilibrium state is 51–52 Å. It is shown that some phospholipid molecules are arranged tighter in the inner layer of the membrane than in the outer layer but at the same time the area per phospholipid molecule head group is almost the same in both layers of erythrocyte membrane model. Detailed investigation of cholesterol molecules orientation in the phospholipid bilayer and the membrane surface roughness was performed. The cholesterol molecules density was calculated and found out that they are mainly localized in the hydrophobic part of the membrane, more precisely, below the polar heads of phospholipid molecules. This kind of cholesterol molecules localization, contribute to more rigid packing of phospholipid molecules in the membrane. The membrane surface molecular structure investigation shows that, in spite of asymmetric character of the membrane, the undulations of its inner and outer layers are similar to each other. The surrounding phospholipids' influence on GpA protein structural properties were also investigated. The Gly79, which plays a vital role in protein dimerization, stabilizes the GpA dimer by hydrogen bonds between Gly79 and Val80, Gly83 amino acids. In this regards, we have measured the distance between Gly79 and Val80, which is found to be about 7Å and close hydrogen- hydrogen contact between two amino acids is about 4.5Å as clearly shown in figure.

SUN-409
Molecular organization and membrane interactions of the cavin coat complex

B. Collins, O. Kovtun, V. Tillu, R. Parton
Institute for Molecular Bioscience, The University of Queensland, Brisbane, Qld, Australia

First observed in the 1950s, caveola membrane invaginations are a striking feature of many vertebrate cell types, and are critical for cell signaling, endocytosis and mechanotransduction. Caveolae formation depends on at least two protein families, the caveolin membrane embedded proteins (Cav1, Cav2 and Cav3) and the cavin peripheral membrane proteins (cavin1, cavin2, cavin3 and cavin4). Their importance in normal cell physiology is highlighted by the identification of caveolin and cavin mutations leading to different diseases including muscular and lipodystrophies. Despite this, there is currently no atomic level information addressing the mechanisms that underpin caveola assembly. Here we show for the first time that a minimal N-terminal domain of the cavin proteins (the HR1 fragment) is required and sufficient for their homo and hetero-oligomerisation. The crystal structures of mouse cavin1 and zebrafish cavin4 HR1 domains reveal highly conserved trimeric coiled-coil architectures, with unique intra-subunit interactions that determine the specificity of coiled-coil formation by the cavin proteins. A conspicuous feature of the HR1 domain is a highly basic surface patch, conserved among all cavins and across all species, which we show is able to mediate interaction with negatively-charged membrane lipids displaying the highest affinity for phosphoinositides (PIs). Mutations in this domain prevent membrane association and perturb caveolae formation in vivo. Interestingly the cavin proteins possess intrinsic membrane remodeling properties in vitro, that we propose is important for the formation of caveolae. Finally, we show that full-length cavin proteins possess characteristic rod-shape structures that reflect the coiled-coil architecture of the HR1 assembly domain. These rod-like structures can assemble through lateral and end-to-end interactions and have dimensions corresponding closely to the striations observed on the surface of caveolae *in vivo*. We therefore propose the striations forming the common coat of caveola are composed of polymerised cavin trimers, with membrane invagination requiring the presence of both caveolin and negatively charged lipid headgroups.

Neuronal SNAREs are sufficient to induce lysis-free endomembrane fusion

Y.-J. Ko, M. Lee, M. Han, Y. Jun
Life Sciences, Gwangju Institute of Science and Technology, Gwangju, Korea

Intracellular membrane fusion requires not only SNARE proteins but also other regulatory proteins such as the Rab and Sec1/

© 2014 The Authors. FEBS Journal © 2014 FEBS

Munc18 (SM) family proteins. Although neuronal SNARE proteins alone can drive the fusion between synthetic liposomes, it remains unclear whether they are also sufficient to induce the fusion of biological membranes. Here, through the use of engineered yeast vacuoles bearing neuronal SNARE proteins, we show that neuronal SNAREs can induce membrane fusion between yeast vacuoles and that this fusion does not require the function of the Rab protein Ypt7p or the SM family protein Vps33p, both of which are essential for normal yeast vacuole fusion. Although excess vacuolar SNARE proteins were also shown to mediate Rab-bypass fusion, this fusion was accompanied by massive leakage of luminal content. By contrast, neuronal SNARE-driven vacuole fusion occurred without impairing membrane integrity. Taken together, these results suggest that neuronal SNARE proteins suffice to induce lysis-free endomembrane fusion independently of Rab and SM protein functions.

Keywords: SNARE, Synaptic vesicle fusion, yeast vacuole.

SUN-411
New complex topology (knots and slipknots) in membrane proteins

J. I. Sulkowska
Chemistry, University of Warsaw, Warszawa, Poland

Currently more than 1000 structures of membrane proteins are known, whereas alpha-helical transmebrane proteins are represented by 76 families. Recently, using so-called matrix model to detect complex topology in proteins, we found that more than 2% of those known membrane proteins possess non-trivial topology! These proteins are secondary transporters that represent 8 out of 76 classified families. These are fascinating and surprising new results, which can help to understand membrane organization. Moreover, our analysis shows that all those proteins represent just three types of topological complexity: slipknots motifs (so called shoelaces motif, when pulled by termini will untie) with trefoil knot or figure-eight knot, and knot motif (pulling by terminal will tight knot inside membrane). Moreover the active site is located inside a knotted core (for knotted proteins). Those results directly indicate that complex topology is strongly conserved in those proteins across different species and should play some important role.

New N-terminal fusion tags for milligram-scale cell-free production of GPCRs

D. Kulbatskii[1,2], E. N. Lyukmanova[2], Z. Shenkarev[3], M. A. Shulepko[2], D. Dolgikh[1,4], M. P. Kirpichnikov[2,4]
[1]*Biological Department, Moscow State University,* [2]*IBCh RAS, Moscow, Russian Federation,* [3]*Biological Department, IBCh RAS,* [4]*Moscow State University, Moscow, Russian Federation*

G-protein-coupled receptors (GPCR) belong to one of the biggest families of membrane proteins. In spite of the fact that they are highly relevant to pharmacy, they have remained poorly explored. One of the main bottlenecks encountered in structural-functional studies of GPCRs is the difficulty to produce sufficient amounts of the proteins. Cell-free systems based on bacterial extracts from *E. coli* cells attract much attention as an effective tool for recombinant production of membrane proteins. GPCR production in bacterial cell-free expression systems is often inefficient because of the problems associated with the low efficiency of the translation initiation process. This problem could be resolved if GPCRs were expressed in the form of hybrid proteins with *N*-terminal polypeptide fusion tags. In the present work, three new *N*-terminal fusion tags are proposed for cell-free production of the human β2-adrenergic receptor, human M1 muscarinic acetylcholine receptor, and human somatostatin receptor type 5. It is demonstrated that the application of an *N*-terminal fragment (6 a.a.) of bacteriorhodopsin from *Exiguobacterium sibiricum* (ESR-tag), *N*-terminal fragment (16 a.o.) of RNAse A (S-tag), and Mistic protein from *B. subtilis* allows to increase the cell-free synthesis of the target GPCRs by 5–38 times, resulting in yields of 0.6–3.8 mg from 1 ml of the reaction mixture, which is sufficient for structural-functional studies.

Keywords: cell-free, fusion tag, GPCR.

SUN-413
Overcoming antibiotic resistance in *Staphylococcus aureus*

A. Mor
Biotechnology & Food Engineering, Technion, Haifa, Israel

Oligomers of acylated lysyls (OAKs) are chemical mimics of host defense peptides presenting broad spectrum antimicrobial activities. Previous studies have documented the ability of a miniature OAK, $C_{12(\omega7)}KKC_{12}K_{amide}$, to affect growth of gram-positive bacteria (GPB) and to act synergistically with certain antibiotics on gram-negative bacteria. Here, we investigated the OAK's ability to affect antibiotic resistance in *S. aureus*.

Despite its activity over a wide range of GPB, the OAK displayed synergistic activity with antibiotics only against *S. aureus* strains. Thus, chemo-sensitization of MRSA clinical isolates to oxacillin was achieved by up to 1000 folds. At the MIC, the OAK exerted a bacteriostatic effect and delayed emergence of resistance to oxacillin even at sub-MIC values. Membrane permeability was mildly compromised, resulting in membrane depolarization and inhibition of the induction and/or export of resistance factors such as β-lactamase and PBP2a. Furthermore, data collected using the mouse peritonitis-sepsis model support the likelihood for synergy to occur under *in-vivo* conditions as well, upon co-administration of the drugs. Based on the current data, we propose a mechanism suggesting that re-sensitization of MDR bacteria to multiple antibiotics is triggered by OAK-induced transient membrane depolarization which, simultaneously hinders multiple drug resistance mechanisms

Collectively, the findings support the view that targeting bacterial membrane potential could represent an efficient means to enhance antibacterial therapy, particularly since depolarization can simultaneously alter a wide range of crucial processes that derive their energy from the proton-motive force, rendering bacterial antibiotic resistance a more difficult task to accomplish.

Prenatal alcohol–induced neuroapoptosis in rat brain: protection by folic acid and betaine

I. Sogut[1], O. Uysal[2], A. Oglakci[3], F. Yucel[4], K. Kartkaya[3], G. Kanbak[3]
[1]*Department of Medical Services and Techniques, Istanbul Bilim University, Istanbul,* [2]*Vocational School of Health Services,* [3]*Faculty of Medicine, Department of Biochemistry,* [4]*Faculty of Medicine, Department of Anatomy, Eskisehir Osmangazi University, Eskisehir, Turkey*

When alcohol is consumed during the prenatal period, it may result in Fetal Alcohol Syndrome (FAS) in the offspring. The aim of this study is to investigate neuroapoptosis on the cerebral cortex of rat pups caused by prenatal alcohol exposure with modified liquid diet and to illuminate the protective effects of betaine and folic acid

© 2014 The Authors. FEBS Journal © 2014 FEBS

supplementation. Being alcohol-induced apoptosis indicators on the cerebral cortex of rat pups, cytochrome c, caspase 3 and calpain levels were checked. Cytochrome c level in ethanol+folic acid group ($p < 0.05$), caspase 3 level in ethanol+betaine+folic acid group ($p < 0.01$), calpain level in both ethanol+folic acid ($p < 0.01$) and ethanol+betaine+folic acid groups ($p < 0.01$) were found to be significantly lower than ethanol group. Cerebral cortex tissues were examined histologically in terms of congestion, edema, necrosis and chromatolysis. While ethanol increased the number of apoptotic cells, it was decreased in ethanol+betaine ($p < 0.05$) and ethanol+betaine+folic acid groups ($p < 0.05$). Morphometric examination showed that while the diameter of apoptotic cells increased with ethanol administration ($p < 0.01$), they were lowered at ethanol+betaine ($p < 0.001$) and ethanol+betaine+folic acid groups ($p < 0.001$). As a result, we found that ethanol is capable of triggering cell death in the ethanol-administered rat pups and folic acid and betaine may reduce apoptosis either alone or together.

Probing membrane protein structure with small angle neutron scattering and molecular modeling

M. Lensink[1], F. Gabel[2], B. Clantin[1], V. Villeret[1], F. Jacob-Dubuisson[3], C. Ebel[2]

[1]Interdisciplinary Research Institute, CNRS USR3078 University Lille North of France, Villeneuve d'Ascq, [2]Structural Biology Institute, CNRS, CEA, DSV, Institute Laue-Langevin, University Grenoble Alpes, Grenoble, [3]Center for Infection and Immunity, CNRS UMR8204, INSERM U1019, University Lille North of France, Lille, France

Probing the solution structure of membrane proteins represents a formidable challenge, notably using small-angle scattering due to residual scattering contributions of detergent molecules. Using SANS measurements, we studied the conformation of the Bordetella pertussis outer-membrane transporter FhaC. By using molecular modeling and starting from six distinct conformations of FhaC embedded in lipid bilayers, we generated ensembles of protein-detergent arrangement models. The computational methodology allows for the generation of a large number of protein-detergent arrangements. The chi square fits of back-calculated versus experimental curves are decidedly discriminative and allow for the elimination of both protein conformation and detergent organization. Good fits were obtained for relatively compact, connected detergent belts, that, however, display small detergent-free patches on the outer surface of the beta-barrel. The combination of SANS and modeling clearly enabled us to infer the solution structure of FhaC. We believe that our strategy that combines explicit atomic detergent modeling with SANS measurements holds significant potential for structural studies of other detergent-solubilized membrane proteins.

Purification and functional characterization of *Saccharomyces cerevisiae* Gdt1p, a novel Golgi-localised Ca^{2+}/H^{+} antiporter

P. Sengottaiyan, D. Demaegd, A.-S. Colinet, M.-C. Duchène, P. Hols, P. Morsomme

Univ Catholique de Louvain, Louvain la Neuve, Belgium

Calcium (Ca^{2+}) is a ubiquitous and versatile intracellular messenger responsible for controlling numerous cellular processes. In yeast, the cytosolic concentration of Ca^{2+} (50–200 nM) is tightly regulated through diverse Ca^{2+} pumps and exchangers located in different compartment of the cell. In a recent study, we showed that the Ca^{2+}:H^{+} Antiporter-2 (CaCA2) family member of yeast, Gcr1-dependent translation factor-1 protein (Gdt1p) contributes to Ca^{2+} homeostasis [1]. Gdt1p is a Golgi-localised membrane protein of 280 amino acids composed of 6 transmembrane domains with an antiparallel topology [1]. Notably, the *gdt1Δ* yeast strain was sensitive to high concentration of external calcium. The WT phenotype is restored by the expression of the human ortholog TMEM165 which is involved in Congenital Disorders of Glycosylation (CDG) in human [2].

The aim of our study is to elucidate how Gdt1p regulates Ca^{2+} homeostasis in the Golgi complex and to demonstrate its primary transport function. Here we have used the nisin-inducible expression system of *Lactococcus lactis* for the production of Gdt1p. The recombinant Gdt1p expressed in the cell membrane of *L. lactis* has been solubilised and purified in the presence of Foscholine. Gel-filtration analysis suggested that the purified recombinant Gdt1 forms a tetramer. We are currently reconstituting the purified recombinant Gdt1 into proteoliposomes in order to measure direct ion transport. Our study will provide us mechanistic insights into the molecular function of Gdt1p in the budding yeast.

The work was supported by grants from the Fonds National de la Recherche Scientifique (FNRS).

Redox regulation of photo-fermentative hydrogen production by *Rhodobacter sphaeroides*

L. Hakobyan[1], L. Gabrielyan[1,2], A. Trchounian[2]
[1]*Biophysics*, [2]*Microbiology & Plants and Microbes Biotechnology, Yerevan State University, Yerevan, Armenia*

Bacterial anaerobic growth has been shown to be coupled with decrease of external redox potential (E_h) from positive down to low negative value, which result transfer of electrons within bacterial membrane and formation of proton motive force [1]. *Rhodobacter sphaeroides* performs a photo-fermentation of organic compounds with hydrogen (H_2) production [2] which can be a redox regulated one. In this work regulation of H_2 photoproduction through the change of E_h during anaerobic growth of *R. sphaeroides* MDC6521 from Armenian mineral springs was represented. Membrane-permeating reducer, DL-dithiothreitol (DTT), maintaining negative values of E_h, was determined to suppress the specific growth rate. Membrane-non(poorly)-permeating oxidizer, ferricyanide, maintaining positive values of E_h, also decreased the bacterial growth rate. However, DTT enhanced H_2 yield by *R. sphaeroides*; whereas ferricyanide inhibited H_2 production. In the presence of 0.5–1 mM DTT H_2 yield was increased during 48–96 h: after 72 h H_2 yield was ~1.3-fold higher compared to control. But in medium with 2 mM DTT H_2 production was not observed during 48–72 h growth. In contrast to DTT, H_2 yield disappeared in the presence of oxidizer: by addition of 0.5–2 mM ferricyanide H_2 yield decreased ~2–5-folds during 72 h growth. Thus, the reduced medium is preferred for H_2 production by *R. sphaeroides*. The relationship between H_2 production and E_h changes has been suggested: H_2 production by these bacteria is observed under strong reducing conditions. This might result redox state of responsible enzymes. The external reagents, which modify the redox environment and affect bacterial photo-fermentation, can be used for understanding of regulatory pathways of bacterial metabolism and for optimization the conditions for efficient H_2 production.

Rim21 senses alteration in plasma membrane lipid asymmetry and elicits the signal at the plasma membrane in a ubiquitination-dependent manner

K. Obara[1,2], K. Nishino[1], A. Kihara[1,2]
[1]*School of Pharmaceutical Sciences*, [2]*Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan*

In the eukaryotic plasma membrane (PM), lipid composition differs between the inner (cytosolic) and outer (extracellular) leaflets, which is called lipid asymmetry. For example, phosphatidylserine and phosphatidylethanolamine are mostly confined to the inner leaflet while phosphatidylcholine and sphingolipids are enriched in the outer leaflet. Lipid asymmetry is generated and maintained by inward (flip) and outward (flop) movement of lipids between the leaflets. We previously reported, in yeast, that alteration in PM lipid asymmetry is sensed by the Rim101 pathway[1], which was originally reported to detect external alkalization.

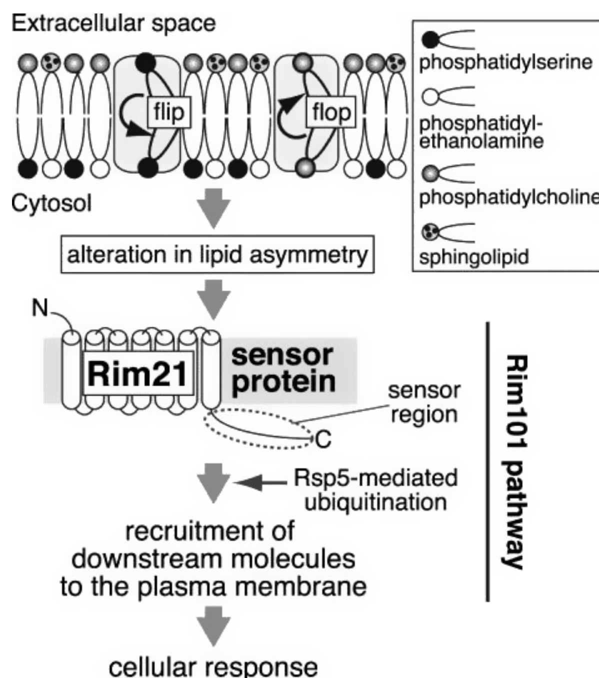

Fig. 1.

In the present work, we have investigated how the Rim101 pathway senses altered lipid asymmetry and ambient pH, and how the signal is transduced. We found that a PM protein Rim21, one of the most upstream molecules in the Rim101 pathway, acts as the sensor molecule detecting altered lipid asymmetry and ambient pH[2]. Biochemical analyses revealed that Rim21 forms a sensor complex with two PM membrane proteins Dfg16 and Rim9. Dfg16 and Rim9 were shown to be required for delivery of Rim21 to the PM. The C-terminal cytosolic region of Rim21 (Rim21C) contains clusters of charged amino acid residues. Rim21C fused with GFP was localized to the PM, although Rim21C is a hydrophilic region. In cells with disturbed lipid asymmetry due to inactivation of plasma membrane flippases, Rim21C dissociated from the PM and dispersed in the cytosol. These observations clearly indicate that Rim21C alone can detect alterations in lipid asymmetry, in another word, sensor motif is included in Rim21C. By mutational analysis of Rim21C, we identified the region playing a critical role in sensing of lipid asymmetry. Together with other results, we will discuss the mechanism of lipid asymmetry sensing.

We also investigated how the signal elicited by Rim21 is transduced. When Rim21 was stimulated by alteration in lipid asymmetry or external alkalization, downstream molecules including the arrestin-related protein Rim8, calpain-like protein Rim13, ESCRT III subunit Snf7, and scaffold protein Rim20 accumulated at the PM. Activity of the ubiquitin ligase Rsp5 was required for recruiting the downstream molecules to the PM, suggesting that ubiquitination mediates Rim101 signaling at the PM.

Role of neutral sphingomyelinase in dopamine transporter trafficking

J. H. Won, S. K. Kim, K. H. Ahn, Z. Fu, M. J. Back, D. K. Kim
Chung-Ang University, Seoul, Korea

Dopaminergic neurotransmission in the brain plays a central role in the control of movement, hormone release, and many complex behaviors. Dopamine (DA) uptake into presynaptic terminals is thought to be a key step in neurotransmission termination. Dopamine transporter (DAT) is Specific transport protein tightly control the availability of DA, in the synaptic cleft by mediating rapid transmitter reuptake at presynaptic terminals. DAT undergo highly regulated trafficking between the cell surface and endosomal compartments (Rao et al., 2011; Sager and Torres, 2011). Here, we suggest that neutral sphingomyelinase 2 (nSMase2) may regulate DA uptake and DAT trafficking. Previously we found that nSMase2 is a mediator of DA uptake (Kim et al., 2010). Interestingly, transfection of nSMase2 siRNA or pretreatment with the nSMase2-specific inhibitor GW4869 resulted in decreased DA uptake. Reciprocally, exposure of PC12 cells to cell-permeable C_6-ceramide induced a concentration-dependent increase in DA uptake. In mouse striatum and PC12 cells, we performed immunoflorescence staining to find out the localization of nSMas2 and DAT. In the dorsolateral mouse striatum, we observed colocalization of DAT and nSMase2. In PC12 cells, DAT are colocalized with nSMase2 in plasma membrane. We examined the physiological relevance of the DAT–nSMase2 interaction by performing coimmunoprecipitation experiments in synaptosomal preparations from mouse striatum as described previously (German et al., 2012). The enrichment of nSMase2 and DAT in striatum is more pronounced. In Immunoblotting with imunoprecipitation of DAT showed nSMase2, but imunoprecipitation of nSMase2 did not showed DAT. anti-nSMase2 antibody does not have good performance to pull down nSMase2 protein from supernatant. In nSMase activity assay with immunoprecipitated pellet, the IP pellet of anti-DAT antibody show nSMase activity to an extent equivalent to that achieved with the IP pellet of anti-nSMase2 antibody. These results indicate a physiological relevance of the DAT–nSMase2 interaction. Further analysis revealed that GW4869, nSMase2 inhibitor, decreased the surface level of DAT in PC12 cells stably expression DAT. In sum, our findings provide that physiological interaction between DAT and nSMase2 and, nSMase2 is suggested to facillitate relocalization of DAT on the presynaptic surface.

Single particle tracking to study the binding of protein misfolded oligomer to membrane ganglioside GM1

E. Evangelisti[1], R. Cascella[1], M. Calamai[2], F. Chiti[1], C. Cecchi[1], M. Stefani[1]
[1]*Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence,* [2]*European Laboratory for Non-linear Spectroscopy (LENS), University of Florence, Sesto Fiorentino, Italy*

Recent results suggest an important role of ordered lipid domains of plasma membranes in amyloid aggregation process and its pathogenic effect. We investigated the contribution to toxicity of the membrane ganglioside GM1 in SH-SY5Y neuroblastoma cells exposed to oligomeric conformers of $A\beta_{42}$ and HypF-N endowed with different ultrastructural properties. By means of real-time single particle tracking, we show that misfolded oligomers bind GM1, decreasing its lateral diffusion on the plasma membrane of living cells. In turn, the biochemical response to the oligomeric species results from the membrane content of GM1 and its clustering. Overall, our results indicate an altered membrane raft mobility and clustering in neurons experiencing aberrant protein oligomers.

State-dependent H-bonds of exceptionally conserved asparagines in S6 helices of sodium and calcium channels: roles in channel gating and ligand action

D. Tikhonov[1], B. Zhorov[2]
[1]*Sechenov Institute, RAS, St. Petersburg, Russian Federation,* [2]*BBS, McMaster University, Hamilton, ON, Canada*

Background: Voltage-gated sodium and calcium channels play key roles in the physiology of excitable cells. The alpha-1 subunit of these channels folds from a polypeptide chain of four homologous repeats. In each repeat, the cytoplasmic halves of the pore-lining helices contain exceptionally conserved asparagines. Such conservation implies important roles, which are unknown. Inherited mutations of the asparagines are associated with some channelopathies. Engineered substitutions of the asparagines affect activation and inactivation gating and the action of pore-targeting drugs and toxins. In the absence of X-ray structures of eukaryotic sodium and calcium channels, underlying mechanisms are unclear.

Methods: X-ray structures of potassium and sodium chandelles in the open and closed states were used as templates to build homology models of the open and closed Cav1.2 and Nav1.4 channels and some of their mutants. The models were optimized with the method of Monte Carlo-energy minimization and state-dependent contacts of the conserved asparagines were analyzed.

Results: In the homology models of the open and closed Cav1.2 and Nav1.4 channels the asparagines do not face the pore. In the open, but not in the closed channels, the asparagine residue in a given repeat forms an inter-repeat H-bond with a polar residue, which is typically nine positions downstream from the conserved asparagine in the preceding repeat. The H-bonds, which are strengthened by surrounding hydrophobic residues, would stabilize the open channel and shape the open-pore geometry. According to calculations, the latter is much more sensitive to mutations of the asparagines, than the closed-pore geometry. Substitutions of the asparagines, their H-bonding partners, or surrounding residues change state-dependent inter-repeat contacts. The changes may affect channel activation, inactivation, and ligand action. Our models suggest the atomistic mechanisms behind a calcium channelopathy (the night blindness) and sodium channelopathies (Braguda syndrome and infantile arrhythmias). We further propose that engineered substitutions of the conserved asparagines influence the state-dependent action of local anesthetics, antiarrhythmic agents, and steroidal agonists like batrachotoxin and veratridine by changing availability of the open channels and affecting the open pore geometry.

Conclusions: The exceptional conservation of asparagines in the inner helices of sodium and calcium channels is due to their involvement in inter-repeat H-bonds that stabilize the open state and shape the open pore geometry.

Structural characterization of the retromer cargo recognition sub-complex

N. Leneva[1], S. Norwood[1], R. Ghai[1], N. Cowieson[2], A. Duff[3], K. Wood[3], B. Collins[1]
[1]*Institute for Molecular Bioscience, The University of Queensland, Brisbane, Qld,* [2]*Australian Synchrotron, Melbourne, Vic.,* [3]*Australian Nuclear Science and Technology Organisation, Sydney, NSW, Australia*

Retromer is a peripheral membrane protein complex that plays a key role in cargo export from the endosomal network. It is involved in many physiological, developmental and pathological processes including Wnt signaling, toxin transport and amyloid production in Alzheimer's disease.

The classical retromer complex consists of five proteins that can be classifide into two sub-complexes. One sub-complex contains a heterodimer of proteins from the sorting nexin family (SNX1/SNX2 and SNX5/SNX6), containing Bin-Amphiphysin-Rvs domains (SNX-BAR proteins) that can drive and/or sense membrane deformation and tubulation. By recruiting the cargo-selective sub-complex to the forming tubules, the SNX–BAR coat complex mediates the retrograde transport of proteins from endosomes to the *trans*-Golgi network. The cargo-selective sub-complex is heterotrimeric and consists of VPS26, VPS29 and VPS35. While there is noticeable diversity of sorting nexins between species, the cargo-selective sub-complex is highly conserved across all eukaryotes. Therefore the core functional component of the retromer complex is considered to be the cargo selective trimer.

Using the SAXS/WAXS and MX beamlines at the Australian Synchrotron, we have acquired crystallographic and small angle scattering data to determine how the core cargo recognition sub-complex assembles. Intriguingly, this trimeric complex is able to form a symmetric dimer, which may have implications for functional interactions *in vivo*. We are also currently exploring the structure of these proteins in the thermophilic fungus *Chaetomium thermophilum*. Recently, we crystallized and solved the structure of VPS29. The crystallization of VPS26 and VPS35, as well as co-crystallization experiments are currently in progress. We are using this structural information in combination with biochemical and biological studies in a synergistic approach to understand retromer-mediated endosomal protein sorting and how this fascinating protein complex contributes to a diverse set of cellular processes.

Recent studies have highlighted the molecular and functional diversity of retromer and the identification of new interacting partners, including the WASH complex, has revealed that the role of retromer extends to aspects of endosome-to-plasma membrane sorting and regulation of signaling events. The structural characterization of the cargo-selective complex of retromer and its interacting partners will provide additional insight into retromer specificity and function.

Keywords: membrane trafficking, protein complex, retromer.

Structural dissection of architecture of caveolar protein coat

O. Kovtun[1], V. Tillu[1], W. Jung[1], N. Leneva[1], N. Ariotti[1], K. Alexandrov[1], R. Parton[1,2], B. Collins[1]
[1]*Institute for Molecular Bioscience,* [2]*Centre for Microscopy and Microanalysis, University of Queensland, Brisbane, Qld, Australia*

Coordinated action of membrane-embedded caveolin and peripheral cavin proteins results in the formation of membrane invaginations called caveolae. Mammalian caveolae play key roles in variety of cell processes, and structural information is critically needed to understand the molecular mechanisms underlying their formation and organization. Using a combination of X-ray crystallography, electron microscopy and biochemical analysis we structurally dissect the architecture of the cavin coat from the atomic to the supermolecular scale. The assembly starts from selective trimerisation of cavins via their conservative helical domain. Resultant formation of the supercoil trimer induces helical folding in disordered regions and cavin association into rod-shaped subcomplexes. Then cavin rods assemble through side-to-side and end-to-end interactions into striated lattices characteristic for native caveolar coat. Subcomplexes' anchoring to lipid membranes involves basic regions located in helical portions of cavins and this association induces membrane curvature characteristic for caveolae.

Keywords: caveolae, cavins, membrane domain.

SUN-426
Structure of the SNX27:VPS26 complex reveals mechanistic details of endocytic recycling

T. Clairfeuille[1], M. Gallon[2], F. Steinberg[2], C. Mas[1], R. Ghai[1], R. Sessions[2], R. Teasdale[1], P. Cullen[2], B. Collins[1]
[1]*Molecular and Cell Biology, Institute for Molecular Bioscience, St Lucia, Australia,* [2]*School of Biochemistry, University of Bristol, Bristol, UK*

Retromer is a highly conserved protein complex composed of three core proteins VPS35, VPS26 and VPS29. It plays a central and essential role in endosomal membrane trafficking, acting as a hub for endosomal tubulovesicular membrane trafficking in coordination with members of the sorting nexin (SNX) protein family and regulatory proteins. Mutation of retromer has been found to cause Parkinson's disease, likely due to disruption of endosomal morphology and trafficking, and its down-regulation is linked to neurodegenerative phenotypes in Alzheimer's disease. It has primarily been associated with endosome-to-trans Golgi network (TGN) trafficking of diverse transmembrane cargos such as the cation independent mannose 6-phosphate receptor (CIMPR), but to-date the mechanism by which it engages cargo and regulatory molecules has remained obscure. Recently, retromer has been shown to be important for endosome-to-plasma membrane recycling, retrieving cargo from lysosomal degradation through its association with the adaptor protein SNX27. This interaction is thought to couple retromer to a wide array of cargo, bound to the SNX27 PSD95-disc large-zonula occludens (PDZ) domain via type-I PDZ binding motifs (PDZbms). The binding of retromer to SNX27 also lies at the heart of a network of regulatory interactions that include bin-amphiphysin-rvs (BAR) domain containing SNX proteins that promote membrane tubulation.

Here we show how retromer engages the PDZ domain of SNX27 to facilitate endosomal recycling of a large variety of transmembrane proteins and prevent their lysosomal degradation. The crystal structure of the PDZ domain of SNX27 bound to the retromer protein VPS26A reveals a unique mechanism of PDZ-domain-mediated interaction. It explains how SNX27PDZ can bind VPS26A as it simultaneously recruits transmembrane cargo molecules via their C-terminal PDZ binding motifs, while also allowing VPS26A to be incorporated into the retromer complex by association with VPS35. Structure-based mutagenesis to perturb the SNX27-VPS26 association shows that this is essential for the recycling of the glucose transporter 1 (GLUT1) model cargo receptor from endosomes to the plasma membrane. Mechanistically, the binding of retromer to the PDZ domain of SNX27 increases the binding affinity for cargo PDZ binding motifs by over an order of magnitude, suggesting an important role for

© 2014 The Authors. FEBS Journal © 2014 FEBS

retromer-SNX27 cooperativity in endosomal cargo selectivity. These results demonstrate a novel mechanism of protein binding by a PDZ supramodule and provide molecular insight into the biologically critical endocytic recycling of cargo proteins via the SNX27-retromer-mediated pathway.

Keywords: endosomal recycling, retromer, sorting nexin.

SUN-427
Substrate rigidity modulates membrane reservoir to alter ion flux in macrophages

G. Ng[1], J. Guck[2]
[1]Physics, University of Cambridge, Cambridge, UK, [2]BIOTEC, Technische Universität Dresden, Dresden, Germany

Macrophages sense the environment in the surrounding tissue for signs of possible danger. In our previous work, we showed that the stiffness of a central nervous system (CNS) implant contributed to the development of the foreign body reaction (FBR). Materials significantly stiffer than brain tissue propagated a more robust FBR and this reaction was initiated by microglia, the macrophages in the CNS. It is possible that these macrophages sensed a foreign stiffness as a sign of possible danger. In our current work, we investigate a possible mechanism for this immunomechanosensitivity. Using a star-polyethylene glycol (star-PEG) cross-linked with heparin gel system, seeded bone marrow derived macrophages (BMM) consistently spread on stiff (~19 kPa) substrates in a pattern resembling frustrated phagocytosis. BMM displayed markedly reduced membrane ruffling patterns upon inspection by scanning electron microscopy (SEM), which suggested a decrease in available membrane reservoir. By pulling membrane tethers using atomic force microscopy (AFM), we confirmed that the membrane reservoir was significantly reduced on cells seeded on stiff substrates. We then investigated potassium (K^+) dynamics because K^+ efflux is a common precursor to inflammation. Colorimetric analysis of potassium channel activity suggests increased channel opening in cells on progressively stiff substrates. This activity is at least partially mediated by caveolae, cholesterol rich invaginations that serve as membrane reservoirs. Overall, these results suggests a link between cell spreading and depletion of the membrane reservoir, which may alter ion flux. These results also suggest that by modulating the membrane, one can directly influence the inflammatory potential of immune cells in a biophysical manner.

Keywords: ion channels, Macrophage activation, mechanotransduction.

Super resolution microscopy-based analysis of RhoD GTPase intracellular localization and transcriptional screening in human cancer tissues

A. Kyrkou[1], T. Fotsis[1,2], C. Murphy[1]
[1]Department of Biomedical Research, Foundation for Research and Technology- Hellas, Institute of Molecular Biology & Biotechnology, [2]Laboratory of Biological Chemistry, Medical School, University of Ioannina, Ioannina, Greece

RhoD GTPase is a member of Rho family of small GTPases, which participate in the regulation of various processes such as the formation of cellular protrusions, vesicular trafficking, transcriptional regulation, cell motility and cell and centrosome cycle. These processes are often deregulated in cancer, and indeed some Rho proteins have been implicated in transformation. As most classical rho GTPases, RhoD cycles between GTP/GDP bound states and exert its function via several downstream effectors such as members of the Diaphanous Related Formins, Plexins, Rabankyrin and others. RhoD is in evolutionary terms the youngest member of the family, since it is only found expressed in therians (marsupials and placentalia). Functional analysis has shown that RhoD is more related to RhoA, B, C than Rac or Cdc42. Similar to RhoB, RhoD is the only other member of the family localizing to vesicular structures.

Many studies have implicated RhoD in the early endocytic pathway and RhoB in the late degradative (lysosomal) pathway. In this study, we performed a super-resolution analysis of the localization of the wild type form of RhoD in human umbilical cord endothelial cells (HUVECs), using Stimulated Emission and Depletion confocal microscopy (STED). Moreover, we performed quantitation of the endosomal colocalization status of RhoD positive vesicles versus various markers of the endocytic cell compartments, using specialized quantitation software (MotionTracking). In cancer, deficient termination of the oncogenic signaling of mutated receptors, such as the EGFRs, through altered kinetics of transport from early to the late endosomal compartment and/or suboptimal lysosomal degradation could contribute to the process of malignant transformation. Furthermore, we have previously shown that RhoD is implicated in cell proliferation and regulation of the centrosome cycle, key cellular processes often altered during the transformation process. Therefore, we also sought to identify the expression profile of this protein in various cancer tissues. For this, we performed an extensive screening of the expression levels of RhoD in 384 cancer tissue samples and we present the data herein

Keywords: RhoD, STED, tissue.

SUN-429
Systematic characterisation of PRAF and YIPF proteins involved in the membrane trafficking

T. Kranjc[1,2], G. Cagney[1], D. C. Shields[1], J. C. Simpson[1,2]
[1]Conway Institute, [2]School of Biology and Environmental science, University College Dublin, Dublin, Ireland

Despite being discovered nearly two decades ago, the membrane protein families PRAF and YIPF, are still poorly characterised in terms of their function in membrane trafficking. The best characterised protein PRAF1 has been associated with the activation of Rab GTPases, switch proteins that regulate membrane trafficking processes, while PRAF3 has been described to interact with Arf proteins, which are also major players in membrane trafficking. In turn, PRAF2 has been shown to have elevated expression levels in different cancer types such as breast, colon, lung, ovary and nervous system. On the other hand there are only a few publications about YIPF proteins and even these report contradicting conclusions.

In this study we systematically characterised proteins from the PRAF and YIPF families. Their subcellular localisation was determined by fluorescence microscopy imaging and unsupervised quantitative image analysis of both GFP-tagged proteins and immunostained samples. Three PRAF proteins localise mostly to endoplasmic reticulum and Golgi complex, while all 7 YIPF proteins localise to Golgi. Interestingly YIPF proteins seem to localise to different microdomains of the Golgi which is being further investigated by electron microscopy and co-localisation techniques. PRAF and YIPF families are membrane proteins with 4 or 5 transmembrane domains respectively, both having their N-terminal region facing the cytosol. The predicted topology has been experimentally confirmed with the fluorescence protease protection assay. These cytosolic regions interact with other cytosolic proteins, with Rabs being of particular importance. Immunoprecipitation experiments followed by mass spectrometry analysis confirmed some previously known interactions between PRAF or

© 2014 The Authors. FEBS Journal © 2014 FEBS

YIPF proteins and Rabs. Other interesting interactors were also identified: for example, proteins related to heat shock and lipid metabolism were detected in PRAF1 immunoprecipitates.

The work presented here provides a systematic characterisation of PRAF and YIPF membrane proteins in terms of their specific subcellular localisation, topology and function. Moreover, the assembled datasets and tools will allow us and other researchers to further investigate these two families of proteins, especially their role in membrane trafficking and their link with cancer.

Keywords: mass spectrometry, membrane trafficking, microscopy.

The capture and characterization of the Fc receptor complex from cultured macrophages

J. Dufresne, J. G. Marshall
Department of Chemistry and Biology, Ryerson University, Toronto, ON, Canada

Cell surface receptors are of critical importance to biomedicine and the treatment of disease but are notoriously difficult to isolate and identify by classical approaches. Thus there is an urgent need to activate and capture receptor associated supramolecular complexes from the surface of live cells using liquid chromatography and tandem mass spectrometry (LC-ESI-MS/MS). The Fc gamma receptor (FCGR) is responsible for the engulfment of foreign particles and pathogens coated with Immunoglobulin G (IgG). The FCGR complex was captured from live human U937 and murine RAW 264.7 macrophages by presenting the cognate ligand (IgG) on micro chromatography beads. Many co-receptors, including innate immune receptors such as Fc-like receptors, scavenger receptors, toll-like receptors, Fc-like killer cell receptor, lectins, epidermal growth factor, interleukin and colony stimulating factor, chemokine, cytokines, histamine and other receptors that are known to modulate immunological response were observed to copurify alongside the Fc receptors on micro beads. As a second method, direct biotinylation of IgG provides for specific capture of the Biotin-IgG-FCGR complex on strepavidin beads, but the biotinylated receptor complex cannot be specifically separated from the contamination and background binding to the strepavidin resin. However, new affinity chromatography reagents such as NHS-SS-biotin may be cleaved with DTT to specifically release the FCGR complex. The monovalent versus aggregated FCGR complex was bound and activated by its IgG-S-S-biotin probe to activate and capture the receptor before collection over streptavidin followed by specific elution with the reducing agent DTT. After binding and activation of the cell surface receptor by its ligand, the cells were disrupted with a French press and the homogenate applied to a streptavidin agarose affinity column. After washing, the activated and assembled FCGR cell surface complex was eluted from the column with a reducing agent DTT, and digested with trypsin. The peptides were analyzed by LC-ESI-MS/MS using a linear ion trap (Thermo) where the peptides identification using the SEQUEST, MASCOT, OMSSA and X!TANDEM algorithms and quantified using R statistical analysis. We propose to define the role of a subset of the IgG-Fc co-receptors by phagocytosis assays and the measurement of phagocytosis and free radical production in the presence of specific siRNA or controls, mutant constructs and pharmacological agents. We also propose to quantify the assembly of the Fc-IgG receptor complex over time and compared to other innate immune receptors. The analysis of a cell surface receptor complex developed and tested on the model FCGR complex may be applied to a wide variety of receptors crucial in human infection, disease and pain.

Keywords: mass spectrometry, receptor complex.

The dynamics of dynamin in vivo

V. Galli[1], A. Roux[2]
[1]Transpol Biochemistry, [2]Biochemistry, University of Geneva, Geneva, Switzerland

Clathrin mediated endocytosis is the process in which cells are able to internalize patches of membrane together with external or transmembrane material. The membrane patch is forced into becoming a vesicle due to the formation of a Clathrin coat, recruited to the membrane by cargo-specific adaptor proteins. The newly formed bud is then severed from the membrane in a fission event mediated by the large GTPase Dynamin.

Dynamin polymerizes around the neck of the bud in form of a helix and, upon GTP hydrolysis, changes conformation and twists and constricts the neck promoting fission.

With the purpose of clarifying the dynamics of memebrane fission in living cells, we selected and characterized conformational antibodies able to recognize the nucleotide-bound state of Dynamin. We are currently using these antibodies by expressing them directly in living cells, coupled with a fluorescent protein. By using TIRF microscopy we can follow over time the colocalization of the antibodies with fluorescent Dynamin or other members of the Clathrin mediated endocytosis machinery.

The effects of 53 GHz irradiation on enhancements of antibiotics antibacterial influence on *Escherichia coli*

H. R. Torgomyan[1], A. H. Trchounian[2]
[1]Biophysics, [2]Microbiology and Microbes and Plants Biotechnology, Yerevan State University, Yerevan, Armenia

Coherent electromagnetic irradiation (EMI) of extremely high frequency - 30 GHz to 300 GHz is widely spread in environment. EMI can cause different biological effects [1, 2]. Because of its disinfecting properties EMI has applications in the environment controlling - water sources, agricultural wastewater, in treatment of food at moderately low temperatures and in therapeutic practice [2].

Bacterial growth has a great significance to understand changed bacterial sensitivity to EMI or antibiotics. Over the years antibiotics have been widely used in food industry, in agriculture and aquaculture, increasing the percentages of antibiotic resistant bacteria [2]. EMI can affect the cellular defense system and makes it vulnerable to antibiotic attacks [2].

The effects of different antibiotics – chloramphenicol (Chl), ceftriaxone (Cef), kanamycin (Kan) and tetracycline (Tet), on bacteria were examined via determination of bacterial growth in a comparative manner – non-irradiated bacteria (control), irradiated bacteria, control and antibiotic, irradiated bacteria and antibiotic, control and irradiated antibiotic (Figure). About the bactericidal effects were inferred from decreased *E. coli* growth [2]. It was shown that 53 GHz irradiation causes bactericidal effects. Also, it changes antibiotic sensitivity or resistance, which is more visible in the cases of Cef and Tet [2].

It was demonstrated that 53 GHz irradiation (1 hour) of antibiotics increased antibiotics antibacterial properties approximately for the same time in the cases of used antibiotics, but was a little more with Kan and Tet. Enhanced bacterial sensitivity to antibiotics by EMI is similar to the effects of higher concentrations of antibiotics.

Interestingly, the enhanced effects of non-irradiated antibiotics on irradiated bacteria are more significant compared with the effects of irradiated antibiotics on non-irradiated bacteria (Fig-

© 2014 The Authors. FEBS Journal © 2014 FEBS

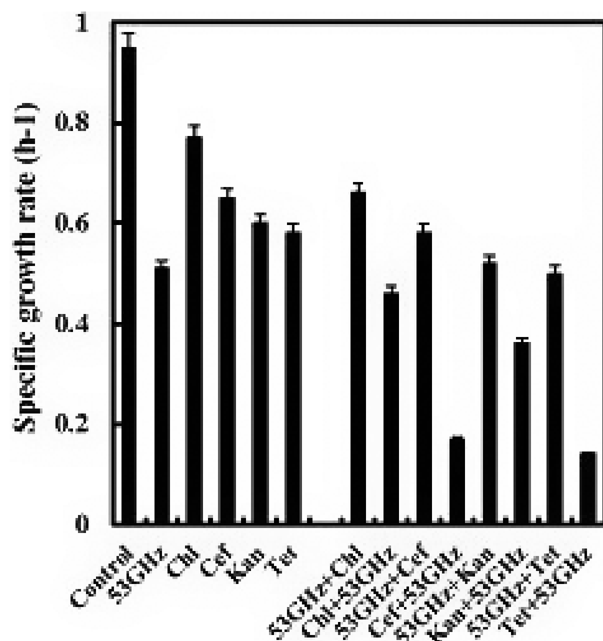

Fig. 1. *E. coli* K12(λ) specific growth rate in different conditions – control (without irradiation and antibiotics); after 53 GHz irradiation; non-irradiated bacteria with antibiotics (Chl, Cef , Kan, Tet); non-irradiated bacteria with irradiated antibiotics (in figure mentioned as 53 GHz + antibiotic); irradiated bacteria with non-irradiated antibiotics (in figure mentioned as antibiotic +53 GHz). Antibiotics Chl, Cef, Kan and Tet non-irradiated and after radiation with 53 GHz frequency added into the grown medium at their minimal inhibitory concentrations (4 μM, 0.4 μM, 15 μM and 4 μM, respectively). Bacteria were grown in peptone medium.

ure). Probably such effects connected with EMI interaction with antibiotics surrounding water molecules.

This study is very interesting new approach, which can be useful in medical, agricultural and food industry applications.

The interplay between the actin cytoskeleton and plasma membrane organization in B cell activation

P. Mattila[1,2], Group of Prof. Facundo Batista, London Research Institute, Cancer Research UK
[1]*Institute of Biomedicine, University of Turku, Turku, Finland,* [2]*London Research Institute, Cancer Research UK, London, UK*

The actin cytoskeleton is involved in numerous cellular events. Thus not surprisingly, increasing evidence also demonstrates the role for the cytoskeleton in various stages of lymphocyte activation. We recently observed that a mere transient alteration of the actin network leads to B cell activation. Here we show that the disruption of the cytoskeleton triggers signaling that not only requires the B cell receptor (BCR), but also the co-receptor CD19. In addition to the cytoskeleton, the co-operation of these two receptors is further coordinated by the CD81-tetraspanin web, which organizes CD19 in the plasma membrane. New insights into the initiation of the BCR signaling are supported by dSTORM super-resolution microscopy, which demonstrates that endogenous IgM, IgD and CD19 exhibit distinct nano-scale organization within the plasma membrane of naïve B cells. Interestingly, these membrane receptor nanoclusters do not change in character during BCR signaling. Thus, we postulate that cytoskeleton reorganization releases pre-existing BCR nanoclusters, which can interact with CD19 held in place by the tetraspanin network. Our results not only suggest that receptor compartmentalization regulates B cell activation by surface-bound antigen, but also imply a potential role for CD19 in mediating ligand-independent BCR signaling necessary for B cell survival.

The role of lipid metabolism during the *Drosophila* spermatogenesis

B. Laurinyecz[1], V. Vedelek[1], P. Maróy[1], M. Péter[2], G. Balogh[2], G. Juhász[3], L. Vígh[2], R. Sinka[1]
[1]*Department of Genetics, University of Szeged,* [2]*Institute of Biochemistry, Biological Research Centre of the Hungarian Academy of Sciences, Szeged,* [3]*Department of Anatomy, Cell and Developmental Biology, Eötvös Loránd University, Budapest, Hungary*

The existence of similar male sterile phenotype in flies, mice and human strongly suggests that many of the genes required during spermatogenesis have been evolutionary conserved. Male sterile mutations of *Drosophila* exhibit a broad range of phenotypes and affect all stages of spermatogenesis. Spermatid individualization is an especially interesting step of the spermatogenesis because it requires an unusual amount of membrane remodelling using a well-defined actin structure. *Drosophila* spermatids increase 150-fold in length and fivefold greater total surface area following individualization. Increasing number of lipid metabolic enzymes show important role during all stages of spermatogenesis, for example in the biosynthesis of phosphatidylinositol (PI) and their phosphorylated forms. We have started the genetic characterization of mutant lines in which membrane transport related genes are affected. One of them is the *CdsA* gene which encodes for phosphatidate cytidyltransferase, CdsA enzyme, which catalyzes the synthesis of CDP-DAG from phosphatidic acid, which is an important player of PI and cardiolipin (CL) biosynthesis. Phosphoinositides play important roles in lipid signalling and membrane trafficking, while cardiolipin is an important component of the inner mitochondrial membrane. We characterized the $CdsA^{ms}$ mutant with classical and molecular genetic methods and analysed its lipid composition using mass spectrometry.

TMEM165 is a protein whose mutations in Congenital Disorders of Glycosylation patients alter Golgi Ca^{2+} and pH homeostasis

D. Legrand, S. Potelle, W. Morelle, C. Rosnoblet, M.-A. Krzewinski, G. de Bettignies, A.-M. Mir, D. Vicogne, C. Loir, S. Duvet, E. Dulary, J.-C. Michalski, F. Foulquier
Structural & Functional Glycobiology Unit, UMR8576 CNRS/ Université Lille1 – Bât. C9, 59655 Villeneuve d'Ascq cedex, France

TMEM165 is a novel gene involved in Congenital Disorders of Glycosylation (Foulquier *et al.*, Am J Hum Genet 2012, 91). The

© 2014 The Authors. FEBS Journal © 2014 FEBS

TMEM165 deficient CDG patients present a peculiar clinical phenotype including severe dwarfism; psychomotor retardation, midface hypoplasia, muscular weakness, fat excess, joint laxity, and hepatosplenomegaly. TMEM165 encodes a putative transmembrane 324 amino acid protein whose cellular functions are unknown. TMEM165 belongs to a well-conserved, but uncharacterized, family of membrane proteins named UPF0016.

We first started by examining the effects of naturally occurring mutations on the intracellular localization of TMEM165 and their abilities to complement the TMEM165-deficient yeast, ΔGdt1. We demonstrated that wild-type TMEM165 was localized within Golgi compartment, plasma membrane and late endosomes/lysosomes, whereas mutated TMEM165 were found differentially localized according to the mutations. We also demonstrated that, in the yeast functional assay with TMEM165 ortholog Gdt1, the homozygous point mutation correlating with a mild phenotype restores the yeast functional assay, whereas the truncated mutation, associated with severe disease, failed to restore Gdt1 function. These results highly suggested that these clinically relevant point mutations did not affect the protein function but critically changed the subcellular protein localization. Moreover, the data pointed to a critical role of the YNRL motif in TMEM165 subcellular localization (Rosnoblet *et al.*, Hum Mol Genet 2013, 22). Since Gdt1p, the budding yeast member of this family, contributes to Ca2+ homeostasis via a unique Ca2+ transport pathway localized in the Golgi apparatus, we used yeasts to approach the cellular function of Gdt1p/ TMEM165. One particularity of the gdt1Δ mutant was to be sensitive to high concentrations of Ca2+, and interestingly, this sensitivity was suppressed by expression of TMEM165, the human ortholog of Gdt1p, indicating conservation of function among the members of this family. Patch-clamp analyses on human cells indicated that TMEM165 expression is linked to Ca2+ ion transport. Furthermore, defects in TMEM165 affected both Ca2+ and pH homeostasis (Demaegd, Foulquier *et al.*, PNAS 2013, 110). We thus propose that Gdt1p and TMEM165 could be members of a unique family of Golgi-localized Ca2+/H+ antiporters and that modification of the Golgi Ca2+ and pH balance could explain the glycosylation defects observed in TMEM165-deficient patients.

SUN-436
Trafficking of the amino acid transporter $B^{(0,+)}$ ($ATB^{0,+}$) to the plasma membrane

L. Samluk[1], S. Sucic[2], M. Freissmuth[2], K. A. Nałęcz[1]
[1]*Department of Molecular and Cellular Neurobiology, Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warsaw, Poland,* [2]*Center of Physiology and Pharmacology, Institute of Pharmacology, Medical University of Vienna, Vienna, Austria*

The amino acid transporter $B^{0,+}$ ($ATB^{0,+}$), coded by the *SLC6A14* gene, transports a broad spectrum of neutral and basic amino acids through the plasma membrane, and is up-regulated in malicious cancer cell lines. It was shown to be phosphorylated by protein kinase C (PKC), correlating with an augmented presence of the transporter at the cell surface. Since several members of the SLC6 transporter family are known to interact with SEC24 proteins of the COPII complex along their pathway from the endoplasmic reticulum (ER) to Golgi, the present study focused on a possible involvement of SEC24 proteins in $ATB^{0,+}$ trafficking. Rat $ATB^{0,+}$ was heterologously expressed with C-terminal 3xFLAG tag in HEK293 cells. Immunoprecipitation experiments suggested a possible interaction between the transporter and SEC24C (but not with the A, B and D isoforms of SEC24), confirming the importance of the ER export 'RI' motif in the binding of cargo proteins with SEC24C. This interaction, however, was not altered upon PKC activation. When SEC24A-D were knocked-down using siRNAs, the amount of $ATB^{0,+}$ detected at the plasma membrane by biotinylation studies remained unchanged. Interestingly, another protein found to interact with $ATB^{0,+}$ was caveolin-1, which apart from its structural role in rafts, is also postulated to play a role in cholesterol and protein trafficking. We here propose an alternative mechanism directing the 12TM transporter $ATB^{0,+}$ from the ER compartments to the plasma membrane.

This work was financed by the National Science Centre grant 2012/B/NZ3/000225.

Translocation of cell-penetrating peptides across the plasma membrane is controlled by cholesterol and microenvironment created by membranous proteins

J. Pae[1], P. Säälik[2], L. Liivamägi[1], D. Lubenets[1], P. Arukuusk[3], Ü. Langel[3,4], M. Pooga[1]
[1]*Institute of Molecular and Cell Biology,* [2]*Institute of Biomedicine and Translational Medicine,* [3]*Institute of Technology, University of Tartu, Tartu, Estonia,* [4]*Department of Neurochemistry, Stockholm University, Stockholm, Sweden*

Cell-penetrating peptides (CPPs) are considered as one of the most promising tools to mediate the import of membrane-impermeable, biologically active molecules into the cells. Despite the extensive research in the field of CPPs' cell entry, the exact mechanisms underlying their cellular uptake and possible role of the cell surface molecules in the internalization process has remained controversial. The full understanding of their cellular uptake methods is of the utmost importance for the design and development of peptide vectors.

Our research focused on the interactions between CPPs and the membrane constituents of giant plasma membrane vesicles (GPMVs). GPMVs comprise a model system which maintains the compositional complexity and protein content of biological membranes and are considered to be a relevant model to study the translocation of CPPs across the plasma membrane in conditions lacking endocytosis [1]. Cholesterol has been shown to be one of the main determinants in formation of more densely packed and more ordered membrane areas. By lowering and enhancing the cholesterol content in GPMVs' membrane, we showed that higher cholesterol content and tighter packing of membrane components reduced predominantly the accumulation of amphipathic CPPs in vesicles, confirming that the internalization of CPPs takes place preferentially via the more dynamic membrane regions. Furthermore, the significance of the membrane dynamics in CPPs internalization was examined by formation of ceramide in the membrane of GPMVs. Ceramide modulates the structure and properties of cellular membranes, which can result in promoting or inhibiting the translocation of CPPs across the plasma membrane. Accumulation of amphipathic peptides into GPMVs was inhibited by formation of ceramide in GPMVs membrane. Ceramide alters the lateral organization of membrane, resulting in the formation of highly ordered ceramide platforms, and thereby also decreasing the microfluidity of membrane, which in turn reduced the uptake of amphipathic peptides. Additionally, we assessed the role of membrane proteins as possible mediators of CPP uptake. The partial digestion of membrane proteins from GPMVs' surface signifi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

cantly reduced the uptake of nonaarginine and Tat peptide, demonstrating that proteinaceous receptor is necessary for the uptake of arginine-rich CPPs.

What is the role of the influenza fusion peptide in membrane fusion? A computational study

D. Lousa[1], B. L. Victor[1,2], C. Fernandez[1], C. M. Soares[1]
[1]ITQB-UNL, Oeiras, [2]BSIM, Biocant Park, Cantanhede, Portugal

Influenza virus (IV) is responsible for worldwide outbreaks of flu, causing hundreds of thousands of deaths every year, which rise to millions in pandemic years. The finding of effective drugs against IV is, therefore, a matter of the utmost importance and urgency. To infect host cells IV fuses its membrane with the host membrane. The fusion process is promoted by the glycoprotein hemagglutinin (HA), which is located on the surface of the virus. HA has a highly conserved N-terminal domain, comprising ~20 residues, which inserts and destabilizes the host membrane during fusion - fusion peptide (FP). To elucidate the molecular determinants that lead to the destabilization of biological membranes by the FP, we used a molecular dynamics approach. These simulations enabled us to analyze the structural properties of the peptide inside the membrane and characterize the interactions between the peptide and the lipids. This knowledge contributes to a better understanding of the role of the FP in the fusion process, which can be useful for the development of anti-viral drugs against influenza.

Engineering new genetically encoded biosensors for quantitative biochemical imaging in the living cell

D. Betolngar[1], M. Erard[1], H. Pasquier[1], Y. Bousmah[1], E. Guiot[2], P. Vincent[2], F. Merola[1]
[1]Laboratoire de Chimie Physique, Université Paris Sud, Orsay, [2]Neurobiologie des Processus Adaptatifs, Université Pierre et Marie Curie, Paris, France

Biosensors incorporating fluorescent proteins (FP) are widely used to image and quantify various interactions and biochemical activities within living cells, tissues and whole organisms. These applications require FPs with not only maximum brightness and photostability but also a full control of their photophysical responses to changes in the environment. When this is the case, their calibrated responses may be used to monitor specific parameters, such as the local pH of secretory compartments (Poëa-Guyon et al., 2013a,b), or the generation of ROS species like the OH° radical (Alvarez et al., 2010). In FRET experiments on the contrary, two spectrally matched donor-acceptor FPs are expected to respond exclusively to changes in their relative spatial arrangement. Despite their poor photophysical performances and strong pH sensitivities, cyan and yellow FPs remain in most cases the prefered option to build FRET biosensors, which has led to many controversial data in the litterature.

Major advances have been achieved recently by our lab and others, in the engineering of cyan fluorescent proteins with emission quantum yields close to unity, fluorescence lifetimes greater than 4 ns, an extended photostability and a remarquable environmental insensitivity, notably towards pH over the whole range of physiological pH values (Erard et al., 2013). We have shown that these improvements stem from only a very few critical mutations having well defined structural consequences on the chromophore pocket (Fredj et al., 2012). These newly engineered FPs now reveal unexpected aspects of the functioning of conventional FRET biosensors, and trace promising routes towards the *de novo* rational design of optogenetic reporters.

Excitation transfer along linear chain of small plasmonic particles and exciting collective modes in circular particles chain in biological tissue

M. Barabanenkov[1], Y. Barabanenkov[2]
[1]Institute of Microelectronics Technology Russian Academy of Science, Chernogolovka, Russian Federation, [2]V.A Kotelnikov Institute of Radioengineering and Electronics RAS, Moscow, Bahamas

Metallic nanoparticles with plasmonic resonance may unite in biological tissue as finite clusters obeying specific optical eigenmodes or line up to transfer excitation between clusters. It is presented simple analytic and physically transparent results for the problem solution of collective modes exciting inside circular chain and the problem excitation transfer along linear chain of coupled small plasmonic spherical particles. The results are obtained with the aid of a system of equations for self-consistent currents excited inside particles by incident electromagnetic wave field. For circular particles chain the coupling matrix between their currents becomes under definite conditions of such favorite properties that enables one immediately to write out the Bloch-like eigenmodes with corresponding eigenfrequencies and their halfwidthes. Besides we get a simple analytic expressions for coupling factor between inner part of a square structure arranged in a circular shape and its bound part. Considering linear particles chain we use a closest neighbour interaction approach which makes the linear chain like the electric filter. In this approximation an analytic expression is obtained for extinction rate of exciting currents' transfer depending on chain particles number and for resonance filtering frequencies.

Keywords: excitation transfer, plasmonic resonance.

The gap junctions of the thermosensory circuit in the nematode *C. elegans* are responsible for isothermal tracking behavior

A. C. C. Calvo, D. A. Colon-Ramos
Cell Biology, Yale School of Medicine, New Haven, CT, USA

The nematode *Caenorhabditis elegans* moves towards the cultivation temperature when placed in a thermal gradient, tracking isotherms once this temperature is reached (isothermal tracking behavior). AFD is the principal thermosensory neuron described until now and is required to perform all modes of thermotactic

© 2014 The Authors. FEBS Journal © 2014 FEBS

behavior. But how one neuron can drive the distinct sensorimotor transformations that underlie movement down or up gradients towards the cultivation temperature vs. isothermal tracking near the cultivation temperature is not well understood. To study this question, we explored the downstream synaptic pathways from AFD. AFD has direct synaptic output to only two interneurons, chemical synapses to AIY and electrical synapses to AIB. While AIY role in thermotaxis has been widely studied and its inactivation is known to cause a constitutive cryophilic movement (movement towards colder temperatures), little is know of the AIB role. We have identified a deletion mutant in an innexin gene, *inx-1*, that displays a constitutively isothermal tracking behavior, regardless of cultivation temperature. Innexins are the proteins responsible for gap junctions in invertebrates. *Inx-1* is primarily expressed in the interneuron AIB, the electrical partner of AFD. Surprisingly, cell specific expression of the *inx-1* cDNA in the sensory neuron AFD, but not in the interneuron AIB, suppresses the constitutively isothermal tracking phenotype of *inx-1* mutants. Moreover, inactivation of AIB renders animals with an enhancement of the isothermal tracking behavior. Taken together, these results suggest that electrical and chemical synaptic pathways from the AFD neuron are differentially used to perform distinct modes of thermotaxis.

Wdr13 knockout mice shows marginally better memory but impaired ability to withstand social isolation stress

S. Mitra[1], G. S. Sameer Kumar[1], V. Tiwari[1], B. Jyothi Lakshmi[1], S. Thakur[1], S. Kumar[1,2]
[1]*Centre for Cellular and Molecular Biology,* [2]*National Institute of Animal Biotechnology, Hyderabad, India*

Wdr13 is a novel WD repeat protein containing gene, knockout of which in mice results in age dependant mild obesity and pancreatic beta cell hyper-proliferation leading to increased insulin secretion (Singh et al, 2012). Our lab also found that this protein interacts in a co-repressor complex with several nuclear receptors and phosphorylation at 70 S of this protein is important for its function. Function of this gene in brain and behavior haven't been studied extensively though literature survey shows association of this gene with memory. RISH localizes wdr13 expression in hippocampal formation, cerebral cortex, cerebellum and striatum. An age window of 2–3.5 months has been chosen for brain and behavior studies in these knockout mice. Using NMR it was found that metabolic changes in brain are not prominent in this interval. Wdr13 -/0 mice in CD1 background show increased anxiety and impaired ability of novel object recognition. In C57BL6/J background also, the knockout mice showed higher anxiety than that in wild types proving that the phenotype was strain-independent. The Wdr13 knockout mice, however, fared marginally better than the wild type mice in memory tests. There was no significant change in the brain morphology of the adult and hippocampal adult neurogenesis (at 2 months) in these mice was not significantly affected under normal conditions. Deep proteomics using iTRAQ revealed increased levels of synapsin1 and down-regulated levels of neurogranin in hippocampus and prefrontal cortex may be causative for this phenotype. Interestingly, upon social isolation for 3 weeks, the anxiety and depression-like symptoms in the knockout mice are aggravated with loss in dendritic branches in hippocampus and significant decrease in synaptic genes like syn1, rab3a, nrxn2 at transcript and protein levels. This was also accompanied with increase in GATA1, a common negative Transcription Factor for the above-mentioned and known to be marker of MDD (Major Depressive Disorder). We are led to believe that Wdr13 regulates GATA1 expression and absence of it leads to de-regulation of the gene and its downstream targets.

3D collagen scaffolds hosting neural stem cells: developing neuroimplants for spinal cord injury (SCI) repair

I. Charalampopoulos[1], A. Kourgiantaki[1], D. Tzeranis[2], P. Efstathopoulos[1], K. Mylopotamitaki[1], I. Pediaditakis[1], I. Yannas[2], A. Gravanis[1]
[1]Department of Pharmacology, Medical School, University of Crete & IMBB-FORTH, Heraklion, Greece, [2]Department of Bioengineering, Massachusetts Institute of Technology (MIT), Boston, MA, USA

Many studies have investigated the effects of engraftment of *in vitro*-propagated Neural Stem Cells (NSC) or committed neuronal or glial progenitors on the recovery of injured Spinal Cord (SC). Most of the studies performed in rodents demonstrate that grafted cells display a short-term beneficial effect on locomotor function. One of the major setbacks of these efforts is that transplantation of NSC cell suspensions results in cell spreading and dispersal within the SC, limiting their efficacy for successful local integration and functional networking. Transplantation of a solid scaffold containing NSCs may successfully overcome these limitations. We are developing neuroimplants using 3D collagen I scaffolds hosting embryonic neural stem cells, isolated from the knock in *sox2-egfp* mice strain. A sox2-positive population more than 90% pure is isolated, using fluorescence-activated cell sorting (FACS) analysis. Scaffolds were prepared with homogenization of microfibrilar bovine collagen I in acetic acid, then freeze-drying: freeze-dry parameters control pick porosity and cross-link with various additives control stiffness and pick degradation rate. Collagen I scaffolds are much more stiffer and degradation-resistant than gels scaffolds have an open foam structure, 0.5% mass fraction and 30 to 400 μm pores and *in vivo* degradation rate at 90 days half life. Confocal and electron microscopy analysis of NSC have shown that composition and microstructure of 3D scaffolds play a significant functional role: scaffolds with a combined composition (50% collagen-50% gelatine or 92% collagen-8% chondroitin-6-sulphate) support more effectively NSC survival and proliferation as measured by TUNEL and Ki67 staining respectively, maintaining stemness (sustained sox2 expression) and propagating neurosphere formation. On the other hand, primary sensory neurons from mouse embryonic dorsal root ganglia, grew better in pure collagen scaffolds with less rigid structures. We are now testing the 3D collagen I scaffolds populated with mouse neural stem cells in mice with experimental spinal cord injury.

This work was supported by the ERC01 and Heraclitus II grants from the General Secretariat of Research and Technology (GSRT).

3D microcarrier cell culture affects proteomic signature of exosomes derived from human dental pulp stem cells

A. Vaitkuviene, A. Jarmalaviciute, V. Tunaitis, A. Venalis, A. Pivoriunas
Stem Cell Biology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania

Microcarrier technology is an efficient method for scaling-up cell production in small volumes, while promoting improved cellular phenotypes in a three-dimensional environment. The main advantage of this system is the possibility to cultivate up to 100 times more cells in the same amount of medium. In addition, these systems could be potentialy used as a factories for the small scale production of different therapeutic factors. Here we present results on the use of BioLevitator™ (Hamilton), a commercially available three-dimensional culturing platform and alginate microcarrier cell culture system (Global Cell Solutions) for the propagation of stem cells derived from the dental pulp of human exfoliated deciduous teeth (SHEDs). Exosomes were purified by ultracentrifugation from SHEDs cultivated under two conditions: standart two-dimensional culture flasks, or from SHEDs grown on the laminin-coated microcarriers in bioreactor. In both cases cells were grown in serum- and xeno- free medium (MSC NutriStem XF, Biological Industries). For proteomic studies liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) analysis was carried out on an EASY-nLC (Thermo Fisher Scientific) connected to a Velos Pro-Orbitrap Elite hybrid mass spectrometer with nano electrospray ion source (Thermo Fisher Scientific). In total we identified 80 proteins in exosomes from standart SHED cultures and 60 proteins in exosomes from microcarrier cultures. The majority of the identified proteins are included in the vesiclepedia database. Importantly, only 28 proteins were common between exosomes from different preparations. These findings indicate, that 3D microcarrier cell culture have a profound impact on the proteomic composition and possibly physiological properties of exosomes.

A multidisciplinary approach to studying crypt-villus homeostasis and regeneration in the intestinal epithelium

A. Parker[1], O. Maclaren[2], A. Watson[1], H. Byrne[2], A. Fletcher[2], S. Carding[1], P. Maini[2], C. Pin[1]
[1]Institute of Food Research/University of East Anglia, Norwich, [2]Wolfson Centre for Mathematical Biology, University of Oxford, Oxford, UK

The luminal surface of the gastrointestinal tract is folded to form invaginations or crypts, and evaginations, or villi. The epithelial cell layer lining these structures performs a sophisticated dual role in maximising nutrient exchange while maintaining a barrier to intestinal pathogens. The epithelial layer is continuously regenerated; stem cells located at the base of crypts proliferate and differentiate into a variety of cell types which migrate upwards along crypts and villi before being shed into the gut lumen. Maintenance of the functional integrity of the intestinal barrier requires tight coordination of cell proliferation, migration and shedding along the crypt-villus axis, with dysregulation of these processes leading to tumourigenesis and inflammatory disease. How these processes are regulated in homeostatic, disease and recovery states is incompletely understood.

Using a multidisciplinary approach combining experimental measurement and mathematical models we aim to define the mechanisms involved in homeostasis of the intestinal epithelium and its recovery after perturbation. Specifically, the mechanisms controlling cell migration along the crypt-villus axis, those regulating cell shedding, and those involved in translating events on the villus to responses in the crypt. We have developed individual based models (IBMs) to study the spatio-temporal dynamics of

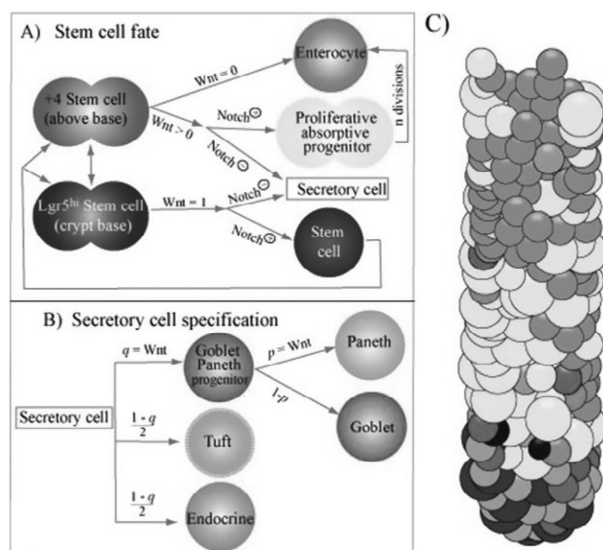

Fig. 1. Model for cellular differentiation and proliferation in the crypt of mouse small intestine.

epithelial cell generation in crypts, providing insight into the dynamics of cell differentiation and localisation, and the propagation of mutations. Using Chaste as a computational framework, and through continual development and refinement of models at different levels of special granularity, we aim to simulate crypt-villus epithelial dynamics in both healthy and diseased mucosa.

In combination with mathematical approaches, we have tracked and manipulated epithelial cell behaviour using a variety of in vivo murine models of healthy and altered epithelia, including inflammatory and pro/anti-proliferative settings. For example, using an LPS–induced model of epithelial damage, we observe intense apoptosis at villus tips and a significant reduction in villus height in the small intestine, with recovery of typical morphology within a few hours. Using in vivo and in vitro microscopic and histological techniques, we have traced epithelial cell proliferation, migration and shedding to better define the processes involved in villus regeneration.

Our ongoing work continues to combine experimental and mathematical approaches to define mechanisms which are essential to maintain lifelong health of the gastrointestinal tract and ultimately aims to identify strategies for intervention in intestinal disease.

A neurofilament-derived peptide targets neural stem cells and alters their self-renewal capacity

C. Lépinoux-Chambaud, J. Eyer
49, Laboratoire de Neurobiologie et Transgenèse EA3143, IBS-IRIS, Angers, France

The neural stem cells (NSC) are characterized by their capacity to self-renew, to form neurospheres in culture, to proliferate, and to generate neurons, astrocytes and oligodendrocytes (multipotency). The characteristics of these cells provide new therapeutic approaches for the treatment of neurodegenerative disorders and

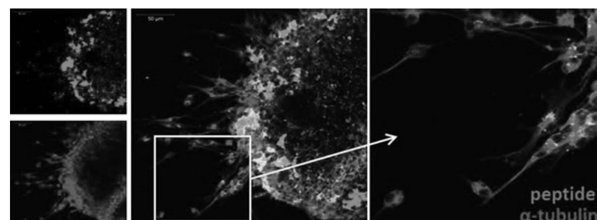

Fig. 1. Confocal microscopy of the peptide (in green) uptake in neural stem cells of new-born rats (stained with anti-tubulin, in red).

for the treatment of malignant glioma. The development of neural stem cell-based therapies may be beneficial to target these cells, increase their mobilization and stimulate neurogenesis for regenerative medicine and for the treatment of brain tumours.

We previously showed that a peptide corresponding to the tubulin-binding sequence located on neurofilament, alone or linked to nanoparticles, is able to target glioblastoma cells *in vitro* and *in vivo*. The selective and massive uptake of this peptide by glioblastoma cells occurs through endocytic pathways and is related to their high proliferative state, whereas a low level of internalization occurs for slow proliferative healthy cells (astrocytes, oligodendrocytes or neurons). Moreover, while the peptide is able to disrupt the microtubule network of glioblastoma cells and inhibit their proliferation, it has no major effect on the microtubule network from healthy cells. Finally, injected in rats bearing glioblastoma, the peptide reduces tumour development (Bocquet et al., 2009; Bergès et al., 2012; Balzeau et al., 2013; L-Chambaud et Eyer, 2013).

In this study we show that this peptide is able to translocate passively in neural stem cells *in vitro*. Moreover, the *in vitro* formation of neurospheres was not altered by the peptide whereas the self-renewal capacity of these cells was slightly reduced and associated with an increase of adherent cells and a decreased of NSC proliferation. Finally, when injected in the cerebrospinal fluid of rats the peptide targets adult neural stem cells *in vivo* without major detectable cytotoxicity. These results indicate that this peptide represents a new molecular tool to target neural stem cells in order to develop new strategies for regenerative medicine and treatment of brain tumours.

Keywords: neural stem cells, self-renewal, targeting peptide.

A novel method to identify and isolate pluripotent human stem cells and mouse epiblast stem cells using lipid body-associated retinyl ester fluorescence

T. Muthusamy, M. M. Panicker
Lab 5, Molecular Neurobiology Group, NCBS, Bangalore, India

We describe a characteristic blue fluorescence exhibited by Human embryonic stem cells which helps in identification and isolation of human pluripotent stem cells. The blue fluorescence is easy to observe with basic epifluorescence microscopy. The intensity of blue fluorescence correlates with the expression of pluripotency markers such as OCT4, SOX2 and NANOG. We show that with the help of FACS, undifferentiated pluripotent stem cells can be easily isolated based on their blue fluorescent intensities. This blue fluorescence phenomenon appears early during reprogramming and arises from cytoplasmic lipid bodies by the sequestration of reinyl esters. These blue fluorescent lipid

A novel peptide for triggering differentiation of hepatocyte-like cells from human induced pluripotent stem cells

N. Kobayashi[1,2], K. Tanaka[1], M. Sawada[3], Y. Yoshida[4], I. Nakase[5], T. Yoshida[1,2]

[1]Institute for Advanced Sciences, Toagosei Co., Ltd., [2]Keio Advanced Research Centers (KARC), Keio University, Tsukuba, [3]Research Institute of Environmental Medicine, Nagoya University, Ngoya, [4]Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, [5]Nanoscience and Nanotechnology Research Center, Osaka Prefecture University, Osaka, Japan

Hepatocytes produced by differentiation from human induced pluripotent stem cells (iPSCs) could potentially contribute to the development of toxicological evaluation for pharmaceutical screening and regenerative therapies such as hepatocellular transplantation. Introduction of Activin A and bFGF; BMP4 and FGF4; HGF, OsM and DEX etc. at each stage induces the differentiation of human iPSCs into mesendoderm and later endoderm (stage I), hepatic progenitors (stage II), and mature, hepatocyte-like cells (stage III), respectively. However, hepatocyte-like cells generated using humoral factors have varying differentiation-inducing efficiencies and drug metabolic activities, making them, at present, unsuitable for use in medical applications. To resolve this issue, we propose using a functional peptide to induce the efficient generation of hepatocyte-like cells from human iPSCs instead of the conventional method of stepwise treatment with the humoral factors. We examined whether it was possible to differentiate hepatocytes from human iPSCs through treatment with the peptide, based on the idea that turning on the fundamental module that controls the differentiation from human iPSCs to hepatocytes would consequently produce more reliable hepatocyte-like cells and remove the variation in the differentiation-inducing efficiencies and the drug metabolic activities. We focused on the signal peptide of amyloid precursor protein and synthesized a peptide sequence combination of the signal peptide (15-27aa: LLLLLLVGLTAPA) of amyloid precursor-like protein 2 (APLP2), a protein ordinarily found in the neural cells differentiated from ectoderm, with a nucleolar localization signal (NoLS) region of LIM kinase 2 (LIMK2). It was demonstrated that the combination peptide strongly induced alpha-fetoprotein (AFP), a common marker of the early stage of hepatocytes, and Albumin (ALB), a common marker of the early-to-mature stage. Consequently, these results suggest that a peptide designed based on the APLP2 signal peptide and LIMK2 NoLS has the potential to trigger the essential factors which directly induce differentiation from human iPSCs to hepatocytes.

Analysis of a factor that induces neuronal differentiation on small cell lung cancer

S. M. B. Muhamad Yusop[1], K. Nagashima[1], Y. Mukai[2], T. Terasaki[2]

[1]Department Electr., Grad. Sch. of Sci. & Tech., [2]Department Electr. & Bioinfo., Meiji University, Kawasaki, Japan

The differentiation of the Small Cell Lung Cancer (SCLC) from neuroendocrine cells based on studying the features of SCLC through biological, pathological and clinical aspects was reported by Shimosato et al. [1]. In a research carried out by Tanaka and Terasaki [2], the morphological change of many SCLC cell lines was found when cultured with the extracellular substrate of human lung adenocarcinoma cell line, PC-9 cells. This phenomenon is thought to be depending on the cell adhesion to the substrate triggering the neurite development on these SCLC cells.

In this study, an experiment of the differentiation from SCLC cells to neuronal cells was conducted using conditioned medium of PC-9 cells. The SCLC cells were clearly changed to neuron-like shape after three days of cell culture. In order to analyze the substrate that causes the differentiation of SCLC cells, the concentrated proteins in the conditioned medium of PC-9 cells were separated by the Native-PAGE and then transferred to a PVDF membrane. Lu-134A cells, one of the SCLC cell lines, were then cultured on this membrane. After three days of culture, the membrane with cells was fixed and stained. As a result, the neurite development of Lu-134A cells was found on several protein bands.

The Two-Dimensional Cell Blot Method [3] was applied to further analyze the protein characteristics on those bands. Concentrated proteins in the conditioned medium of PC-9 cells were separated two-dimensionally by isoelectric focusing and SDS-free

© 2014 The Authors. FEBS Journal © 2014 FEBS

polyacrylamide gel electrophoresis. Separated proteins were transferred to a PVDF membrane, and Lu-134A cells were then cultured on the membrane. The protein distribution and the Lu-134A cell morphologies on the membrane were observed by microscope. Through the analysis of the protein spots where Lu-134A cells changed their morphologies, the main factor was identified based on the molecular weight and pI value, and further amino-acid sequences of the protein would be examined using the MALDI-TOFMS technique.

Basal lamina mimetic nanofibrous peptide networks for skeletal myogenesis

N. Gunduz, C. I. Garip, M. Kilinc, M. O. Güler, A. B. Tekinay

Materials Science and Nanotechnology, Bilkent University, Ankara, Turkey

Skeletal muscle is a collection of muscle fibers, which function together as a unit to generate contractile longitudinal forces for physical movement. Traumatic injury, tumor excision, congenital defects or myopathies disrupt muscle function and mobility and lead to muscle tissue reconstruction. One of the promising treatment methods for muscle damages is muscle stem cell transplantation; however, isolated stem cells drastically lose their ability to form myotubes and function appropriately after *in vitro* expansion. Also, there is a need for high numbers of stem cells for transplantation which requires harvesting around 3–4 kg of muscle tissue. The muscle stem cell transplantation method is still challenging due to the lack of donor tissue availability and limited autologous graft surgeries. Thus, regenerative medicine is a promising alternative solution for the treatment of various muscle related problems. It is still challenging to engineer skeletal muscle, yet numerous techniques are constantly being developed such as soft lithography, hot embossing, electrospinning, photolithography etc. Basal lamina of muscle tissue is vital for repair, maintanance and fiber force transmission. Fibrous architecture and biochemical components of this extracellular matrix support development and function of skeletal muscle. Thus, scaffolds mimicking ECM are promising candidates of efficient tissue engineered systems. In this study, we developed a novel ECM mimetic peptide nanofiber scaffold for myogenic differentiation of myoblasts (C2C12 cells) by mimicking the compositional and structural properties of native skeletal muscle basal lamina. The peptide nanofiber scaffolds were designed to mimic active site of laminin (IKVAV) and fibronectin (RGD) which take roles in muscle regeneration and development. Our results showed that self-assembled peptide nanofibers decorated with laminin derived epitopes support adhesion, growth and proliferation of the cells and significantly promoted the expression of skeletal muscle-specific marker genes (MyoD, myogenin, and MHC). Overall, functional peptide nanofibers used in this study present a biocompatible and biodegradable microenvironment, which is capable of supporting the growth and differentiation of C2C12 cells into myotubes. The laminin derived (IKVAV-incorporated) peptide nanofiber material offers a promising platform for future clinical applications due to its biocompatibility, biodegradability, and convenience in delivery by injection to damaged tissue site.

Stem cell research focusing on cardiovascular regeneration aims to achieve stem cell mediated cardiomyogenesis leading to sistolic and diastolic cardiac functional improvement and/or development of new, functional cardiac tissue. Fusion of mesenchymal stem cells (MSCs) and host cardiomyocytes has been proposed as one of the mechanisms for cardiac regeneration. However, the mechanisms and the functional consequences of cell fusion remain undefined. The aim of this study is to elucidate the role of fusion in cardiac reprogramming characteristics of MSCs with microarray methodology.

We established an in vitro model that stimulates the fusion of h-MSCs and hCM/AC16, which allowed functional evaluation of hybrid cells. Firstly, fusion between hMSCs/hCMs was induced with PEG. After, hybrid cells were examined for their karyotype analysis, immunohistochemical and electrophysiological characteristics. Gene expression changes between hMKH, hCM and hybride cells were analysed with microarray methodology.

Hybrid cells were positive for both MKH and CM markers. As a part of electrophysiological studies, calcium channels were also examined by patch-clamp. No significant difference was found between hybrides and human cardiomyocytes regarding response to ATP and caffeine. According to microarray results, 1494 and 139 genes were found to be expressed differently between MKH/hybride cells and AC16/hybride cells respectively. To investigate the upregulation or downregulation of specific cellular pathways, genes present on the array were assigned to 23 groups, based on their biological function.

Hybrid cells maintain the cardiomyocyte characteristics. Gene analaysis data showed that MSCs support cardiomyocytes in a way to promote their differentiation to cardiomyocytes. Progress in cellular therapy for cardiovascular diseases can be achieved by further analysis of cells with cardiac differentiation and fusion capacity. Cell fusion can be an important therapeutic mechanism in cardiovascular regeneration and also can be applied to translational science.

SUN-454
Cellular memory in nuclear reprogramming

E. Hörmanseder, J. B. Gurdon
Wellcome Trust/Cancer Research UK Gurdon Institute, Cambridge, UK

As development progresses, cells lose their pluripotent status and enter a differentiation process to give rise to the different cell types of the adult organism. Once a cell has established a differentiated cell identity, it only rarely if ever changes to another type. This stable commitment is usually maintained through many sequential cell divisions, and is likely to depend on the memory of an epigenetic state of chromatin. Xenopus eggs can be used to induce the reversal of differentiation processes. Yet, the egg is not fully efficient in reprogramming a somatic nucleus, as certain genes retain an epigenetic memory of their somatic cell of origin. To identify such genes on a genome wide level, endoderm or mesoderm donor cell nuclei were transplanted to eggs and gene expression was assessed by RNA-sequencing in the individual cloned embryos. Substantial expression of donor cell type-specific genes could be observed in the wrong cell type. For example, embryos prepared from transplanted endoderm cells overexpressed endoderm marker genes like Sox17, GATA6 and A2 m in their neuroectoderm cells. Because, in Xenopus, there is no transcription for the first 12 cell cycles, some somatic cell nuclei must remember a developmentally activated gene state and transmit this to their mitotic progeny independent of ongoing transcription and in the absence of the conditions that induced that state. We will address which epigenetic mechanisms are important for the propagation of the active state of gene transcription using the newly identified memory genes as candidates. Results from this study are expected to help to understand how epigenetic memory is important in stabilizing cell differentiation in normal development, and in resisting nuclear reprogramming.

Characterization of ABC transporter pattern in human pluripotent stem cells and their differentiated derivatives

Z. Erdei[1], B. Sarkadi[2], L. Homolya[1], T. I. Orbán[1], **Á. Apáti**[1]
[1]*Research Centre for Natural Sciences, Institute of Enzymology, Hungarian Academy of Sciences, Budapest, Hungary,* [2]*Molecular Biophysics Research Group of the Hungarian Academy of Sciences, Semmelweis University and National Blood Service, Budapest, Hungary*

Human pluripotent stem cells are special type of stem cells with a broad differentiation capacity and unlimited cell growth potential. ATP-binding Cassette (ABC) transporters provide chemical defense and stress tolerance in human tissues. The presence of these transporters in human pluripotent stem cells may significantly contribute the stem cell defense mechanisms. Our group previously showed that ABCG2 is functionally expressed in human pluripotent stem cells [1] and this expression is required to tolerate malicious effects resulting from different stress conditions [2]. Recently we have investigated the expression of all ABC genes in human embryonic stem cells (hESCs) and in their differentiated offsprings, such as cardiac, neural and mesenchymal cells. Cellular features regarding pluripotency and tissue identity, as well as ABC transporter expression were studied by flow cytometry, immuno-fluorescence microscopy and qPCR-based low-density arrays. Statistical analysis showed upregulation of pluripotency markers in hESCs, whereas the differentiated offspring showed upregulation of the proper lineage-specific markers. Cluster analysis indicated the upregulation of several ABC transporters in a cell-type specific manner. The cellular localization of the relevant ABC transporters has been established in the pluripotent and differentiated hESC-derived samples by using well-characterized specific antibodies in flow cytometry and in confocal microscopy. The protein and mRNA expression results showed proper correlation in the samples examined. These studies provide valuable information regarding ABC protein expression in human stem cells and in their differentiated progenies. The results may also help to obtain further information concerning the specialized cellular functions of selected ABC transporters.

Characterization of the slowly cycling label-retaining stem cell population in mouse liver

J. Viil, V. Jaks
Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia

Tissue homeostasis in adult organs is typically maintained by undifferentiated stem/progenitor cells with the ability to self-renew and provide more differentiated progeny. In general these tissue specific somatic stem cells (SSCs) are believed to be slowly cycling cells residing in the specific niches. In the liver, however, the normal tissue turnover is achieved by replication of parenchymal cells and the contribution of stem cells in liver maintenance is still under debate. It is currently believed that only when the proliferation ability of hepatocytes or biliary epithelial cells is compromised, e.g. in chronic injury, liver progenitor cells are activated.

Hepatic SSCs are believed to reside in the canals of Hering although the true localization and characteristics of liver SSCs remain unclear. In order to identify slowly cycling label-retaining cell (LRC) population we used transgenic mice expressing 1) reverse tetracycline-dependent transactivator under the control of a ubiquitous promoter, and 2) Histone2B-EGFP fusion (H2B-GFP) controlled by tetracycline response element. By feeding these mice with a tetracycline analogue doxycycline the H2B-GFP expression is induced in all cells. After removing doxycycline from drinking water, dividing cells gradually lose their label whereas quiescent cells retain their GFP label (LRCs).

We performed a time-series experiment to determine the optimal time for the admission of doxycycline, traced the label up to 20 weeks and identified the localization and the repertoire of liver stem cell markers of label-retaining GFP-positive cells under normal conditions. We discovered that slowly cycling liver cells concentrated mainly in the portal areas, particularly in bile ducts, and expressed biliary epithelial cell markers. We also found LRCs among hepatocytes. These parenchymal LRCs, however, were individually scattered throughout the liver and had lower GFP expression. In addition, we investigated the behaviour of

© 2014 The Authors. FEBS Journal © 2014 FEBS

LRCs in chronic injury and looked at the changes in LRC compartment after partial hepatectomy (PHx). We found that proliferation of liver LRCs, indicated by the loss of GFP signal in bile ducts, occurred after induced chronic injury (DDC diet and bile duct ligation). PHx, on the other hand, did not affect the quiescent state of biliary LRC, although we could detect less parenchymal LRCs after liver regeneration. These results suggest that LRCs take part in liver regeneration after cholestatic chronic injury and that only part of parenchymal LRCs contribute to the recovery from liver resection.

Comparative study between the effects of human CD34 + and rat bone marrow mesenchymal stem cells on amelioration of CCL4 induced liver fibrosis

D. Sabry[1], **A. Osama**[2], N. Idriss[2], M. Magdy[3]
[1]Medical Biochemistry and Molecular Biology, Faculty of Medicine, Cairo University, [2]Medical Biochemistry and Molecular Biology, Faculty of Medicine, Asuot University, [3]Pathology, Tuodor Bilharzial, Cairo, Egypt

Human umbilical cord blood (UCB) cells and rat bone marrow mesenchymal stem cells (BM-MSCs) have many advantages as grafts for cell transplantation. Here, we transplanted UCB cells and BM-MSCs into injured liver fibrosis and investigated the reversal of hepatic fibrosis after in vivo transplantation. A CCl4 rat model with liver fibrosis was induced. Human (UCB) CD34+ stem cell was isolated with MACS (magnetic cell sorting). Rat BM-MSCs was isolated, cultured and propagated. Cells were labeled in vitro with green fluorescent protein (GFP). Rats were divided into 4 groups; group (1): control healthy, group (2): CCl4 injected rats, group 3: CCl4/CD34+injected rats with human undifferentiated cells and group 4: CCl4/BM-MSCs injected rats with rat bone marrow undifferentiated cells through intravenous (IV) route. A significant elevation was estimated in serum albumin in CCl4/CD34+ compared to the CCl4 group ($p < 0.001$). Serum ALT had a significant decrease of its level after administration of stem cells (CD34 + or BM-MSCs) compared to the CCl4 group ($p < 0.001$). However, it was still significantly higher than control ($p < 0.001$) with no significant difference between the groups that received different sources of stem cells. Histopathological and immunohistochemical examination of liver tissue showed that stem cells have a significant antifibrotic effect. GFP labeled cells were detected in groups injected with stem cells. Concerning gene expression, the collagen and TGF-β genes were highly expressed in the CCl4 group whereas its expression was significantly decreased after administration of both different sources of stem cells. Albumin, matrix metalloproteinase (MMP2) genes and TNF-α were expressed in liver tissues in the groups that received stem cells. Higher expression was observed in the group that received undifferentiated CD34 + I.V compared to BM-MSCs. Human UCB CD34+ stem cells have antifibotic effect in rats with induced liver fibrosis.

Comparison of autolog versus artificial serum albumin usage in the efficiency of dendritic cell isolation and differentiation

A. M. Yilmaz[1,2], E. M. Altundag[1,2], S. Kocturk[1,3], A. Suha Yalcin[1,2], Y. Taga[1,2]
[1]Genetic and Metabolic Diseases Research and Investigation Center (GEMHAM), [2]Department of Biochemistry, Faculty of Medicine, Marmara University, Istanbul, Turkey, [3]Department of Biochemistry, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey

Dendritic cells (DC) are antigen-presenting cells (APCs) which play a critical role in the regulation of adaptive immune response and potentially represent valuable tools for the therapy of tumors. However there is requirement for a method that provides high yield monocytes which are differentiated into clinical grade dendritic cells. Most of the methods which have been tried for enrichment of the yield have not provided enough quantity and quality of monocytes. We believe that the type of serum used is important to increase the yield cell adherence to the flask in the isolation procedure. For this purpose different types of sera were compared for the efficiency of monocyte adherence. Fetal bovine serum (FBS), human serum albumin (HSA) and autolog serum were compared. Peripheral blood mononuclear cells (PBMCs) were isolated from the blood of healthy donors by standard density gradient centrifugation with Ficoll-Paque and differentiated to immature dendritic cells in the medium which contained different type of serum. PBMCs were seeded in different media which had different amount and type of serum. Serum ratio of the media were: group A 10% FBS+ complemented medium, group B 1% HSA + complemented medium, group C 1% autolog serum+ complemented medium, group D complemented medium without any serum supplement. After the maturation period (7 days), DCs maturation were assessed by determining the characteristic markers of PBMC and DC by a flow cytometric assay. We have also analyzed the cytokine production during maturation time by ELISA.

Our findings demonstrate the important of culture medium role in DC generation from peripheral blood monocytes and will make easy to work out a reproducible method that will be the most appropriate for experimental and clinical applications.

This study was supported by Marmara University Scientific Research Commission (SAG-A-110412-0083).

Aims: Therapy of central nervous system diseases accompanied with neuronal loss is limited. Neurotransplantation has a great potential for future treatments of these diseases. Lurcher (Lc) mutant mouse is a model of olivocerebellar degeneration suffering from complete loss of Purkinje cells and cerebellar ataxia. The aim of the study was to assess morphology and functional effects of three types of cerebellar grafts in Lc mice.
Methods: Adult Lc mutant or healthy wild type (WT) B6CBA mice received embryonic carcinoma stem cell-derived neuropro-

© 2014 The Authors. FEBS Journal © 2014 FEBS

genitors (NPG), suspension of embryonic cerebellar (ECB) cells or solid ECB grafts. All types of grafts were injected into the cerebellum (CB) of host mice. Motor skills were tested using rotarod 2 months after the surgery in graft-treated and control mice. The mice were then sacrificed and their brains were examined for presence and morphology of the grafts. Presence of donor–derived Purkinje cells and density of astrocytes in the grafts and their surrounding was assessed using immunohistochemistry.

Results: In Lc mice, the NPG graft did not survive. On the other hand, the NPG graft survived well in WT mice and cerebellar cell suspension and solid grafts survived in most WT as well as Lc mice with similar survival rate. While in WT mice the grafts were always localized inside the CB, in Lc cerebellar location of the graft was rare. The grafts were rather in the mesencephalon. If the grafted tissue was in contact with the Lc CB, no signs of integration were observed. Donor-derived Purkinje cells were found only after transplantation of ECB tissue either in the form of cell suspension or a solid graft. All types of grafts contained numerous astrocytes of both host and donor origin. In none of the graft types improvement of motor performance was seen.

Conclusions: Lc mutant CB seems to provide less permissive milieu for grafts of all types than the healthy tissue. ECB cell suspension grafts showed the most promising appearance compared with the other two types of grafts in WT mice. Nevertheless, in Lc insufficient integration into the host CB developed and improvement of signs of the ataxia was not observed.

[1]Neurobiology, IBG RAS, APTO-PHARM, [2]Neurobiology, IBG RAS, [3]Oncology, Blokhin National Oncological Research Center, Moscow, Russian Federation

A complete human GDNF has both pre-pro regions and mature GDNF. Several versions of modified GDNF have been created to study a role of 'pro' region during factor secretion from the cell as well as an ability of factor to stimulate neural cell differentiation. All versions of GDNF were cloned into HEK293 cells, and stable transgenic cell lines were maintained. After culturing the cells harboring modified GDNF, the condition media was added into culture of rat embrional spinal ganglion explant and growth of neural sprouts were analyzed. Deletion of 'pro' region essentially enhances modified GDNF effects as neural inductor.

GDNF therapy is effective against disorders associated with degeneration of dopaminergic neurons such as Parkinson's disease. This treatment not only increases the dopaminergic synaptic neurotransmission in the corpus striatum but also decelerates the degenerative processes in the nigrostriatal projections. We obtained a modified GDNF (mGDNF) to stimulate neural differentiation of progenitor cells. The effect of the transgenic products on growth of sprouts was studied in the spinal ganglia of 14 day rat embryos. Media conditioned by the transgenic cells were used to culture spinal ganglia attached to the bottom of the plate. Spinal ganglia cultured in a medium, supplemented with conditioned media containing mGDNF, demonstrated active growth of sprouts which are immunopositive for neuronal marker, beta-3-tubulin. Therefore modified GDNF is a potent stimulator of neural differentiation. Using mouse model of ischemic stroke induced by endothelin-1, it was shown that the transgenic cells harboring mGDNF actively migrate from the injection zone towards the thrombosed vessel. Using the neurotoxin MPTP we got the model of Parkinson's disease. It was found that in a mouse model of Parkinson's, motor effects significantly restored by transplantation of transgenic cells producing mGDNF. Immunohistochemical staining of brain sections showed that transplantation of transgenic cells harboring mGDNF greatly increases number of tyrosine hydroxylase immunopositive cells in the substantia nigra in animal models of Parkinson's disease.

GDNF can be modified to be applied for the therapy of neurodegenerative diseases and ischemia. Res. is supported by Grants RFBR, MCB

Differentiation of human induced pluripotent and mesenchymal stem cells on a 3D scaffold for Anterior Cruciate Ligament regeneration

A. Kyrkou[1], D. Kouroupis[1,†], E. Triantafyllidi[2], M. Katsiboulas[3,4], D. Stellas[5], G. Chalepakis[6], M. Syrrou[7], A. Klinakis[5], A. Georgoulis[2], C. Murphy[1,†], T. Fotsis[1,8,†]

[1]Division of Biomedical Research, Foundation of Research and Technology- Hellas, Institute of Molecular Biology & Biotechnology, [2]Department of Orthopaedic Surgery, Orthopaedic Sports Medicine Center, Ioannina, [3]Center for Experimental Surgery, Biomedical Research Foundation of the Academy of Athens, [4]Attikon Animal Hospital, [5]Center for Basic Research, Biomedical Research Foundation of the Academy of Athens, Athens, [6]Department of Biology, Electron Microscopy Laboratory, University of Crete, Crete, [7]Laboratory of Biology, Medical School, University of Ioannina, [8]Laboratory of Biological Chemistry-Medical School, University of Ioannina, Ioannina, Greece

In vitro manipulation of pluripotent stem cells, either derived from the early blastocyst or generated upon reprogramming of differentiated cells towards induced pluripotency (iPS), opened the possibility for the development of new reparative and therapeutic approaches. Damaged tissues can be also be regenerated using adult stem cells, which demonstrate a more restricted differentiation and proliferation potency, however, human mesenchymal stem cells (MSC) are considered good candidates for the study and treatment of injuries related to musculoskeletal tissues. Herein, we report an easy and efficient protocol for differentiation of human iPS cells towards the MSC lineage (hiPS-MSC) and further differentiation of hiPS-MSC and MSC for the formation of a 3D structure mimicking the Anterior Cruciate Ligament (ACL). Simultaneous differentiation towards two lineages (osseous and fibrous) of mesenchymal cell types, on a Leeds-Keio 3D scaffold, leads to the formation of a functional ACL structure in vivo. 3D platforms are the milestone for regenerative technology of complex organs and common behavior of hiPS derived cells and MSC in this system confirms the reliability and further development of such approaches to the medical industry.

Keywords: hiPS, MSC, ligament.

Dysfunctional mitochondrial fission impairs cell reprogramming

J. Prieto, M. León, J. Torres
Cell Biology and Parasitology, University of Valencia, Burjassot, Spain

We have investigated the role of mitochondrial dynamics in cell reprogramming. Mitochondrial fission is observed at day 4 after retroviral expression of reprogramming factors in Mouse Embryonic Fibroblasts (MEFs). By day 8, most of the epithelial-like cells undergoing reprogramming displayed fragmented mitochondria. In MEFs lacking expression of the fission factor Gdap1 reprograming-induced mitochondrial fragmentation and mesenchymal to epithelial transition were reduced, and the efficiency of reprogramming was strongly decreased. In the Gdap1-/- MEFs, mitophagy was not activated and mitochondrial mass increased during reprogramming. Finally, Gdap1-/- MEFs showed a 3-fold increase in the percentage of cells in the G2/M cell cycle phase when compared to wild-type controls. We propose that dysfunctional mitochondrial fission impairs reprogramming by interfering with cell cycle progression.

Keywords: cell reprogramming, mitochondrial dynamics.

Effects of OCT4, SOX2 and NANOG expression on imatinib resistance in CML

Y. Hekmatshoar[1], T. Ozkan[1,2], B. Altinok Zaim[2,3], A. Karadag[1], A. Sunguroglu[1]
[1]Medical Biology, [2]Biotechnology Institute, [3]Vocational School of Health, Ankara University, Ankara, Turkey

Overview: Oct4 and Nanog are homebox transcription factors essential to the self-renewal of stem cells and are expressed in several cancers, the role of OCT4/NANOG signaling in tumorigenesis is still elusive.

Infinitely self-renewing cells could conceivably account for the immortal nature of tumor cells at the population level, and accumulating evidence supports the notion that ESC self-renewal and pluripotency genes, including the transcription factor triad OCT4, SOX2 and NANOG, serve as neoplastic engines driving oncogenesis. Chronic myeloid leukemia (CML) is a clonal disorder of the pluripotent hemopoietic stem cell, in which a reciprocal translocation t(9;22)(q34;q11) forms a Philadelphia(Ph) chromosome and creates a novel fusion gene, bcr–abl. Imatinib mesylate is one of the most widely used drugs for CML. Imatinib resistance, occurring in nearly 33% of patients, has been associated with a variety of mechanisms, subclassified as bcr-abl gene expression or mutations in the bcr-abl gene. In the present study we examined mRNA expression levels of genes which have important roles in self-renewal and pluripotency in K562r and K562s cells.

Methods: K562s(sensitive)and K562r(resistance) were grown in RPMI-1640. K562r cells were maintained in RPMI-1640 medium supplemented with 5 μM imatinib. RNA isolation, cDNA synthesis, RT- PCR was performed respectively.

Results: The results showed that NANOG(3.7),OCT4(2.7) and SOX2(4.7) mRNA expression levels in K562r cells was higher than levels in K562s cells.

According to our findings, enhancement of imatinib doses in K562r teratment increase expression level of NANOG,OCT4 and SOX2, so it can be suggested that up-regulation of these genes and CSC are responsible of imatinib resistance

Keywords: Drug resistance, Chronic myeloid leukemia, Imatinib.

Effects of embryonic neural stem cell therapy on DNA damage products in urine and tissue after spinal cord injury in rats

S. Konyalioglu[1], T. Dagci[2], E. Kilinc[3], A. M. Ozgonul[4]
[1]Biochemistry, Pharmacy of Faculty, Ege University, [2]Department of Physology, School of Medicine, [3]Analytical Chemistry, Pharmacy of Faculty, Ege University, [4]Department of Biochemistry, School of Medicine, İzmir, Turkey

We tested the hypothesis that embryonic neural stem cell (ENSC) therapy reduces neuronal DNA damage in the lesional spinal cord region and evaluated the significance of some DNA breakdown products in urine and tissue samples in order to reflect efficiency of the ENSC therapy. DNA damage were measured by using single cell gel electrophoresis (SCGE/Comet Assay) in spinal cord (SC) tissue of rats 7 (acute group) and 28 (chronic group) days after surgical resections of a 10 mm segment of the cord below T8-T9 and sham operations. As biomarkers of DNA damage, urinary 5-(hydroxymethyl) uracil (5HMU) and 2'-deoxyuridine (2dU) were analyzed by high-performance liquid chromatography (HPLC) with electrochemical detection (ED). Comet scores of the lesioned tissues were significantly higher in the acute and chronic spinal cord injury (SCI) compared to the sham operated groups ($p = 0.009$ and $p = 0.009$, respectively). After the ENSC transplantation, tail %, tail length and tail moment (T%, TL and TM) decreased in acute ($p = 0.009$, $p = 0.009$ and $p = 0.009$, respectively) and chronically ($p = 0.009$, $p = 0.009$, $p = 0.009$ respectively) injured rats. 5HMU and 2dU were significantly higher in the acute and the chronic groups than sham operated groups ($p = 0.009$ and $p = 0.009$, respectively). 5HMU concentration in the acute SCI group was found a correlate more strongly with tail moment ($r = 0.9039$, $p = 0.02$). In the chronic injury group, 5HMU and 2dU concentrations were found a correlate strongly with tail length ($r = 0.9990$, $p = 0.001$ and $r = 0.9272$, $p = 0.016$, respectively). While 5HMU seems to be a better biomarker for acute injury, both HMU and 2dU excretions increase in chronic damage.

Keywords: Spinal Cord Injuries; Comet Assay; Chromatography, High Pressure Liquid; 2'-deoxyuridylic acid; 5-hydroxymethyluracil.

Effects of low intensity/very low frequency electromagnetic fields on stem cells proliferation and differentiation

R. Albulescu[1,2], E. Codrici[2], S. Mihai[2], A.-M. Enciu[2], B. Vladila[3], S. Neagoe[4], A. Albulescu[4], C. Tanase[2]
[1]Pharmaceutical Biotechnology, National Institute for Chemical Pharmaceutical R&D, [2]Biochemistry-Proteomics, Victor Babes Natl. Inst. of Pathology, [3]SC Denticare SRL, [4]Biochemistry, Faculty of Biology, Bucharest University, Bucharest, Romania

Background: EMF, at different frequencies and intensities, is used in therapeutical purposes, like teh treatment of chronic inflamamtory diseases, oncology, etc. This study aimed to evaluate the effects of low intensity/low frequency electromagnetic fileds on the proliferation of stem cells and on the differeniation into adipocytic and osteocytic phenotypes, investigating the potential uses of such EMFs in regenerative medicine.

Material and Methods: ADMSC (Adipose Derived Mesenchymal Stem Cells) – ATCC PCS 500-011), were cultivated in Mesenchymal Stem Cells Basal Medium with MSC Growth Kit, according to the suppliers instructions. Cells on pasage 3 were used for monitoring the effect of variants of EMF, by cultivating

© 2014 The Authors. FEBS Journal © 2014 FEBS

in 96 well tissue culture plates overlapped on a devices generating EMF in the external 1–3 and 10–12 rows, while the internal rows (4–9) were not exposed. Using a low seeding rate (2000/well), the cultures were exposed to EMF for 2 hrs daily, for 4 days. On day 5, cell growth ratio was determined by MTT assay.

Cells on pasage 4 were cultivated for differentiation into adipocytes and osteocytes, according to the instructions and using ATCC kits.

The process of growth and of differentiation was investigated by Luminex-xMAP, with a set of Milliplex MAP-mates for total signaling molecules.

Results and Discussion: Exposure to EMF resulted in a statistical significant improvement in mesenchymal stem cell proliferation at one of the four experimental frequencies tested; average 23% stimulation, $p < 0.05$. Other frequencies resulted in lower rates of stimulation or no stimulation.

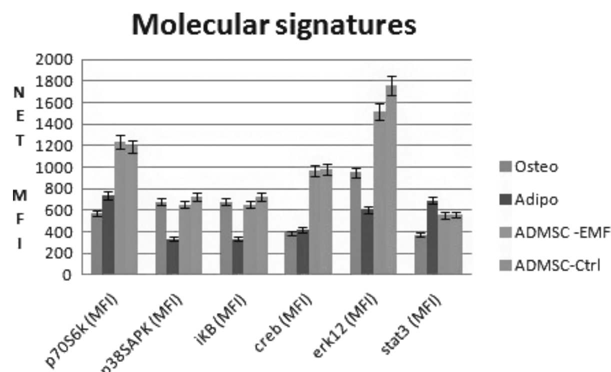

Fig. 1.

The differentiation process, monitored similarly by the MTS assay, showed some stimulatory effects for the same EMF settings, however, lower in intensity and statistical significance. Aparently, the effect is more intense in those cells that undergo more active proliferation than on low growing, differentiating cells.

The xMAP assays revealed a cvasi-constant profile of signaling molecules for the MSCs cultivated in standard conditions and exposed to EMF. The same preservation of profile appeared also for the process of differentiation, however, with particular profiles for each differentiation phenotype (Figure 1)

Certain EMF settings in the very low frequency range can stimulate the proliferation of stem cells, while not affecting the overall signature of signal transduction molecules.

Acknowledgment: The study was supported by Grants POS-CCE Nr. 502/2013 and P-N 09.33-03.10/2009.

SUN-468
Effects of MK2 gene silencing on vitality, proliferation and differentiation of mesenchymal stem cells under hypoxic culture conditions

Z. S. Unal[1], M. Cengiz[2], O. Saglam[1], G. Gacar[1], C. Subasi[1], B. Bayoglu[2], E. Karaöz[1]
[1]Stem Cell, Kocaeli University Center for Stem Cell and Gene Therapies Research and Practise, Kocaeli, [2]Medical Biology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Bone marrow derived mesenchymal stems (BM-MSCs) are expanded in long-term culture with maintained proliferation capacity, differentiation potential, immune-modulating property and have limited tendency to form tumors. BM-MSC are main candidate cellular source in stem cell therapy applications. Cultivation of cells is performed under atmospheric oxygen tension, in recent years, many researchers reported hypoxic conditions have positive effects on stem cell proliferation and differentiation. For this reason, in our study, MAPKAPK2 (MK2; mitogen-activated protein kinase-activated protein kinase 2) gene, which belongs to MAP kinase family member related with proliferation, cellcycle, apoptosis, differentiation and inflamatory response, was silenced permanently with shRNA lentiviral vector. Its effect on proliferation and differentiation were analysed both in 20% (normoxia) and 3% (hypoxia) oxygen levels. The physiological roles of MK2 activation are most clearly revealed by the targeted disruption of theMK2 gene. We investigate the effects of long-term hypoxia (72 h) on cell proliferation and osteogenic differentiation in both oxygen concentrations, and the role of MK2 gene under hypoxic condition was focused. MK2 gene was silenced in rat BM-MSCs by lentiviral shRNA vector permanently. Cells were cultured in two different culture conditions (20% normoxia and 3% hypoxia); western blotting, real-time PCR analysis, proliferation and viability tests, WST-1, Annexin V-7AAD and cell cycle analysis with flow cytometry and immuno-histochemical analyses were performed before and after differentiation. MK2 protein is activated by phosphorylation under hypoxic condition, and shRNA was used for silencing. But this process does not change MK2, it left in inactive form. By silencing MK2 gene in MSCs, the cell proliferation capacity and anti-apoptotic effects were observed to improve cell proliferation capacity. Furthermore, the expression of osteogenic markers decreased in silenced cells before and after osteogenic differentiation compared to normal cells, but the decline is more significant in 3% hypoxic oxygen concentration. By revealing the crucial role of MK2 gene in the proliferation and differentiation of silenced rBM-MSCs cultured under different oxygen concentrations, the importance of this gene and related pathways were demonstrated with their possible mechanisms. This study provides an evidence for the importance of hypoxic conditions in the cell cultures. In future aspects, possible new mechanisms, like MK2 pathway, might be used in pathological processes for cell therapies in ischemic conditions.

Enhancement of angiogenic and cardiomyogenic potential of murine mesenchymal stem cells by MCPIP1 expression

E. Zuba-Surma[1], A. Labedz-Maslowska[1], B. Lipert[2], D. Berdecka[1], S. Kedracka-Krok[3], Z. Madeja[1], J. Jura[2]
[1]Department of Cell Biology, [2]Department of General Biochemistry, [3]Department of Physical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Monocyte chemoattractant protein-induced protein 1 (MCPIP1) has been identified as a silencer of inflammatory response. However, MCPIP1 was also described as new modulator of angiogenesis and adipogenesis. Mesenchymal Stem Cells (MSCs) are multipotent subset of adherent bone marrow (BM) cells and are capable of osteogenic, chondrogenic and myogenic differentiation. In this study, we examined angiogenic and cardiomyogenic potential of MCPIP1- transduced MSCs *in vitro*.

MCPIP1 overexpression was obtained by double retroviral infection of MSCs (passage 3 to 4). We investigated MCPIP1 influence on metabolic activity, cytotoxity, apoptosis and proliferation of MSCs. We also executed the expression of Oct-3/4,

© 2014 The Authors. FEBS Journal © 2014 FEBS

Sox-2, Klf-4 as well as angiogenic potential via capillary tube formation assay. Then, MCPIP1-overexpressing cells were differentiated into endothelium or cardiomyocytes. Expression of differentiation-related genes was analyzed by real-time PCR. Moreover, after 5 and 10 days of angiogenic differentiation, capillary tube formation assay was performed. We measured the level of selected angiogenesis-related proteins secreted by MSCs as well as proteomic analysis of MCPIP1- overexpressing MSCs was performed.

We found that MCPIP1-overexpressing MSCs exhibited elevated angiogenic potential, which was accompanied with change in expression of genes guiding their angiogenic differentiation (Gata-2, Tie-2, vWF, VE-cadherin). These cells in cardiomyocytes differentiation displayed increased level of mRNA for Gata-4, Nkx2.5, Myl-2, Myh-6. Moreover, MCPIP1 did not influence morphology, metabolic condition and apoptosis. Antigenic profile of MCPIP1-overexpressing cells was comparable to control cells. However, MCPIP1 overexpression slightly decreases proliferation of MSCs.

We showed for the first time that MCPIP1 positively modulates conversion of MSCs into endothelium cells and cardiomyocytes. Therefore, MSCs with overexpression of MCPIP1 may be potentially applied in regenerative medicine.

Keywords: MCPIP1, mesenchymal stem cells (MSCs), regeneration.

Enhancing adipose-derived stem cell proliferation and differentiation into β-cells by fibroblast growth factors

Y.-T. Chang[1], H.-Y. Liu[1], Y.-J. Chen[1], C.-W. Huang[1], S.-T. Ding[1,2]

[1]Department of Animal Science and Technology, [2]Center for Biotechnology, National Taiwan University, Taipei, Taiwan

Insulin deficiency resulting from pancreatic β-cell destruction leads to type 1 diabetes which accounts for 5–10% of all cases of diabetes. Due to the developmental plasticity of mesenchymal stem cells (MSC), MSC-based therapeutic intervention has become a promising strategy to replace injured tissues such as islets. However, a major obstacle of applying MSC is required large amounts of MSC for transplantation and significant cell loss after transplantation. To tackle this issue, we seek for adipose-derived stem cells (ADSCs) owing to their ease of isolation, abundant sources and multipotency and would like to further enhance their proliferative ability and differentiation characteristics.

We isolated ADSCs from porcine back fat region of subcutaneous adipose tissues (pADSCs) and showed that these ADSCs expressed the MSC surface markers including CD29, CD44, CD90 and MHC I. These pADSCs also sustained the pluripotency to differentiate into different kinds of cells originated from three distinct germ layers such as adipocytes, chondrocytes and osteocytes. We cultured pADSCs in basal medium supplemented with or without growth factors such as fibroblast growth factor 2 (FGF2) or FGF4 to determine the proliferation by MTT analysis and cell counting. Our results demonstrated that both FGF2 and FGF4 increased the proliferation of pADSCs. In our experiments, FGF2 also induced ERK phosphorylation. Therefore we speculate that FGF2 may work on ERK pathway to promote pADSC proliferation. Furthermore, FGF-supplemented pADSCs could be induced to differentiate into insulin producing cells. Determined by immunofluorescent staining and examined by confocal microscopy, quantitative PCR and ELISA, β-cells markers such as islet-1 and insulin were highly expressed in FGF-supplemented pADSCs. These results indicated that FGF2 increases pADSC proliferation without compromising the β-cell differentiation characteristics of pADSCs.

To conclude, in this study, we determined the optimal culture condition for pADSCs with either FGF2 or FGF4. These preconditioned pADSCs provide a potential strategy to increase pADSC proliferation for transplantation in treating type 1 diabetes or other autoimmune diseases.

Keywords: fibroblast growth factor, proliferation, β-cells.

Epigenetic and genetic profile of human mesenchymal stem cells from adipose and synovial tissue

S. Jarmalaite[1], K. Daniunaite[1], R. Misgirdaite[1], I. Serenaite[1], A. Unguryte[2], E. Bernotiene[2]

[1]Faculty of Natural Sciences, Vilnius University, [2]State Research Institute Center of Innovative Medicine, Vilnius, Lithuania

Adult stem cells have more restricted differentiation potential than embryonic stem cells (ESCs), but upon appropriate stimulation can differentiate into cells from different germ layers. Genetic and epigenetic control of ESCs differentiation is well characterized, while adult stem cells remain poorly explored. For better understanding of molecular pathways involved in mesenchymal stem cell (MSC) differentiation, RNA and miRNA expression was profiled in MSCs from adipose tissue and synovial membrane. DNA methylation and hydroxymethylation marks in stemness genes were analysed in MSCs in comparison to cancer cell lines (T24, MX-1, CX-1).

Genome-wide RNA and miRNA expression profiling was performed on Agilent microarrays. Expression of more than 800 genes and 23 miRNAs were significantly changed during MSCs differentiation into osteogenic lineages in both cell types. Among the known targets of identified miRNAs, 143 genes were also deregulated in our data-set. The main biological processes targeted during cell differentiation were cell signalling, innate immunity and regulation of cell proliferation. Of interest, expression levels of the main pluripotency factors *OCT4*, *SOX2,* and *NANOG* remained unchanged during MSCs differentiation. This result was validated by real-time PCR. Bisulphite-based DNA methylation analysis of the pluripotency-associated loci showed partial methylation of *OCT4* and *NANOG* promoters in MSCs, while the promoter of *SOX2* was rarely methylated. More specific analysis of DNA modifications in MSCs, revealed an accumulation of 5-hydroxymethylcytozine (5hmC) in parallel with 5-methylcytosine (5mC) in the pluripotency-associated loci, with the most abundant levels detected in regulatory regions of *OCT4* and *NANOG*. However, no significant changes in 5hmC levels were observed during MSCs differentiation. DNA modification profile of the same loci was quite different in cancer cell lines. Promoters of the pluripotency genes contained more 5mC marks and reduced levels of 5hmC. Expression of the TET1 enzyme was also decreased in cancer cell lines in comparison to MSCs. In summary, the data of our study shows that the plasticity of MSCs is regulated by an interplay between genetic and epigenetic factors also involved in regulation of pluripotency of ESCs.

Keywords: 5-hydroxymethylcytosine, DNA methylation, mesenchymal stem cells (MSCs).

Exosomes from dental pulp stem cells suppress 6-hydroxy-dopamine-induced apoptosis in human dopaminergic neurons

A. Pivoriunas, A. Jarmalaviciute, V. Tunaitis, A. Venalis
Stem Cell Biology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania

Recent findings demonstrated the importance of paracrine mechanisms in the therapeutic action of human mesenchymal stromal cells (MSCs). It must be noted, however, that MSCs isolated from different tissues are not equivalent in their therapeutic potential and display tissue-specific differentiation capacity. Several studies demonstrated that in contrast to the MSCs derived from other tissues, MSC-like cells isolated from dental pulp (also known, as stem cells derived from the dental pulp of human exfoliated deciduous teeth, SHEDs) have unique neurogenic properties which could be potentially exploited for therapeutic use.

In the present study we investigated neuroprotective effects of exosomes derived from SHEDs on human dopaminergic neurons during oxidative stress induced by 6-hydroxy-dopamine (6-OHDA). For this purpose, ReNcell VM human neural stem cells (Millipore) were differentiated into dopaminergic neurons and treated with 100 μM 6-OHDA alone, or in combination with exosomes purified by ultracentrifugation from SHEDs cultivated under two conditions: standart two-dimensional culture flasks, or from SHEDs grown on the laminin-coated microcarriers in bioreactor (BioLevitator, Hamilton). Real-time monitoring of apoptosis was performed using Leica SP8 (Leica Microsystems) confocal microscope and CellEvent™ Caspase-3/7 green detection reagent (Life technologies). We found that exosomes derived from SHEDs grown on the laminin-coated three-dimensional alginate microcarriers significantly postponed 6-OHDA-induced apoptosis in dopaminergic neurons. Strikingly, no such effects were observed for the exosomes derived from SHEDs grown under standart culture conditions.

Our results demonstrate that exosomes derived from SHEDs are potential new therapeutic tools against Parkinson's Disease.

Keywords: dental pulp, exosomes, Stem cells, neuroprotective strategies.

Expression of cancer-testis antigens of Mage family in mouse pluripotent stem and teratocarcinoma cells

O. Gordeeva
Institute of Developmental Biology, Russian Academy of Sciences, Moscow, Russian Federation

Embryonic stem (ESCs) and embryonic germ cells (EGCs) are pluripotent while embryonic teratocarcinoma cells (ECCs) are their malignant counterparts. Despite similar growth rate of ESCs, EGCs and ECCs, their differentiation and developmental potentials are significantly different. Moreover, different ECC lines show variable differentiation and tumorigenic potentials. Previously it was demonstrated that cancer-testis antigens (CTA) may be involved in lineage determination in course of differentiation of mouse and human embryonic stem cells. CTAs have specific expression pattern in cancer and normal adult somatic and germ cells, as well as in different embryonic cells. Therefore, changes in CTA profiles may be considered as marker for transformed and abnormally differentiated cells.

In order to understand a role of CTAs in the differentiation of normal and cancer cells the gene expression profiles of Mage-a and Mage-b families were studied in undifferentiated and differentiating upon retinoic acid stimulation mouse ESCs, EGCs and ECCs. Quantitative real time PCR analysis of Mage-a2, Mage-a4, Mage-a6, Mage-a8 and Mage-b1, Mage-b3, Mage-b4, Mage-b5 expression identified similar expression patterns in ESCs, EGCs and ECCs. However, the expression levels of Mage-a2 and Mage-a6 were significantly higher in the undifferentiated nullipotent ECC F9 than in pluripotent stem cells and ECC P19, which are capable to differentiate. On the other hand, expression patterns of all genes studied were almost identical in the ESCs, EGCs and both ECC lines differentiating after retinoic acid exposure. Positive correlations of gene expression levels of Mage-a4 and C-myc were also found for all cells studied. In general, undifferentiated and differentiating ESCs, EGCs and ECCs express higher level of Mage-a family genes than the Mage-b. Based on these data we suggest that Mage-a2 and Mage-a6 expressed at higher levels in nullipotent teratocarcinoma cells may be considered as markers for malignant pluripotent cells with abnormal differentiation potentaial.

Keywords: pluripotent stem cells, cancer, oncogenes, differentiation.

Generation and characterization of neuralized mesenchymal stem cells from multiple sclerosis patients

I. Kassis
Hadassah-Hebrew University Medical Center, Jerusalem, Israel

Background: Lot of preclinical studies showed the theraputic potential of MSC in MS. Moreover, few clinical stuies showed positive results with the use of MSC in MS. The mechanisim of action of MSC in the disease model are mainly via immunomodulation and neuroprotection. The possibility of tissue repair with the use of MSC is very debatatble and seems to be not a major mechanisim in the action of disease amelioration. Therefore, the employment of neuroprecursors derived from MSC (MSC-NPs) instead of naïve MSC can be useful also in terms of neuro-regeneration and remyelination (while keeping the immunomodulatory properties) similar to potential of neural stem cells without ethical hurdles that neural stem cells have in clinical applications.
Methods: MSC were isolated from the BM of five MS patients. The MSC were cultured in a medium contatining EGF, bFGF and B27 supplement to generate MSC-NPs. The MSC-NPs were characterized using FACS. The neural differentaion of MSC-NPs by culturing with neural differentiation commercial media (NeuroCult™ NS-A). The immunomdualtory effects of MSC-NPs were tested with lymphocytes suppression assay in vitro.
Results: We were able to generate MSC-NPs successfully from 5 donors. The spheres stained positively for the neurosphere markers Nestin and PS-Ncam (>90%) while loosing the mesenchymal markers CD90 and CD105 (<5%). As well the MSC-NPs lost their ability to differentiate in mesodermal tissues (adipocytes and osteocytes). MSC-NPs differentiated successfully to neurons (MAP2 marker), astrocytes (GFAP marker) and oligodendrocytes (CNPase marker). Morevover, MSC-NPs induced dose-dependent suppression of lymphocytes.
Conclusions: The generation of MSC-NPs (which hold the neural differentiation potential of neural stem cell) from naïve MSC isolated while keeping there immunomodulatory properties open for us new possibilities for neuroregeneration and remyelination in future autologous cell-therapy treatments for multiple sclerosis.

hASCs exhibit chondrogenic potential of differentiation inside collagen-sericin hydrogels improved with hyaluronic acid and chondroitin sulfate designed for cartilage reconstruction

S. Dinescu[1], M. Albu[2], B. Galateanu[1], E. Radu[3], A. Hermenean[4], M. Costache[1]
[1]Department of Biochemistry and Molecular Biology, University of Bucharest, [2]Collagen Department, Leather and Footwear Research Institute, [3]Molimagex, University Hospital Bucharest, Bucharest, [4]Institute of Life Sciences, Vasile Goldis Western University of Arad, Arad, Romania

Aim: The aim of this study was to investigate human adipose derived stem cells (hASCs) chondrogenic potential in contact with novel 3D collagen hydrogels improved with sericin, hyaluronic acid and chondroitin sulfate (CollSSHACS), which were designed for cartilage tissue engineering (CTE). hASCs biological activity in contact with CollSSHACS was permanently compared to hASCs behavior in contact with a control hydrogel of pure collagen (Coll).
Materials and Methods: 3D cell-scaffold culture was achieved, exposed to chondrogenic induction cocktail for 28 days and the *in vitro* differentiation process was monitored at 7, 14 and 28 days post-induction. Cell distribution and scaffold structure before and during differentiation were analyzed by scanning electron microscopy (SEM). Actin filaments visualized by confocal microscopy revealed cell cytoskeleton architecture in contact with biomaterials. Safranin-O and Alcian Blue histological stainings were performed to monitor the chondrogenic differentiation process. Chondrogenic markers SRY (sex determining region Y)-box 9 (Sox9) and cartilage oligomeric matrix protein (COMP) gene expression was assessed via qPCR, while the protein levels of the same markers were qualitatively evaluated by confocal microscopy.
Results: SEM confirmed that hASCs populated the pores of the hydrogels and adhered to the CollSSHACS better than to control Coll, probably due to the sticky properties of sericin protein. Safranin-O and Alcian Blue stainings revealed matrix accumulation around cells during differentiation starting from 14 days. Sox9 was found to be upregulated starting with 7 days post induction in CollSSHACS as compared to control, where these markers were expressed later. Extracellular matrix marker COMP displayed an increasing profile of gene and protein expression from 14 to 28 days post osteogenic induction, with higher levels registered in cells cultivated in CollSSHACS than in cells embedded in Coll.
Conclusion: hASCs/CollSSHACS could be an appropriate 3D bioconstruct for CTE, considering its good biocompatibility and ability to support hASCs chondrogenic differentiation.
Acknowledgments: These studies were supported by research project funds PCCE248/2010 and ESF for Human Resources Development POSDRU/159/1.5/S/133391.
Keywords: cartilage tissue engineering, chondrogenic differentiation, human adipose derived stem cells.

Hippocalcin promotes neuronal differentiation and inhibits gliogenesis through the activation of PLD1 in rat neural stem cells

S.-Y. Park, S. N. Yoon, Y. Y. Lee, M. J. Kang, S.-Y. Lee, J.-S. Han
Biohemistry, Biomedical Research Institute, Hanyang University, Seoul, Korea

The purpose of this study is to investigate how hippocalcin induces neuronal differentiation in rat neural stem cells (rNSCs). When hippocalcin was overexpressed in rNSCs, Tuj1 was increased, and GFAP was decreased. This result implies that hippocalcin facilitates neuronal differentiation while it suppresses astrocyte differentiation in rNSCs. We found that hippocalcin binds to PKCα, and down regulation of hippocalcin inhibited phosphorylation of PKCα (Thr 638/642). Interestingly, overexpression of hippocalcin promotes dephosphorylation of STAT3 (Y705). Furthermore, we elucidated that SHP-1, a tyrosine phosphatase, is located at upstream of STAT3. To find out molecular mechanism of PKCα on activation of SHP-1, we focused on phospholipase D1 (PLD1) which is activated by PKC. Down regulation of PLD1 decreased SHP-1 activation and consequently blocked dephosphorylation of STAT3 (Y705) resulting in neuronal differentiation. These results suggest that hippocalcin promotes neuronal differentiation of rNSCs through the activation of PLD1 by PKCα during differentiation, and followed by SHP-1 which dephosphorylates STAT3 (Y705). >

Identification and characterization of murine dermal precursor cells with myogenic potential

P. Garcia-Parra[1], N. Naldaiz-Gastesi[1], M. Goicoechea[2], S. Alonso-Martín[3], A. Aiastui[2], M. López-Mayorga[4], P. García-Belda[5], J. Lacalle[6], V. Le Berre[7], A. Matheu[8], J. M. García-Verdugo[5], J. Carvajal[4], F. Relaix[3], A. L. de Munain[2], A. Izeta[9]

We have recently shown that bona fide, pulsating skeletal muscle myofibres may be generated from dermis-derived cells through recreation of 3D myogenic niche (Garcia-Parra et al., 2014). Interestingly, and after one month culture engineered muscle constructs showed progressive degradation of the myofibres concomitant with fatty infiltration, paralleling the natural course of muscular degeneration. However a critical point to translate these results to humans is to determine the origin and identity of myogenic precursor cells enriched within murine dermal cultures. Knowing that dermal and muscle cells share a common embryonic origin at the dermomyotomal stage, and taking into account that there might be different types of cells within adult skin presenting myogenic potential, our main objective was to identify and characterize the origin and identity of myogenic cells present in dermal cultures. To this end, we tested as working hypotheses the enrichment of (i) satellite cells from the dermal *Panniculus carnosus* (PC) muscle, (ii) dermomyotome-derived adult stem/precursor cells, (iii) perivascular cells, and (iv) neural crest-derived precursor cells. In order to trace the origin and identity of dermal myogenic cells, we took advantage of the following transgenic mice to perform lineage tracing experiments: (i) Pax3-GFP and $Pax7^{CE}$ (tracers of PC-derived satellite cells); (ii) Myf5-Cre (dermomyotome), (iii) Cspg4-Cre (perivascular and glial marker), and (iv) Sox10-Cre (neural crest). Cell tracing combined with FACS-based isolation and myogenic differentiation assays showed a major contribution of

In vitro generation of endothelial progenitor cells differentiated from mouse induced pluripotent stem cells

M. Dastouri[1], A. Karadag[2], D. Balci[1], G. Çubukçuoğlu Deniz[1], S. Durdu[3], A. Can[4], A. R. Akar[3,5]
[1]Biotechnology Institute, Ankara University, [2]Department Medical Biology, School of Medicine, Ankara University, [3]Department of Cardiovascular Surgery, Heart Center, School of Medicine, Ankara University, [4]Departement of Histology-Embryology, Ankara University, [5]Stem Cell Institute, Ankara University, Ankara, Turkey

Autologous iPS cells after reprogrammed into endothelial progenitor cell (EPC) may offer several advantages in the treatment of cardiovascular disorders because of their cardiogenic and vasculogenic differentiation potential. To reach that purpose, we reprogrammed and then characterized mouse iPS cells into Flk-1^{+} cells. Further maturation of EPC was characterized by the expression of CD31 and CD133. We analyzed Flk-1 gene and protein expression levels with qRT-PCR and immunocytochemical methods on each days between 2.5 and 7.5. Flk-1 expressing cells were selected by magnetic activated cell sorting (MACS) at day 5. Purified Flk-1^{+} cells were cultured in differentiation medium with 2.6 nM human $VEGF_{165}$ to induce EPC formation. On day 2 following induction, CD31 and CD133 gene expression were analyzed with qRT-PCR and immunocytochemical methods.. In the second step, CD31 and CD133 positive cells were generated and enriched during day 2–3 of induction. We concluded that optimal time for harvesting Flk-1^{+} cells on by MACS was is day 5 of initial differentiation. Following isolation of Flk-1^{+} progenitor cells they were further matured into CD31^{+}/CD133^{+} cells within 2–3 days of induction. In conclusion, we showed that early EPC cells could be successfully derived from mouse fibroblast-driven iPS cells. We suggest that those iPS cell-derived EPC cells may be used in the treatment of heart failure, ischemic heart disease, and critical limb ischemia by remodeling the blood vessels and could be considered for an in vivo model for the translational research.

In vivo modelling of TSC1 SEGAs for intraventricular mTOR inhibitors administration

A. Magini[1,2], A. Polchi[1], E. Tinelli[1], B. Tancini[1], M. Di Cristina[1], D. Dolcetta[1], C. Emiliani[1]
[1]Department of Chemistry, Biology and Biotechnology, University of Perugia, Perugia, [2]Department of Medical and Biological Sciences, University of Udine, Udine, Italy

Tuberous sclerosis (TS) is an autosomal dominant genetic disorder caused by mutations of either TSC1 gene, encoding for the protein hamartin, or TSC2 gene with the consequent constitutive activation of the mammalian target of rapamycin complex 1 (mTORC1) [1]. This results in the loss of control of cell proliferation and differentiation and, thus, the onset of several benign tumors, called hamartomas, on various organs [1]. An important pathological characteristic of TS is the presence of subependymal giant cell astrocytomas (SEGAs) in the brain that is the main cause of patients' death [2]. The standard therapy for SEGAs, represented by the surgical resection, may cause several complications during and post surgical intervention [1,2]. At present, the best approach to overcome surgical intervention is to orally administer mTOR inhibitors (mTOR-Is) [1–3]. However, this strategy is hindered by the immunosuppressive properties of mTOR-Is. This side effect can be overcome by establishing intraventricular administration of mTOR-Is [4]. The limiting factor for developing this TS treatment is the lack of suitable cellular or animal models.

We first tried to produce a TS cell line to be used as *in vitro* SEGAs model. We isolated neural stem cells (mNSCs) from brain of *Tsc1^{tm1Djk}*/J mouse that carries a "flox box" within TSC1 gene. Successively, we deleted a portion of this gene by transient transfection of mNSC cells with a GFP. Cre plasmid to express Cre recombinase. Neurospheres were screened by genomic PCR to identify clones displaying loss of the flox box. Immunoblotting analysis confirmed that hamartin protein was not expressed in selected clones. The resulting TSC1^{-}/$^{-}$ mNSCs showed mTOR pathway activation, as attested by immunoblotting analysis of phospho p70S6K (T389) and 4E-BP1 (T 36/47). They are stably self-renewing in typical neurospheres and are nestin-positive, as assessed by IF staining. We are currently performing experiments to assess

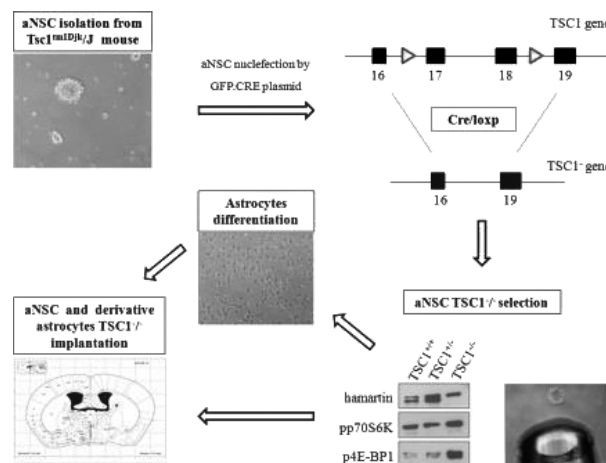

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

if mTOR-Is treatment gives rise to a restored mTOR pathway, and its implication on proliferation rate.

TSC1^{-}/$^{-}$ mNSCs or derivative astrocytes have been implanted in the brain parenchyma of syngenic *Tsc1*^{tm1Djk}/J mouse by using stereotaxic surgery and *in vivo* SEGAs generation will be assessed by MRI.

Irisin modifies the differentiation program of subcutaneous human white adipocytes and induces "browning"

E. K. Kristof[1], D. X. Minh[2], P. Bai[3], Z. Bacsó[2], L. Fésüs[1], Stem Cells, Apoptosis and Genomics Research Group of the Hungarian Academy of Sciences
[1]*Department of Biochemistry and Molecular Biology,* [2]*Department of Biophysics and Cell Biology,* [3]*Department of Medical Chemistry, University of Debrecen, Debrecen, Hungary*

Although brown adipose tissue (BAT) can be found only in small amounts in the human body after infancy, recent studies revealed that it has a major importance in regulating the energy balance of the entire body. Its oxidative metabolism contributes to energy expenditure during cold exposure and diet or physical exercise induced thermogenesis by triggering the differentiation of "brown adipocyte-like" or "beige" cells interspersed in subcutaneous white adipose tissue depots in a process called "browning". A very strong negative correlation has been found between obesity and BAT amount in humans. Targeting the currently known and unknown regulatory systems of "browning" might open up better strategies to specifically stimulate BAT in obese individuals to aid weight reduction.

Irisin is a recently identified peptide hormone which is cleaved from the Fndc5 transmembrane protein and induces a "browning" program in subcutaneous white adipose tissue in mouse models. In humans, however, an escalating debate revolves around the secretion and metabolic effects of irisin. Our aim was to clarify whether human recombinant irsin was able to induce a browning program on differentiating human adipocytes.

Human primary preadipocytes obtained from herniotomy were differentiated into white or brown adipocytes with or without long or short-term irisin treatment. Expression of white, brown and general adipocyte markers were determined by RT Q-PCR, immunoblotting or immunocytochemistry and changes in morphology (size and number of lipid droplets, expression of Ucp1 and Cidea *in situ*) were visualized and quantified by Laser Scanning Cytometry. Functional analysis was carried out using a Seahorse Bioscience XF-96 Analyzer.

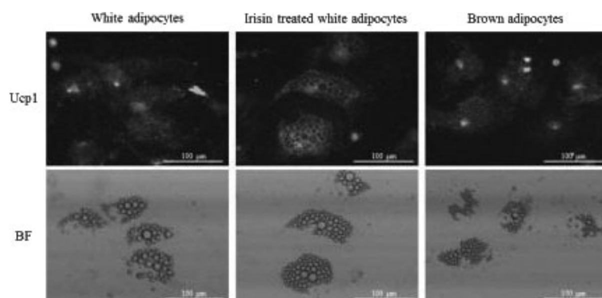

Fig. 1.

Irisin administration during white adipogenic differentiation resulted in a significant overexpression of several brown adipocyte marker genes (UCP1, ELOVL3, CIDEA, CYC1, PGC1A). Irisin treated cells had more and smaller lipid droplets, more mitochondrial DNA, higher functional mitochondrial respiration and expressed more Ucp1 and Cidea *in situ* than the *in vitro* differentiated white adipocytes. We conclude that irisin treatment is able to induce a browning program in differentiating human subcutaneous white adipocytes in culture conditions.

microRNA-9 maintains adult neural stem cells in a quiescent state

S. Katz, D. Cussigh, L. Bally-Cuif, M. Coolen
Neurobiology and Development laboratory UPR3294 Zebrafish Neurogenetics group, CNRS, Gif sur Yvette, France

Adult neurogenesis is the generation of new neurons from neural stem cells (NSCs) present in the adult brain. Fundamentally, this process is a balance between maintaining a quiescent NSC pool and recruiting them into the neurogenesis cascade. Using the adult zebrafish telencephalon as a model, we aim at deciphering the molecular mechanisms governing this balance. We place special focus on microRNA-9 (miR-9), which we previously showed to control the transition between commitment states in embryonic neural progenitors. Our recent work demonstrates that miR-9 is expressed and fluctuates over time in quiescent NSCs of the adult zebrafish telencephalon. Moreover, abrogation of miR-9 function *in vivo* leads to a significant increase in actively dividing NSCs, indicating that miR-9 is necessary for maintaining NSC quiescence. Previous work from our laboratory demonstrated that active Notch signaling maintains NSC in a quiescent state. We further show that miR-9 and Notch signals belong to the same regulatory cascade. Lastly, we have observed that miR-9 expression in the quiescent NSCs is highly concentrated in the nucleus. We also detected nuclear localization of Argonaute2 (Ago2), the effector protein of microRNAs. These data raise the intriguing possibility of a non-canonical mechanism of miR-9 action in quiescent NSCs, which we are currently investigating by modulating the subcellular localization of Ago2.

MicroRNA-mediated mechanism for direct conversion of dental pulp cells to endocrine lineage cells

T. Nozaki, K. Ohura
Department of Pharmacology, Osaka Dental University, Osaka, Japan

To further evaluate the multipotency of dental pulp cells, and to investigate the possible direct reprogramming of these cells, we

© 2014 The Authors. FEBS Journal © 2014 FEBS

examined their *in vitro* induction of direct conversion to an endocrine cell lineage. *In vitro* induction was carried out using similar conditions to those reported for regulating the differentiation of undifferentiated intestinal cells into endocrine progenitor cells. Specifically, the transcription factors *Pdx1* and *Neurog3* were transfected into rat dental pulp cells to induce their direct conversion to endocrine lineage cells. The degree of induction was evaluated by detecting insulin-producing cells. Using microRNA arrays, the microRNA expression profiles were comprehensively analyzed. At 10 days after induction, insulin-producing cells were detected. Specifically, at 10 days after induction, the expression levels of *Ins1* and *Ins2* were each increased by about 7-fold compared with their levels before induction. Based on the expression profiles, eight microRNA probes showing significant differences at 10 days after induction compared with their pre-induction baseline values were extracted after filtering. Notably, miR-183 was downregulated by less than 40% after induction. Following a target scan of miR-183, we identified 242 conserved targets, including molecules crucial for the development of pancreatic beta-cells such as Forkhead box O1 (*Foxo1*). *Foxo1* was upregulated by more than two-fold after induction. These findings indicate that dental pulp cells have potential for direct reprogramming to insulin-producing cells. This potential ability for the direct reprogramming of dental pulp cells shows promise for clinical applications.

Keywords: dental pulp, direct conversion, multipotency.

miR-140-5p suppresses BMP2-mediated osteogenesis in undifferentiated human mesenchymal stem cells

N. Suh, S. Hwang, S.-K. Park
Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea

Human mesenchymal stem cells (hMSCs) have self-renewal and differentiation capabilities but the regulatory mechanisms of MSC fate determination remain poorly understood. Here, we aimed to identify microRNAs enriched in hMSCs that modulate differentiation commitments. Microarray analysis revealed that miR-140-5p is commonly enriched in undifferentiated hMSCs from various tissue sources. Moreover, bioinformatic analysis and luciferase reporter assay validated that miR-140-5p directly represses bone morphogenic protein 2 (BMP2). Furthermore, blocking miR-140-5p in hMSCs increased the expression of BMP signaling components and critical regulators of osteogenic differentiation. We propose that miR-140-5p functionally inhibits osteogenic lineage commitment in undifferentiated hMSCs.

Keywords: bone morphogenic protein 2, human mesenchymal stem cells, miR-140-5p.

Molecular and histological analysis of osteoblast induced by novel collagen helix fibrils

S. Kunii[1], E. Yamamoto[1], Y. Horiuchi[2], H. Ito[1], Y. Hiraoka[3], K. Morimoto[1]
[1]Biology-Oriented Science and Technology, Kindai University, Kinokawa, [2]Life Science Institute, Kindai University, Osakasayama, [3]Nitta-gelatin Inc., Yao, Japan

Background: Osteoblasts are distinguished by the characteristic morphology and by the deposition of the mineralized matrix. Another characteristic is the synthesis of type I collagen and other specialized bone proteins. In particular, collagen that is the principal component of matrix provides the deposition of mineral with a template. Since collagen has biocompatibility with bone, collagen is a poor bone graft material when used alone. Probably, collagen is an inactive biomaterial against osteoblast. Therefore, much attention has been directed to find the biomaterial that induces osteogenic progenitor cells. However, best material still remains to be developed. It is essential to clarify the molecular mechanism of osteogenesis and understand how it induces. We have developed a novel collagen type I (N-Col) with enzyme treatment. Interestingly, N-Col has ability in spheroid formation. In this study, we report that N-Col markedly facilitated osteogenic differentiation of mouse osteogenic cells (MC3T3-E1) and Sprague-Dawley (SD) rat mesenchymal stem cells (rMSC). Furthermore, we investigated bone wound healing effects of N-Col graft by in vivo experiments.

Methods: Collagen was treated with an enzyme X, and we obtained a cleaved collagen preparation (N-Col) (patent pending). Culture dish was coated with N-Col or pepsin-treated collagen (Pep-Col). Subsequently, MC3T3-E1 cells or rMSC cells were cultured on each coated-dish with osteogenic basal medium. We observed cell morphology by using a phase-contrast microscope for a period of 20 days. To evaluate the osteogenic differentiation, we investigated the mineralization by Alizarin red S reagent. Furthermore, we transplanted each collagen material into 2.5 mm critical-sized defects (CSDs) of SD rat shinbone. After 15 days, the bone repair efficiency of CSDs in rat was evaluated by the histological observation of shinbone horizontal section with HE staining.

Results: MC3T3-E1 cells formed the spheroid-like morphology by only culturing on the dish coated with N-Col. Adhesion to N-Col significantly promoted the activity of mineralization and alkaline phosphatase of MC3T3-E1. The results of rMSC were the same as those of MC3T3-E1. In our experiments, we showed that N-Col graft induces bone regeneration of rat shinbone and is more bioabsorbable material than Pep-Col. The precise mechanism of osteogenic differentiation with N-Col culture system is not yet fully understood. However, Our results demonstrated that N-Col has remarkable effects in bone wound healing.

Nanoscaffolds with immobilized bio-factors enhance the induction of stem cell differentiation into chondrocytes

E. Papachristou[1], T. Kodjapashi[2], P. Kavatzikidou[2], E. Georgaraki[2], S. Petrakis[3], E. Pavlidou[2], K. Kouzi-Koliakou[3], V. Karagkiozaki[2], S. Logothetidis[2], **T. Choli Papadopoulou**[1]
[1]Chemistry, [2]Physics, Aristotle University of Thessaloniki, [3]Company, Biohellenika, Thessaloniki, Greece

Chitosan nanoscaffolds (8% chitozan and 30% PolyCaproLactone) for cartilage regeneration endowed with *in vivo* biotinylated factors immobilized via streptavidin/biotin interaction induce dental mesenchymal stem cells into chondrocytes. In particular, the differentiation of human dental MSCs (DPSCs) into chondrocytes with recombinant biotinylated bone morphogenetic protein-2 (BMP2), Transforming Growth Factors TGFβ1 and TGFβ2 as well as the LAP-TGFβ (TGFβ -Latency Associated Peptide) has been shown to be proceeded effectively by all of the above mentioned factors all together or separately. The aforementionmed factors after being cloned into pAN5 plasmids, were purified and refolded for adopting their functional conformation,

© 2014 The Authors. FEBS Journal © 2014 FEBS

e.g the correct disulfidge bridges. The factors were purified and refolded by following the combination of different methodologies in a two step procedure. Mesenchymal stem cells were growth in their presence and their differentiation into chondrocytes has been visualized by RT-PCR or by identification of the typicall cartilage extracellular matrix components (ECM). The presence of aggrecan and collagen type II in high-density cultures (after 21 days) upon stimulation with BMP2 (50 ng/ml) and TGFb1 and TGFb2 (10 ng/ml each of them) confirmed undoubtely the induction of chondrocytic phenotype. In addition, staining of proteoglycans with Alcian blue after 21 days, revealed the deposition of typical cartilage extracellular matrix components indicating the effective functionality of the immobilized biotinylated factors and the low expression levels of osteocalcin revealed the absence of osteocytes. Remarkable is the contribution of the LAP-TGF, which exhibited in vitro an opposite behavior as that has been shown in vivo. Namely, LAP-TGFβ was fully active and did not prevent the binding of TGFβ to the appropriate receptors as it was firstly expected based on the international literature. To summarize, we propose the use of all three factors in order to endow effectively the nano-scaffods with the required properties for reconstruction of injured chondro tissue.

Neuronal differentiation of mouse ES cells by Rho kinase inhibitor

Y. Kamishibahara[1], H. Kawaguchi[1], N. Shimizu[2]
[1]Graduate school of Life Sciences, Toyo University, Gunma, [2]Bio-Nano Electronics Research Center, Toyo University, Saitama, Japan

Mouse embryonic stem (ES) cells are pluripotent cells derived from the inner cell mass of 3.5-day-old blastocysts of preimplantation mouse embryos and have a pluripotent ability to differentiate into various cell lineages *in vitro* including neurons. Recently, it was reported that Y-27632, a specific inhibitor for Rho-dependent protein kinase (ROCK), permits the survival of human ES cells by inhibiting the dissociation-induced cell death. Because ROCK regulates the function of several target proteins through its kinase activity, the inhibition of ROCK activity may provide new possibilities of controlling the *in vitro* differentiation of the ES cells into neurons. Therefore, we investigated the effect of ROCK inhibitor on the differentiation of mouse ES cells into neurons.

We investigate the effect of ROCK inhibitor addition on differentiation into neurons and muscle cells from ES cell colonies (approximately 200 μm in diameter). When ES cell colonies at 12 days of cultivation were labeled with an antibody against βIII-tubulin (a marker of postmitotic neurons), they efficiently differentiated into neurons by the addition of ROCK inhibitor. In addition, ES cell colonies differentiated not only into neurons but also into muscle cells by the addition of ROCK inhibitor. Because the percentages of neurons differentiated from ES cells as a result of incubation with ROCK inhibitor were 60–70%, we concluded that the ES cells primarily differentiated into neurons. We characterized the types of neurons that differentiated from the ES cells by immunofluorescence analysis. ROCK inhibitor promoted the differentiation of the ES cells into motor and sensory neurons.

Mitogen-activated protein kinase (MAPK) /extracellular signal-regulated kinase (ERK) signaling pathway was known to require for neuronal differentiation of ES cells. We investigated whether the addition of ROCK inhibitor promoted phosphorylation of ERK in ES cells by western blotting. When ROCK inhibitor was added to the culture medium, the amount of p-ERK was higher than that without ROCK inhibitor. Furthermore, when ES cells were treated with MAPK/ERK kinase (MEK) inhibitor, ROCK inhibitor did not promote the neuronal differentiation of the ES cells.

ROCK inhibitor promoted the differentiation of ES cells into neurons and muscle cells. We found that the ROCK inhibitor may promote the neuronal differentiation of the ES cells by activating the ERK signaling pathway. These results show that the addition of ROCK inhibitor to the culture medium is useful for the differentiation of ES cells.

Keywords: Differentiation, ES cell, ROCK inhibitor.

Osteogenic differentiation of mesenchymal stem cells by bioactive self-assembled peptide hydrogels

G. Tansik, M. Ö. Güler, A. B. Tekinay
Institute of Materials Science and Nanotechnology, National Nanotechnology Research Center (UNAM), Bilkent University, Ankara, Turkey

Replacement and repair of bone lost due to trauma, degenerative diseases and infections still remain major clinical challenges. Autografting, allografting and xenografting are indicated as current strategies for the treatment of bone defects. However, these strategies cause problems in clinical applications such as immunological response and disease transmission, together with the donor site morbidity. To overcome these limitations, regeneration of new bone can be induced by the usage of new synthetic bioactive materials. One of the most promising strategies is to develop synthetic scaffolds mimicking functional components of extracellular matrix (ECM). ECM plays important roles in bone regeneration and mineralization. Collagens and hydroxyapatite provide the bone mechanical strength and flexibility. Glycosaminoglycans, one of the non-collagenous components of ECM, promote bone remodelling by affecting cellular proliferation and differentiation through stabilizing growth factors and enhancing growth factor-receptor interactions. In this study, we aimed to direct the differentiation of mesenchymal stem cells into osteogenic lineage by peptide amphiphile nanofiber scaffolds decorated with various functional groups mimicking chemical and morphological characteristics of glycosaminoglycans and collagen. Peptide amphiphile molecules self-assembled into a supramolecular nanofibrous network similar to natural ECM. We observed that the peptide nanofiber system induced osteogenic activity of mesenchymal stem cells and calcium deposition, which offers novel platforms for selective induction of mesenchymal stem cells into osteogenic lineage.

Phospholipase D1-induced Bcl-2 expression is required for neuronal differentiation in rat neural stem cells

S.-Y. Park, H.-J. Choi, M. J. Kang, Y. Y. Lee, S.-Y. Lee, J.-S. Han
Biohemistry, Biomedical Research Institute, Hanyang University, Seoul, Korea

We studied the possible role of phospholipase D1 (PLD1) in the neuronal differentiation, including neurite formation of neural stem cells. PLD1 protein and PLD activity increased during neuro-

© 2014 The Authors. FEBS Journal © 2014 FEBS

nal differentiation. Bcl-2 also increased. Down regulation of PLD1 by transfection with PLD1 siRNA or a dominant-negative form of PLD1 (*DN-PLD1)* inhibited both neurite outgrowth and Bcl-2 expression. Moreover, treatment with arachidonic acid (AA) which is generated by the action of PLA2 on phosphatidic acid (a PLD1 product), increased the phosphorylation of p38 MAPK and CREB, as well as Bcl-2 expression, indicating that PLA2 is involved in the differentiation process resulting from PLD1 activation. PGE2, a cyclooxygenase product of AA, also increased during neuronal differentiation. Moreover, treatment with PGE2 increased the phosphorylation of p38 MAPK and CREB, as well as Bcl-2 expression, and this effect was inhibited by a PKA inhibitor (Rp-cAMP). As expected, inhibition of p38 MAPK resulted in loss of CREB activity, and when CREB activity was blocked with CREB siRNA, Bcl-2 production also decreased. We also showed that the EP4 receptor was required for the PKA/p38MAPK/CREB/Bcl-2 pathway. Taken together, these observations indicate that PLD1 is activated by PLCγ/PKCα signaling and stimulates Bcl-2 expression through PLA2/Cox2/EP4/PKA/p38MAPK/CREB during neuronal differentiation of rat neural stem cells.

Keywords: Bcl-2, Neuronal differentiation, Phospholipase D1.

Rapid, unbiased and reproducible large scale gene expression profiling from limited samples: analysis of individual embryoid bodies and pluripotent stem cell colonies

M. Kibschull[1], S. J. Lye[1], S. Okino[2], H. Sarras[3]
[1]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, [2]Gene Expression Division, Life Science Group, Bio-Rad Laboratories, Hercules, ID, USA, [3]Gene Expression Division, Life Science Group, Bio-Rad Laboratories, Mississauga, ON, Canada

Transcriptional profiling during stem cell differentiation and cellular reprogramming has become a powerful tool for studying biological mechanisms of lineage determination and reprogramming progression. Current workflows require tedious column-based RNA purification from high amount of starting materials; projecting in either limitation of analyzed targets or high running costs for conducting a thorough study. Here, we present a novel workflow using validated reagents that allow researchers the ability to assess up to 100 specific gene targets from as little as a single embryoid body (EB) or a small biopsy of human pluripotent stem cell (hPSC) colonies.

The 4-step workflow is initiated by a single step sample preparation enabling high throughput isolation of genomic DNA-free RNA lysates directly from the cultured cells, without the need for column purification. The lysate is then directly reverse transcribed to cDNA. To allow analysis of a large number of targets from limited samples, such as a single EB, the cDNA is pre-amplified for a panel of 100 pre-validated targets previously shown to be essential for human pluripotency and lineage determination. Lastly the pre-amplified targets are analyzed by SYBR Green qPCR.

Using a single EB (~1000 cells) as the starting sample, we demonstrated that the above workflow enables the successful analyses of differentiation progression and lineage determination. We proved excellent correlation and reproducibility in gene profiling between the pre-amplified cDNA samples compared to the non-amplified starting cDNA samples. Out of the 58 expressed targets 97% show a Cq difference below 0.75 cycles from predicted pre-amplified cDNA values, thus confirming that the workflow introduces no or minimal bias. Similarly, we successfully applied this workflow to gene expression profiling of small hPSC biopsies (<1000 cells) to monitor culture quality or reprogramming progression. This would not have been possible using the conventional column based RNA purification approach. In summary, we have developed a complete workflow enabling rapid, unbiased and reproducible gene expression profiling of a large panel of targets from very limited samples. The flexibility and adaptability of this workflow facilitates integration in a high throughput screening environment. Furthermore, the minimal amount of material required by this workflow highlights a more cost effective way for culturing and analyzing hPSC.

Keywords: limited sample quantification, gene expression profiling, pluripotent stem cells, embryoid body differentiation, target-specific preamplification.

Regulation of embryonic genome activation

C. Fassnacht, C. Tocchini, J. Merlet, R. Ciosk
Friedrich Miescher Institute, Basel, Switzerland

Embryonic genome activation (EGA) describes the onset of gene expression in the early embryo. Before this event maternal factors expressed during oogenesis control the development. The onset of EGA is species-specific and controlled in time and space. Across species several factors have been implicated in EGA regulation including chromatin regulators, transcription factors and RNA binding proteins. However, a regulatory mechanism and the evolutionary conservation still remain largely unknown. We use the model organism *Caenorhabditis elegans* to identify new factors involved in EGA regulation. As a tool to visualize EGA a reporter strain was created expressing GFP from the promoter of *vet-4,* one of the early embryonic genes. In a genetic screen for EGA repressors performed in our lab, several mutants with precociously misexpressed EGA in the germline have been identified. A first class of mutants forms relatively normal oocytes expressing embryonic genes, whereas in a second class of mutants the EGA expressing germline cells form a teratoma. These findings propose EGA as a first reprogramming event towards pluripotency. However, at the same time, the phenotype of the class I mutants indicates that an additional reprogramming step is needed for the teratomatous differentiation as these mutants show embryonic gene expression but no differentiation. I aim to dissect the reprogramming event leading to EGA via identification of the mutated genes with Whole Genome Sequencing (WGS), further characterization of the mutants and identification of the pathways they are involved in. Furthermore, after several EGA repressors have been identified in this first screen I perform a second genetic screen to identify EGA activators. I will use the already mentioned reporter strain and screen for embryos that lost GFP expression and therefore EGA. The finding of EGA repressors and activators will shed light on the regulation in *C.elegans* but may also reveal evolutionary conserved mechanisms of regulation.

Keywords: embryonic genome activation, germline, pluripotency.

neurodegenerative diseases, degenerative muscle diseases and osteoporosis as well as trauma, inflammations, burns and injuries. Human tooth germ stem cells are an adult stem cell source; they have mesenchymal stem cell properties and show high proliferative and differentiation capacity. Melatoninhas been demonstrated to regulate differentiation of human and mouse mesenchymal stem cells into various cell lineages in addition to its other functions in the body. In the current study, the effects of melatonin on osteogenic, neurogenic, adipogenic, chondrogenic, myogenic and odontogenic differentiation of human tooth germ stem cells were investigated. The results showed that melatonin increases the viability of cells. It significantly augments osteogenic, neurogenic, chondrogenic, myogenic and odontogenic of the cells whereas it reduces adipogenic differentiation capability. These results suggest that melatonin has a great potential to increase differentiation capacity of human tooth germ stem cells and might be useful in regenerative therapy applications involving stem cell differentiations in addition todefining potential treatments for obesity because of its suppressor effects on adipogenesis.

Role of STRO-1 positive porcine dental germ stem cells in dental stem cell-mediated bone tissue engineering

G. Gürel Peközer[1,2], M. Ramazanoglu[3], K. A. Schlegel[4], G. Torun Köse[1]

[1]Genetics and Bioengineering Department, Yeditepe University, [2]Molecular Biology, Genetics and Biotechnology, İstanbul Technical University, İstanbul, [3]Oral Surgery, Istanbul University, Istanbul, Turkey, [4]Maxillofacial Surgery, Friedrich-Alexander-University of Erlangen-Nuremberg, Erlangen, Germany

Collection of bone marrow stroma from patients is an invasive precedure. Thus, scientists focused on minimally invasive procedures for collection of mesenchymal stem cells. In humans, tooth germ tissues derived from third molars undergo organogenesis to give rise to dental structures at around age 6. As a result of this, some of the progenitor cells reside in dental tissues meaning that these cells remain developmentally and replicatively young. In addition, third molar tooth germs are routinely extracted as an orthodontic treatment and discarded as surgical waste. Therefore, stem cell harvesting from this source causes no ethical controversy.

In this study, pig was used as an experimental model for the isolation of tooth germ stem cells (TGSCs) due to its anatomical, physiologic, and metabolic similarities and its similar diphyodont and heterodont dentition to that of humans.

Mandibular third molar tooth germs were surgically removed from the jaws of 6-month-old domestic pigs. Tooth germ tissue, including the dental mesenchyme and its surrounding follicle, was minced into small pieces and used for the explant culture. Passage 1 (P1) porcine TGSCs (PTGSC) were analyzed by flow cytometry and found positive for CD105, CD90, and CD44 and negative for CD45 and CD34 surface markers showing their MSC characteristics. P1 PTGSCs were also tagged with STRO-1 antibody and 21.6% of cells were detected and sorted as positive for STRO-1. STRO-1 positive (STRO-1+) cells identifies a subpopulation of MSCs which are highly clonogenic and can differentiate into adipocytes, osteoblasts, chondrocytes and smooth muscle cells. Unsorted and Unsorted (US) and STRO-1+ cells were induced for osteogenesis and analyzed for their proliferation behaviors and differentiation capacities towards osteogenic lineage by assessing ALP activity, calcium content and mineralized nodules in cultures.

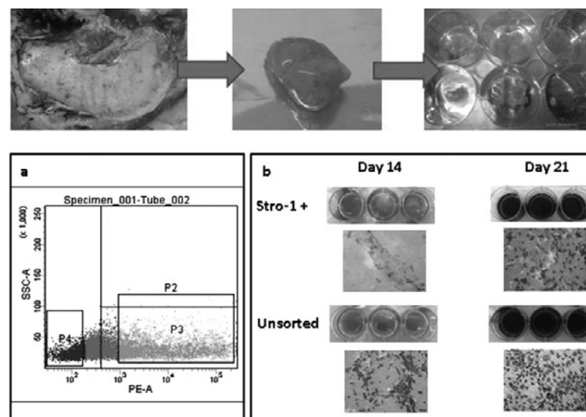

Fig. 1. Extraction of tooth germ from porcine third molars and isolation of cells by explant culture. (a) Stro-1 selection of PTGSCs by FACS (b) von Kossa staining of PTGSCs osteogenically induced for 21 days.

There was no significant difference between proliferation rates and ALP activities of STRO-1+ and US cells whereas calcium deposition by US cells were significantly higher. von Kossa staining of mineralized nodules of both STRO-1+ cells and US cells showed high levels of dark-black staining of mineralized nodules especially after 21 days of incubation being slightly higher in US cells. Results showed that after 21 days of culture, both groups differentiated towards osteogenic lineage without any significant difference created by STRO-1+ cells. Besides, US cells even deposited more calcium as shown by calcium assay and von Kossa staining. This might indicate that STRO-1+ cells might require a heterogeneous population of cells in their niche to perform their proposed role in osteogenesis.

Keywords: osteogenic differentiation, Stro-1, tooth germ stem cells.

Rspondins are required for adrenal gland homeostasis

S. Zaddam[1,2,3], R. Bandiera[1,2,3], V. Vidal[1,2,3], F. Ranc[1,2,3], B. Ragazzon[4], J. Bertherat[4,5], H. Okamoto[6], A. Martinez[7], A. Schedl[1,2,3]

[1]Inserm, UMR1091, [2]CNRS, UMR7277, [3]Institute of Biology Valrose, Université de Nice-Sophia antipolis, Nice, [4]Institut Cochin, Université Paris Descartes, CNRS UMR 8104; Inserm U1016, [5]Assistance Publique Hôpitaux de Paris, Hôpital Cochin, Department of Endocrinology, Paris, France, [6]RIKEN Brain institute, Saitama, Japan, [7]CNRS UMR6293, Clermont Université, Aubière, France

Wnt/β-catenin signaling is a key pathway in organ development and tissue homeostasis and is implicated in proliferation and differentiation of stem cells. Constitutive activation of β-catenin is the most frequent event that induces adrenocortical tumors. We are interested in Rspondins, a family of proteins that have been reported to act as activators of canonical Wnt/b-catenin signaling. Our analyses show that expression of *Rspo1 and Rspo3*, two members of this family, are maintained within the adrenal capsule throughout life, a site that has been proposed to contain a stem/progenitor cell compartment. To address the role of *Rspondins* in development and homeostasis we performed loss-of-function approaches using genetically modified mice. Analysis of *Rspo1* knockout mice did not reveal an overt adrenal phenotype.

© 2014 The Authors. FEBS Journal © 2014 FEBS

In contrast, deletion of *Rspo3* at embryonic day E11.5, lead to significantly smaller adrenals exhibiting a disrupted cortex structure at E16.5. Moreover, removing *Rspo3* in adult mice caused a reduction of cortex size within 6 weeks after deletion suggesting a requirement for this gene in adrenal homeostasis. To complement these loss-of-function studies, we ectopically expressed *Rspo1* within the developing adrenal cortex. Strikingly transgenic mice displayed dramatic overgrowth of the adrenal cortex as early as E15.5. Interestingly, the size of the adrenal cortex increased in a time- and dosage-dependent manner without an overall disturbance of the cortical architecture. At later stages of life (>6 months), however, a proportion of mice developed adreno-cortical tumors. Taken together, these data demonstrate an essential role for *Rspo3* in adrenal gland development and homeostasis and reveal a growth promoting and oncogenic capacity of *Rspondins*. Our results might also suggest that overexpression of these genes may be at the basis of adrenocortical tumors in human patients.

Keywords: adrenal glands, Rspondin, stem cells.

Spatial regionalization and heterochrony in the formation of adult pallial neural stem cells

L. Dirian[1], S. Galant[1], M. Coolen[1], W. Chen[2], S. Bedu[1], C. Houart[3], L. Bally-Cuif[4], I. Foucher[4]
[1]Institute of neurbiology Alfred Fessard, Gif-sur-Yvette, France, [2]Vanderbilt University School of Medicine, Nashville, TN, USA, [3]King's College, London, UK, [4]Institute of neurobiology Alfred Fessard, Gif-sur-Yvette, France

Little is known on the origin and related heterogeneity of adult neural stem cells (aNSCs) in the vertebrate brain. We used the zebrafish to investigate the contribution of embryonic neural progenitors to the population of aNSCs of the dorsal telencephalon (pallium). We first assessed the adult fate of a large population of embryonic radial glial progenitors expressing the E(spl) transcription factor Her4 (orthologous to mouse Hes5), which highlights actively neurogenic zones in the early embryo. Using a conditional Cre/lox genetic strategy driven by the *her4/Hes5* promoter, we could specifically and permanently fate map this population at chosen developmental stages. We report that this population, when traced from embryonic stages onwards, generates the entire aNSC compartment of the dorso-medial pallium, but fails to contribute to aNSCs of the lateral pallium. In contrast, we demonstrate that the lateral aNSC population is established progressively, from larval stages onwards, following an anterior to posterior gradient. We identify its origin in a restricted pool of neuroepithelial progenitors present at 30 hours-post-fertilization at the dorsal telencephalic roof, and amplifying post-embryonically. These progenitors express signalling pathways components such as Wnt3a/Wnt8b. The dorso-medial and lateral aNSC populations remain strictly segregated in space, and we further demonstrate that these differential origins progenitors differ in their sensitivity to Notch signaling. Together, these results demonstrate a dual origin and formation mode of pallial aNSCs, which derive from spatially and molecularly distinct as well as strongly heterochronous progenitors. This allows the temporally organised building of pallial territories as a patchwork of juxtaposed compartments.

SUN-497
Studying epithelial-mesenchymal plasticity of human somatic cells in 3D culture

I. Saburina[1,2], I. Zurina[1], N. Kosheleva[1,3], A. Gorkun[1], T. Kolokoltsova[1,2], V. Repin[1,2]
[1]The Institute of General Pathology and Pathophysiology RAMS, [2]Russian Medical Academy of Postgraduate Education, [3]M.V. Lomonosov Moscow State University, Moscow, Russian Federation

It is known, that epithelial-mesenchymal transitions (EMTs) which were first described in embryogenesis, are also taking place during physiological and reparative regeneration, fibrosis, oncology and cell reprogramming. Studying epithelial-mesenchymal plasticity (EMP) of human somatic cells (HSC) has an enormous scientific and practical significance. The aim of this research was to study and compare EMP of epithelial and mesenchymal HSC.

In this work we used epithelial (retinal pigment epithelium, placental cytotrophoblasts) and mesenchymal cells (limbal stromal cells, umbilical cord multipotent mesenchymal stromal cells). It was shown that initially epithelial cultures had classical epithelial "cobblestone" morphology. But after the third passage they acquired mesenchymal phenotype, which was accompanied by redistribution of E-cadherin expression from cell membrane to cytoplasm and acquiring N-cadherin and vimentin expression. Addition of dexamethasone to culture medium resulted in changing cell phenotype to epithelial. Mesenchymal cells in monolayer culture didn't change their phenotype even in presence of dexamethasone, expressed N-cadherin and vimentin.

Transfer of cultures from 2D to 3D non-adhesive conditions let us use resulting single spheroids as a model for studying EMP of HSC. Live time-lapse microscopy (Cell-IQ, Finland) revealed regularities in the process of spheroid formation from epithelial and mesenchymal cells. Regardless of cell phenotype and initial cell concentration aggregation and compaction of spheroids took place in the first 7 days; diameter of resulting spheroids didn't grow.

Scanning electron microscopy showed that the surface of spheroids from epithelial and mesenchymal cells consisted of epithelial-like polarized cells, whereas central zone was represented by small non-polarized cells. According to transmission electron microscopy spheroid compaction was accompanied with formation of tight junctions in surface cell layer.

Immunocytochemical analysis showed that surface cells of mature spheroid co-expressed E-cadherin (localized primary on cell membranes) and N-cadherin (mainly in cytoplasm). Central cells didn't express E-cadherin, but highly expressed N-cadherin. According to real-time PCR analysis spheroid formation resulted in gradual increase in expression of three pluripotency markers Oct4, Sox2 and Nanog.

Thus, this study showed that HSC *in vitro* can be either in epithelial or mesenchymal status. 2D culture promotes EMT, whereas 3D conditions stimulate reversibility of EMT which results in formation of mesenchymal-epithelial spheroids. Such spheroids can serve as a unique model for studying EMT phenomena.

Suppression of the SOX2 neural effector gene by PRDM1 promotes human germ cell fate in embryonic stem cells

K.-I. Lin[1], I.-Y. Lin[1], H.-C. Kuo[2]
[1]Genomics Research Center, [2]Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan

The mechanisms of transcriptional regulation underlying human primordial germ cell (PGC) differentiation are largely unknown. Transcriptional repressor Prdm1/Blimp-1 is known to play a critical role in controlling germ cell specification in mice. Using human embryonic stem cells (hESCs) as an *in vitro* differentiation platform, we previously established that the BMP and/or WNT signaling pathways promote the formation of meiotic germ cells from hESCs and that PRDM1 is induced by BMP/WNT signaling. Here, we show that PRDM1 contributes to the determination of germline vs. neural fate in early development. We show that knockdown of PRDM1 in hESCs impairs germline potential and up-regulates neural genes. Conversely, ectopic expression of PRDM1 in hESCs promotes the generation of cells exhibiting phenotypic and transcriptomic features of early PGCs. Furthermore, PRDM1 directly suppresses transcription of *SOX2*; overexpression of *SOX2* in hESCs under the condition favoring germline differentiation skews cell fate from the germline to the neural lineage. Collectively, our results demonstrated that PRDM1 serves as a molecular switch to modulate the divergence of neural or germline fates through repression of *SOX2* during human development.

Tenascin-C mimetic peptide nanofibers direct in vitro differentiation of stem cells to osteogenic lineage

M. Sever, B. Mammadov, A. B. Tekinay, M. O. Güler
Institute of Materials Science and Nanotechnology, National Nanotechnology Research Center (UNAM), Bilkent University, Ankara, Turkey

Regeneration of damaged bone tissue is essential for the treatment of large bone defects associated with reconstruction surgery of trauma, cancer, and total hip arthoplasties. Nanofiber scaffolds made of self-assembling peptides offer a promising approach for regenerative medicine due to their biocompatible and biodegradable properties. Extracellular matrix (ECM) contains several signals for cell surface receptors contributing to cell fate through regulation of cellular activities such as proliferation and differentiation. Cues from ECM components can be used for the development of new materials to direct the stem cell fate. Short peptides derived from ECM proteins are commonly used to incorporate bioactivity to synthetic scaffolds. Bioactive scaffolds can induce adhesion, migration, proliferation or even differentiation depending on the epitope selection. In this study, we exploited the functional role of extracellular matrix on osteogenic commitment and differentiation by mimicking bone extracellular matrix by incorporating functional sequence of Fibronectin Type III domain from native Tenacin-C, an important glycoprotein found in the matrix on bone surfaces, on peptide nanofiber network. Overall, our results showed that the attachment, proliferation, and osteogenic differentiation of rat Mesenchymal Stem Cells (rMSCs) were enhanced by peptide nanofibers including Tenascin-C mimetic peptide even in the absence of any external bioactive factors and regardless of their mechanical properties, which provides a promising new platform for bone regeneration.

The correlations between growth factors release and stem cells maintenance in hippocampus of amyloid exposure rats

K. B. Yenkoyan[1], T. K. Davtyan[2], T. Margaryan[3], V. A. Chavushyan[4], M. I. Aghajanov[1]
[1]Biochemistry Department, Yerevan State Medical University after M. Heratsi, [2]Immunology Department, Armenicum Center, [3]Drug Technology Department, Yerevan State Medical University after M. Heratsi, [4]Laboratory of Neuroendocrine Interrelations, Physiology Institute of NAS RA, Yerevan, Armenia

Purpose of the Study: The pathogenesis of dementia-linked neurodegenerative disorders like has it's specify and various from disease to disease, but the general concerns are probably the same. In the most of them there is the disturbance in metabolism of growth factors, neurotransmitters, up-regulated oxidative stress, and the weakness of the potency of the adult stem cells for regeneration. A wide range of biological active substrates are aprobated as neuroprotectors, but just few of them have less or more efficiency in clinic. In this study we tried to find out correlations between the release of growth factors like IGF-1 and NGF, and adult stem cells maintenance in hippocampus after experimental modeling of Alzheimer's disease (AD).

Mathods Used: Experiments were performed on 40 mature white Sprague-Dawley male rats. The control group consisted of vehicle-treated animals. The experimental model of AD was made in rats by intracerebroventricular (*i.c.v.*) injection of aggregated amyloid-betta (Ab) 1-42. IGF-1 and NGF were determined by ELISA in hippocampus of rats' brain. Markers of neurogenesis (Vimentin, Nestin), dividing cels (BrdU, Wnt) were determined in hippocampus of rats' brain on the 90th day from *i.c.v.* injection of Aβ by flow cytometric detecti

Summary of Results and Conclusion: In hippocampus after *i.c.v.* injection of Aβ1-42 there were no significant changes in fluorescence intensity of Nestin, Wnt and BrdU/Wnt double-labeled cells, but the quantity of Vimentin, Nestin/Vimentin double-labeled cells decreased compared with the control cells, which suggested the inhibitory effect of neurodegeneration on neural stem cells maintenance and survival. On contrary, the expression BrdU positive cells increased, which suggested that neurodegeneration could play a trigger role in stem-cells proliferation. These findings are in line with changes of growth factors: it was observed a significant up-regulation of IGF-1 and slight increase of NGF in hippocampus. Increase in growth factors level and in particularly IFG-1, evidently, is an adaptive response of brain neurons to damage, something like a "cry to survive", which is accompanied by high proliferation of hippocampal adult stem cells.

Summarizing the study, we conclude that the new therapeutic strategies in neurodegeneration have to be focused on activation the adult stem cells proliferation and differentiation via growth factors.
Keywords: amyloid, growth factors, neurogenesis.

The differentiation of Wharton's jelly mesencymal stem cells into hepatocyte cells

M. Ersoz[1], A. Allahverdiyev[2]
[1]*Molecular Biology and Genetics, Istanbul Bilim University,*
[2]*Bioengineering, Yildiz Technical University, Istanbul, Turkey*

Liver diseases are amongst the crucial health problems the world and they cause a loss in hepatocyte functions. Despite the number of methods used to treat liver diseases, an effective treatment hasn't yet been found. Therefore, alternative methods based on stem cells are currently being investigated. Mesenchymal stem cells give promising results to cure liver diseases with their high reproduction potential, low immunogenecity and capacity to differentiate. In order to treat patients with liver diseases; different protocols containing cytokines, growth hormones and chemical agents were used to differentiate mesenchymal stem cells into hepatocyte cells.

The purpose of this study is to investigate a relatively effective new protocol to differentiate mesencyhmal stem cells into hepatocyte cells using human Wharton's Jelly.

The methods used in the experiments were; isolation, microscopic, Periodic Acid Shift Dye, Real Time Polymerase Chain Reaction and Flow cytometric. The data was evaluated using SPSS version 16.0 for Windows.

As a result of the microscopic and flow sytometric analysis, surplus number of healthy mesencyhmal stem cells was isolated from Wharton's Jelly using explant method. According to the histological and molecular results, with this new protocol; using bFGF, HGF, FGF-4, EGF, Dexamethasone, Nicotinamide, ITS, Napyruvate, OSM, DMSO containing as the differentiating and maturing culture medium the most effective hepatogenic differentiation was conducted. Comparing with the other protocols, the hepatogenic cells obtained by using this new protocol in comparison to the control (mesenchymal stem cell) and hepatocyte (Hep 3B) cell groups; Real Time Polymerase Chain Reaction made as a result of albumin (ALB) and alpha fetoprotein (AFP) gene expression levels in a statistically significant way to express that most were determined.

As a result of studies; dissimilar to the previous protocols, this new one enabled the differentiation of a more hepatocyte characterized hepatogenic cells from Wharton's Jelly mesencyhmal stem cells.

The human foetal globin genes exhibit a two-wave pattern of transcription in primary erythroid cultures

R. H. Hristova, Y. Petseva, A. Gospodinov, L. Chakalova
Molecular Biology of the Cell Cycle, Institute Molecular Biology (Bulgaria), Sofia, Bulgaria

Foetal haemoglobin, the major haemoglobin type produced in the human foetus, is almost entirely replaced by adult haemoglobin shortly after birth. This transition is the result of switching from high-level expression of the foetal globin genes *HBG1* and *HBG2* to predominant expression of the adult *HBB* gene in erythroid cells. Several reports, however, suggest that the foetal globin genes are not completely silenced in adult erythroid cells but rather experience a period of expression during adult erythroid differentiation. We have used primary transcript RNA fluorescent *in situ* hybridisation to study the transcription of the foetal globin genes in cultures of primary erythroid cells. We show that foetal globin gene transcription changes in the course of culture progression following a two-peak pattern. We present evidence suggesting that this is the result of parallel differentiation of two haematopoietic progenitors that take different periods of time to reach the differentiation stage when the foetal globin genes are expressed. Our results support the notion of the existence of a short window of *HBG* activity during adult erythroid differentiation.

SUN-503
The role of glycans in osteogenesis

K. Wilson, P. Genever, D. Ungar
Biology, University of York, York, UK

Multipotent stromal cells/mesenchymal stem cells (MSCs) are capable of differentiating into various cell types; osteoblasts, adipocytes and chondrocytes. This ability has resulted in the use of MSCs in clinical trials to treat a wide variety of diseases, from osteoporosis to heart disease. Much research into the role of cell signalling pathways in directing stem cell fate is underway, but relatively little is known about the role of glycans. *N*-glycosylation is the addition of sugar residues to proteins in the endoplasmic reticulum and Golgi, which can alter their properties including their ability to bind to target proteins. Consequently, glycosylation has a major role in many cellular mechanisms including cell adhesion, signal transduction, and non-self-recognition. Previous studies have described distinct glycan profiles of cells at different stages of development. However, whether glycans play a functional role in directing stem cell differentiation is unknown. To identify the importance of glycosylation during differentiation, we determined the glycan profiles of multipotent stromal cells/mesenchymal stem cells (MSCs) and then disrupted the *N*-glycan synthesis pathway and tested if the ability of MSCs to differentiate had been altered. Telomerase (hTERT)-immortalised clonal MSC lines were generated, to account for the broad glycan-heterogeneity often observed in cell cultures and to generate sufficient material for in-depth analysis of glycans. *N*-glycans were isolated from hTERT-MSCs using filter aided *N*-glycan separation (FANGS) method. This low-throughput method, followed by permethylation to stabilise glycans, allowed

© 2014 The Authors. FEBS Journal © 2014 FEBS

us to repeatedly profile samples using mass spectrometry (MALDI-TOF/TOF) and quantitatively compare relative glycan abundance in different cellular states.

The *N*-glycan profile of osteoblasts derived from hTERT-MSCs had increased complex type glycans, as well as a higher abundance of fucosylated glycans compared to undifferentiated hTERT-MSCs. To assess if this change is functionally important the Golgi synthesis pathway was genetically disrupted, by transducing hTERT-MSCs with shRNA for Cog4, a subunit of the COG complex. COG is an 8 subunit protein involved in the sorting of Golgi resident enzymes, therefore required for correct glycan synthesis. Interestingly, Cog4 knock-down cells (Cog4KDs) had reduced osteogenic potential, with significantly less calcium staining and less alkaline phosphatase activity compared to controls. Crucially, these results show, for the first time, that disruption of glycan synthesis can effect MSC differentiation. Since COG defects disrupt all glycosylation pathways, not just *N*-glycosylation, further work using specific inhibitors of *N*-glycan processing to elucidate the role of *N*-glycans in the loss of osteogenic capacity of Cog4KDs,will also be discussed.

Keywords: Glycosylation, Mesenchymal stem cells, Osteogenic Differentiation.

Time-dependent modulation of mesenchymal stem cells osteogenic differentiation by FGF2

L. Sima, M. Chiritoiu, G. Chiritoiu

Molecular Cell Biology, Institute of Biochemistry, Romanian Academy, Bucharest, Romania

Bone regeneration during fracture healing or following implant surgery is essential for the efficient recovery in orthopaedic pathology. To this end, the efficient direction of proliferating mesenchymal stem cells (MSCs) towards the osteogenic fate is mandatory. FGF-activated signalling pathways are known to play essential roles in endochondral and intramembranous bone development[1,2]. Moreover, FGFs are considered potent regulators of cell growth and wound healing that are produced in bone by osteoblasts, macrophages, and endothelial cells, and are stored in their active form in the extracellular bone matrix[3]. FGF2 was already described as an efficient proliferation enhancer when added in the expansion media of MSCs[4]. FGF2 was shown to maintain osteogenicity[5] and increase osteogenic and chondrogenic differentiation *in vitro*[6]. There are also contradictory reports stating the inhibitory effect of FGF2 on osteogenesis[7,8]. However, little is known about the potential molecular mechanisms involved. We have used a combinatorial approach to study the role of FGF2 addition to the osteogenic induction medium (OIM) on MSCs that were pre-treated or not with 1 ng/mL FGF2 for two weeks. The effect of FGF2 on MSCs proliferation and osteogenic differentiation was characterized by MTS assay and Alizarin Red mineralization staining. We have screened for optimal time and dose of growth factor treatment that would be beneficial for the efficient generation of bone tissue. Using image cytometry, we quantified cell differentiation during treatment with FGF2. Our results revealed a dose- and time-dependent effect of FGF2 on MSC-derived osteoblast proliferation and mineralization. We correlated this effect with an increase in beta-catenin expression and with an upregulation of pERK1/2 and pp38 following FGF2 priming. The impact of signalling pathways modulation on Runx2 transcription factor-driven osteogenic commitment was investigated by flow cytometry and Real-time PCR. Our studies will guide the design of laser-transferred polymeric scaffolds embedding FGF2 and other growth factors to improve osseointegration and angiogenesis during bone healing by controlled release of these molecules.

Tumor stem cells markers for intracranial tumour evaluation

C. Tanase[1], A.-M. Enciu[1], I. D. Popescu[1], E. Codrici[1], L. G. Necula[1], I. Radu[1], M. L. Cruceru[2], A. Popa[2], R. Albulescu[1]

[1]Biochemistry Proteomics Department, "Victor Babes" National Institute of Pathology, [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Tumor stem cells (TSCs) involvement in brain tumorigenesis has gained field during the last years. The present study is focused on the markers involved in identifying TSCs; their molecular markers have shown differences between malignant/benign intracranial tumors, as well as future clinical application. Several markers that characterize the stem cells of intracranial tumors were identified in this study: CD133, NESTIN, C-kit, Sox-2, CD44, NOTCH. 80% of the malignant tumors and 35% of the benign ones have revealed positive expressions for at least one stem cell marker. The array of studied biomarkers revealed statistical differences for CD133, nestin and notch signaling between malignant and benign intracranial tumors. These markers have been correlated with angiogenic factors, leading to aggressiveness and invasiveness of these tumours. When associated with malignancy potential, they can be considered prognostic markers for intracranial tumor patients. The similarities and differences in the TSC involvement in benign/malignant intracranial tumors should be determined in the following few years. These cells may be responsible for intracranial tumor initiation and aggressiveness, either malignant or benign. Considering their complex pathophysiology and diversity, their decisive role in intracranial tumor evaluation is to be established in the following years.

This work is partially supported by Grants 09.33-03.10 and POSDRU 141531/2014.

20S proteasome gating, cellular chronological life span and resistance to oxidative stress

M. Demasi
Instituto Butantan, Sao Paulo, Brazil

It has recently demonstrated that two Cys residues in the α5-subunit of the yeast 20S proteasome are post-translationally modified by S-glutathionylation when yeast cells grow to stationary phase into glucose-containing medium. Moreover, such modification implies on the opening of the 20S gate and on the increased degradation of oxidized model proteins, as studied in vitro. The set of data accumulated allowed hypothesizing S-glutathionylation as a redox regulation of proteasomal gating. In the present work it is shown that the mutation of those two Cys residues (α5-C76 and α5-C221) to Ser renders opposite 20S proteasome structures regarding their gating status. The closed conformation (Figure, left panel) prevails in the C76S mutant 20S particle when purified from cells grown to stationary phase into glucose-containing medium opposing the C221S mutant counterpart where the open conformation (Figure, right panel) represents 90% of the 20S pool. The cells carrying these mutated 20S forms present opposite phenotypes regarding oxidative stress response and chronological life span. Cells carrying the C76S mutant 20S core particle are either less resistant to oxidative stress or present reduced life span when compared to the wild type cells. Opposite results were obtained with cells carrying the C221S mutant proteasome. The rate of in vitro degradation of model proteins by the C221S-mutated 20S proteasome was twice that observed with the wild type counterpart. Our conclusion to date is that S-glutathionylation of the C221 residue, placed on the 20S surface, is actually a negative regulation of proteasomal gating while the C76 residue, highly conserved through yeast to human, is the true redox regulator of proteasomal gate opening. Most importantly, the difference of phenotype and gate conformation between cells carrying the mutated 20S proteasome together to the ability of the C221S-mutated form to degrade non-ubiquitinylated substrates, clearly demonstrate the importance of the 20S gate conformation on cellular response to redox imbalance. This work has been supported by the São Paulo Research Foundation (FAPESP) and the National Institutes of Science and Technology of Redox Processes in Biomedicine (FAPESP, CNPq, CAPES).

A new pathway regulating DNA replication and common fragile site stability: the RBBP6/ZBTB38/MCM10 axis

P.-A. Defossez[1], B. Miotto[2]
[1]CNRS, [2]Epigenetics and Cell Fate, Paris, France

The faithful replication of DNA is essential to maintain the integrity of the genome. Incomplete genome replication leads to DNA breaks and chromosomal rearrangements, which are causal factors in cancer and other human diseases. In spite of their importance, the molecular mechanisms controlling human genome stability are incompletely understood. Here we report a new pathway required for the replication and the stability of the human genome. This pathway has 3 components: an E3 ubiquitin ligase, a transcriptional repressor, and a replication protein. The E3 ubiquitin ligase, RBBP6, ubiquitinates and destabilizes the transcriptional repressor, ZBTB38. This repressor negatively regulates the transcription and the amount of the MCM10 replication factor on chromatin. Cells lacking RBBP6 experience reduced replication fork progression and increased damage at common fragile sites because of ZBTB38 accumulation and MCM10 down-regulation. Our results delineate a new pathway ensuring genome-wide DNA replication and chromosomal stability (Miotto et al, Cell Reports, in press).

Keywords: Replication, Transcription Repression, ubiquitination.

SUN-509
A novel pathway regulating CD20 level – influence of the inhibition of HDAC6 on the efficacy of anti-CD20 antibodies

M. Bobrowicz, M. Dwojak, K. Bojarczuk, M. Siernicka, M. Winiarska
Department of Immunology, Medical University of Warsaw, Warsaw, Poland

CD20, an integrate membrane protein expressed on the surface of normal and malignant B-cells is used as a molecular target for monoclonal antibodies (mAbs) in the therapy of non-Hodgkin's lymphomas and chronic lymphocytic leukemia (CLL). CD20 antigen has been reported to be regulated epigenetically e.g. by histone deacetylases (HDACs). The results of our preliminary experiments show that blocking the activity of a single HDAC isoform - HDAC6 with selective inhibitors (tubacin, ACY-1215 and tubastatin) leads to up-regulation of CD20 protein in B-cell lymphoma cell lines, EBV-transformed B-cells and primary cells from CLL patients but not in normal B-cells. We observed that HDAC6 silencing with shRNA also increases CD20 surface level. On the contrary, overexpression of HDAC6 does not induce changes in CD20 level. The observed up-regulation of CD20 level correlates with increased efficacy of anti-CD20 mAbs - rituximab and ofatumumab in complement-dependent cytotoxicity (CDC) assays. Neither tubacin nor HDAC6 silencing with shRNA does alter the expression of complement inhibitors. However, the increase in CD20 level does not influence antibody-dependent cellular cytotoxicity of NK cells.

In order to elucidate the mechanism by which HDAC6 inhibition increases CD20 level we performed experiments assessing HDAC6 inhibition on CD20 transcription. The results of qRT-PCR using SyBR Green and hydrolysis probes indicate that

© 2014 The Authors. FEBS Journal © 2014 FEBS

HDAC6 inhibition with tubacin and its silencing with shRNA does not alter CD20 mRNA. HDAC6 inhibition does not change CD20 promoter activity and leads to increase of CD20-tagged protein level expressed in Raji under CMV promoter. HDAC6 inhibition and silencing lead to increase in total CD20 protein level assessed in Western blotting.

Since HDAC6 is a unique member of HDAC family reported to be engaged mainly in the acetylation of non-histone substrates, protein degradation and transport we sought to determine HDAC6 role in CD20 protein transport. Using nocodazole we observed that the effect of HDAC6 on CD20 relies on stable microtubules. What is more, we observed that blocking protein anterograde protein transport with Golgistop abrogates tubacin effect. These results suggests that HDAC6 may be implicated in CD20 transport/degradation pathways.

The results of our study suggest that combining HDACi with anti-CD20 antibodies can be a successful modality for patients suffering from B-cell malignancies. The use of isoform-selective inhibitors may be an effective strategy in enhancing the efficacy of anti-CD20 mAbs. Potentially these compounds would have less adverse effects than HDAC pan-inhibitors. However, their use in the therapy requires further investigation.

An original approach to identify E3 ubiquitin ligase substrates to be degraded

I. Lamsoul[1], S. Uttenweiler-Joseph[1], A. Stella[2], A. Métais[1], O. Burlet-Schiltz[2], C. Moog-Lutz[1], P. G. Lutz[1]

Ubiquitin-mediated protein degradation is the major controlled proteolysis pathway in Eukaryotes that ensures that specific protein functions are turned off at the right time and in the right place. In this pathway, E3 ubiquitin ligases (E3s) are involved in the recruitment of specific substrates to be polyubiquitylated and subsequently degraded. Despite the identification of many E3s, the identities of their substrates remained largely unresolved.

In this work, we provided an original approach to identify substrates of E3s to be degraded. ASB2α is the specificity subunit of an E3 complex of the Cullin 5 RING E3 family that exerts its effects in hematopoietic cells through the targeting of specific substrates for degradation by the proteasome. Specifically, a global quantitative proteomic strategy applied to primary cells of wild-type and ASB2α knockout mice was used to identify new substrates of the ASB2α E3. Label-free quantitative proteomic analyses were performed to measure relative changes in protein abundance between primary hematopoietic cells isolated from ASB2-/- and ASB2 + /+ mice. Indeed, potential substrates of ASB2α correspond to proteins detected only in ASB2-/- cells but not in ASB2 + /+ cells or detected to a higher level in ASB2-/- cells compared to ASB2 + /+ cells. The robustness of this label-free quantitative proteomic approach was highlighted by a decrease of known ASB2 substrates, filamins A and B, in ASB2α-expressing cells.

Altogether, our results contribute to the understanding of the mechanisms of action of ASB2α, unravel new regulators of hematopoiesis in primary cells and will aid future studies aimed to the identification of novel E3 substrates.

Bci is a new component of the autophagy pathway

P. A. Manque[1], M. Nassif[2], E. Vicencio[1], C. Gherardelli[1], J. M. Matamala[1], R. L. Vidal[3], R. Arias[1], M. Rojas[1], V. Maracaja[1], C. Hetz[4], U. Woehlbier[1]
[1]Centro de Genomica & Bioinformatica, [2]Universidad Mayor, [3]Neurounion, [4]Institute of Biomedical Sciences, University of Chile, Santiago, Chile

Autophagy, a mechanism for clearance of intracellular components in lysosomes, plays an essential role regulating and maintaining cellular homeostasis. Thus defects of this process contribute to the development of a series of pathologies including cancer and neurodegenerative diseases. Recently, a proteomic analysis of the autophagy interaction network (AIN) in human cells under conditions of basal autophagy, revealed a network of 751 interactions among 409 candidates, for many of those no function was assigned. Thus we decided to characterize the gene KIAA0226L that was initially described as a potential interactor of Beclin-1. This gene, here termed *bci* (Beclin1 interactor) has been previously studied only in the human cervical cancer context, as one of the most methylated genes present in human samples, suggesting a tumor suppressor function of the encoded protein in this tissue. In-silico analysis of the amino acid sequence of Bci showed several phosphorylation sites and a domain of unknown function (DUF4206). Bci expression exhibits a tissue-specific pattern with high expression levels in the brain and spinal cord. Moreover, Bci expression levels changed when autophagy is induced. Using immunoprecipitation experiments, we confirmed the binary interaction of Bci with Beclin1, a key regulator of autophagy. Furthermore, when Bci was overexpressed, we observed a decrease in LC3-II conversion, under nutrient deprivation as well as treatment with lysosome inhibitors, suggesting that BCI negatively regulates autophagy. In localization studies, we showed that Bci is localized to the Golgi apparatus, similar to other autophagy pathway components, such as Beclin1. Together, our data suggest that Bci is a potential new key regulator of autophagy.

Bilirubin oxidase: enzyme of choice to biofuel cells

C.-H. Jacquot, G. Lamicq, D. Salvador, S. Gounel, C. Stines-Chaumeil, N. Mano
Université de Bordeaux/CNRS, Centre de Recherche Paul Pascal (CRPP-UPR 8641), Pessac, France

Enzymatic miniature membrane-less glucose/O_2 Biofuel Cells (BFCs) are of particular interest because they may be used, in the near future, as *in-vivo* power source for implantable medical devices requiring low-power density. At the anode glucose oxidizing enzymes are used while at the cathode it is oxygen reducing enzymes such as bilirubin oxidases (BODs) or laccase. BODs will be preferred because unlike laccases they show high activity and stability in physiological conditions. Even tough, their performances are continuously improving, the power output and lifetime of BFCs are still not sufficient for direct applications, especially because the cathode is the limiting part of the cell.

BODs belong to the multi-copper oxidase family, catalyze the oxidation of bilirubin to biliverdin and reduces oxygen to water without producing toxic oxygen intermediates. The catalytic center consists of four copper atoms classified according to their

© 2014 The Authors. FEBS Journal © 2014 FEBS

optical and magnetic properties. They are of three types. The type I (TI) copper allows the transfer of electrons from the substrate to the trinuclear center (TCN), composed of a type II copper and the two type III copper, where the O_2 is reduced to water. We recently discovered two news BODs, from fungus (2) and bacteria (3). The use of these enzymes to the cathode of the glucose/O_2 biofuel cell is promising (2, 3, 4), because there are more tolerant to chloride ion and are more active in neutral pH than laccase, which is an enzyme extensively studied in this field of application.

By combining different analytical techniques (stopped-flow, circular dichroïsm,..) our work consist in characterizing these new enzymes and determine the rate-limiting step of the reactions, to be able to improve those enzymes for our applications.

Biological consequences of intron 6 retention for LAT (linker for activation of T-cells) adaptor function

M. Klossowicz[1], K. Marek-Bukowiec[1], M. M. Arbulo-Echevarria[2], M. Majkowski[3], B. Scirka[1], E. Aguado[2], A. Miazek[1,4]

[1]Department of Tumor Immunology, L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland, [2]Department of Biomedicine, Biotechnology and Public Health (Immunology), Core Research Facility for Health Sciences, University of Cadiz and Puerto Real University Hospital Research Unit, School of Medicine, Cadiz, Spain, [3]Laboratory of Cytobiochemistry, Biotechnology Faculty, University of Wrocaw, [4]Department of Biochemistry, Pharmacology and Toxicology, Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland

Intron retention (IR) is a frequent phenomenon in the human transcriptome. Mostly it leads to a reduction in gene expression by triggering intron retaining mRNA degradation by the nonsense-mediated decay (NMD) pathway. However, number of mRNAs retaining short introns, especially in the open reading frame with adjacent exons have been shown to undergo productive expression. In the present study we assessed biological consequences of intron 6 retention within the human *LAT* gene. We found that intron 6 retaining *LAT* mRNA, here denoted as LAT_{i6}, undergoes productive expression but its level is approximately 20-fold lower than that of canonical *LAT* isoform. Since LAT is a key transmembrane adaptor protein controlling TCR signaling during development and activation of T cells, it seems crucial to understand if additional amino acids encoded by the retained intron 6 may affect LAT function. Western blotting analysis of human LAT_{i6} transduced lymphoid cells revealed that alternative LAT isoform can be translated into protein. Moreover it was targeted to the outer plasma membrane similarly to the canonical LAT isoform. Additionally, confocal microscopy of human lymphoid cell line transduced with C-terminal fusion proteins composed of LAT isoforms and a fluorescent protein (Zs-Green) showed a proper LAT accumulation in the immunological synapse area. Thus, seemingly intron 6 retention does not impair LAT function, however as revealed by the cycloheximide chase assay the half life of LATi6 isoform is significantly shorter (5 hours) in comparison with the canonical LAT isoform (8 hours). We propose that a possible consequence of an increased turnover of LATi6 protein is a more efficient proof reading control of T cell receptor signaling. We discuss how this evolutionary innovation may influence the immune response in various mammalian species expressing orthologous LATi6 proteins.

Central domain of yeast transcription factor Rpn4 facilitates degradation of green fluorescent protein in human cells

A. V. Morozov, D. S. Spasskaya, D. S. Karpov, V. L. Karpov

W.A. Engelhardt Institute of Molecular Biology RAS, Moscow, Russian Federation

Background: Little is known about universal protein degradation signals. It was shown that mammalian ornithine decarboxylase (ODC) contains portable universal degradation signal (degron) which when fused with a stable protein induces fast proteasomal hydrolysis of chimera in both mammalian and yeast cells. No universal degrons from yeast, capable to stimulate protein degradation in mammalian cells are known.

The Rpn4 is 531 amino acid (aa) long yeast transcription factor with a short half-life. It contains ubiquitin-dependent and –independent degrons. We investigated degradation of the wild type yRpn4 in human cells and compared activity of its degradation signals with mammalian ODC degron.

Methods: First, eukaryotic vectors encoding green fluorescent protein (GFP), yRpn4 and GFP-ODCsignal chimera were obtained. Next, eight vectors were designed to express chimeras, containing ubiquitin-dependent and –independent degrons, as well as N-terminal and central domains of yRpn4 fused with either N- or C-terminus of the GFP. HEK 293T cells were transfected with the plasmids and gene expression was analyzed by Real-time PCR and Western blot (WB). Nuclear and cytoplasmic fractions of cells transfected with yRpn4 were examined for the protein localization. Proteasome inhibition assays with MG132/lactacystin and cycloheximide/puromycin chases were performed to evaluate stability and degradation kinetics of recombinant proteins, fluorescent microscopy and flow cytometry were used to confirm the obtained results. To affirm fast hydrolysis of yRpn4 in transfected cells accumulation kinetics of the recombinant protein in presence of proteasome inhibitor was examined. The yRpn4 accretion was compared with that of two fast and two slow degrading proteins.

Results: Fast proteasomal degradation of recombinant yRpn4 was shown in human HEK 293T cells and yRpn4 was detected in both nuclear and cytoplasmic fractions. N-terminal ubiquitin-independent and canonical ubiquitin-dependent degrons of yRpn4 did not induce proteasomal degradation of the yRpn4-GFP chimeras in mammalian cells. In contrast the central domain (aa 177–327) of yRpn4 effectively stimulated degradation of yRpn-GFP fusion protein (half-life 1–1.5 h); half-life of the GFP-ODCsignal was estimated to be 2–3 h.

Conclusions: Yeast transcription factor Rpn4 undergoes fast proteasomal degradation in human cells and its central domain contains a universal degron that is capable to destabilize GFP more efficiently than the ODC degron. Obtained results not only extend our knowledge about evolution of the degradation processes in micro and macro organisms, but also reveal a new universal degron, which can be used to direct highly efficient proteasomal degradation of required proteins in human cells.

SUN-515
Chaperone activity of monomeric human 14-3-3 Zeta protein on different model protein substrates

N. N. Sluchanko[1], S. Roman[1], N. Chebotareva[1], N. Gusev[2]
[1]Structural Biochemistry of Proteins, Institute of Biochemistry of RAS, [2]School of Biology, Moscow State University, Moscow, Russian Federation

14-3-3 proteins are ubiquitous, conservative and relatively small (~30 kDa) proteins found in many eukaryotes and have multiple diverse cellular functions. First of all, members of the family are known for their ability to bind hundreds of different protein partners specifically phosphorylated at certain motifs including phosphoserine or phosphothreonine. By this means 14-3-3s regulate stability, enzymatic activity, subcellular localization and many other properties of target phosphoproteins. 14-3-3 can form stable dimers and it has long been discussed that dimeric 14-3-3 can serve as adaptor or scaffold, bridging together two partners simultaneously. Moreover, recently, 14-3-3s were found as chaperones being able to dissolve pre-formed protein aggregates and to prevent aggregation of a range of partially denatured proteins, thereby participating in protein quality control. However, structural elements responsible for the chaperone action of 14-3-3 have not been identified and the question remained whether the dimeric structure is necessary for the chaperone activity of 14-3-3.

Our recent work was devoted to investigation of properties of an engineered mutant of 14-3-3ζ (14-3-3ζm) unable to form dimers and imitating 14-3-3 monomer, which may accumulate under unfavorable cellular conditions. 14-3-3ζm was properly folded, however demonstrated increased surface hydrophobicity at different temperatures, presumably, due to the exposed interface hydrophobic residues normally involved in 14-3-3 dimerization. Despite decreased thermostability and stability to proteolysis, 14-3-3ζm retained phosphosubstrate binding ability and therefore seemed to be functionally active. Moreover, we surprisingly found that it displays pronounced chaperone-like activity by preventing heat shock-induced aggregation of myosin subfragment 1 (S1), alcohol dehydrogenase (ADH), and phosphorylase kinase (PhK) and DTT-induced aggregation of insulin. Importantly, the effect of 14-3-3ζm was concentration-dependent and at all tested chaperone/substrate ratios 14-3-3ζm was more effective chaperone comparing with the wild type dimeric 14-3-3ζ. Moreover, in some cases chaperone-like activity of 14-3-3ζm was even higher than that of the specialized chaperone proteins HspB6 and HspB5. We believe that chaperone-like activity of 14-3-3 monomers can at least partially account for the general chaperone function of 14-3-3 and is presumably due to the hydrophobic clusters located near the 14-3-3 subunit interface that become exposed upon 14-3-3 dissociation, which could therefore be benefitful for the cell upon stress conditions.

Keywords: 14-3-3 proteins, anti-aggregating activity, small heat shock proteins.

SUN-516
Characterization of an E3 liagse, RING finger protein 182 (Rnf182) in the zebrafish embryos

S. Maddirevula, M. Anuppalle, A. Kumar, M. Rhee
Biological Science and Biotechnology, Chungnam National University, Daejeon, Korea

Ubiquitin proteasome system (UPS) largely associated with most common neurodegenerative conditions including Alzheimer's (AD) and Parkinson's disease (PD). Recent reports have shown, an E3 ligase RING finger protein 182 (RNF182) is a brain abundant cytoplasmic protein and upregulated in AD brains. Little is known about the RNF182 roles in vertebrate embryogenesis. We are reporting the expression and function of *rnf182* in zebrafish. Annotation of domain architectures found that Rnf182 is a RING-finger E3 ligase with a RING domain at N-terminal region together with two transmembrane domains at C-terminal region. WISH analysis detected that *rnf182* is expressed at the end of the gastrulation. Interestingly, and are abundant in the brain, pharyngeal arches, and lateral line system at 46 hpf through 98 hpf. Considering that Rnf182 has a RING finger domain, we ectopically expressed Rnf182 and performed ubiquitylation assays in HEK293T cells, demonstrating that Rnf182 undergoes self-polyubiquitylation. Furthermore, when Rnf182-R lacking the RING domain was overexpressed, it failed self-ubiquitylation of Rnf182, suggesting that Rnf182 might function as an E3 ubiquitin ligase via its RING domain. Overexpression of Rnf182 in zebrafish embryos caused defects in the developing CNS. We are currently generating a zebrafish germ line mutant using CRISPR-CAS9 system.

Convergence of ubiquitylation and phosphorylation signaling in rapamycin-treated yeast cells

V. Iesmantavicius, B. T. Weinert, C. Choudhary
NNF Center for Protein Research, University of Copenhagen, Copenhagen, Denmark

The target of rapamycin (TOR) kinase senses the availability of nutrients and coordinates cellular growth and proliferation with nutrient abundance. Inhibition of TOR mimics nutrient starvation and leads to the reorganization of many cellular processes, including autophagy, protein translation, and vesicle trafficking. TOR regulates cellular physiology by modulating phosphorylation and ubiquitylation signaling networks, however, the global scope of such regulation is not fully known. Here, we used mass spectrometry (MS)-based proteomics approach for the parallel quantification of ubiquitylation, phosphorylation, and proteome changes in rapamycin-treated yeast cells. Our data constitutes a detailed proteomic analysis of rapamycin-treated yeast with 3,590 proteins, 8,961 phosphorylation sites, and 2,498 di-Gly modified lysines (putative ubiquitylation sites) quantified. The phosphoproteome was extensively modulated by rapamycin treatment, with more than 900 up-regulated sites one hour after rapamycin treatment. Dynamically regulated phosphoproteins were involved in diverse cellular processes, prominently including transcription, membrane organization, vesicle-mediated transport, and autophagy. Several hundred ubiquitylation sites were increased after rapamycin treatment and about half as many decreased in abundance. We found that proteome, phosphorylation, and ubiquitylation changes converged on the Rsp5-ubiquitin ligase, Rsp5 adaptor proteins, and Rsp5 targets. Putative Rsp5 targets were biased for increased ubiquitylation, suggesting activation of Rsp5 by rapamycin. Rsp5 adaptor proteins, which recruit target proteins for Rsp5-dependent ubiquitylation, were biased for increased phosphorylation. Subcellular localization and stability of transmembrane permeases and transporters is known to be regulated by Rsp5. We found that permeases and transporters were biased for reduced ubiquitylation and reduced protein abundance. The convergence of multiple proteome-level changes on Rsp5 indicates a key role for Rsp5 in the response to rapamycin treatment. Collectively, these data reveal new insights into the global proteome dynamics in response to rapamycin treatment and provide a first detailed view of the co-regulation of phosphorylation and ubiquitylation-dependent signaling networks by this compound.

Endoplasmic reticulum-associated degradation controls the levels of amyloid precursor protein

C. Yefi, A. Gonzalez, V. Cavieres, H. Bustamante, G. Mardones, P. Burgos
Universidad Austral de Chile, Valdivia, Chile

Alzheimer's disease (AD) is characterized by the overproduction of pathogenic amyloid-b peptide (Ab), which is generated by proteolytic cleavage of the b-amyloid precursor protein (APP). The action of b-secretase on APP produces a C-terminal fragment (C99) that is subsequently processed by g-secretase to release Ab. It has been proposed that substrate availability contributes to Ab production, and that this may in turn be affected by the rate of APP/C99 turnover. We have demonstrated that the degradation of C99 can be triggered at the ER in an ubiquitin- and proteasome-dependent manner. In this study we investigated the contribution of the ER-associated degradation (ERAD) machinery on APP/C99 endogenous levels. It is known that misfolded glycoproteins that fail to attain their correct conformation at the ER are recruited by the ER Degradation Enhancer Mannosidase alpha like 1 (EDEM1) from the calnexin/calreticulin folding cycle, and are directed to the dislocation channel for cytosolic degradation by ERAD. This last step relies on the hexameric ATPase p97/VCP, and on a small p97/VCP-interacting protein (SVIP) that functions as an inhibitor of the ERAD pathway. The aim of this study was to investigate the outcome of ERAD inhibition on APP and C99 levels by either stable expression of an EDEM1 shRNA, transient overexpression of SVIP, or pharmacological inhibition of p97/VCP. Our results support a model in which the levels of APP and C99 are highly controlled at the ER.

Enhanced proteasome degradation extends *Caenorhabditis elegans* lifespan and ameliorates neurodegeneration

K. Georgila[1], N. Chondrogianni[1], N. Kourtis[2], N. Tavernarakis[2], E. S. Gonos[1]
[1]*Institute of Biology, Medicinal Chemistry & Biotechnology, National Hellenic Research Foundation, Athens,* [2]*Institute of Molecular Biology and Biotechnology, Foundation of Research and Technology-Hellas, Heraklion, Greece*

Aging and various age-related diseases are associated with progressive decline in proteostasis and accumulation of damaged macromolecules. The proteasome is the major cellular protease implicated in the disposal of normal and damaged proteins, having an impaired function during aging. In previous reports, using human primary cells, we demonstrated that proteasome activation through overexpression of proteasome subunits confers extension of replicative senescence and resistance to oxidative stress. Herein, we have investigated the impact of enhanced proteasome function on organismal longevity and aggregation-related pathologies by employing *Caenorhabditis elegans* as a model system. We have found that overexpression of a single core proteasome subunit in wild type worms enhanced proteasome content, assembly and function. The activation of the proteasome extended animal lifespan, healthspan and survival under proteotoxic conditions. The longevity prolonging effect of the ectopic expression of the core proteasome subunit was found to depend on the FOXO transcription factor DAF-16 and was associated with its elevated transcriptional activity. Finally, we have unveiled a major role of enhanced proteasome activity in aggregation-related pathologies underlying neurodegenerative diseases. Genetic activation of the proteasome minimized the detrimental effect of polyglutamine-induced toxicity, whereas knockdown of a key component of the proteasome exaggerated the disease phenotypes. Similar results were obtained by using a temperature inducible model of Amyloid beta (Aβ) –induced toxicity mimicking Alzheimer's disease. Collectively, our findings demonstrate that enhanced proteasome function alleviates proteotoxicity and promotes longevity in synergy with other key nodes of lifespan regulation in *C.elegans*. Understanding the mechanism by which preservation of proteostasis, via enhancement of proteasome function, decelerates the aging process and alleviates age-related pathologies may lead to new therapeutic and anti-aging interventions.

SUN-521
Expression of SUMO negatively regulates interferon signaling

G. Maarifi, M. A. Maroui, S. Nisole, M. K. Chelbi-Alix
INSERM, Paris, France

Interferons (IFNs) exhibit pleitropic functions including antiviral, growth inhibitory and apoptotic activities. IFNs activate the JAK/STAT pathways to trigger the transcription of IFN-inducible genes (ISGs) whose products mediate their biological functions. It has been established that ubiquitin or ubiquitin-like modifiers such as SUMO or ISG15 modify many ISGs or key regulators of IFN signaling. However, little is known on the role of SUMO in IFN signaling, cell regulation and antiviral response.

Here, we report that stable expression of each of the SUMO paralog in different human cell lines altered type II IFN signaling. SUMO1, SUMO2 or SUMO3 stable expression led to a lower STAT1 phosphorylation and binding to DNA in response to IFNγ, resulting in a selective inhibition of IFNγ-induced transcriptional activity. Indeed, the expression of SUMO did not affect the increase of IRF1 mRNA in response to IFNγ whereas it blocked IP10 mRNA expression. Importantly, enhanced SUMOylation reduced the capacity of IFNγ to inhibit cell growth and to protect cells from viral infection, a finding that implicates SUMO as a negative regulator of IFNγ responses.

Taken together, these results identify SUMOylation as a mechanism that attenuates cell sensitivity to IFNγ by decreasing STAT1 activation and its binding to DNA, preventing hyperresponsiveness to this cytokine, thus adding the SUMO-mediated inhibition as part of other negative IFN signaling pathways known to date.
Keywords: interferon, STAT1, SUMO.

Functional and structural studies of the BiP chaperon protein and his role in protein translocation

C. A. Wilson, M. Vega, A. Tapia
Bioquímica y Biología Molecular, Universidad de Chile, Santiago, Chile

BiP (Binding inmmunoglobulin protein) also known as Kar2p in yeast, is a Chaperon involved on protein translocation from the citoplasm to the endoplasmatic reticulum (ER), the first step on protein trafficking. BiP helps to the correct folding of various

© 2014 The Authors. FEBS Journal © 2014 FEBS

proteins and promote of destruction of missfolded ones. Moreover, BiP facilitates assembling of antibodies. BiP has two domains, one ATPase domain and a peptide binding domain that binds the polypeptide while is translocating (We know the polypeptide domain has a triptophan at position 662, although the crystal structure isn't complete). Until now, it's unclear if BiP uses the energy of ATP and transforms it in mechanical energy, in order to translocate polypeotide through the ER. We have developed a strategy to purified the BiP protein in only two steps, with very good yields and very pure for structural studies. The method consists by a nickel affinity column and subsequently an ATP-agarose column that binds specifically proteins that binds ATP, and after these two steps BIP is obtained pure. We follow the intrinsic fluorescence of tryptophan (W) at different concentrations of guanidinium chloride (GdHCl) and found that BiP shows an increase in tryptophan fluorescence and a red-shift of the maximum emission wavelength longitude as concentration of GdHCl have higher values. Therefore, these results imply that the tryptophan is buried within the protein structure and is a good probe to follow structural changes in this protein upon unfolding. Finally, we have developed an in vitro translocation assay with detergent soluble translocon and pure BiP in order to determine the translocation rates. This method will allow us to test the different components in order to determine how BiP uses the energy of ATP binding/hydrolysis to move a polypeptide chain through the Sec61 translocon complex at the single molecule level by optical tweezers. Functional roles of the lysine residues in the AXH domain of the ataxin-1 protein

A.-R. Kang, Y.-H. Lee, H.-R. Jang, S. Kang
Division of Life Sciences, Korea University, Seoul, Korea

Spinocerebellar ataxia type 1 (SCA1) is an autosomal dominant neurodegenerative disease that leads to the loss of Purkinje neurons in the cerebellum. SCA1 is associated with expansion of a polyglutamine tract of ataxin-1 which is found predominantly in the nucleus and cytoplasm of neurons. Previously, we found that the E2-conjugating enzyme UbcH6 interacts with the AXH domain and that the AXH domain is preferentially ubiquitinated. Human AXH domain contains six lysine residues. We speculated that the lysine residues of AXH domain may play important roles in the interaction and ubiquitination. As a first step toward characterizing biological functions of the lysine residues, we employed the site-directed mutagenesis techniques to replace lysine residues with arginines. Co-IP and ubiquitination experiments showed that a lysine residue among six lysine residues is mostly ubiquitinated and is important for the interaction between AXH domain and UbcH6. Our study will contribute to elucidating roles of ataxin-1 in the SCA1 pathogenesis.

Keywords: Ataxin-1, AXH, SCA1.

Galectin-8 as a novel regulator of proteasomal activity

C. Holmes[1,2], T. Feuerhake[1], P. Cortes[1,2], C. Oyanadel[1,2], R. Shaughnessy[1,2], A. González[1,2], A. Soza[1,2]
[1]Departamento de Inmunolgía Clínica y Reumatología, [2]Centro de Envejecimiento y Regeneración (CARE), Facultad Ciencias Biológicas, P.Universidad Católica de Chile, Santiago, Chile

Galectin-8 (Gal-8) is a lectin that regulates diverse cellular processes relevant to the function of the immune system and to diseases such as autoimmunity and cancer, in which the ubiquitin proteasomal system is also involved. Gal-8, like other galectins, is secreted through an unconventional mechanism. Secreted Gal-8 interacts with beta-galactosides (poly-N-acetyllactosamines) present on glycoproteins and glycolipids at the cell surface. The proteasome (20S) is a large protein complex that degrades cytosolic and nuclear proteins. The 20S proteasome binds to different regulators (activators), which affect its catalytic activity. The 19S regulator binds to the 20S proteasome forming the 26S proteasome, which degrades proteins conjugated with polyubiquitin chains. The 11S regulator attaches to the 20S proteasome forming a complex that promotes the production of antigenic peptides. Here we show that Gal-8 increases the activity of the proteasome, both when overexpressed or hexogenously added. Such an effect was inhibited by lactose, indicating its dependency on interactions with glycans at the cell surface, and was associated with an increment in the 19S proteasomal regulator, while the 11S regulator, as well as the proteasomal mass, both remained unchanged. These results are the first to show that a member of the galectin family regulates proteasomal activity. (Financed by CONICYT PFB12/2007, Fondecyt N° 1131122).

GATA3 is a novel target for an E3 ligase SCF-Fbw7 in T-cell development

M. Kitagawa, K. Kitagawa
Molecular Biology, Hamamatsu University School of Medicine, Hamamatsu, Japan

We have studied cellular targets and functions of SCF-Fbw7, an SCF-type E3 ubiquitin ligase (thereafter Fbw7) and had reported that Fbw7 promotes ubiquitin-dependent degradation of c-Myb, a hematopoietic transcription factor (Kitagawa et al. ***Oncogene*** **28,** ***Cell Div.*** **5**). Moreover, it has been reported that Fbw7 targets other important cellular proteins such as c-Jun, Notch1, c-Myc, NFkB2 and MCL1. Here, we show that GATA3, one of GATA family transcription factor is a novel target for Fbw7 in T-cell development. Fbw7 bound to, ubiquitylated, and destabilized GATA3 using overexpressed proteins in cultured cells. Two Cdc4 phosphodegron (CPD) candidate sequences, consensus Fbw7 recognition domains, were identified in GATA3 and phosphorylation of Thr-156 in CPD was required for Fbw7-mediated ubiquitylation and degradation. Phosphorylation of Thr-156 GATA3 was detected in mouse thymocytes and CDK2 was identified as a respondent for phosphorylation at Thr-156. Moreover, we found that augmented GATA3 in CD4/CD8 double negative (DN) stage 4, CD4 single positive (SP), and CD8 SP lineages in Fbw7-deficient thymocytes. The conditional KO mice exhibited reduced thymic CD4 SP, and splenic $CD4^+$ and $CD8^+$ subcell proportions. Furthermore, the Fbw7 deficiency skewed CD8 SP lineage differentiation, which exhibited a higher incidence of apoptosis. Similar perturbations during development of CD8 positive cells were reported with transgenic mice, which enforced GATA3 expression throughout T-cell development (Nawijn et al. ***J Immunol.*** **167**). Therefore, our observations suggest Fbw7-mediated GATA3 regulation with CDK2-mediated phosphorylation of CPD contributes to the precise differentiation of T-cell lineages.

Keywords: ubiquitin, Fbw7, GATA3.

SUN-526
ISG'ylation increases stability of hundreds proteins including STAT1 that prevents premature termination of immune responses in LPS stimulated microglia

P. Przanowski[1], S. Loska[1], D. Cysewski[2], M. Dabrowski[1], B. Kaminska[1]
[1]Laboratory of Molecular Neurobiology, Nencki Institute of Experimental Biology, [2]Laboratory of RNA Biology and Functional Genomics, Institute of Biochemistry and Biophysics, Warsaw, Poland

The initiation, progression and termination of brain inflammation requires changes in gene expression, posttranslational protein modifications and regulation of protein degradation. Microglia are brain resident macrophages which become activated in most neurological diseases. Inflammatory activation could be mimicked in primary microglial cultures by treatment with lipopolisacharide (LPS). We demonstrated the increase of Uba7 expression – an E1 enzyme that is crucial for ISG'ylation – posttranslational modification similar to ubiquitination in inflammatory microglia. ISG'ylation is an important part of antiviral response and inflammatory processes, but unlike ubiquitination, ISG'ylation do not lead to protein degradation and its function remains unclear. We found the increased level of ISG'ylation after LPS stimulation. Silencing of UBA7 expression in immortalized BV2 microglial cells led to decrease in a steady state level of hundreds proteins as demonstrated by mass spectrometry. many of these proteins have been described as ISG'ylated proteins in earlier studies. One of such proteins is transcription factor STAT1, which is also a main activator of UBA7 expression. We demonstrated that in microglia stimulated by LPS STAT1 is ISG'ylated and the levels of both total and phosphor- STAT1 decrease after UBA7 silencing. This is accompanied by premature termination of the immune response, as shown by the reduction of *iNos* and *Ccl5* expression. Those observations suggest that ISG'ylation increases stability of many proteins, including STAT1, that prevents premature termination of immune responses.
Keywords: Inflammation, ISG'ylation, STAT1.

SUN-527
Ki-1/57 SUMOylation and its function in the cell

A. Saito[1], F. C. Costa[1], K. A. Gonçalves[1], M. T. Santos[2], J. Kobarg[1]
[1]Brazilian Biosciences National Laboratory, Brazilian Center for Research in Energy and Materials, Campinas, [2]Innovation, Research & Development (IP&D), Grupo Fleury, São Paulo, Brazil

Ki-1/57 is a nuclear and cytoplasmic human protein that was first identified in malignant cells from Hodgkin's lymphoma. It is involved in gene expression regulation on both transcriptional and mRNA metabolism levels. Ki-1/57 belongs to the family of intrinsically unstructured proteins, undergoes phosphorylation by PKC and methylation by PRMT1. Previous characterization of protein interaction profile by yeast two-hybrid screening showed that Ki-1/57 interacts with proteins of the sumoylation machinery: the SUMO E2 ligase UBC9 and the SUMO E3 ligase PIAS3. We aimed to investigate whether Ki-1/57 is sumoylated and its possible roles in the cell. We have indentified seven potential SUMO target sites (lysines residues) on Ki-1/57 sequence through program SUMOplot Prediction. In fact, we have observed that Ki-1/57 is sumoylated by both SUMO-1 and SUMO-2/3 *in vitro* and *in vivo*. Through immunocytochemistry we have found that EGFP-Ki-1/57 co-localizes with SUMO-1 and SUMO-2/3 in both the nucleus and the cytoplasm of HEK293 cells. To identify which lysine residues are covalently attached to SUMO-1 and SUMO-2/3, site-directed mutagenesis of the sumoylation target lysines was performed. Ki-1/57-Flag wild-type and mutants were superexpressed in HEK293 cells, immunoprecipitated with the antibody anti-Flag and probed with anti-SUMO-1 or anti-SUMO-2/3. We have identified three lysines as the major sumoylation sites by immunoprecipitation. Moreover, we have found that Ki-1/57 sumoylation is important to the regulation of the E1A pre-mRNA processing. These results can help to better understand the mechanisms underlying the sumoylation of Ki-1/57 regulate the protein functions of the cells.

SUN-528
Low expression level of OB-Rb results from constitutive translocational attenuation attributable to less efficient signal sequence

S.-W. Kang, I. Choi
Department of Biomedical Sciences, University of Ulsan College of Medicine, Seoul, Korea

OB-Rb is a crucial factor for leptin signaling. This study was initially motivated by the observation that OB-Rb expression is constitutively inhibited at early secretory pathway. Our analyses reveal that OB-Rb contains less hydrophobic, but functionally active N-terminal signal sequence. Constitutive translocational attenuation attributable to less efficient signal sequence proved to be a reason for low protein level of OB-Rb. By contrast, enhanced signal sequence efficiency rescues translocation and cell surface expression of OB-Rb, and eventually potentiates leptin signaling. These observations provide considerable insight into the therapeutic enhancement of OB-Rb translocation as a potential strategy for leptin resistance.

Multivesicular body pathway-dependent amino acid recycling is required for metabolic homeostasis and survival during starvation

O. Schmidt[1], M. Müller[1], M. Angelova[2], K. Faserl[3], Z. Trajanoski[2], H. Lindner[3], D. Teis[1]
[1]Cell Biology, [2]Bioinformatics, [3]Protein Microanalysis Facility, Biocenter – Medical University, Innsbruck, Austria

The ESCRT machinery drives the multivesicular body (MVB) pathway in eukaryotic cells, which regulates cell signaling by selectively targeting ubiquitinated cell surface receptors for degradation in lysosomes. How ESCRT-dependent membrane proteome remodeling contributes to cellular homeostasis was unknown. Using an unbiased quantitative proteomics and transcriptomics approach in yeast, we show that the ESCRT pathway is essential to maintain free amino acid levels, particularly during nutrient limitation. Early during starvation membrane protein degradation via MVBs supplies amino acids for the efficient synthesis of vacuolar hydrolases, which is required to boost the catabolic activity of vacuoles. This is essential to enhance intracellular amino acid recycling further and thereby – together with autophagy – maintains protein synthesis and promotes the extensive proteome remodeling processes that allow cells to complete cell division and to enter quiescence. These findings reveal an important mechanism by which ESCRT-dependent membrane

Non-degradative and non-lysine mediated ubiquitination of the Dopamine D4 receptor

K. Skieterska, P. Rondou, B. Lintermans, K. Van Craenenbroeck
Laboratory of Eukaryotic Gene Expression and Signal Transduction (LEGEST), Ghent University, Ghent, Belgium

G protein-coupled receptors are integrated in a complicated network of interacting proteins and are often regulated by post-translational modifications. Ubiquitination is a post-translational modification that targets proteins for degradation but can also regulate other cellular processes such as endocytosis, trafficking and DNA repair.

We are investigating the dopamine D_4 receptor (D_4R) signaling. Several polymorphic variants of the D_4R exist, which differ in the number of 16-amino acid repeats in the third intracellular loop. The functional role of the receptor polymorphic region is not known but persons with the seven-repeat allele show a predisposition to develop Attention Deficit Hyperactivity Disorder (ADHD) [1].

We have identified a protein, KLHL12, which specifically interacts with the polymorphic region [2] and enhances ubiquitination of all common D_4R variants but not of the D_4R with seven repeats. This differential ubiquitination can have functional implications. First, KLHL12-mediated D_4R ubiquitination does not lead to receptor degradation [3]. Next the influence of ubiquitination on receptor signaling was explored and a role in modulation of cAMP levels upon D_4R activation was found. To obtain a broader picture of the involvement of ubiquitination in receptor signaling, gene expression profiling using microarray technology will be performed.

In this study we are also testing the hypothesis that KLHL12 promotes ubiquitination on non-lysine residues of the D_4R. First, the ubiquitination pattern of the receptor with all intracellular Lys mutated to Arg was verified. Next, the importance of the Cys and Ser/Thr residues in the ubiquitination process of the receptor was examined. The obtained results suggest that Ser/Thr residues are the preferred ubiquitin-conjugation sites in case of KLHL12-mediated ubiquitination, but further confirmation by mass-spectrometry is necessary.

Acknowledgments: This work was supported by Research Foundation – Flanders (FWO).

Nuclear role of human endocytic adaptor intersectin

M. Dergai[1], O. Dergai[1], S. Pankyvskyi[1], S. Reshetniak[1], O. Novokhatska[1], M. Miaczynska[2], A. Rynditch[1]
[1]*Institute of Molecular Biology and Genetics NASU, Kyiv, Ukraine,* [2]*IIMCB, Warsaw, Poland*

Internalization of different molecules via clathrin-mediated endocytosis, their intracellular transport and cellular signalling events are intimately interwined. The mutual coregulation of endocytosis and mitogenic signalling enables finely tuned regulation of information processing within the cell, cell-dependent and context-dependent cellular responses.

More than a decade ago adaptor protein intersectin (ITSN) was discovered. It was named after «intersection» because of its predicted position on crossroads between signalling and endocytosis. ITSN is a pivotal regulator of clathrin-mediated endocytosis, enhancer of cell proliferation and survival. The project is focused on regulation of mitogenic signalling by ITSN. Recently endocytic proteins were shown to be transported to the nucleus; certain proteins from this cohort regulate gene expression.

Biochemical and cell biology studies demonstrated nucleocytoplasmic shuttling of ITSN. In the nucleus ITSN-positive signal with increased molecular weight was observed. We showed that this is due to monoubiquitination of ITSN. Monoubiquitinated form of ITSN is predominantly localized in nucleus, moreover recombinant fusion protein Ubiquitin-ITSN demonstrated nuclear localization. We have identified ubiquitin ligase AIP4 responsible for modification of ITSN.

We identified heterogeneous nuclear ribonuclear protein K (HNRNPK) as binding partner for ITSN. HNRNPK is involved in regulation of gene expression and transport of transcripts from the nucleus. First, we investigated whether ITSN could be associated with specific transcripts. Antibodies against ITSN precipitated transcripts of proto-oncogene Fyn. These transcripts are specifically bound with HNRNPK to be transported in the cell. Thus, for the first time we showed that endocytic protein could be bound to the transcripts.

To investigate whether ITSN can affect level of expression of HNRNPK targets, nuclear-targeted variant of ITSN was obtained. A set of genes regulated by HNRNPK crucial for cellular proliferation and survival was screened for changes in the level of expression. Overexpression of wild-type ITSN and its nuclear-targeted variant enhanced expression of p53 and c-Myc genes. Notably, both forms of ITSN, wild-type and nuclear-targeted, affected expression levels of mentioned genes. Thus, ITSN may contribute to signalling events in the cytosolic and nuclear parts of signalling cascades. Moreover, nuclear localization of ITSN had significantly higher impact on the level of expression of c-Myc proto-oncogen than wild-type one.

Zinc-induced aggregation of the amyloid-b peptide (Ab) is a hallmark molecular feature of Alzheimer's disease (AD). Recently it was shown that phosphorylation of Aβ at Ser8 promotes the for-

© 2014 The Authors. FEBS Journal © 2014 FEBS

mation of toxic aggregates. In this work, we have studied the impact of Ser8 phosphorylation on the mode of zinc interaction with the Ab metal-binding domain 1–16 using isothermal titration calorimetry, electrospray ionization mass spectrometry and NMR spectroscopy. We have discovered a novel zinc binding site (^{6}HDpS^{8}) in the phosphorylated peptide, in which the zinc ion is coordinated by imidazole ring of His6, phosphate group attached to Ser8 and a backbone carbonyl group of His6 or Asp7. Interaction of zinc ion with this site involves His6, thereby withdrawing it from the interaction pattern observed in the non-modified peptide. This event was found to stimulate dimerization of peptide chains through the ^{11}EVHH^{14} site, where the zinc ion is coordinated by the two pairs of Glu11 and His14 in the two peptide subunits. The proposed molecular mechanism of zinc-induced dimerization could contribute to the understanding of initiation of pathological Aβ aggregation, and the ^{11}EVHH^{14} tetrapeptide can be considered as a promising drug target for the prevention of amyloidogenesis.

Pin1 modulates the ADP-induced migration of human dental pulp cells through P2Y1 stabilization

S.-G. Ahn[1], S.-M. Park[1], S.-A. Kim[2]
[1]Department of Pathology, School of Dentistry, Chosun University, Gwangju, [2]Department of Biochemistry, Dongguk University, Gyeongju, Korea

The present study was aimed to investigate the importance of Pin1 expression in human dental pulp cells (hDPCs) and to understand the possible involvement of Pin1 in the regulation of P2Y1 and the subsequent activation of ADP-mediated P2Y1 signaling. Here, we show, by Pin1 pharmacological inhibition and by using small interfering RNAs, Pin1 is involved in the P2Y1-mediated hDPC migration. In addition, Pin1-P2Y1 mediated migration is associated with the mitogen-activated protein kinase pathways as evidenced by inhibitors of ERK1/2, JNK, and p38 kinase. Functionally, Pin1 directly binds and stabilizes P2Y1 and high levels of Pin1 sustain P2Y1 signaling, which correlates with cell migration. These results strongly suggest Pin1 mediates cell migration through the P2Y1 stabilization and Pin1-P2Y1 signaling pathways may serve as a novel mechanism for the cell migration progression in human dental pulp cells (This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government MSIP (No.2008-0062283).

Pupylation and proteasomal degradation in mycobacteria

E. Weber-Ban, J. Barandun, C. L. Delley
Institute for Molecular Biology, ETH Zurich, Zurich, Switzerland

Mycobacteria encode a proteasome assembly restricted to the actinobacterial phylum. Proteins are targeted for degradation by this proteasome complex through a post-translational modification termed pupylation that shows functional analogies to ubiquitination in eukaryotes (for review see 1–3). For the human pathogen *Mycobacterium tuberculosis*, the Pup proteasome system contributes to pathogenicity by supporting the bacterium's persistence within host macrophages, rendering it a feasible drug target.

Pupylation involves the covalent attachment of a small protein termed Pup (prokaryotic ubiquitin-like protein) to lysine residues of the target substrate. A single ligase termed PafA

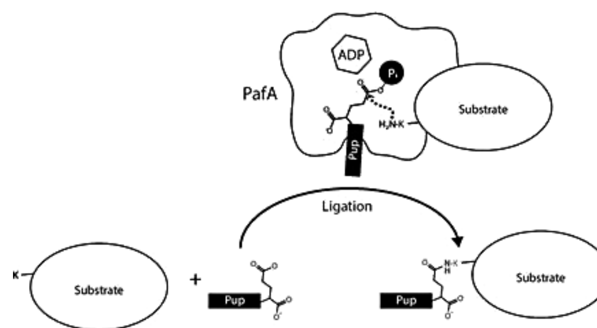

Fig. 1.

(proteasome-accessory factor A) is responsible for the formation of the isopeptide bond. PafA catalyzes the covalent attachment of Pup's C-terminal glutamate residue to the side chain of the target lysine. We are studying the Pup-proteasome system by biochemical and structural techniques with a particular focus on how the intrinsically disordered Pup is recognized by the pupylation enzymes and how target proteins are selected for modification and degradation.

Quantitative proteomics and phosphoproteomics of human LRRK2 (R1441C) *Drosophila* model of Parkinson's disease

M. Islam[1], W. Jacob[2], A. Ziegler[3], H. Nolte[4], B. Hovemann[2], R. Heumann[2], M. Krüger[4], H. Heumann[5]
[1]Transpol and Silantes, Max Plank Institute for Heart and Lung, Badnauheim, [2]Ruhr University, Bochum, Germany, [3]Université de Bourgogne, Dijon, France, [4]Max Plank Institute for Heart and Lung, Badnauheim, [5]Silantes, Transpol, Munich, Germany

Parkinson's disease (PD), occurring in late mid-life, is the second most prevalent neurodegenerative disorder after Alzheimer's disease. *Drosophila melanogaster*, the fruit fly, is already an accepted PD model and has been investigated vastly in the last couple of years. Stable isotope labeling of amino acids in cell culture (SILAC) is a widely used powerful tool for the quantification of proteomics based on mass spectrometry and recently SILAC was also extended for labeling of living animal including mouse, zebra fish and fruit flies. In this study we showed a quantitative proteomics study of human LRRK2-R1441C overexpressing transgenic *Drosophila melanogaster* as a PD model at different disease stages. In total 3570 proteins were identified from fly head and 1753 proteins were quantified. Overall 183 (>10%) proteins were found to be significantly regulated at 30 days old flies. Up-regulated proteins are mostly associated with cytoskeleton and mitochondrion that may presage the development of PD symptoms. In the fraction of down-regulated proteins, we found protiens linking with catecholamine synthesis which determined the selective vulnerability to hLRRK2 (R1441C). Protein phosphorylation

© 2014 The Authors. FEBS Journal © 2014 FEBS

is a crucial regulatory event for most biological process and since LRRK2 has a kinase activity, we performed phosphoproteomics experiment in order to have a deeper understanding about signal transduction pathways during PD development in *Drosophila*. In total, 5518 phosphorylated sites were identified and among the significant candidates, we quantified Futsch which was already known to be phosphorylated by LRRK2. As a summary, this study provides dynamic and temporal proteomic and phosphoproteomics changes due to over-expressed human LRRK2 (R1441C) in *Drosophila melanogaster* as a PD model that may shed light on the fundamental etiology of PD.

Relevance of disulfide bridge upon IFNAR1 flexibility

H. N. Sharma[1], N. Sharma[2]
[1]*Biological Chemistry,* [2]*Weizmann Institute of Science, Rehovot, Israel*

Members of the Type I interferon acts through a single cell surface receptor composing of IFNAR1 and IFNAR2 subunit inducing measurable antiviral and cell growth inhibition. Since last two decades many research groups have been trying to dissect the mechanism of how the members of the type I interferon which has 90% sequence similarity bind with the same receptor resulting in the inhibition of different activities. Recently we solved the structure of the bound receptor complex and its unbound component, showing significant structural arrangements upon ligand binding.

Here we propose to investigate the relationship between receptor flexibility, domain movement and signalling upon interferon binding. In order to restrict the receptor flexibility and domain movement we introduce single disulfide bridge between different extracellular domains of IFNAR1 ie SD1, SD2, SD3 and SD4. Corresponding proteins with N349C mutation were produced using the baculovirus expression system. The binding affinities of type I interferon mutant (YNS) toward the IFNAR1-EC mutants were measure by Surface Plasma Resonance. All SD12 and SD23 mutants exhibit lower affinity when compared to the SD34, which is mainly due to slower dissociation. At present we are in process to label the IFNAR-EC mutants with ATTO655 in order to study the conformational flexibility of receptor upon interferon binding using FRET or florescence quenching.

In order to analyse change in signalling pathway and gene induction upon interferon stimulus due to different disulphide bonds we examine the interferon stimulating genes using realtime qPCR. Differential up-regulation is clearly observed for the IFI6 and MX1 which are antiviral related, while TRAIL and CXCL11 maintain almost basal expression level. Additions to single additional disulfide bond we have HUH7 stable cell line expressing multiple additional disulfide bonds on same IFNAR1 to further rigidify the receptor.

Structure of the DDB1-CRBN E3 ubiquitin ligase in complex with thalidomide: insights into CRL4 inhibition by small molecules

E. S. Fischer, K. Böhm, N. H. Thoma
Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland

In the 1950s the drug thalidomide administered as a mild sedative to pregnant women led to the birth of thousands of children with multiple defects. Despite its teratogenicity, thalidomide and its derivatives lenalidomide and pomalidomide (together known as Immunomodulatory Drugs: IMiDs) recently emerged as effective treatments for multiple myeloma and 5q-dysplasia. While the discovery of the $CRL4^{CRBN}$ ubiquitin ligase as the primary cellular target of thalidomide and its lenalidomide mediated ubiquitination of Ikaros/Aiolos transcription factors has provided a conceptual framework for understanding drug action, a detailed molecular understanding remains elusive. We will present (i) the crystal structure of the DDB1-CRBN complex bound to thalidomide, lenalidomide and pomalidomide. Our structures establish CRBN as a $CRL4^{CRBN}$ substrate receptor, which enantioselectively binds IMiDs. (ii) We further provide evidence that the COP9 Signalosome (CSN) mediates the inhibitory effects of thalidomide. (iii) Using an unbiased biochemical screen we identify the homeobox transcription factor MEIS2 as an endogenous substrate of $CRL4^{CRBN}$. We find that IMiDs block endogenous substrates (e.g. MEIS2) from binding to $CRL4^{CRBN}$ when recruiting Ikaros/Aiolos for degradation. This dual activity implies that small molecules can principally modulate a ligase to up- or down-regulate the ubiquitination of proteins. We expect these insights into the molecular workings of thalidomide and its

Study of the role of the proteasome in senescence of stem cells Marianna Kapetanou, Niki Chondrogianni and Stathis Gonos

M. Kapetanou, N. Chondrogianni, S. Gonos
National Hellenic Research Foundation, Athens, Greece

Ageing is an intricate phenomenon which remains a major challenge to modern biology. It can be defined as a multifactorial process leading to a gradual decline of self-defensive mechanisms, reduced regenerative capacity of all tissues and organs and an exponential accumulation of damage at the molecular, cellular and organismal level. Stem cells are responsible for tissue renewal and loss of their stemness may contribute to the physiological decline in tissue homeostasis during ageing. The proteasome, being the main cellular proteolytic system, plays a key role in maintenance of cellular homeostasis and its alterations are associated with various biological phenomena including cellular senescence and ageing. However, little is known regarding the role of proteasome and other antioxidant responses in senescence of stem cells. In order to shed light on the limited data on stem cell ageing, we employed both Wharton-jelly and Adipose derived adult mesenchymal stem cells. We observed a significant decrease in proteasomal peptidase activities accompanied by a reduction of proteasomal subunits and alterations of proteasomal complexes in senescent hMSCs. Simultaneously, a senescence-related increase in levels of oxidatively modified proteins was detected. Additionally we assessed the expression levels of some well-know stemness markers during the ageing process of MSCs. Analysis of antioxidant defense mechanisms will open the road to innovative stem cell-based interventions to improve the quality of human life in old age ('healthspan'), including treatment of late-onset diseases.

Keywords: ageing, proteasome, stem cells.

The delineation of the role of ATP13A2, a P5 type ATPase with unknown function in melanoma

S. Demirsoy, S. Martin, P. Vangheluwe, P. Agostinis
Department of Cellular and Molecular Medicine, KU Leuven, Leuven, Belgium

In the last decade, melanoma has become a global issue due to its aggressive progression, as well as the poorest prognosis of all metastatic cancers. The accumulation of many epigenetic or genetic changes results in intrinsic and/or extrinsic signaling events culminating in the malignant transformation of melanocytes. Additionally, the poor prognosis of melanoma is a consequence of its highly metastatic and aggressive potential and notorious resistance to current therapies. Likewise, the limits and undesired side effects of current cancer therapeutics create a great interest to investigate and develop new targets.

ATP13A2 is a lysosomal/late endosomal P5-type ATPase with undefined function. Recent research however demonstrates an important role for ATP13A2 in efficient lysosome and autophagy functioning, although the molecular mechanisms by which ATP13A2 exerts these effects are still elusive. Loss of function effects of mutations in ATP13A2 underlie the Kufor-Rakeb syndrome, a form of autosomal Parkinsonism, and several studies have pointed out a relevant protective role of ATP13A2 in the suppression of α-synuclein toxicity. Intriguingly, epidemiological studies have reported co-occurrence of melanoma and Parkinson's disease, suggesting shared common genetic components. Of note α-synuclein, a Parkinson's disease-related protein is expressed in both malignant and benign melanocytic lesions. Interestingly according to CCLE database, ATP13A2 is expressed highly in melanoma cell lines as compared to any other cancer cell lines.

The purpose of this study is to delineate the putative role of ATP13A2 in melanoma cell, under homeostatic basal and stress conditions. Preliminary data shows that human melanoma (A375p) cell lines overexpressing either wild type or a catalytically dead ATP13A2 mutant display difference in autophagic flux following loss of proteostasis, induced by the proteasomal inhibitor bortezomib. Moreover, our data show that ATP13A2 over expression reduces the accumulation of ubiquitinated proteins following bortezomib treatment, whereas ATP13A2 silencing increases it. To determine if the reduced amount of ubiquitinated proteins was a consequence of changes in endosome-exosome trafficking, we tested the total protein secretion carried by exosomes in these melanoma cells. Initial results show a reduction in the release of exosomal proteins when ATP13A2 is overexpressed and heightened in the absence of ATP13A2. Moreover, preliminary data points to an increase in the number of lysosomes in ATP13A2 overexpressed cells but a reduction in number of lysosomes in ATP13A2-silenced cells. Taken together these preliminary results suggest an important role of ATP13A2 in the maintenance of cellular proteostasis and endosomal-lysosomal extracellular trafficking.

The highly flexible and heterogeneous nature of E1A from human Adenovirus (HAdV) characterized at atomic resolution through NMR

I. C. Felli, T. Hošek, E. Calçada, T. Pagani, M. Nogueira, M. Salvi, R. Pierattelli
CERM, University of Florence, Sesto Fiorentino, Italy

The small DNA tumor viruses encode some of the most versatile hub proteins like the E1A protein from human Adenovirus (HAdV). The E1A protein is essential for productive viral infection in human cells and a vast amount of data are available on its interactions with host proteins. Up to now no high-resolution information on the full-length E1A protein is available despite its important biological role.

Here we present the NMR characterization of the entire 243 residue long 12S isoform of the E1A protein from HAdV (E1A-12S). The protein results very heterogeneous in terms of structural and dynamic properties with highly flexible modules. This study opens the way to characterize the many interactions in which this protein is involved.

ome and of proteins coded by the nuclear genome. Among the nuclear-encoded and imported proteins of this machinery, aminoacyl-tRNA synthetases (mt-aaRSs) play a crucial role by charging amino acids on their cognate tRNA.

In the last years, increasing number of mutations affecting mt-aaRSs and leading to severe disorders in human has been reported (as reviewed in [1]). The link between mutations and disorders is, however, not so obvious. Several of these mutations affect mt-Aspartyl-tRNA synthetase (mt-AspRS) and cause LBSL (Leukoencephalopathy with Brainstem and Spinal cord involvement and Lactate elevation) disease. Intriguingly, pathogenic-related mutations of mt-AspRS have neither the same onset and progression nor the same seriousness on patients, witnessing of mosaic effects [2]. We aim at understanding the differences between mutations impacts at the molecular and cellular levels, by investigating a large panel of mt-AspRS properties.

In the present work, we adapted and validated an engineered mammalian expression system that leans on the controlled-expression of recombinant proteins (developed and published earlier in the lab [3]), combined with mitochondrial purification and fractionation, and other tools in order to study mt-AspRS and define its sub-mitochondrial organization. Altogether, this optimized technique will allow us to place mt-AspRS (and other mt-aaRS) mutants in their cellular environment, and to have a more precise overview of their impacts.

TXNIP increase p53 stability and activity through interaction with hEcd

S. R. Yoon[1,2], H. Jung[1], Y.-J. Park[1], I. Choi[1], H. G. Lee[2], B.-Y. Kim[2]

[1]*Immunotherapy Research Center,* [2]*Human Genomics, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea*

The p53 protein plays a central role in cell cycle arrest and apoptosis in response to diverse stress stimuli. Human ecdysoneless (hEcd) is known for its role in stabilizing the p53 protein level and increasing p53-mediated transcription. Here, we report that thioredoxin interacting protein (TXNIP), a member of the tumor suppressor family, interacts with hEcd and decreases murine double minute-2 (MDM2)-mediated p53 ubiquitination, leading to p53 stabilization and an increase in p53 activity. The ectopic overexpression of both TXNIP and Ecd increased actinomycin D-mediated cell death in MCF-7 cells, whereas knockdown of TXNIP and Ecd decreased cell death. These results show that TXNIP is a new regulator of the Ecd-MDM2-p53 loop

A view to montelukast drug products in terms of impurity regulations: impurities analysis in drug products and in silico/in vitro genotoxicological assessment of sulfoxide impurity

E. Emerce[1], I. Cok[1], T. Degim[2]
[1]Toxicology Department, [2]Pharmaceutical Technology Department, Gazi University, Ankara, Turkey

During manufacturing and storage of drugs that include montelukast, various impurities -particularly genotoxic impurities- which affect safety, efficacy and quality of drugs, can form. The montelukast from leukotrien antagonists is commonly used for control of asthma on adults and children. Probable chronic impurity exposures should be scrutinized thoroughly to avoid unnecessary exposures, particularly in children. This study aims analysis of impurities in montelukast drug products and their in silico and in vitro toxicological assessments considering regulatory aspects.

Quantitation of impurities (sulfoxide, cis-isomer, Michael adducts I&II, methylketone, methylstyrene) was conducted using reverse phase HPLC analysis on pediatric and adult drug products on market. Validation of analytical method was conducted according to ICH guideline. For sulfoxide impurity that was above qualification limits, prediction analysis in in silico QSAR method and bacterial gene mutation test were performed. The cytotoxicity and genotoxicity were investigated respectively by determining mitotic index and using in vitro chromosomal aberration (CA) test.

Impurities except sulfoxide were under qualification limits in the analysis of different batches of 20 products at 4 mg/10 mg doses for 11 companies. The sulfoxide exceeds limits in 2 companies for pediatric chewable tablets and in 7 companies for adult tablets. Sulfoxide impurity was not mutagenic in Leadscope QSAR analysis and bacterial gene mutation assay (Ames MPF Penta I) in Salmonella typhimurium TA98, TA100, TA1535, TA1537, Escherica coli wp2[pKM101] and wp2uvrA with/without metabolic activation system. Sulfoxide impurity was dose-dependent cytotoxic in human peripheral lymphocytes with/without metabolic activation system, however, it was nongenotoxic in CA test.

These results indicate that sulfoxide impurity should be considered a nonmutagenic/nongenotoxic and to be classified as an ordinary impurity according to guidelines.

This study is funded by The Scientific and Technological Research Council of Turkey. Project No:111T506.
Keywords: drug impurities, genotoxicity, qsar analysis.

Dicentric chromosomes breakage is coupled to cytokinesis

V. Lopez, N. Barinova, S. Pobiega, S. Marcand
IRCM, CEA, Fontenay-aux-Roses, France

Most eukaryotes contain a single centromere per chromosome ensuring accurate chromosome segregation. Dicentric chromosomes, holding two centromeres, are abnormal structures resulting from erroneous genomic rearrangements (e.g. accidental telomere fusion). Dicentrics are inherently unstable and often undergo breakage when the two centromeres of the same chromatid are pulled towards opposite poles during mitosis. The mechanism by which breakage occurs and the precise moment in the cell cycle when it takes place remain unclear.

Our goal is to elucidate, at the molecular level and using budding yeast as a model system, the mechanism of dicentric chromosome breakage. The mechanism we will decipher will give valuable clues about this issue in all eukaryotes and how cells maintain genome stability. For this purpose, we have optimized a tool to stabilize and select individual dicentrics. A chromosome with a conditional centromere under the control of two galactose-inducible promoters is fused to another native chromosome by telomere fusion or recombination-induced rearrangements. This structural dicentric chromosome behaves as a functional monocentric when the conditional centromere is inactivated. On glucose, the centromere is rapidly reactivated, thus allowing the study of dicentric breakage during a single mitosis in synchronized populations of cells.

Previous work carried out in our laboratory on dicentrics with telomere fusion showed that they often break at the fusion (Pobiega and Marcand 2010, Genes & Dev). Recently, we have found that dicentrics created by recombination-induced rearrangements tend to break at pericentric regions. In both cases, breakage requires anaphase exit indicating that mitotic spindle tension is not enough to account for breakage. In cells released from anaphase, breakage occurs at a time coincident with cytokinesis. In yeast, cytokinesis comprises a set of sequential and interdependent processes: actomyosin ring contraction, plasma membrane ingression, and primary and secondary septa deposition. Actin is a structural component of the ring and is also required for the other steps through cargo vesicles delivery. We have observed that in the presence of Latrunculin A, a drug inhibiting actin polymerization, dicentric breakage is abolished. Depletion of the ring myosin Myo1, via an auxin-inducible degron, has the same effect. Both results indicate that dicentric breakage is coupled to cytokinesis. Breakage could be generated enzymatically through a nuclease activated by cytokinesis. We decided to look for dicentric breakage in cells defective for known nucleases. So far, we have tested eight nucleases and breakage still occurs. Currently, we keep on testing other candidate activities.

Keywords: centromere, cytokinesis, dicentric.

Fluorescent probes for imaging repeated DNA sequences: synthesis of fluorescent polyamide minor groove binders and studies of their interaction with double-stranded DNA in vitro and in fixed and living cells

A. Boutorine[1], K. Nozeret[1], F. Loll[1], M. Bonan[2], S. M. Yarmoluk[3], D. S. Novopashina[4], C. Escudé[1]
[1]RDDM, UMR 7196 – INSERM U1154, Muséum National d'Histoire Naturelle, [2]Université René Descartes, Paris, France, [3]Combinatorial Chemistry, Institute of Molecular Biology and Genetics NAS, Kiev, Ukraine, [4]Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

Hairpin N-methylpyrrole/N-methylimidazole polyamides are able to penetrate into living cells and to bind a specific sequence in the minor groove of the native dsDNA. Nine hairpin polyamides and two antiparallel tandem *bis*-polyamides, targeting mouse pericentromere repeated sequences, were synthesized by manual solid-phase synthesis and click chemistry. After labeling by fluorophores

© 2014 The Authors. FEBS Journal © 2014 FEBS

these ligands can be used as probes for fluorescence microscopy imaging of repetitive genomic DNA regions (centromeres, telomeres) in living cells. The polyamides were purified and characterized by HPLC, UV-visible spectroscopy and mass-spectrometry. Interaction of polyamides with the murine pericentromere dsDNA fragment has been studied *in vitro* by the gel shift electrophoresis, thermal denaturation, circular dichroism and fluorescent spectroscopy. Our results reveal different binding affinity of various polyamides for the target DNA. These differences depend on the target sequence, position of the ligand on the target sequence, the number and position of N-methylimidazole units, the nature of conjugated fluorophores and the presence of ß-alanine residues replacing N-methylpyrrole carboxamides. Thus, the correspondence of the polyamide structure to recognition/binding rules is necessary but insufficient condition for construction of the probes. Fluorescent labeling of the ligands by fluorescein or cyanine fluorophores also affects their DNA binding. Each probe has to be studied individually in order to determine its suitability for cellular imaging applications.

The probes labeled by cyanine fluorophores demonstrate specific increase of fluorescence intensity upon interacting with the target DNA. FRET is observed when two polyamides (one labeled by Cy3 and second by Cy5) bind to neighboring DNA sequences.

The proof of the concept has been done in the fixed mouse cells where these probes specifically mark chromocenters. They are suitable for the FISH-like DNA imaging. They are able to penetrate inside living mouse and human cells, however, the specific staining of DNA chromocenters in the nucleus is observed only in several cases depending on the polyamide structure and fluorophore or linker nature.

MON-004
Genome size and chromosome number in some Centaurea (Asteraceae) from Croatia

I. Carev[1], M. Ruščić[2], O. Politeo[1], S. Brown[3], S. Siljak-Yakovlev[4]

[1]Biochemistry Department, Faculty of Chemisty and Technology, [2]Biology Department, Faculty of Natural Sciences, Split, Croatia, [3]Institut des Sciences du Végétal, CNRS UPR 2355 and Imagif, Gif-sur-Yvette, [4]Université Paris-Sud, Laboratoire Ecologie Systématique et Evolution, CNRS, Orsay, France

Croatian Adriatic coast and islands are unique and distinctive area, thanks to its general features, unusual relief features, climate, complicated geological history and the relatively good preservation. Five world areas characterized by a Mediterranean climate, make 2% of the world area which manage 20% of all known plant species, European Mediterranean with 10% of all known species in only 1.6% of the world surface.

The genus *Centaurea* is one of the largest in the Asteraceae family, containing at least 400 species (even 700). East Anatolia and Transcaucasia are the primary center of the origin and diversification of the genus *Centaurea*, while the Mediterranean area, including the Balkan Peninsula, is the second one. In Croatia 79 *Centaurea* taxa have been listed, comprising 27 endemics.

Our preliminary chemical and biological observations, of extracts and volatiles isolated from few endemic species from *Centaurea* genus, from Adriatic region, showed that there are differences in chemical composition and biological activity of volatile substances between different localities of the same species. In order to determine whether these differences were generated from different ecological conditions or because of different genetic structure, cytogenetic analysis of selected plant species of *Centaurea* taxa from Croatia were made.

The plant samples, leaves and seeds, were collected from natural populations of Croatia. The studied species belong to 7 different sections and present four different basic chromosome numbers, x = 8, 9, 10 and 11. Cytogenetic analysis was performed on a sampling covering 28 populations of 9 *Centaurea* species among which 4 endemic for Croatia or Croatia and Italy. Flow cytometry method, according to Marie and Brown (1993) were used to asses the total DNA amount.

The ploidy levels, dyploid and tetraploid, were detected. The nuclear DNA amounts (2C DNA), assessed by flow cytometry, range from 1.63 to 3.61 pg for diploid and to 6.86 pg when including tetraploid species. Intraspecific genome size polymorphism was observed among populations of five out of nine studied species: *C. dalmatica, C. ragusina, C. rupestris, C. spinosociliata and C. salonitana*. The genome size of a tetraploid *C. salonitana* populations were nearly twice that those of the diploids.

Dysploidy, changement of basic chromosome number, and polyploidy are observed as the main evolutionary mechanisms among studied representatives of the genus *Centaurea* in Croatia.

Keywords: flow cytometry, genome size, polyploidy.

MON-005
hTR (hTERC) and Tankyrase-1 mRNA expression in a human primary fibroblast-like stem cell line culture after treating with hydrogen peroxide

E. Zole[1], K. Narels[2], L. Pliss[3], R. Ranka[3]

[1]Molecular Biology, Latvian Biomedical Research and Study Center, [2]University of Latvia, [3]Latvian Biomedical Research and Study Center, Riga, Latvia

Introduction: hTR is a telomerase RNA component and together with hTERT (protein component of telomerase) maintains telomere ends by addition of the telomere repeat TTAGGG. Telomeres are highly sensitive to damage by oxidative stress due to their high content of guanines, and H_2O_2 shorter telomeres length. Previously it was shown that hTERT overexpression not only reduces the basal cellular reactive oxygen species (ROS) levels but also inhibits endogenous ROS production in response to stimuli that induce intracellular ROS generation. Tankyrase-1 is involved in regulation of DNA damage responses at telomeres and it can act as a positive telomere length regulator in telomerase positive cells.

The aims of this study were to detect if hTR expression is affected by incensement of exogenous H_2O_2 as ROS agent, and if it also influences Tankyrase-1 expression in the cells.

Methods: For the study a human primary fibroblast-like stem cell line (ASD-1) was used. Cells were treated with 100 μM H_2O_2 for 30 min at 37 °C. After treatment a part of a treated (H_2O_2) passage was harvested and the remaining part was incubated with H_2O_2, a half of the last part was used for the next passage. During all experiments controls (cell without H_2O_2 treatment) were included. For gene expression detection and telomere length measuring the real-time qPCR assay was used.

Results: hTR expression profile showed that after the treatment with H_2O_2 the hTR mRNA expression was elevated in comparison to control cells. The treated (H_2O_2) passage line harvested before the treatment of H_2O_2 exhibited less hTR mRNA expression in comparison with the same passage after the treatment with H_2O_2. In contrast, very small gradual decrease of Tankyrase-1 mRNA expression was observed during passaging. The treated (H_2O_2) passage line harvested before treatment of H_2O_2 showed less Tankyrase-1 mRNA expression in comparison with

© 2014 The Authors. FEBS Journal © 2014 FEBS

the same passage after the treatment with H_2O_2. Changes of telomere length during passaging did not demonstrate any tendency of elongation or shortening.

Discussion: The study shows that H_2O_2 affects hTR expression by increasing it on the response to exogenous ROS but does not increase expression of Tankyrase-1 showing that potential DNA strand breaks do not stimulate Tankyrase-1 expression. ROS rather reduces it for small amount. In conclusion it is possible that hTR is expressed as potential struggle against stem cells death.

Keywords: hTR (hTERC), Tankyrase-1, telomeres, mRNA expression.

MON-006
Identify the topoisomerase II isozyme-specific targeting agents and investigate their biological responses

H.-L. Hsu[1], C.-C. Wu[2], N.-L. Chan[2], T.-K. Li[2]
[1]Deaprtment of Microbiology, College of Medicine, [2]Department of Biochemistry and Molecular Biology, College of Medicine

Topoisomerase II (TOP2) plays crucial roles in cells and TOP2-targeting drugs are effective anticancer drugs but with side-effects. There are two types of TOP2-targeting agents: (i) Poisons stabilize TOP2 cleavable complex (TOP2 cc) and induce DNA break; (ii) Inhibitors only interfere with catalytic activity and antagonize the poisoning action. In human cells, the alpha (α) and beta (β) isozymes share similar enzymatic action but play differential functions. Etoposide (VP-16), an active TOP2 poison, induces 2nd malignancies. Notably, TOP2β is mainly responsible for the VP-16-induced DNA sequence rearrangement and carcinogenesis as well as the doxorubicin-induced cardiotoxicity. We screened anthracenedione derivatives and identified potential TOP2 isozyme-specific poisons and/or inhibitors. First, we used comet assay to detect DNA breakage and found anthracenedione derivatives didn't significantly induce DNA damage responses. The inhibitory ability of TOP2 activity was assessed by an *in vitro* relaxation assay. We then selected compound CL-14 that preferentially inhibits TOP2β relaxation activity for further study and found that CL-14 only induced few DNA break, but antagonized (~15~20%) TOP2-mediated DNA damage induced by VP-16 as well as doxorubicin. TOP2β-mediated DNA cleavage, but not TOP2α, induced by VP-16 *in vitro* was also antagonized by CL-14. Together, we suggested that CL-14 is a potential TOP2β-specific inhibitor, which is clinically helpful in preventing TOP2-targeting side-effects. In agreement with above notion, our data also revealed that CL-14 still antagonized VP-16-induced DNA break in TOP2α-knockdown cells. Furthermore, we also found CL-14 could preferentially antagonize VP-16-induced TOP2β-cleavable complex formation in both trapping and *In vivo* complex of enzyme assays. CL-12 and CL-13, though sharing a similar structure with CL-14, but didn't show the isozyme specific inhibition. A structure-based study has also been initiated to unravel the molecular mechanism(s) underlying this isozyme-specific action.

MON-007
Leo1 regulates heterochromatin spreading by establishing H4K16 acetylation at boundaries

L. Verrier, E. Bayne
Institute of Cell Biology, University of Edinburgh, Edinburgh, UK

Eukaryotic chromatin structure is tightly regulated and defines distinct functional domains; the condensed form, heterochromatin, plays important roles in genome regulation and accurate chromosome segregation. Studies in the model organism *Schizosaccharomyces pombe* have given us a good understanding of the mechanisms promoting heterochromatin assembly, however less is known about how this is regulated. A key property of heterochromatin is its ability to spread from an initiation point to coat large portions of DNA. However, expansion of heterochromatin domains needs to be controlled to avoid mis-regulation of gene expression. Boundary elements found between heterochromatin and euchromatin domains control cis-spreading of heterochromatin along the chromosome fiber. Several DNA elements that function as boundaries have been identified, but only a few proteins have been described to regulate cis-spreading of heterochromatin.

In order to identify new negative regulators of heterochromatin, we performed a large-scale genetic screen using a recently described fission yeast deletion library. Silencing of a *ura4*$^+$ marker gene inserted outside a pericentric heterochromatin domain was used as a read-out for heterochromatin spreading across the boundary, indicative of a disruption of barrier functions. Several mutants showed increased *ura4*$^+$ silencing, including a deletion of the previously described negative regulator Epe1. We have focused on Leo1, a member of the Paf1 complex with a previously un-described role in heterochromatin regulation. *Leo1* deletion mutants display a disruption of the boundary function, characterized by an increase in H3K9 methylation on the *ura4*$^+$ gene. Our analyses suggest that Leo1 is involved in the establishment of a specific chromatin environment at the boundary locus to counteract heterochromatin spreading outside its normal domain.

This study uncovers the function of Leo1 in the activity of chromatin boundaries, helping to develop a more comprehensive view of chromatin domains regulation.

Keywords: chromatin boundaries, Fission Yeast, heterochromatin spreading.

MON-008
Molecular cloning and in silico analysis of human ADAMTS-3 (a disintegrin and metalloprotease with thrombospondin motifs) gene promoter

M. Alper[1], A. Aydemir[2], F. Kockar[2]
[1]Aksaray University, Aksaray, [2]Department of Biology, Balıkesir University, Balıkesir, Turkey

ADAMTS (a disintegrin and metalloprotease with thrombospondin motifs) is a family of extracellular proteases found in both mammals and invertebrates. They have nineteen members. ADAMTSs have significant roles in processing amino terminus of the procollagen molecules, cleavage of the matrix proteoglycans aggrecan, versican and brevican; inhibition of angiogenesis; blood coagulation homoeostasis as the von Willebrand factor cleaving protease. ADAMTS-3 mainly processes amino terminus of the type II fibrillar collagen molecules, specific component of the articular cartilage. Increased *ADAMTS-3* gene expression was also observed in some pathological conditions such as osteoarthritis, myocardial infarction and breast cancer. However, there is no information in the transcriptional regulation of *ADAMTS-3* gene. Thus, in order to identify transcriptional regulation of *ADAMTS-3* gene, the 5'-flanking region (1381 bp) upstream of the translation start site (TSS) of the *ADAMTS-3* gene was amplified from MG-63 genomic DNA by PCR with a pair of specific primers. PCR Enhancers were also introduced into reaction mixture specific to GC rich sequences. Amplified fragment was cloned into pGEMT-Easy vector using T:A cloning strategy for further studies. The (-1341/+40) promoter fragment was analyzed for putative transcriptional factor binding sites, promoter elements

© 2014 The Authors. FEBS Journal © 2014 FEBS

and CpG islands by matinspector genomatix, EMBOSS CpG plot and TRANSFAC software applications and database. Bioinformatic analysis of this promoter didn't identify a TATA box but detected several SP1/GC and GA boxes, NFKβ, interferon regulatory factors, E2F, STAT and krueppel like transcription factor binding sites. CpG plot analysis identified a putative CpG island around 350 bp to 700 bp upstream of the TSS of the ADAMTS-3 gene.

Keywords: transcriptional regulation, ADAMTS-3, GC rich promoter.

Regulatory interaction of human telomerase reverse transcriptase (hTERT) with CST complex

A. Sharma, P. K. Yadava
School of Life Sciences, Jawaharlal Nehru University, New Delhi, India

Telomerase is chromosome end replicating enzyme that lengthens telomere by its reverse transcriptase activity using its RNA component as template. Chromosomal ends get shortened in each replication cycle; thus telomerase is necessarily required in actively dividing cells like cancer cells. On the other hand Shelterin and CST complexes bind to the telomeres and construct a telomere protecting structure without which chromosomal ends are vulnerable to nucleolytic attacks. CST complex consists of three proteins CTC1, STN1 (OBFC1) and TEN1. Loss of function of any of the three components of CST complex results in degradation of C- strand, and as a result G-overhangs get accumulated. It has been found that CST mediates C-strand fill in through interaction with Polymerase α after telomere elongation by telomerase. CST complex regulates telomere length homeostasis by directly interacting with TPP1-POT1 (components of shelterin complex) and competes with telomerase enzyme for binding to the telomere, thereby inhibiting the telomere elongation by telomerase. Although chromosome end elongation is viewed as primary function of telomerase, recent researches have shown that the telomerase is involved in diverse biological activities. Here we demonstrate that unavailability of hTERT (catalytic component of telomerase) affects the expression of telomere binding proteins. We studied the effect of hTERT knockdown using RNA interference in cancer cells on expression level of CST. Upon hTERT knock down we observed drastic retardation in the growth of cancer cells. When the hTERT level is low in the cells, expression of STN1 and TEN1 was increased and that of CTC1 was decreased. CST is a telomere protecting complex so the expression of STN1 and TEN1 increases in the scarcity of hTERT to increase the protection level of telomeres. Probably CTC1 expression goes down because its function is to bring CST complex to telomere and compete with telomerase for binding to telomere. The mechanism by which hTERT regulate CST expression is not clear at this stage; the regulatory relationship of hTERT with CST needs to be further studied. This study indicates that hTERT not only lengthens telomeres but also regulates the availability of telomere binding proteins. As the telomere protection does not depend on single factor, a combinatorial targeting of telomerase along with disrupting the telomere binding protein complexes would be more effective strategy to inhibit cancer cell growth.

Keywords: CST complex, hTERT, Telomere.

MON-010
Control of telomerase action in fission yeast by SUMO

M. Garg[1], R. L. Gurung[2], S.r Mansoubi[2], J. O. Ahmed[2], F. Watts[2], A. Bianchi[2]
[1]*Genome Damage and Stability Centre,* [2]*UNIVERSITY OF SUSSEX, Brighton, United Kingdom*

Telomeres protect chromosome ends through the assembly of a nucleoprotein complex called shelterin that also has the function of regulating the action of telomerase, the enzyme responsible for the synthesis of telomeric (G-rich) DNA repeats. After telomerase action, telomere replication is completed by synthesis of the complementary (C-rich) strand by lagging strand DNA polymerases through the activity of the CST complex, composed of CTC1/Cdc13, Stn1 and Ten1. In budding yeast, the interaction of Stn1 with overhang-binding Cdc13 is increased by SUMOylation of the latter. In humans, instead, CST interacts with overhang-binding shelterin proteins TPP1/POT1, but it remains unclear whether this interaction is regulated. We show that fission yeast Tpz1, an ortholog of TPP1, is SUMOylated at lysine 242 and that this modification is important to limit telomere length by restricting telomerase action. Our analysis suggests that SUMOylation of Tpz1 is the most important event in the control of telomerase by SUMO in this organism. Chromatin immunoprecipitation analysis indicates that the association of telomerase with telomeres is increased in a tpz1-K242R mutant, whereas the association of shelterin components is unchanged. Strikingly, instead, loss of SUMOylation of Tpz1 leads to strongly reduced association of Stn1 and Ten1 with telomeres. In addition, a SUMO-Tpz1 fusion protein displays increased affinity for Stn1, in yeast two-hybrid assays. Our data indicate that SUMOylation down-regulates telomerase in fission yeast by promoting Stn1/Ten1 action at telomeres through Tpz1. Our findings highlight the evolutionary conservation of the regulation of CST function by SUMOylation.

Understanding the role of telomerase in skin homeostasis

E. Nascimento[1], A. Garbuzov[1,2], M. Pech[1,3], R. J. Zhang[1], S. Artandi[1,3,4]
[1]*Medicine,* [2]*Genetics,* [3]*Cancer Biology,* [4]*Biochemistry, Stanford University, Stanford, CA, USA*

Many tissues with high cell turnover, such as skin, maintain tissue homeostasis by continuous replenishment and mobilization of short- and long- lived epidermal stem and progenitor cells. Strong evidence suggests that telomerase contributes and is required for efficient stem cell self-renewal, but in-depth understanding of TERT regulation and expression pattern in normal tissues has been hampered by challenges in detecting telomerase at the single cell level using current *in situ* detection methods. We have successfully identified and isolated TERT expressing epidermal cells using a mouse model generated in our lab where GFP is expressed from the endogenous TERT promoter, and used as reporter of TERT promoter activity. A combinatorial approach of tail skin wholemounts microscopy and flow cytometry enabled quantification and identification of TERT expression in most epidermal stem and progenitor cell compartments. In the interfollicular epidermis (IFE), TERT expression is focal and not uniformly expressed throughout the Krt14^{+} basal layer of the epidermis. In the hair follicle (HF), TERT is expressed in the junctional zone, isthmus, bulge, outer root sheath and hair bulb. Expression appears to be dynamic since in telogen (HF resting

© 2014 The Authors. FEBS Journal © 2014 FEBS

phase), TERT is mainly detected in the bulge, whereas in anagen (HF growth phase), it is detected along the ORS and hair bulb. In catagen (HF regression phase), TERT expression decreases substantially, except in the HF bulge. We compared telomerase enzymatic activity between isolated TERT-eGFP$^+$ and TERT-eGFP- sorted cells and found increased telomerase activity in TERT-eGFP$^+$ cells. We are pursuing experiments to identify the function of TERT in each of these compartments using a combination of lineage-tracing and gene expression analysis. Understanding the role of TERT in this context might help elucidate the mechanisms underlying the phenotypes in patients with dyskeratosis congenita, where telomerase mutations lead to epidermal defects. These patients show, among other symptoms, hair loss or greying, abnormal skin pigmentation, oral mucosa leukoplakia and an increase incidence of head and neck squamous cell carcinomas.

Keywords: Epidermal stem cells, Telomerase, Tissue homeostasis.

Evaluation of uncertainty for coagulation parameters based on EURACHEM/CITAC guide

E. Sertoglu[1], M. Uyanik[2], S. Tapan[2], O. Ozturk[2], I. Kurt[2]
[1]Department of Medical Biochemistry, Ankara Mevki Military Hospital, Anittepe Dispensary, [2]Department of Medical Biochemistry, Gulhane School of Medicine, Ankara, Turkey

Background: The blood coagulation process represents the initial phase of the biological repair mechanism designed to respond to injuries to the vasculature that result in leakage of blood into the surrounding tissue. Poor standardization of preanalytic and analytical variables exerts a strong influence on the reliability of coagulation testing, consuming valuable health care resources and compromising patient outcome. In this study, it was aimed to estimate uncertainty of 8 parameters according to the EURACHEM/CITAC guide and to determine the analytical performance of our coagulation laboratory.
Materials and Methods: The parameters which were used to calculate uncertainty are as follows: Activated *partial* thromboplastin time (aPTT), prothrombin time (PT), fibrinogen, antithrombin III (AT III), factor 7, factor 8, protein C and protein S. Siemens BCS® XP System (Siemens Healthcare Diagnostics Products GmbH, Germany) and original calibrators and reagents of manufacturer were used in the study. We evaluated Internal and External Quality Control (IQC and EQC, respectively) results of 8 parameters for last 12 months between period January 2013 and December 2013. The mathematical calculations and uncertainty of measurements are derived from the EURACHEM/CITAC guide. Then we assessed the analytical performances and uncertainty of measurements according to CLIA, Rilibak and Fraiser.
Results: aPTT, PT and fibrinogen, the only available CLIA rules, met the criterias for CLIA. Fibrinogen, protein C and S % TE values were within the appropriate limits defined by Fraser while aPTT, PT, AT III, factor 7 and 8 did not meet criteria.
Discussion: Although there are regulatory standards like CLIA, Fraser and Rilibak offering allowable limits of performance for the majority of routine measurements (Routine biochemistry, complete blood count, etc.), only Fraser determined criterias for each parameter of 8 coagulation tests. As the result of inadequacy of regulatory standards and poor standardization of preanalytic and analytical variables, laboratories are slog to determine their own uncertainty and to increase their standard. More detailed studies are needed to be performed in this regard.

Native architecture of the centriole proximal region reveals features underlying its 9-fold radial symmetry

P. Guichard[1], V. Hachet[1], N. Majubu[1], A. Neves[1], D. Demurtas[2], N. Olieric[3], I. Fluckiger[1], A. Yamada[4], K. Kihara[4], M. Steinmetz[3], Y. Hongoh[4], P. Gönczy[1]
[1]Life Science, [2]CIME, EPFL, Lausanne, [3]Biomolecular Research, PSI, Villigen, Switzerland, [4]Department of Biological Sciences, Tokyo Institute of Technology, Tokyo, Japan

The centriole and the related basal body is a macromolecular structure that is fundamental for the assembly of cilia and flagella across evolution. Moreover, the centriole is required for the assembly of the centrosome, the principal microtubule-organizing center (MTOC) of animal cells and cilia in most of Eukaryotes. Centrioles are evolutionarily conserved microtubule-based cylindrical macromolecular structures that in human cells are ~500 nm long and ~230 nm in outer diameter. Centrioles are characterized by the presence of nine triplets of microtubules surrounding a cartwheel structure at their proximal end, which is critical for imparting the 9-fold symmetry of the entire structure. We recently showed that the evolutionary conserved SAS-6 proteins, essential for cartwheel assembly and forming a 22 nm ring *in vitro*, is likely to form a ring in vivo, as revealed by the 50A resolution 3D map of the cartwheel from *Trichonympha*, a symbiotic flagellate present in the hindgut of termites. Although this work uncovered the cartwheel architecture, how it connects to the peripheral microtubules is not understood. More generally, a comprehensive structural view of the proximal region of the centriole is lacking, thus limiting understanding of the underlying centriolar assembly mechanisms.

Using cryotomography and sub-tomogram averaging, we report the complete architecture of the *Trichonympha* centriole proximal region. The resulting 3D map at 38A resolution reveals several features, including additional densities in the cartwheel that exhibit a 9-fold symmetrical arrangement, as well as the structure of the Pinhead and the A-C linker that connect to microtubules. Moreover, we uncover striking chiral features that might impart directionality to the entire centriole. Furthermore, we identify *Trichonympha* SAS-6 and demonstrate that it localizes to the cartwheel in vivo.

Our work provides unprecedented insight into the architecture of the centriole proximal region, which is key for a thorough understanding of the mechanisms governing centriole assembly.

Porphyrias in Turkey: from Porphyria Turcica to present

M. Uyanik[1], I. Kurt[1], E. Sertoglu[2], S. Tapan[1]
[1]Department of Medical Biochemistry, Gulhane School of Medicine, [2]Department of Medical Biochemistry, Ankara Mevki Military Hospital, Anittepe Dispensary, Ankara, Turkey

In 1956 an epidemic of PCT occurred between 1956 and 1961 due to hexachlorobenzene (HCB) in southeastern Turkey and it was estimated that over 3000 individuals were affected. The registered history of the porphyrias and the awareness of this disease started at these years for Turkey. But from that epidemia until 1994 researches were performed individually and there was no institutional development.

Although it was a late decision for the country, Gulhane Porphyrin Laboratory was established in 1994. Nowadays 12 types of porphyrin analysis [porphobilinogen scanning and quantitation (urinary), aminolevulinic acid (urinary), total porphyrin (urinary, stool, plasma, whole blood), fluorescence emission scanning (plasma), free/metal protoporphyrin, porphyrin fractionation with HPLC (urinary and stool), erythrocyte porphobilinogen deaminase activity] are performed by using different analytical techniques (fluorimetric measurement and scanning, spectrophotometric, UV-spot test, TLC, HPLC) in our laboratory. Gulhane Porphyria Laboratory, which is a member of European Porphyria Network since December 2011, is participating in The Royal Collage of Pathologists of Australia external quality assurance scheme for porphyrias since 1996. A total of 61 patients were diagnosed in this twenty-year period.

© 2014 The Authors. FEBS Journal © 2014 FEBS

As in all developing countries, there are some outstanding issues to overcome for our lab and country. For example there is no foundation for rare diseases including porphyrias. The efforts for being the "Reference (Service) Laboratory" and accreditation process have been initiated. In the future, genetic diagnosis and counseling with DNA mutation analysis are aimed. As a result, we should not forget that none of us are protected from rare diseases like porphyrias by statistics.

Primary cilia incidence after ionizing irradiation and serum starvation stress in a myoblast cell line (C2C12)

A. Filipova[1], D. Diaz Garcia[2], D. Cizkova[2], A. Bezrouk[3], M. Seifrtova[1], J. Vavrova[4], M. Rezacova[1]
[1]Department of Medical Biochemistry, [2]Department of Histology and Embryology, [3]Department of Medical Biophysics, Medical Faculty in Hradec Kralove, Charles University in Prague, [4]Department of Radiobiology, Faculty of Military Health Science, University of Defence Brno, Hradec Kralove, Czech Republic

Primary cilia (PC) act as physical-chemical sensors and their biological functions include perception of the extracellular milieu, regulation of organogenesis and cell polarity. PC are dynamically regulated during cell cycle progression, the axoneme's major component is α-tubulin whereas the basal body is composed of γ-tubulin. Its size ranges between 2 and 10 μm long and 200–300 nm wide although these dimensions may change under stress such as starvation, hypoxia or ionizing radiation. In the present study we concentrated on the analysis of primary cilia incidence after ionizing radiation exposure (2, 6, 10, 20 Gy) and serum starvation stress in a myoblast cell line (C2C12).

A significant number of ciliated cells was observed 1 day after the irradiation within the whole dose range (2–20 Gy), with the highest PC incidence three days after the treatment as compared to non-irradiated cells. However, PC incidence (%) observed in cells exposed to doses of 2, 6 and 10 Gy was significantly lower than that observed in cells irradiated by 20 Gy. Further dynamic of primary cilia formation was evaluated only after 20 Gy dose and it was found that the PC incidence remained significantly higher than in non-irradiated cells even at 6 days post-irradiation. Unexpectedly, multi-ciliated cells were also detected in irradiated cells. In 2–4% of irradiated cells two or more cilia were detected 1 day after the irradiation. A further pronounced increase in cells with multiple cilia was observed 3 days after irradiation by the doses of 10 and 20 Gy (15% and 35% of cells, respectively).

Cell proliferation was inhibited after serum starvation stress, decreasing the number of cells in S phase after 24 h of starvation. Cell viability was not affected and apoptotic cells were not observed. The percentage of ciliated myoblasts increased significantly as soon as after 6 hours of serum starvation as compared with the control. The PC incidence increases further during the starvation, peaking at 24 hours and reaching nearly 80%. Thereafter, the percentage of ciliated cells was increased for the remaining duration of the experiment (120 hours of starvation).

The role of EGF and TGFβ in modulating the expression of stearoyl CoA desaturase 1 in association with metastatic breast cancer development

F. Bouazizi, C. Mounier, M. Cartier-Millon, C. Mounier
Biologie, UQAM, Montreal, Canada

Despite the significant scientific progress in the prevention, detection and treatment of cancer in recent decades, cancer remains a leading cause of death in Canada. Moreover, breast cancer is the leading cause of female cancer deaths in the world. Similarly, the percentage of mortality significantly increases when the cancerous cells acquire metastatic potential. We have previously shown that the high expression of stearoyl CoA desaturase 1 (SCD1), which is a key lipogenic enzyme, was associated with an increase in the metastatic potential of breast cancer cells. SCD1 desaturated fatty acids with long chain forming monounsaturated fatty acids. We believe that SCD1 could be a new therapeutic track for finding new active molecules against metastatic breast cancer.

EGF (Epidermal Growth Factor) and TGFβ (Transforming Growth Factor -beta) are associated with the acquisition of metastatic power. In fact, in breast cancer cells, EGF activates signaling pathways JAK / STAT, PI3K, Src kinase, PLCγ, ERK and TGFβ, pathways involving Smad proteins. Preliminary studies have shown that the expression of the SCD1 protein is increased after treatment of breast cancer cells MDA- MB- 231 by these two hormones.

Project's Objectives: The aim of our study is to verify if EGF and TGFβ regulate transcription of SCD1. Furthermore, we want to characterize the signaling pathways induced by the above two hormones in the MDA-MB 231.

Methodology: The experiments were performed in the MDA-MB 231 cells transfected with a construct containing the 3.7 kb SCD1 promoter which is cloned upstream of the luciferase reporter gene.

The promoter activity was measured in the presence or absence of EGF (10 ng/ml) or the presence or absence of TGF β (0.2 nM).

Specific inhibitors of kinases which are involved in signaling pathways induced by conventional EGF and TGFβ, were used to assess the role of each lane on the activation of SCD1. For that reason, the MDA- MB- 231 cells were preincubated for one hour with specific inhibitors and then treated for twenty four hours with EGF or TGF β inhibitors. The effect of each inhibitor on SCD1 expression was evaluated by RT -PCR.

Results and Conclusion: The preliminary results show that following the addition of the two hormones EGF and TFGβ, a three times greater increase in the expression level of SCD1 was detected in MDA-MB-231. In fact, previous studies have shown transcriptional SCD1 increase in epithelium's cells of the retinal pigment. Therefore, EGF and TGFβ appear to regulate the transcription of SCD1. Indeed, SCD1 appears to play a role in the acquisition of metastatic potential through signaling pathways that will be defined later.

Keywords: breast cancer, EGF and TGFβ, stearoyl CoA desaturase 1 (SCD1).

Circadian CLOCK mediates activation of TGF-β signaling and renal fibrosis through cyclooxygenase 2

C.-Y. Wang[1], W.-D. Chen[1], M.-T. Peng[2], Y.-J. Wu[1]
[1]Cardiology, [2]Oncology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

Circadian rhythm regulates blood pressure and maintains the fluid and electrolyte balance with central and peripheral clock. However, the role of circadian rhythm in the pathogenesis of tubulointerstitial fibrosis remains unclear. Here we found that the amplitudes of circadian rhythm oscillation in kidneys significantly increased after unilateral ureteral obstruction. In mice deficient of circadian gene *CLOCK*, renal fibrosis and renal parenchymal damage were significantly worse after ureteral obstruction. CLOCK–/– mice exhibited increased synthesis of type I collagen, enhanced apoptosis, increased activation of fibroblasts, and greater TGF-b–induced PAI−1 expression. TGF-b mRNA expression oscillated with circadian rhythms and were under the control of CLOCK-BMAL1 heterodimers. Renal tubular epithelial cells from CLOCK–/– mice exhibited increased apoptosis and decreased proliferation. Moreover, expressions of *cyclooxygenase 1* and *2* significantly increased in kidneys from CLOCK–/– mice with or without ureteral obstruction. Treatment of cyclooxygenase inhibitor, Celecoxib, improved renal fibrosis in CLOCK–/– mice. Taken together, these data establish an important role of circadian rhythm in tubulointerstitial fibrosis and suggest a novel therapeutic target of CLOCK/TGF-b through cyclooxygenase inhibition.

Circadian clock regulates c-MYC oncoprotein via rhythmic acetylation

A. Repouskou, A. Prombona
Institute of Biosciences and Applications, Chronobiology Laboratory, National Center of Scientific Research "Demokritos", Agia Paraskevi, Greece

Circadian clock function has been implicated in cell cycle progression both *in vivo* and *in vitro*. Clock deregulation is associated with increased tumor incidents and expression of core clock components is greatly reduced in several cancers. Among clock controlled genes there are many key regulators of cell proliferation, such as the *c-MYC* proto-oncogene. c-MYC transcription factor regulates the expression of several hundred genes responding to mitogenic signals. Its own regulation of transcription is rather complex and remains largely unknown. One exciting feature of *c-MYC* promoter is that the circadian activators CLOCK and BMAL1 recognize its E-box elements but their binding results in decreased transcriptional activity. In fact, *c-MYC* is the only known gene whose expression is negatively regulated by the circadian dimer BMAL1/CLOCK and this molecular mechanism has not been unraveled.

In an attempt to elucidate this "discrepancy", we studied c-MYC promoter activity driven by BMAL1 and WT or a lysine acetyltransferase (KAT) deficient CLOCK using a luciferase reporter system. Contrary to our expectations, acetylation status of BMAL1 did not affect c-MYC transcription. On the other hand, manipulating acetylation levels via treatment with deacetylase inhibitor Trichostatin A (TSA) repressed oncogene transcription in a circadian manner. This prompted us to analyse protein accumulation in synchronized neuroblastoma (N2A) cells before and after TSA treatment. Rhythmicity in expression levels was confirmed while TSA resulted in a substantial and prolonged reduction of the oncoprotein only when applied at the peak of c-MYC oscillation. This was also accompanied by cell cycle arrest of N2A on G1. Delayed protein accumulation with respect to maximum of transcription indicates that clock regulates c-MYC at post-translational level as well. Indeed, protein synthesis and degradation rates vary according to circadian time. Both rates were affected by TSA treatment at a specific phase of the circadian rhythm resulting in elimination of c-MYC. Finally, acetylation status of endogenous oncoprotein was analysed. Maximum acetylation was observed at the peak of c-MYC rhythm indicating an interplay between this modification and protein stability.

Thus, our results document a complex role of the circadian clock on c-MYC expression. This includes not only transcriptional regulation but also control of oncoprotein levels via acetylation-dependent mechanisms.

Keywords: acetylation, circadian clock, c-MYC oncoprotein.

Direct involvement of HIF1αi n the circadian oscillation of Per2 gene

M. Ikeda[1], M. Kumagai[1], T. Okabe[1], Y. Nakajima[2]
[1]Physiology, Saitama Medical University, Moroyama, [2]AIST, Takamatsu, Japan

PAS factors have been named after the discovery of common domains in Per, Arnt and Sim proteins. The factors sense and bind small molecules, such as oxygen, dioxins and cellar metabolites. These factors are known to be involved in the adaptation to external and internal changes of environment, such as circadian, hypoxic, toxic state changes in mammals. In the circadian system, the core feedback loop that account for the generation of about 24 hours rhythm consists of couple of PAS factors, that is, BMAL1, CLOCK, NPAS2, BMAL2 and three PER proteins. The cross-talk between PAS factors in hypoxic responses and circadian systems have been reported. On the way of our finding cross talk among adaptation system involved in PAS factors, we found transcriptional regulation of *Per2* genes by HIF1α. We will discuss the mechanism of the transcriptional regulation of *Per2* gene by HIF1α and role of HIF1α on *Per2* regulation in tumor cells.

Keywords: circadian rhythm, clock genes, HIF1α.

Melatonin signalling controls circadian swimming behaviour in marine zooplankton

M. A. Tosches, D. Bucher, P. Vopalensky, D. Arendt
EMBL, Heidelberg, Germany

Melatonin, the "hormone of darkness", is a key regulator of vertebrate circadian physiology and behavior. Despite its ubiquitous presence in Metazoa as radical scavenger, the ancestral function of melatonin receptor-dependent signaling remains unknown.

We investigated the effect of melatonin signaling on circadian swimming behavior in a zooplankton model, the marine annelid

© 2014 The Authors. FEBS Journal © 2014 FEBS

Platynereis dumerilii. We found that melatonin is produced at night in the "clock region": a population of brain photoreceptors with a vertebrate-type opsin-based phototransduction and a light-entrained clock. Using microfluidic high-throughput qPCR, we determined that in these cells the expression of several genes is regulated by the light-dark cycle. We also found that the clock region comprises vertebrate-type ciliary photoreceptors, and develops from neuroblasts expressing a battery of vertebrate eye-field transcription factors.

Platynereis larvae swim with locomotor ciliated cells, and the rate of ciliary arrests affects the vertical position in the ocean. At night melatonin signaling causes an increase of ciliary arrests, hence larval sinking. To dissect the underlying neural circuit, we first established two-photon imaging of the calcium indicator GCaMP6 in *Platynereis*. Melatonin changes directly the firing pattern of cholinergic neurons that innervate locomotor ciliated cells. These cholinergic neurons switch from sparse firing to a rhythmic activity, characterised by the regular discharge of bursts of action potentials. The change of firing mode has a facilitatory effect on synaptic transmission; therefore the rate of ciliary arrests is enhanced during the night.

To summarize, in *Platynereis* melatonin is the output of the circadian clock and modulates neuronal activity to establish a nocturnal behavioral state. We propose that this neuromodulatory system controls the rhythmic swimming of zooplankton in the ocean, known as diel vertical migration. Moreover, we hypothesize that melatonin receptors and opsins coevolved from the duplication of the same GPCR to regulate, together with the circadian system, the vertical position of zooplankton in response to light-induced oxidative stress.

Keywords: circadian rhythm, evolution, Neural circuits.

MON-023
Oxidative stress and insulin resistance in policemen working shift

I. Demir[1], A. Toker[2], S. Zengin[3], E. Laloğlu[4], H. Aksoy[4]
[1]Istanbul Police Department, Training Bureau, Turkish National Police, Istanbul, [2]Department of Biochemistry, Necmettin Erbakan Universiy, Medical Faculty, Konya, [3]Gaziantep Police Department, Turkish National Police, Gaziantep, [4]Department of Biochemistry, Ataturk Universirty, Medical Faculty, Erzurum, Turkey

Shift work is a work schedule involving irregular or unusual hours, compared to those of a normal day time work schedule. In developed countries, night shift work is very common. In several cities of our country, 12/24 shift system is implemented in police organization. While night shift work composes half of the 20 shift in a month, in ergonomic shift system, an alternative shift schedule, shift work can be performed in three shifts in a day. This system has minimal effect on circadian rhytm. In this study we aimed to investigate the effects of 12/24 shift work system on insülin resistance and oxidative stress and systemic inflammation.

204 12/24 shift workers (age, 44.3 ± 5.6) and 193ergonomic shift workers (age, 42.6 ± 5.5 years) were included to study. Serum oxidized LDL (ox-LDL), neutrophyl gelatinase lipocalin-2 (NGAL) as oxidative stress markers, glucose, insülin, ferritin, high sensitive C reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR) values were measured. HOMA was calculated to evaluate insülin resistance.

Serum ox-LDL, HOMA, hsCRP and NGAL levels in 12/24 shift system were found to be significantly higher compared with ergonomic shift workers ($p < 0.0001$, $p = 0.02$, $p = 0.03$, $p = 0.02$, respectively). When evaluated all subjects, weak but significant correlation was found between HOMA with ox-LDL ($r = 0.12$, $p = 0.01$), hsCRP ($r = 0.17$, $p = 0.001$) and ferritin ($r = 0.15$, $r = 0.003$). Also in 12/24 shift work group, there were significant correlations between HOMA with hsCRP ($r = 0.17$, $p = 0.01$) and ferritin ($r = 0.25$, $p = 0.0001$).

It may be concluded that 12/24 shift system may cause insülin resistance and oxidative stress. Additionally, workers in this system may under risk for systemic inflammatory responce. Working hours must be arranged in accordance with the physiological rhythm.

This study was financially supported by a research fund from the Scientific and Technological Research Council of Turkey (TUBITAK).

Paraspeckles: nuclear mRNA anchorages responsible for circadian gene expression

J.-L. Franc, B. Boyer, M.-P. Blanchard, S. Guillen, M. Moreno, D. Becquet, A.-M. François-Bellan
Aix-Marseille-Université, CNRS, CRN2M UMR-7286, Marseille, France

Post-transcriptional controls appear increasingly essential to the circadian system functioning. We recently reported that two multifunctional nuclear proteins, NONO and SFPQ, display a circadian expression pattern in pituitary cells. In addition to their function in transcriptional processes, these proteins participate in post-transcriptional mechanisms such as nuclear RNA retention by paraspeckles. The present study aimed to determine whether one of the post-transcriptional mechanisms responsible for circadian gene expression involves circadian nuclear retention by paraspeckles. We showed that all key components of paraspeckles including both the major protein components and the structural long noncoding RNA Neat1 were shown to display a circadian expression pattern. This later component was also rhythmically expressed in other circadian oscillators including the master clock, the suprachiasmatic nucleus. We reported examples of mRNA whose circadian rhythmicity was post-transcriptionally controlled in pituitary GH4C1 cells and that were associated with paraspeckle components. These mRNA lost their circadian expression pattern when paraspeckles were disrupted by treatment with Neat1 siRNA. Paraspeckles appear then responsible for post-transcriptionally controlled circadian gene expression by way of the rhythmic nuclear retention of the corresponding mRNA. Rhythmic mRNA retention by paraspeckles is then proposed as one of the post-transcriptional mechanisms involved in the circadian clock system functioning.

Keywords: Circadian rhythm, Long non coding RNA Neat1, paraspeckles.

MON-025
Peripheral biological clock and its role in age-related decline in function of rat Leydig cells

A. Baburski, S. Sokanovic, M. Janjic, S. Radovic, M. Bjelic, D. Drljaca, N. Stojkov, S. Andric, T. Kostic
Faculty of Sciences, Novi Sad, Serbia

Reproductive physiology is profoundly influenced by circadian rhythms. In mammals, growing body of evidence indicates that the circadian clock regulates the serum concentrations of many reproductive hormones including testosterone. Although the association between circadian rhythms and testosterone is a long-established phenomenon, the molecular mechanisms by which the circadian clock regulates testosterone production are still unknown. In this study, we analised the presence of peripheral circadian clock in Leydig cells. Results supported hypothesis

© 2014 The Authors. FEBS Journal © 2014 FEBS

about peripheral circadian nature of Leydig cell function. First, the secretion of testosterone from Leydig cells has a low-amplitude of diurnal rhythm. In long day model (14 hours day – 10 hours night) the circulating LH and testosterone levels fluctuate in a circadian fashion. LH reach zenith in the morning and have nadir in the late evening while testosterone levels reach zenith at the end of the day. Second, the circadian rhythm in transcription of the main steroidogenic genes (*Star*, *Cyp11a* and *Cyp17*) in Leydig cells of adult rats was also observed. A peak of their expression was registered a few hours before of the peak of testosterone concentration in blood. In addition, *Nur77* (a positive steroidogenic regulator) showed very strong diurnal rhythm, representing the gene regulated by clock. Third, analysis of gene expression of clock elements showed oscillatory pattern of *Bmal-1*, *Per1,2,3*, as well as *Rev-erb a* and *b* expression in Leydig cells of adult rats. Accordingly, it is possible that those genes could be clock candidates involved in diurnal regulation of steroidogenic genes expression. Several preliminary results obtained from 24-month old rats (corresponds to 60 year in humans) support involvement of clock system with functional deficits of Leydig cells during aging. First, the circadian rhythm of circulating LH and androgens was preserved in aged rats. Second, aging attenuated Leydig cell *Star*, *Cyp11a* and *Cyp17* transcription but those genes retained the similar oscillatory pattern as in Leydig cells from adult rats. In addition, the transcription of *Nur77* decreased in old rats, but the rhythm was preserved. In parallel, aging also decreased the expression of the clock genes (*Clock*, *Bmal-1*, *Cry1*, *Per1*, *Npas2*, and *Rev-ebra*) in Leydig cells but again they oscillatory pattern was retained as in Leydig cells from adult rats. Altogether, these observations, support correlation between clock system and functional deficits of Leydig cells during aging.

The circadian rhythm controls telomeres and telomerase activity

C.-Y. Wang[1,2], W.-D. Chen[3], Y.-J. Wu[3]
[1]Cardiology, Chang Gung Memorial Hospital, [2]Chang Gung University College of Medicine, Taoyuan, Taiwan, [3]Cardiology, Chang Gung University College of Medicine, Taoyuan, Taiwan

Circadian clocks are fundamental machinery in organisms ranging from archaea to humans. Disruption of the circadian system is associated with premature aging in mice, but the molecular basis underlying this phenomenon is still unclear. In this study, we found that telomerase activity exhibits endogenous circadian rhythmicity in humans and mice. Human and mouse *TERT* mRNA expression oscillates with circadian rhythms that are temperature compensated and are under the control of CLOCK-BMAL1 heterodimers. CLOCK deficiency in mice causes loss of rhythmic telomerase activities, *TERT* mRNA oscillation, and shortened telomere length. Physicians with regular work schedules have circadian oscillation of telomerase activity while emergency physicians working in shifts lose the circadian rhythms of telomerase activity. These findings identify the circadian rhythm as a mechanism underlying telomere and telomerase activity control that serve as interconnections between circadian systems and aging.

Keywords: circadian rhythm, Telomerase, telomerase activity.

A novel approach towards finding regulatory microRNAs during phagosomal maturation in infection

K. Pawar, J. Sharbati, R. Einspanier, S. Sharbati
Department of Veterinary Medicine, Institute of Veterinary Biochemistry, FU, Berlin, Germany

Studies have found microRNAs to be involved in various diseases including mycobacterial infections (*M. tuberculosis, M. avium* etc.). In this context, they control mechanisms in the host cell e.g. regulates caspase activity in *M. Avium* infection. But generally bacteria are engulfed and degraded inside host cell via mechanism of phagosomal maturation and there is paucity of knowledge about association of microRNAs in this mechanism. So here we have used a targeted approach to address involvement of microRNAs in phagosomal maturation. After infecting THP-1 cells, three time points (15, 30, 240 min) were identified where microRNAs could possibly be involved in phago-lysosomal inhibition. As *Mycobacterium bovis* BCG was known to inhibit phagosomal maturation it was used for our study as a model for the *M. tuberculosis* complex. In addition, *M. avium* as well as *M. smegmatis* were considered. Differences in LAMP-1 localization on phagosome (present and absent in heat killed and viable bacterial phagosome respectively) were observed at 30 min and 240 min, however Rab7 signal was prominent in all time points. Based on these observations total RNA at given time points post infection were isolated for evaluation of *in silico* predicted target-interactions based on microRNA-specific RT-qPCR. For the *in silico* analysis, we have focused on 15 relevant genes that were found to be mutually targeted by 10 identified microRNAs. Out of these 10, three microRNAs were down regulated upon infection. Ongoing functional experiments will determine their involvement in phagosomal trafficking and maturation.

Keywords: microRNA, Mycobacteria, phagocytosis.

A possible regulation of ACTC1 expression by miR-30b in the peripheral blood of dogs with ACVIM stage B heart failure

M. Hulanicka[1], M. Garncarz[2], M. Parzeniecka-Jaworska[2], M. Jank[1]
[1]*Department of Physiological Sciences,* [2]*Department of Veterinary Diagnostics and Pathology, Warsaw University of Life Sciences, Warsaw, Poland*

It is known that miRNAs are a crucial regulators of a wide range of physiological and pathological processes and they can influence the transcription profile of many genes. miR-30b have been earlier described in literature as being involved in cardiovascular pathology. The aim of the present study was to investigate the level of miR-30b in the plasma of dogs in the early stage of heart disease and screening for potential miR-30b target genes in the peripheral blood nuclear cells.

The miRNA study was conducted on 16 dogs. A clinical examination and echocardiographic examination were carried out. The dogs were divided into groups according to ACVIM (American College of Veterinary Internal Medicine) classification scheme as stage A (healthy – control) – 8 dogs, stage B (asymptomatic) – 8 dogs. Circulating RNA was extracted from the plasma and the level of miR-30b was measured using qPCR method. The results showed that the expression of miR-30b differed significantly study groups. The level of these miRNA was 2.63 times lower in ACVIM stage B than in healthy dogs (2-ΔΔCT method, $p < 0.05$). In order to verify the influence of miR-30b on peripheral blood nuclear cells transcriptomic profile next transcriptomic study was conducted. 24 dogs after clinical and echocardiographic examinations were divided into groups according to the above mentioned classification as stage A – 11 and stage B – 13 dog. Total RNA was extracted from whole blood samples. The transcriptomic profile analysis of peripheral blood nuclear cells was performed using microarray technology (Agilent, USA). The results were analysed with Gene Spring and Pathway Studio software. Microarray experiment revealed 426 differentially expressed transcripts between healthy dogs (ACVIM A) and ACVIM stage B (FDR<0.05). The most significantly regulated signalling pathway was EphrinR -> actin signalling. Among differentially expressed genes involved in this pathway was ACTC1 – actin, alpha, cardiac muscle 1 which was upregulated in ACVIM stage B dogs in comparison to healthy control. Using an online database – miRDB we found out that 6 out of 426 differentially expressed genes are predicted targets of canine miR-30b (cfa-miR-30b). Moreover, one of them is ACTC1. The results of recent studies revealed that circulating miRNAs may be delivered to recipient cells where then they regulate expression of target genes. Having this in mind we can conclude that the downregulation of miR-30b in the plasma may result in upregulation of ACTC1 – its target gene in the peripheral blood nuclear cells.

A role for miRNAs regulate prostate cancer metastasis and tyrosine kinase inhibitors (TKIs) resistance by targeting EGFR signaling pathway

Y.-S. Chang[1], M. K. Siu[1], W. Abou-Kheir[2], J. J. Yin[3], I.-H. Chien[1], F. Suau[3], O. Casey[3], K. Kelly[3], Y.-N. Liu[1]
[1]*Graduate Institue of Cancer Biology and Drug Discovery, Taipei Medical University, Taipei, Taiwan,* [2]*Department of Anatomy, American University of Beirut, Beirut, Lebanon,* [3]*Cell and Cancer Biology Branch, National Institutes of Health/National Cancer Institute, Bethesda, MD, USA*

Several mechanisms have been suggested to affect prostate cancer progression, including activation of EGFR signaling pathway, either genetically or epigenetically during prostate cancer metastasis. However, therapies targeting EGFR have demonstrated limited effectiveness and acquired drug resistance. miR-203 and miR-34a levels are down-regulated in clinical samples of primary prostate cancer and further reduced in metastases. Here we show that ectopic miR-203 and miR-34a expression displayed reduced bone metastasis and induced sensitivity to tyrosine kinase inhibitors (TKIs) treatment in a xenograft model. Our results demonstrate that the induction of bone metastasis and TKIs resistance are miR-203 and miR-34a down regulation, activation of the EGFR pathway by altered EGFR ligands (AREG, EREG and TGFA), and anti-apoptosis proteins (API5, BIRC2, and TRIAP1) gene expression. Importantly, a sufficient reconstituted invasiveness effect and resistance to TKIs treatment were observed in cells transfected with anti-miR-203 or anti-miR-34a.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Human AREG, EREG, and TGFA 3'UTR reporters containing miR-203 and/or miR-34a homology sites were analyzed with reporter assays, indicating the directly regulatory role of miR-203 and miR-34a. We observed decreased miR-203 and miR-34a and increased AREG, EREG and TGFA correlated to metastatic prostate cancer with analysis of clinical gene expression databases and patients. Our results support the existence of a miRNA, EGFR, TKIs resistance regulatory network in prostate cancer progression. We propose that loss of miR-203 and miR-34a is a molecular link in the progression of prostate cancer metastasis and TKIs resistance characterized by high EGFR ligands output and anti-apoptosis proteins activation.

Keywords: bone metastasis, prostate cancer, tyrosine kinase inhibitors (TKIs) resistance.

MON-031

Analyses of microRNA-34b and c-myc expression profile in papillary thyroid carcinoma

A. Plesa[1], I. V. Iancu[1], A. Botezatu[1], I. Huica[1], D. Manda[2], S. Vladoiu[2], G. Anton[1], C. V. Badiu[3]

[1]*Molecular Virology, Stefan S. Nicolau Institute of Virology,* [2]*Research Laboratory,* [3]*Department of Endocrinology, CI Parhon" National Institute of Endocrinology, Bucharest, Romania*

Background: Papillary thyroid cancer (PTC) is the most common type of thyroid cancer, exibiting 75-85% of all thyroid malignancies. Thyroid cancer initiation and progression occurs through gradual accumulation of various genetic and epigenetic alterations, including activating and inactivating somatic mutations, alteration in gene expression patterns, microRNA (miRNA) deregulation and aberrant gene methylation. Recent studies have shown a difference in expression of certain miRNAs between normal thyroid tissue and tumour tissue and have highlighted their potential as diagnostic markers. Study aims to examine and establish the relationship between miR-34b expression and one of its predictive target for PTC cases (c-myc).

Methods: Total RNA was extracted from histologically confirmed PTC and non-cancer thyroid tissue from patients (n = 16). miRNA was isolated from 32 samples (16 matched PTC and their adjacent normal tissues as controls) using mirVana kit. miR-34b expression levels were estimated in qRT-PCR with RNU43 as reference. Since it is known that miRNAs regulate gene expression by promoting the degradation of targeted mRNAs, we performed *in silico* analysis (miRTarBase) in order to identify the possible targets for miR-34b. One potential target was chosen c-myc oncogene, and its expression levels were determined in RT-PCR. Statistical analysis was performed with GraphPad Prism.

Results: Compared with corresponding normal tissue, miR-34b was found to be downregulated (>2 fold, $P < 0.003$) in PTC samples, as for its target an inverse corelation between miR-34b and c-myc expression levels was noted. Results indicates a significantly increased c-myc expression in PTC subjects ($P < 0.001$). For PTC patients, c-myc could be a target of miR-34b and the incresed levels of c-myc oncogene, underlying tumorigenic changes in thyroid cancer, may be due to miR-34b downregulation. Further studies are needed to establish the relationship between miR-34b and its target in papillary thyroid carcinoma.

Keywords: c-myc, miR-34b, Papillary thyroid cancer.

Analysis of miRNA expression in canine mammary cancer stem-like cells shows epigenetic regulation of TGF-Beta signalling

A. Homa, M. Król

Department of Physiological Sciences, Warsaw University of Life Sciences-SGGW, Warsaw, Poland

Cancer stem cells (CSCs) posse the unique ability to self-renewal and differentiate into all kind of cancer cells. That is why they are responsible for cancer initiation, recurrence and drug resistance [1]. Despite a variety of methods are currently employed to target them, just a little is known about miRNA regulation of CSCs. However, miRNA may constitute a new element of combined therapy targeting these cells [2].

The aim of our study was to assess miRNA expression in canine mammary cancer stem cells. Using FACS Aria II we sorted out subpopulation of cells expressing Stem cell antigen 1 (Sca1; these cells also expressed CD44 and epCAM) from canine mammary tumour cell lines (CMT-U27, CMT-309 and P114). Next, we conducted colony formation assay, which confirmed that only stem-like cells were able to form colonies from single cell in all the examined cell lines. In these cells we examined miRNA expression profiles using Agilent custom-designed miRNA microarrays. These results were validated by Real-time rt-PCR analysis of expression of randomly selected miRNAs.

The results revealed 33 significantly deregulated miRNAs in Sca1-positive cells comparing with differentiated tumour cells. Twenty-four of them were down- regulated whereas nine were up-regulated. Further, we graded them by number of miRNAs in which they occurred. We selected 240 target genes of down-regulated miRNAs and analysed over-represented pathways using Gene Set Enrichment Analysis (GSEA). According to KEGG and BioCarta databases these target genes were involved in MAPK signalling pathway, TGF-Beta signalling, ALK, and PGC1A pathways. Genes targeted by up-regulated miRNAs have not been significantly involved in particular pathways. However, analysis of single-gene overlapping with different pathways showed that the most important were: TGFBR1, TGFBR2, SOS1, CHUK, PDGFRA, MEF2C, TGFBR1, MEF2D and MEF2A. All of them are involved in TGF-Beta signaling showing its important role in cancer stem cells biology.

The results of our study showed significant epigenetic regulation of cancer stem cells transition to differentiated cancer cells and are important not only for veterinary medicine but also for comparative oncology and cancer research in general.

This work was supported by the grant no. N N308574940.

Prostate cancer (PCa) is one of the most prevalent malignancies characterized by high mortality rates among males in Lithuania

© 2014 The Authors. FEBS Journal © 2014 FEBS

and world-wide. PCa, compared to non-cancerous prostate tissue (NPT), contains various molecular alterations including aberrant expression of small non-coding RNAs. MicroRNAs (miRNAs) are 21–22 nt RNAs responsible for gene expression regulation and coordination of multiple physiological processes. In cancer, expression of various human miRNAs is markedly deregulated which causes subsequent changes in multiple cellular pathways and impacts disease outcome. The aim of this study was to identify differentially expressed miRNAs specific to PCa and suitable for early and non-invasive disease detection and prognosis.

Expression profile of 754 mature miRNAs was assessed using TaqMan Low Density Array (TLDA) cards A and B v3.0. Selected miRNAs were further analyzed with Custom Design TLDA cards to confirm the expression changes in an expanded set of samples. To evaluate miRNAs circulating in urine of PCa patients qPCR assays were applied.

In PCa tissues (N = 42), expression of 95 miRNAs significantly differed as compared to NPT samples (N = 12), 68 of them were up- and 27 downregulated. Comparison of miRNA profile in PCa cases with and without biochemical disease progression (BCR) revealed a marked upregulation of expression of 61 miRNAs. Based on the most significant differences between PCa and NPT and correlations with several clinicopathologic characteristics, 19 miRNAs were selected for further validation in the expanded set of samples. Significant upregulation of miR-19a, miR-21, miR-148a, and miR-375 was confirmed in PCa (N = 52) as compared to NPT (N = 12) samples, while expression of miR-340 was significantly increased in BCR-positive in comparison to BCR-negative cases. In further analysis, miR-19a and miR-21 were successfully quantified in urine collected from PCa (N = 137) and benign prostatic hyperplasia (BPH, N = 25) patients. Higher expression level of miR-19a was observed in PCa than in BPH, while in BCR-positive PCa cases both miR-19a and miR-21 were more abundant as compared to BCR-negative cases.

In conclusion, targeted inactivation of tumorigenic miRNAs might be considered as a novel treatment strategy for PCa. Non-invasive detection of selected miRNAs in urine might serve as a molecular tool for early identification of PCa.

Characterization of the cellular factors involved in microRNA destabilization by mouse cytomegalovirus

S. Cetin, G. Haas, M. Messmer, B. Chane-Woon-Ming, S. Pfeffer

Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France

miRNA biogenesis and their functions have been extensively studied during the last decade, however less is known about the regulation of their stability. Nonetheless, an increasing number of examples illustrating the need to control mature miRNA stability (i.e. adaptation to biotic and abiotic stress) has emerged recently in the literature.

Our laboratory has previously discovered the destabilization of the cellular miR-27 upon mouse cytomegalovirus (MCMV) infection. A viral transcript (called m169), harbouring a functional miR-27 binding site, was found to be solely responsible of directing miR-27 for degradation [(1)]. High-resolution northern blot analyses and small RNA sequencing, demonstrated that the interaction between miR-27 and m169 induces the tailing and trimming of miR-27, a mechanism previously described in Drosophila and human cells [(2)].

While an extensive miRNA-target mRNA pairing seems to be a prerequisite to induce miRNA tailing and trimming, how this mechanism works or which factors are involved in this process is currently unknown. By using both MCMV infection and miR-27/m169 interaction as model systems, a biochemical approach based on the transfection of biotinylated-antisense oligonucleotides was used to induce the tailing-trimming of specific miRNAs and to pull down protein complexes for their analysis by mass spectrometry.

We identified novel factors that could be involved in the tailing-trimming of miRNAs, of which the roles of Terminal Uridylyl Transferase-1 (TUT1) and 3′-5′ exoribonuclease DIS3 like 2 (DIS3L2) proteins in the miRNA decay pathway will be discussed.

Clinical relevance of VKORC1 genotype and response to warfarin therapy

S. Karaca[1,2], M. Karaca[3], E. Cosgun[4], N. H. Aksoy[2], N. C. Bozkurt[5]

[1]Public Health and Genomics Research Center, GENAR Institute, Ankara, [2]School of Health Science, [3]Biology Department, Faculty of Science and Arts, Aksaray University, Aksaray, [4]Department of Biostatistics, Faculty of Medicine, Hacettepe University, [5]Department of Endocrinology and Metabolism, Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey

Background: The management of warfarin therapy is challenging because it shows large inter and intra individual variability. The aim of current study was to characterize the effects of the *VKORC1* (−1639G>A) polymorphism and other personal characteristics on warfarin dose requirements in Turkish patients.

Methods: Unrelated 183 subjects with (n = 90 cases) and without (n = 93 controls) hemorrhagic complications during warfarin therapy were consecutively enrolled. MALDI-TOF based Sequenom MassARRAY platform was used for genotyping process. Multiple statistical analyses were performed to define the relation of VKORC1 variants with warfarin dose requirement, INR level, hemorrhage points, hemorrhage risk and severity, comorbidity and medications.

Results: The cases and controls did not have a significant difference in terms of VKORC1 (−1639 G>A) genotype distribution (p = 0.084). Frequencies were determined as 30.1%, 52,5% and 17.5% for AA, GA, GG genotype respectively. Allele distribution was 56.2% for (A) and 43.7% for (G) (HWE, p = 0.001) in the screened cohort. A multiple linear regression model revealed a strong relation between warfarin dose and age (p = 0.001), INR level (p = 0.001), hemorrhage risk (p = 0.02). The VKORC1 AA variant have significant association with higher INR (p = 0.01) and lower warfarin dose (mean dose was 3.37 ± 1.43 mg/day vs 5.75 ± 2.63 mg/day among cases) requirement (p = 0.001). The number of the cases with long term (>1 year) warfarin usage was higher, however, significant relation was not found between VKORC1 variants and treatment period.

Conclusions: VKORC1 −1639AA genotype is associated with lower warfarin dose and higher INR status and its frequency in the screened cohort was higher than it has already been reported for Turkish population. Determining the impact of genetic factors in a given population is important for research, development and implementation of personalized health care models which allows developing individualized pharmacological and medical follow-up advices and more targeted preventative healthcare strategies.

MON-036
Detection of microRNAs in hair roots and hair shafts as the novel potent biomarker: evaluation of the usefulness for the diagnosis of systemic sclerosis

M. Jinnin, Z. Wang, S. Fukushima, H. Ihn
Kumamoto University, Kumamoto, Japan

A lot of researches has indicated serum microRNA levels are useful as the biomarkers for various diseases. In this study, we compared several methods to extract hair microRNAs, and evaluated their usefulness for the diagnosis of scleroderma.

A single hair root and 5 pieces of hair shafts (about 5 cm) were obtained from 11 scleroderma patients and 13 normal subjects at the time of serum sampling. microRNA was extracted from sera or hair roots using commercially available kits. Hair shaft microRNAs were purified using four different methods. microRNA expression was determined by PCR array and real-time PCR.

We found microRNAs were detectable and quantitative in hair roots and hair shafts using our method. We demonstrated the difference of microRNA levels in hair roots and hair shafts obtained from different places of head in each individual were within 2-fold, thus indicating the reproducibility of hair microRNA levels by our method. PCR array results indicated microRNAs from sera, hair roots and hair shafts have different expression pattern, and can be independent biomarkers.

Serum and hair root miR-196a levels were not significantly altered in scleroderma patients, whereas miR-196a levels in hair shafts were significantly down-regulated in scleroderma patients compared to those in normal subjects.

Because hairs are more accessible than sera, microRNAs levels in hair roots and hair shafts may become effective and independent biomarkers.

Keywords: hair, microRNA.

MON-037
Early differential miRNA expression following in vitro fertilization of mouse eggs incubated in two standard culture media

E. Barrey[1,2], B. Banrezes[3], T. Sainte-Beuve[3], A. Vaiman[1], J.-P. Ozil[3]
[1]*INRA-GABI-UMR-1313, Jouy-en-Josas,* [2]*Inserm-U902, Evry,* [3]*INRA-BDR-UMR1198, Jouy-en-Josas, France*

Background: At fertilization, the incoming sperm triggers the increase in egg metabolism by causing a series of repetitive Ca^{2+} signals that stimulate mitochondrial oxidative phosphorylation. Several reports have shown that the culture media impacts egg functioning and may affect the long-term developmental processes either in animal or in human. According to the recent discovery of mitochondrial function in microRNA pathway, we assumed that early miRNA expression in the egg should be functionally linked with mitochondrial activity during the period of egg activation. The aim of the study was to measure whether the miRNA expressions are differentially regulated by culture media during the initial period of fertilization.

Material and Method: Four groups of 30 freshly ovulated oocytes were used as control. Eight groups of 30 mouse oocytes were fertilized by Intra Cytoplasmic Sperm Injection (ICSI) and incubated for 4 hours in standard M16 or KSOM medium which have the same 10 compounds but at lower concentrations in KSOM (inorganic ions, energy substrates and protein). All the groups were used to isolate total cells and mitochondria, cytosolic and nucleus fractions by differential centrifugations in specific buffers. RNA extraction kit adapted for small amount of materials was used to extract total RNA from the egg or cell fractions and perform a multiplex RT-qPCR (742 mouse and rodent miRNA).

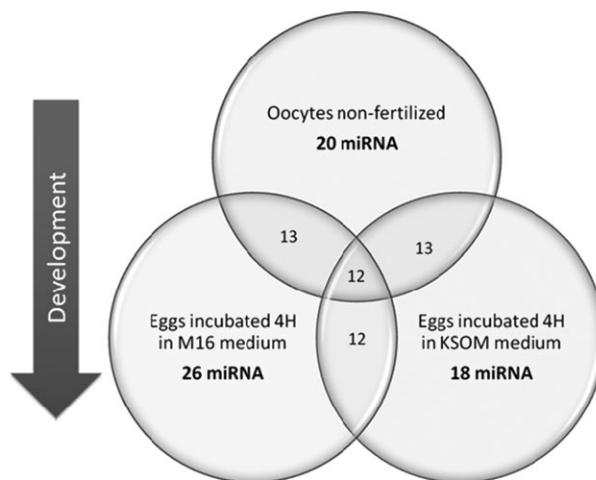

Fig. 1. Number of miRNA expressed in oocytes and eggs after 4 hours of incubation in two standard culture.

Results: Significant changes of miRNA expressions were recorded 4 hours following ICSI. The total number of miRNA expressed per group was highly significantly different after fertilization in KSOM (18 miR) *versus* M16 (26 miR) or in non-fertilized oocytes (20 miR) (figure). Moreover, differential miRNA expressions were observed between cytosolic (15 *vs* 32 miR), mitochondrial (15 *vs* 18 miR) and nuclear (17 *vs* 17 miR) fractions in eggs according to the medium (KSOM *vs* M16). Among the predicted genes targeted by the more expressed miRNA, the following pathways were significantly identified by miRPath: MAPK signaling, PI3K-Akt, metabolic pathway, calcium signaling, Jak-STAT and dorso-ventral axis regulation.

Conclusion: We reveal a functional linkage between the culture media formula and the initial miRNA expressions immediately after fertilization. Such miRNA activity could regulate transcription of thousands of maternal mRNA which are further involved in zygotic genome activation. Such functional genomic analysis provides a potential lever to identify the molecular mechanisms involved in phenotype programming following in-vitro fertilization.

EBV-Epstein Barr virus miR-BART20-5p regulates cell proliferation and apoptosis by targeting BAD

H. Kim, H. Choi, S. K. Lee
Department of Medical Lifescience, The Catholic University of Korea, Seoul, Korea

Although Epstein-Barr virus (EBV) BART microRNAs (miRNAs) are ubiquitously expressed in EBV-associated tumors, the role of most BART miRNAs is unclear. In this study we showed that Bcl-2–associated death promoter (BAD) expression was significantly lower in EBV-infected AGS-EBV cells than in EBV-negative AGS cells and investigated whether BART miRNAs target BAD. Using bioinformatics analysis, five BART miRNAs showing seed match with the 3' untranslated region (3'-UTR) of

© 2014 The Authors. FEBS Journal © 2014 FEBS

BAD were selected. Of these, only miR-BART20-5p reduced BAD expression when individually transfected into AGS cells. A luciferase assay revealed that miR-BART20-5p directly targets BAD. The expression of BAD mRNA and protein was decreased by miR-BART20-5p and increased by an inhibitor of miR-BART20-5p. Annexin V staining and cell proliferation assays showed that miR-BART20-5p promoted cell proliferation and reduced apoptosis. Furthermore, miR-BART20-5p increased chemoresistance to 5-fluorouracil. Our data suggest that miR-BART20-5p contributes to tumorigenesis of EBV by directly targeting the 3'-UTR of BAD.

Keywords: BAD, BART miRNA, Epstein-Barr virus.

Expression profile of MAGI2 as a novel biomarker in combination with major deregulated genes in prostate cancer

R. Mahdian[1], S. Shahbazi[2]
[1]Molecular Medicine Department, Pasteur Institute, [2]Tarbiat Modares University, Tehran, Iran

Complex molecular changes that occur during prostate cancer (PCa) progression have been described recently. Specifically, whole genome sequencing of PCa tissue identified gene rearrangements which disrupt the gene loci of PTEN and MAGI2 (PTEN scaffolding protein). In the present study, we analyzed the expression profile of *MAGI2* gene in a cohort of clinical PCa ($n = 45$) and benign prostatic hyperplasia (BPH) samples ($n = 36$) as well as three PCa cell lines. We also studied the expression of PCa-related genes including *PTEN, NKX3.1, SPINK1, DD3, AMACR, ERG,* and *TMPRSS2-ERG* gene fusion in these samples. The expression of *MAGI2* mRNA was significantly down regulated in PC3, LNCaP and DU-145 PCa cell lines ($p = 0.000$) and also in clinical tumor samples (*Relative expression*=0.307, $p = 0.002$, 95% C.I., 0.002–12.08). The expression of *PTEN, NKX3.1, SPINK1, DD3,* and *AMACR* genes was significantly deregulated in prostate tumor samples (*p* range: 0.000–0.044). A significant correlation was observed between *MAGI2* and *NKX3.1* expression in tumor samples ($p = 0.006$). Furthermore, the inclusion of *MAGI2* in the gene panel improved the accuracy for discrimination between PCa and BPH samples with the sensitivity and specificity of 0.88 (CI: 0.76 to 0.95) and 0.83 (CI: 0.68 to 0.92), respectively. The data presented here suggest *MAGI2* gene as a novel component of the gene signatures for the detection of PCa .

Keywords: MAGI2, prostate cancer.

Fenofibrate prevention of increased mitochondrial fatty acid oxidation capacity in skeletal muscle of DIO mice is associated with muscle-specific microRNA

A. C. Rodrigues[1], F. Frias[1], A. Martins[2], L. G. de Sousa[2], S. Hirabara[3], R. Curi[2]
[1]Pharmacology, [2]Physiology and Biophysics, ICB-USP, [3]ICAFE, UNICSUL, Sao Paulo, Brazil

Mitochondrial disfunction is claimed to be a risk factor for insulin resistance, and consequently type 2 diabetes (T2D). MiRNAs are small non-coding RNAs that negatively regulate gene expression by promoting degradation or repressing translation of target mRNAs. The aim of this study was to investigate in skeletal muscle of diet-induced obesity mice, treated or not with fenofibrate, the expression of muscle-specific miRNAs and their correlation with expression of genes involved in mitochondrial metabolism. Male C57bl/6 mice (n = 20) were fed for 6 wk with a standard lab diet (SD) or with a high-fat diet (HFD). Subsequently, the mice were maintained on SD/HFD for 2 more wk, but half of the mice were treated with fenofibrate (50 mg/Kg/day) via oral gavage. At the end of the treatment, soleus muscles were isolated and subjected to insulin-induced glucose uptake and CO2 production or flash-frozen in liquid nitrogen immediately for total RNA extraction. Muscle specific microRNAs (miR-1, miR-206 and miR-133a and -133b) and expression of genes involved in mitochondrial fatty oxidation were measured by TaqMan[â] Real-time PCR assay, using snoRNA202 or Rpl, for normalization, respectively. Soleus muscles from HFD-fed mice were unresponsive to insulin, and fenofibrate treatment restored insulin mediated glucose uptake and glycogen synthesis, but had no effect on glucose oxidation. HFD significantly down regulated muscle-specific miRNAs compared with SD group levels in muscle. Fenofibrate treatment restored only miR-1 expression to levels identical of the SD-fed group. Using targetscan software, we found that miRs-1, 206, 133a/b were predicted to target carnitine palmitoyltransferase 1 (Cpt1b), uncoupling protein (*UC*P)3, peroxisome proliferator-activated receptor ϒ coactivator (Pgc1-α), and estrogen-related receptor gamma (Esrrg); all genes involved in mitochondrial metabolism. HFD up-regulate these genes, except Ucp3, compared with SD in muscle, but fenofibrate treatment restored mRNA levels of these genes to SD-fed mice levels. Fenofibrate induced a down regulation of *UC*P3 expression compared to HFD-fed mice. In HFD-fenofibrate group, a significantly negative correlation was observed between miR-1 and Esrrg ($r^2$0.81), Pgc1a ($r^2$0.87) and Ucp3 ($r^2$0.70). Our results demonstrate that muscle specific-miRs may be involved in pathogenesis of T2D, given that they were down regulated in mice on HFD. Fenofibrate improves glucose metabolism in muscle from diabetic mice, and treats increased mitochondrial fatty acid oxidation, probably through up-regulation of miR-1.

From mice to men: fine tuning of cholinergic signaling by non-coding RNAs

H. Soreq
The Institute of Life Sciences and the Edmond and Lily Safra Center for Brain Sciences, The Hebrew University of Jerusalem, Jerusalem, Israel

Continuous communication between the nervous and the immune system is essential both for maintaining homeostasis and for ensuring rapid and efficient response to stressful and infection insults. Non-coding and microRNA (miRNA) regulators provide exciting and challenging models for studying this communication in anxiety and inflammation. Global genomic analyses show that miRNAs co-evolved with their target transcripts to efficiently control neuronal signaling pathways and enable contribution to the development of higher brain functions while avoiding damaging evolutionary impact. Specifically, miRNA controllers of acetylcholine signaling modulate both anxiety and inflammation reactions to external insults through physiologically relevant bidirectional competition on interaction with their targets. We found rapid increases of the evolutionarily conserved neuro-modulator acetylcholinesterase (AChE)-targeted CholinomiR-132 in acute stress, intestinal inflammation and post-ischemic stroke, inversely to its drastic reduction in the Alzheimer's disease brain. Furthermore, single nucleotide polymorphisms interfering with the AChE-silencing capacities of the primate-specific CholinomiR-608 associate with elevated trait

© 2014 The Authors. FEBS Journal © 2014 FEBS

anxiety, inflammation and diverse aging-related diseases in human volunteers, whereas long non-coding RNAs complementary to such miRNAs are modulated in Parkinson's disease and by deep brain stimulation. Deepened understanding of the evolution and complexity of neuronal non-coding RNAs may highlight their role in the emergence of human brain functions while enhancing the ability to intervene with diseases involving cholinergic signaling impairments.

Functional high-throughput screening identifies microRNAs regulating *Salmonella* infection

C. Maudet[1], U. Sunkavalli[1], M. Sharan[1], K. Forstner[1], M. Mano[2], A. Eulalio[1]
[1]Institute for Molecular Infection Biology (IMIB), University of Würzburg, Würzburg, Germany, [2]International Centre for Genetic Engineering and Biotechnology (ICGEB), Trieste, Italy

In recent years it has become clear that microRNAs, in addition to their pervasive and well-established functions in physiological and pathological processes, also play crucial roles during infection by different pathogens. However, apart from a small number of microRNAs involved in the host inflammatory response, no microRNAs have been shown to directly modulate infection by bacterial pathogens.

Salmonella enterica serovar Typhimurium, a common and highly investigated facultative intracellular bacterium, is one of the most important causes of lethal food-borne diseases.

To systematically identify microRNAs able to regulate *Salmonella* infection, we performed a high-content, fluorescence microscopy-based screening using a genome-wide library of microRNA mimics. Using this unbiased approach, we identified 17 microRNAs able to decrease *Salmonella* infection by at least 2-fold, as well as microRNAs able to increase *Salmonella* infection (11 microRNAs by at least 2-fold). Detailed time-course infection experiments showed that the identified microRNAs affect *Salmonella* infection at different stages of the infection cycle (e.g. invasion, maturation of the *Salmonella* containing vacuole, replication). Interestingly, many of the identified microRNAs do not affect infection by *Shigella flexneri*, a closely related bacterial pathogen, demonstrating their specificity towards *Salmonella*.

By performing deep-sequencing analysis of the small RNA population of *Salmonella* infected cells, we also determined that some of the microRNAs that strongly inhibited infection in our functional screening are downregulated during infection. Using a combination of experimental and bioinformatic approaches, we have identified and characterized the targets of these microRNAs that play a relevant role in the context of infection.

Overall, these findings uncover a novel mechanism whereby *Salmonella* promotes its own survival and replication by modulating the levels of host cell microRNAs, targeting pathways not previously shown to be relevant for infection.

Functional muscle microRNAs in type 2 diabetes mellitus

I. Kilinc, N. Ozer, T. Balci
Department of Medical Biochemistry, Necmettin Erbakan University, Meram Faculty of Medicine, Konya, Turkey

Maintenance of appropriate levels of circulatory glucose levels results from a balance between normal insulin secretion and action.

Diabetes mellitus (DM) is a complex, multisystem disease that represents the most common metabolic disorder. Type 1 DM (T1DM) results from insulin deficiency, usually secondary to autoimmune beta-cell destruction; and type 2 diabetes mellitus (T2DM) is a progressive metabolic disorder characterized by reduced insulin sensitivity, insulin resistance in tissues such as skeletal muscle, liver and adipose tissue, combined with pancreatic β-cell dysfunction, resulting in systemic hyperglycaemia. Improper treatment of T2DM can lead to severe complications such as heart disease, stroke, kidney failure, blindness and nerve damage.

The discovery in mammalian cells of hundreds of small RNA molecules, called microRNAs, with the potential to modulate the expression of the majority of the protein-coding genes has revolutionized many areas of biomedical research, including the diabetes field. MicroRNAs function as translational repressors and are emerging as key regulators of most, if not all, physiological processes.

microRNAs also control insulin signalling in target tissues, including the liver, skeletal muscle, and adipose tissues.

microRNAs circulating in the blood can potentially serve as novel noninvasive biomarkers of diseases including diabetes.

The potential role of microRNAs as biomarkers in diabetes and how aberrant pathways could be corrected therapeutically.

Target recognition relies on rules that are relatively easily satisfied within the transcriptome, each microRNA can potentially regulate translation of a large number of different mRNAs. Each mRNA can possess multiple binding sites for a single or for many different microRNAs. One microRNA can potentially target several genes. These discrepancies and facts reflect the challenges of microRNA-based therapeutics.

Increase and decrease of microRNA levels are important in the pathophysiology.

Understanding of the relationship between functional analysis of microRNAs and insulin resistance is important.

Molecular therapeutic approach, should include interactions of physiological and pathological events with treatment.

Identifying the role and regulation of skeletal muscle miRNAs during various phases of muscle development, as well as in healthy and diseased conditions,will significantly enhance our understanding of skeletal muscle biology and may result in new therapies to target muscle diseases or chronic diseases associated with impaired muscle growth, regeneration or function. Understanding miRNA biology and function will enhance our understanding and application of current therapies.

Keywords: functional microRNA, Muscle microRNA, Type 2 Diabetes Mellitus.

GSEA for the circuitry genes NF-κB/Snail/YY1/RKIP in multiple myeloma

A. Zaravinos[1], D. A. Spandidos[2]
[1]*Department of Laboratory Medicine, Karolinska Institutet Huddinge, Sweden,* [2]*Department of Clinical Virology, University of Crete, Heraklio Crete, Greece*

Background: The presence of a dysregulated NF-κB/Snail/YY1/RKIP loop was recently established in metastatic prostate cancer cells and non-Hodgkin's lymphoma; however, its involvement in multiple myeloma (MM) has yet to be investigated.
Objectives: Aim of the study was to investigate the role of the NF-κB/Snail/YY1/RKIP circuitry in MM and how each gene is correlated with the remaining genes of the loop.
Methods: Using GSEA and Gene Neighbors Analysis in data received from four datasets included in the Multiple Myeloma Genomics Portal (MMGP) of the Multiple Myeloma Research Consortium, we identified various enriched gene sets associated with each member of the NF-κB/Snail/YY1/RKIP circuitry.
Results: In each dataset, the 20 most co-expressed genes with the circuitry genes were isolated subjected to Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment. The FOXO4, GATA binding factor, Sp1 and AP4 were the transcription factors that most likely affect the expression of the NF-κB/Snail/YY1/RKIP circuitry genes. GEO datasets computational analysis revealed elevated YY1 and RKIP levels in MM vs. the normal plasma cells, as well as elevated RKIP levels in MM vs. normal B lymphocytes.
Conclusion: The present study highlights the relationships of the NF-κB/Snail/YY1/RKIP circuitry genes with specific cancer-related gene sets among four MM datasets.

MON-046
Identification of full-length 3′UTR of ITSN1-L and possible regulation of ITSN1-S by miR-19 and miR-30

D. Gerasymchuk, S. Kropyvko, I. Skrypkina, L. Tsyba
Functional Genomics, Institute of Molecular Biology and Genetics NASU, Kyiv, Ukraine

MicroRNAs appear to be important posttranscriptional regulators of many cellular processes through targeting of 3'UTRs of different genes participated in cell life. Human intersectin 1 gene (*ITSN1)* encodes two isoforms (ITSN1-S and ITSN1-L) of multidomain adapter protein involved in clathrin-mediated endocytosis, cell signaling and cytoskeleton reorganization. The aim of our work was to identify whether microRNAs could regulate ITSN1-S and define full-length 3'UTR of ITSN1-L.

To find full-length 3'UTR of ITSN1-L we performed computational analysis of GenBank EST database and identified 11 ESTs which showed that the most probable end of 3'UTR of ITSN1-L mRNA could be located approximately 11600 downstream from the characterized 3' end of exon 41. Then we performed 3'RACE, RT-PCR, cloning of RT-PCR products in pGEM-T-easy vector, and sequencing and confirmed this prediction.

Using web servers TargetScan and miRanda for microRNA target prediction we identified 12 conserved target sites for different microRNAs. To confirm these results we performed luciferase assay using the construct based on pTKluc vector with insertion of full-length ITSN1-S mRNA 3'UTR on HEK 293 cells. Results of the essay showed the 5-fold inhibiting of pTKluc-3′UTR ITSN1-S construct luciferase activity in 293 compared to the intact pTKluc vector. Among the high-ranked target sites we found sites for miR-30 and miR-19. Mir-30 is associated with antioncogenic effect in different tissues while miR-19 is considered to be prooncogenic microRNA. As far as ITSN1 participates in clathrin-associated endocytosis, MAPK-pathway and reorganization of actin cytoskeleton and disorders in these processes are associated with cancer we decided to investigate if these microRNAs could regulate ITSN1-S. We cultivated 293 cells 72 h and transfected them every 24 h with pre-miR-30a and pre-miR-19a. Levels of endogenous ITSN1-S were estimated by Western-blot analysis. Obtained results showed inhibition of ITSN1-S expression by both microRNAs. Opposite, we found no effect from transfection by miR-181a – microRNA with two high-ranked predicted target sites. This suggests that both, miR-30 and miR-19 could negatively regulate ITSN1-S in processes ITSN1-S takes part.

To further investigate ITSN1-S posttranscriptional regulation more precisely we will perform luciferase assays using ITSN1-S mutants with fully or partially deleted 3'UTR and qRT-PCR to estimate microRNA impact on ITSN1 expression on RNA level.

Implication of Epstein–Barr Virus-encoded microRNAs in immune evasion of infected B cells

M. Bouvet, M. Albanese, T. Tagawa, W. Hammerschmidt, Unit Gene Vectors
Hematology, Helmholtz Zentrum, München, Germany

Epstein-Barr virus (EBV) is a prevalent, persistent human pathogen that preferentially infects primary B cells. EBV resides in its host for a lifetime and is a major cause of lymphomas in immunocompromised patients. In order to achieve viral persistence,

© 2014 The Authors. FEBS Journal © 2014 FEBS

EBV employs several strategies that have an impact on cellular gene expression and immune surveillance. The first stage of infection is key for EBV's success and requires mechanisms of immune escape to allow establishment of its latent cycle (Jochum et al., 2012). Apart from viral proteins, certain viruses including EBV resort to RNA interference (RNAi) to dampen the host immune response. RNAi is a posttranscriptional regulation of gene expression used by metazoans, plants and certain DNA viruses. RNAi requires non-coding RNAs of ~23 nucleotides in length called microRNAs (miRNAs). They specifically interact with target messenger RNAs (mRNAs) and direct either the degradation of the mRNA or the inhibition of its translation (Bartel, 2009). EBV encodes 44 miRNAs that are widely represented in infected cells at early time post-infection. Functions of these viral miRNAs are poorly understood but few examples indicate a role in controlling cellular immune responses of the host. Published cellular targets of EBV-encoded miRNAs include the T-cell attractive chemokine CXCL-11 (Xia et al., 2008), the NK cell ligand MICB (Nachmani et al., 2009), and the NRLP3 inflammasome subunit (Haneklaus et al., 2012). Each miRNA may regulate a large number of target genes suggesting that the presumed functions of EBV's many miRNAs are mostly unknown. We have preliminary evidence that some cellular genes, which are involved in immune response, are among the targets of EBV's miRNAs. We developed a set of tools to uncover these genes. These tools include mutant viruses that encode all, none or only subsets of viral miRNAs, bioinformatics prediction tools, miRNA reporter assays, and cellular immune assays in order to identify cellular targets of EBV-encoded miRNAs and to decipher the implication of EBV-encoded miRNAs in viral immune evasion of infected human B cells.

Metabolic pathways are deregulated in kidney cancer

A. Zaravinos
Department of Laboratory Medicine, Karolinska Institutet Huddinge, Stockholm, Sweden

Clear cell renal cell carcinoma (ccRCC) is the predominant subtype of renal cell carcinoma (RCC). It is one of the most therapy-resistant carcinomas, responding very poorly or not at all to radiotherapy, hormonal therapy and chemotherapy. A more comprehensive understanding of the deregulated pathways in ccRCC can lead to the development of new therapies and prognostic markers. We performed a meta-analysis of 5 publicly available gene expression datasets and identified a list of co-deregulated genes, for which we performed extensive bioinformatic analysis coupled with experimental validation on the mRNA level. Gene ontology enrichment showed that many proteins are involved in response to hypoxia/oxygen levels and positive regulation of the VEGFR signaling pathway. KEGG analysis revealed that metabolic pathways are mostly altered in ccRCC. Similarly, Ingenuity Pathway Analysis showed that the antigen presentation, inositol metabolism, pentose phosphate, glycolysis/gluconeogenesis and fructose/mannose metabolism pathways are altered in the disease. Cellular growth, proliferation and carbohydrate metabolism, were among the top molecular and cellular functions of the co-deregulated genes. qRT-PCR validated the deregulated expression of several genes in Caki-2 and ACHN cell lines and in a cohort of ccRCC tissues. *NNMT* and *NR3C1* increased expression was evident in ccRCC biopsies from patients using immunohistochemistry. ROC curves evaluated the diagnostic performance of the top deregulated genes in each dataset. We show that metabolic pathways are mostly deregulated in ccRCC and we highlight those being most responsible in its formation. We suggest that these genes are candidate predictive markers of the disease.

Micro RNA'S in cancer: is their a potential for targetting strategies

S. Bhargava[1], V. Bhargava[2]
[1]*Manav Bharti University,* [2]*KRV Hospitals Pvt. Ltd., Kanpur, India*

Over the past few years, scientists have discovered that a new class of genetic regulators called "microRNAs" influence normal human growth and development. There is a growing evidence that microRNAs may also play an important role in human cancer and its etiology. Cancer is a complex and dynamic disease, involving a variety of changes in gene expression and structure. Traditionally, the study of cancer has focused on protein-coding genes, considering these as the principal effectors and regulators of tumorigenesis. Recent advances, however, have brought non-protein-coding RNA into the spotlight. MicroRNAs (mi RNAs), one such class of non-coding RNAs, have been implicated in the regulation of cell growth, differentiation, and apoptosis. While their study is still at an early stage, and their mechanism of action along with their importance in cancer is not yet fully understood, they may provide an important layer of genetic regulation in tumorigenesis, and ultimately become valuable therapeutic tools. Targeting strategies for these genes and m RNA which are supposed to control and regulate more than one target, estimates indicate they may be able to regulate up to 30 percent of the protein-coding genes in the human genome. Therefore, by using novel carriers such as liposomes, appended liposomes, fusosomes etc. and targeting to the regulated sites for therapeutic benefits.

Keywords: Cancer, micro RNA, targetting.

MicroRNA biomarkers for detection of lung ischemia reperfusion injury

L. Rancan[1], E. Marchal-Duval[1], S. D. Paredes[2], K. Aymonnier[1], M. C. Garcia[1], C. Simon[3], I. Garutti[4], E. Vara[1]
[1]Biochemistry and Molecular Biolgy III, School of Medicine, [2]Physiology, Universidad Complutense de Madrid, [3]Thoracic Surgery, [4]Anesthesiology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Ischemia reperfusion injury (IRI) is a leading cause of acute lung injury, a common problem in various clinical settings associated with significant morbidity and mortality. MicroRNAs (miRs) are a class of small single stranded noncoding RNAs that function as post-translational regulators of specific target mRNAs. Changes of miRs expression have been associated with different diseases and pathophysiological conditions. Accumulating evidence underlines a critical function for miRNAs in the modulation of innate and adaptive immune responses. In the last years they have emerged as regulators of IRI and it has been suggested that the miRs are potentially involved in the pathogenesis of solid organ rejection, including renal, intestinal and hepatic rejection. However the role of miRs on lung IRI has not been completely understood yet. Lidocaine (lido), a commonly used local anesthetic agent, has proved its anti-inflammatory activity in several tissues including lung but its possible modulation of miRs has not been investigated.
Aim: To investigate a potential involvement of miRNAs in lung IRI in a lung auto-transplant model. In addition the effect of lidocaine was investigated.
Animals and Methods: 3 groups (Sham-operated, control and lido) of 6 large-white pigs each were submitted to a left lung auto-transplant. All groups received the same anesthesia. In addition animals of lidocaine group received a continuous IV administration of lidocaine (1.5 mg/Kg/h) during surgery. In order to measure the expression of miRs, lung tissue samples were taken at: 1) 5 minutes before pulmonary artery clamp (PPn), 2) 5 min before reperfusion (PRp), 3) 30 min post-reperfusion (PR30) and 4) 60 min post-reperfusion (PR60). Lung tissue samples were analyzed for miRs (miR-122, miR-145, miR-146a, miR-182, miR-107, miR-192, miR-16, miR-21, miR-126, miR-127, miR142-5p, miR152, miR155, miR-223 and let7) using RT-QPCR. Results were normalized using miR-103.
Results: The expression of miR-127 and mir-16 did not increase after IRI. All the other miRs investigated exhibited more than two-fold differences at the PR60 time point and this effect was positively correlated with the severity of IRI. This increase in miRs levels was significantly down-regulated by lido administration.
Conclusions: Our results support the notion that IRI causes changes in miRs expression that can be used as markers of injury. In addition, lidocaine administration modifies miRs expression.
Keywords: ischemia reperfusion injury, lung, miRNAs.

MicroRNA expression profiling predicts melanoma metastatic potential

A. V. Kudryavtseva[1,2], A. A. Dmitriev[1,2], A. V. Snezhkina[1], A. F. Sadritdinova[1,2], N. V. Melnikova[1], V. A. Lakunina[1], L. A. Uroshlev[1], A. A. Rogozhnikova[1], G. A. Petukhova[2], E. N. Slavnova[2], B. Y. Alekseev[2], N. N. Volchenko[2], A. S. Zasedatelev[1,3]
[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, [2]P.A. Herzen Moscow Cancer Research Institute, Ministry of Healthcare of the Russian Federation, [3]N.N. Blokhin Russian Cancer Research Center of Russian Academy of Medical Sciences, Moscow, Russian Federation

Melanoma is aggressive skin, uveal or mucosal tumor with early metastatic onset. Even small tumors are capable of producing distant metastases. Uncertainties in the detection of metastases complicate the choice of a suitable treatment strategy.

The aim of our work is to develop a set of microRNA capable of discrimination between non-invasive and metastatic melanoma. We performed miRNA-seq analysis of 14 benign skin tumors, 18 primary melanoma neoplasms including 7 metastatic ones. We identified the set of 23 microRNA with statistically significant expression alterations between metastatic and non-metastatic melanomas ($p < 0.05$) and 17 microRNA – between benign tumors and malignant melanomas. Additionally we performed a screening of literature results obtained previously by other groups and finally collected a set of 31 microRNA with presumably differential expression patterns between metastatic and non-invasive melanomas, and a set of 25 microRNA – between melanomas and benign tumors. RT-qPCR validation allowed to identify a subset of miR-145, miR-150, miR-155, miR-193a/b, miR-196a, miR-211, miR-214, miR-221/222, miR-342-3p, miR-455-3p and miR-497 capable of discrimination between melanoma skin cancer and benign tumors (with overall sensitivity of approx. 90% and specificity of 85%), and subset of miR-30b miR-145, miR-149, miR-155, miR-182, miR-200a/b/c, miR-221/222 and miR-497 for the evaluation of the presence of metastases (sensitivity 87% and specificity 79%). These biomarker sets includes well-known miR-182 targeting *FOXO3* and miR-30b targeting *GALNT7*.

Further validation of these microRNA biomarker candidates on an extended cohort of patients would allow the creation of test-systems capable of detecting both malignant melanomas and discriminate tumors with high metastatic potential to facilitate the choice of appropriate therapy strategy.

This work was supported by grant 14-35-00107 from the Russian Science Foundation, grant from the Program of Molecular and Cellular Biology RAS and state contract 14.595.14.9399 with the Ministry of Education and Science of the Russian Federation. Part of this work was performed at the EIMB RAS “Genome” center.
Keywords: melanoma, metastases, microRNA.

MicroRNA-15b/16 enhances the induction of regulatory T cells by regulating the expression of Rictor and mTOR

Y. Singh[1,2], O. A. Garden[3], B. Cobb[1]
[1]Department of Comparative Biomedical Sciences, Royal Veterinary College, London, UK, [2]Department of Physiology I, Eberhard-Karls-University of Tübingen, Tübingen, Germany, [3]Department of Clinical Sciences, Royal Veterinary College, London, UK

Background: Regulatory T cells (Tregs) are required for maintenance of immune tolerance and protect from unwanted immune

© 2014 The Authors. FEBS Journal © 2014 FEBS

responses. The development of Tregs requires microRNA (miRNA) regulation of gene expression. Previous work has identified microRNAs (miRNAs) as important regulators of Tregs. Conditional knockouts of the genes encoding Drosha and Dicer, which are RNases required for miRNA synthesis, significantly decrease Tregs development and function. However, the question of how individual miRNAs regulate the gene expression program controlling the development and function of Tregs remains to be elucidated.

Methods: *In vitro* induction of Tregs, over-expression and inhibition of miRNAs using retroviral based vectors, Protein estimation by Western Blot, Flow-cytomix for cytokine measurement, Flow cytometry and *in vivo* model of inflammatory bowel disease.

Findings: To understand miRNA function in Treg development, we set about to identify important miRNAs and their relevant target genes. Of the more abundantly expressed miRNAs in Tregs, only miR-15b/16, miR-24, and miR-29a impacted the *in vitro* induction of Tregs (iTregs) in overexpression and blocking experiments. miRNA mimics for these significantly enhanced the induction of iTregs in *Dicer*$^{-/-}$ CD4^{+} T cells. Furthermore, the overexpression of miR-15b/16 in conventional CD4^{+} T cells reconstituted into *Rag2*$^{-/-}$ mice increased the *in vivo* development of peripheral Tregs and diminished the autoimmune response. In looking for targets of miR-15b/16, it was observed that the mTOR signaling pathway was enhanced in *Dicer*$^{-/-}$ CD4^{+} T cells, and its pharmacological inhibition restored induction of iTregs. The mTORC2 component Rictor contained a functional target site for miR-15b/16. Rictor was more abundantly expressed in *Dicer*$^{-/-}$ T cells as was mTOR, and their expression was downregulated by the overexpression of miR-15b/16. Finally, knockdown of Rictor by siRNAs enhanced Treg induction in *Dicer*$^{-/-}$ CD4^{+} T cells.

Conclusion: Our data provide an important mechanism of miRNA regulation of Tregs development is through regulation of the mTOR signaling pathway and its novel role in the development of inflammatory bowel disease.

MON-054
microRNA-9 – in ALS pathogenesis and therapy

T. Yardeni[1], D. Wang[2], G. Gao[2], E. Hornstein[1]
[1]Molecular Genetics, Weiazmann, Rehovot, Israel, [2]Gene Therapy Center, University of Massachusetts Medical School, Worcester, MA, USA

Amyotrophic lateral scleroses (ALS) is a progressive neurodegenerative disorder of the motor system, which is characterized by the loss of upper and lower motor neurons. ALS patients rapidly deteriorate after the onset of symptoms and the expected survival time is of only a few years. The development of therapies is halted by limited knowledge about the patho–mechanisms underlying the disease.

Pioneering studies from recent years discovered ALS-causing mutations in several genes including SOD1, TDP-43, FUS, hnRNPA1 and C9ORF72. Many of these genes encode for RNA-binding proteins, thus raising the hypothesis that dysregulation of RNA activity is involved in the pathogenesis of ALS.

microRNAs (miRNAs) are small non-coding RNAs that silence gene expression post transcriptionally, in a sequence-dependent manner, and have been suggested by our group and others to play a role in ALS pathology. One particular miRNA gene that gathers significant attention is miR-9, one of the most highly abundant miRNAs in the brain. miR-9 was previously suggested to play important roles in brain development, post-mitotic neural development and neurite morphogenesis. Interestingly, dysregulation of miR-9 expression was demonstrated in neurodegenerative disorders including Alzheimer's disease and Huntington's disease. Importantly, miR-9 was recently found to be upregulated in the spinal cord from ALS mice (SOD1 G93A). We therefore hypothesize that miR-9 upregulation contributes to pathogenesis and investigate if inhibition of miR-9 is beneficial in ALS.

We utilize a unique method for manipulation of miRNA expression in vivo. The method is based on delivery of recombinant adeno-associated virus, pseudotype 9 (rAAV9), which effectively transduces motor neurons after stereotactic intraventricular (ICV) injection. We utilize rAAV9 to overexpress miR-9 or inhibit miR-9 activity, (sing a tough decoy (TuD) in SOD1 G93A mice and assess the clinical impact of miR-9 on overall survival, body weight, neurological score and locomotion.

Our data demonstrate that reduction of miR-9 expression in spinal cord and brain of SOD1 G93Amice increases survival and improves neuromuscular function. Accordingly, miR-9 overexpression resulted in notable decreases SOD1G93A mice survival. We further identified specific targets of miR-9 and investigate novel pathways downstream of miR-9 in ALS pathogenesis.

miRNA research has broad implications for understanding mechanisms of brain integrity, and the pathogenesis of ALS and other neurodegenerative disorders. miRNA research may lead in addition to the development of a novel RNA-based therapeutic approaches.

Micro-RNA-mediated targeting of Runx2 reduces breast cancer metastasis and progression of osteolytic bone disease

H. Taipaleenmäki[1], G. Browne[2], A. J. van Wijnen[3], J. L. Stein[4], E. Hesse[1], G. S. Stein[4], J. B. Lian[4]
[1]Heisenberg-Group for Molecular Skeletal Biology, Department of Trauma, Hand & Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Department of Biochemistry & Vermont Cancer Center, University of Vermont College of Medicine, Burlington, VT, [3]Department of Orthopedic Surgery, Mayo Clinic, Rochester, MN, [4]Department of Biochemistry & Vermont Cancer Center, University of Vermont College of Medicine, Burlington, VT, USA

Progression of breast cancer to metastatic bone disease is associated with an aberrantly elevated expression of Runx2, which promotes the disease progression by activating many genes involved in the 'vicious cycle' of cancer-induced bone disease. Because transcription factors are not readily targetable for therapeutic intervention, our goal was to evaluate the potential clinical use of Runx2-targeting miRNAs to reduce tumor growth and bone metastatic burden. Expression analysis of a panel of miRNAs regulating Runx2 revealed a reciprocal relationship between the abundance of Runx2 protein and two miRNAs, miR-135 and miR-203. These miRNAs are highly expressed in normal breast epithelial cells where Runx2 is not detected, and conversely are absent in metastatic breast cancer cell lines and tissue biopsies that express Runx2. Reconstituting metastatic MDA-MB-231-Luc cells with miR-135 and miR-203 reduced the abundance of Runx2 and the expression of the metastasis-promoting Runx2 target genes IL-11, MMP-13, and PTHrP. Additionally, tumor cell viability decreased and cell migration was suppressed *in vitro*. *In vivo* implantation of MDA-MB-231-luc cells stably expressing miR-135 or miR-203 into the mammary gland, followed by additional intratumoral administration of the synthetic miRNAs reduced tumor growth and importantly, spontaneous metastasis to bone. Furthermore, intratibial injection of these miRNA-expressing cells impaired

© 2014 The Authors. FEBS Journal © 2014 FEBS

tumor growth in the bone environment, inhibited bone resorption and secondary metastasis to lung. We conclude that miRNAs targeting Runx2 are protective against metastasis, while deregulated expression of Runx2 in aggressive tumor cells is related to the loss of specific Runx2-targeting miRNAs. Our studies have also demonstrated for the first time that delivery of synthetic miRNAs is a viable therapeutic strategy to target transcription factors for the prevention of metastatic bone disease.

Keywords: bone metastasis, breast cancer, micro rna.

miR-199a-5p regulates urothelial permeability and bladder smooth muscle cell morphology and plays a role in bladder dysfunction

K. Monastyrskaya[1], A. Hashemi Gheinani[1], H. Rehrauer[2], C. Aquino Fournier[2], F. Burkhard[3]
[1]Clinical Research, University of Bern, Bern, [2]FGCZ, University of Zurich, Zurich, [3]Urology, University Hospital Bern, Bern, Switzerland

Chronic lower urinary tract diseases, including bladder pain syndrome / interstitial cystitis (BPS/IC) and bladder outlet obstruction-mediated overactive bladder, pose a recurrent problem in urological practice. Epithelial dysfunction resulting in a leaky urothelium has been suggested as a possible cause of BPS. Some of the changes in the expression levels of signalling and adhesion molecules in the bladder can be attributed to the alterations in the levels of regulatory microRNAs, which we have identified in the biopsies of BPS patients. Recently we showed that microRNA miR-199a-5p, which was elevated in BPS, is an important regulator of intercellular junctions. Upon overexpression in urothelial cells it directly targeted mRNAs encoding LIN7C, ARHGAP12, PALS1, RND1 and PVRL1 and impaired correct tight junction formation leading to increased permeability. MiR-199a-5p is predominantly expressed in the bladder smooth muscle, but also detected in the mature bladder urothelium and primary urothelial cultures. In the urothelium its expression can be up-regulated following activation of cAMP signaling pathways. Ectopic expression of miR-199a-5p in TEU-2 urothelial cells and subsequent mRNA-sequencing analysis revealed the activation of cytoskeleton remodelling, TGF, WNT and cell adhesion signalling pathways.

We sought to elucidate the function of mir-199a-5p in the bladder smooth muscle cells (SMC), and investigated its levels in the biopsies of patients with bladder outlet obstruction-induced fibrotic changes in the detrusor. In contrast to BPS, the miR-199a-5p levels were significantly down-regulated in the patients with end-stage fibrotic acontractile bladders. Using primary cultures of bladder smooth muscle cells we show that, concomitant with the smooth muscle cell de-differentiation, miR-199a-5p expression was decreasing, and the levels of its target mRNAs increased. Anti-miR-199a-5p expressed in SMC using lentiviral vectors selectively inhibited miR-199a-5p function. It caused an increase of cell proliferation, a significant cell size reduction and an up-regulation of WNT2 and other miR-199a-5p targets. Concomitant down-regulation of WNT2 in antimiR-transduced SMCs using WNT2 shRNA-expressing lentiviruses normalized WNT2 mRNA levels, and restored the cell phenotype and proliferation rates.

Our results point to a crucial role of miR-199a-5p in the WNT-mediated regulation of proliferative, developmental and fibrotic processes in the bladder smooth muscle. MiR-199a-5p thus may behave as a key modulator of the smooth muscle hypertrophy and fibrosis, relevant for bladder obstruction-induced organ remodelling.

miR-449 controls apical actin network formation during multiciliogenesis of *Xenopus laevis* embryos

A. Adamiok, L. Kodjabachian, A. Pasini
IBDM, Marseille, France

Multiciliated cells (MCCs), found throughout the metazoan kingdom, contribute to multiple biological processes. Recently, we demonstrated that microRNAs of the miR-449 family control vertebrate MCCs differentiation by repressing the Notch pathway (REF). Here, we report that the apical actin cytoskeleton reorganization, a prerequisite for basal bodies anchoring and cilia elongation, is also controlled by miR-449. Using *Xenopus* embryonic epidermis as a model system, we show that miR-449 silencing inhibits apical actin web formation in MCCs. We identify transcripts coding for the small GTPase R-Ras as miR-449 validated targets. Apical actin reorganization and multiciliogenesis were impaired when the *RRAS* mRNA was protected from miR-449 binding. Multiciliogenesis was rescued when the translation of protected *RRAS* transcripts was prevented. Altogether, our data demonstrate that miR-449 acts at several distinct steps of multiciliogenesis in vertebrates, and identify R-Ras as a new player in apical actin reorganization.

Keywords: cilia, microRNA, R-Ras.

MON-058
miRNA profiles in the mammary gland of dairy and beef cattle breeds

Z. Wicik[1,2], M. Gajewska[1], E. Osińska[1], A. Majewska[1], T. Motyl[1]
[1]Department of Physiological Sciences, Faculty of Veterinary Medicine, Warsaw University of Life Sciences, [2]Department of Human Epigenetics, Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland

Micro RNA (miRNAs) are small non-coding RNAs which participate in gene regulation and various metabolic processes. Its function during mammary gland development and activity of mammary gland stem cell niche is still unknown. In the present study, we performed high-throughput microarray analysis of miRNAs expression in mammary gland of 2 years-old non-pregnant Holstein–Friesian (HF) and Limousin (LM) heifers to identify miRNAs associated with high dairy potential. Statistical analysis was based on unpaired t-test with Benjamini-Hochberg multiple testing correction ($p \leq 0.05$). Ontological analyses of miRNA targets were carried out using binomial overrepresentation test with Bonferroni correction ($p \leq 0.05$). We identified 52 miRNAs differing significantly between mammary gland of dairy and beef cattle. The highest interbreed differences in expression changes were observed in the following miRNAs: bta-miR-375, bta-miR-218, bta-miR-24, bta-miR-183, bta-miR-147, bta-miR-204, bta-miR-421, bta-miR-155, bta-miR-146b, bta-miR-218_v13.0, bta-miR-29b, bta-miR-154c, bta-miR-101, bta-miR-194, bta-miR-1434-3p, bta-miR-2285t. Results obtained showed higher levels of miRNA expression in the mammary glands of LM heifers. Enrichment analyses performed for targeted genes revealed that major differences between miRNA activity in mammary glands of dairy and beef heifers are associated with regulation of signalling pathways crucial for mammary gland development. Among highly significantly targeted signalling pathways were: inflammatory pathways, TGF-beta, EGFR, insulin and WNT signalling pathways. Based on performed ontological and interactions network analyses we identified more than 20 genes associated with stem cells activity

© 2014 The Authors. FEBS Journal © 2014 FEBS

significantly targeted by differentially expressed miRNAs. These results indicate that high mammogenic potential of dairy cattle is not only dependent of genetic and central neuro-endocrine regulation, but also epigenetic control by miRNA from local intramammary factors. We suppose that this release from miRNAs inhibitory influence on genes whose products are associated with stem cell renewal and constitute the microenvironment for stem cells niche, may be an important mechanism promoting mammary gland development and high milk productivity.

Keywords: mammary gland, Microarrays, miRNAs.

MON-059
Modulation of PTEN expression by SET/TAF-Ibeta

C. S. Matsumoto[1], L. O. Souza[1], C. Curti[2], A. M. Leopoldino[1]
[1]Department of Clinical Analyses, Toxicology and Food Sciences, [2]Department of Physics and Chemistry, School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

PTEN (phosphatase and tensin homolog) protein controls the levels of the phospholipid phosphatidylinositol (3,4,5) -trisphosphate (PIP3), and consequently, the PI3K-Akt signals to cell survival, proliferation and growth. SET/template-activating factor-Ibeta (TAF-Ibeta) participates in histone acetylation control, as a subunit of the inhibitor of the histone acetyltransferases (INHAT) complex; recently, it has been reported that SET inhibits p53 acetylation resulting in transcription repression of the p53 target genes. Although it is known that p53 positively regulates PTEN expression, we previously observed that SET protein accumulation increases phosphorylated PTEN (inactive form) levels and this coincided with cell survival and Akt activation in head and neck squamous cell carcinoma (HNSCC). This observation suggests that when SET is accumulated, PTEN expression can be regulated by mechanisms other than p53. Then, in this study we hypothesized that SET can regulate PTEN by modulating the levels of microRNAs associated with PTEN expression, such as mir-19a, mir-21 and mir-214. For this, we analyzed by quantitative real time PCR (Syber Green®) the levels of PTEN mRNA in the HNSCC cell lines Cal27, HN12 and HN13, as well as in HEK293 cells overexpressing SET (HEK293/SET). The levels of mir-19a, mir-21 and mir-214 were assessed by using the TaqMan® Assay in HEK293-SET and HNSCC cells transfected with small interfering RNA (siRNA) for SET (Qiagen). The levels of PTEN were altered in HEK293/SET, as well as in HN12, HN13 and Cal27 cells with siRNA for SET. Also, the levels of the microRNAs studied were modulated in the presence of SET silencing. Therefore, we can propose that SET regulates the PTEN mRNA levels through modulation of the microRNAs mir-19a, mir-21 and mir-214. This new SET action in PTEN is in line with our previous evidence that SET accumulation induces PTEN inactivation, considering that both the responses to SET accumulation contribute to activate Akt signaling and promote cell survival.

MON-060
Pathophysiological role of inflammation-related microRNA in murine skin wound healing

R. Mori
Department of Pathology, School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

MicroRNAs (miRNAs) belong to the small, non-coding RNA family; they consist of approximately 20–25 nucleotides of single stranded RNA and regulate translational processing of target mRNAs. In this study, we screened for known and novel miRNAs that showed altered expression dynamics during repair of murine skin wounds, using next generation sequencing. We identified inflammation-related miRNAs by comparing WT and PU.1 KO mice, which possess no neutrophils, macrophages, mast cells, or T-cells, and thus cannot raise a standard inflammatory response. These mice exhibit rapid repair and scarless healing in contrast to their WT littermates. The candidate miRNAs identified may be involved in various level regulation of the inflammatory response at sites of tissue repair. We are currently analyzing the functions of these inflammation-related miRNAs in skin wound healing using knockout mice.

Keywords: inflammation, micro rna, wound healing.

Ponatinib inhibits breast cancer cell proliferation by regulating miRNA expressions

C. Kayabasi, S. Yılmaz Süslüer, T. Balcı, B. Özmen Yelken, Z. Mutlu, C. Caliskan, B. Goker, Ç. Biray Avcı, C. Gündüz
Medical biology, Ege University Medical School, İzmir, Turkey

Breast cancer remains the most common malignancy in women. Dysregulated FGFR is a significant risk factor in breast cancer. Ponatinib is a multi-targeted, ATP-competitive tyrosine kinase inhibitor that inhibits BCR-ABL and also several kinases such as SRC family kinases, FGFR, KIT, VEGFR, PDGFR. MicroRNAs (miRNAs) are single strand, non-coding RNA molecules with the length of 18–25 nucleotides which have role in the epigenetic regulation of gene expressions.

The aim of the study was to evaluate the effect of ponatinib on the miRNA expression levels associated with breast cancer in MCF-7 cells. Also we aimed to investigate cytotoxic and apoptotic effects of ponatinib.

Cytotoxic effects of ponatinib in MCF-7 cells were measured online with xCELLigence system. Apoptotic effects of the IC_{50} dose of ponatinib were evaluated by ApoDIRECT In Situ DNA Fragmentation Assay with flow cytometry. For this study, custom design 96-well plates consist of miRNA primers which are important in breast cancer progression were used for miRNA expression analysis by using Light Cycler 480 real time online qRT-PCR. $_{\Delta\Delta}$CT method was used for data analysis. Statistical analysis was performed by web based RT² Profiler PCR Array Data Analysis program.

IC_{50} dose of ponatinib was calculated as. It was shown that IC_{50} dose of ponatinib induced apoptosis approximately 3 fold according to the control cells. The tumor suppressor hsa-let-7a-5p that is down-regulated in breast cancer is up-regulated 24.99 fold with ponatinib treatment (4.59 μM). Two of the members of oncogenic miR-17-92 cluster hsa-miR-19b-3p expression down-regulated 4.37 fold change and hsa-miR-19a-3p expression completely suppressed. In breast cancer hsa-miR-210-3p overexpression is associated with tumor growth and proliferation, migration and invasion and this oncomiR is also down-regulated 5.16 fold with ponatinib treatment.

© 2014 The Authors. FEBS Journal © 2014 FEBS

In conclusion, ponatinib can be an attractive drug for inhibiting breast cancer cell proliferation via deregulating expressions of miRNAs which are related with breast cancer.

Keywords: breast cancer, miRNAs, Ponatinib.

MON-062
Profiling of circulating miRNAs in response to toxic or traumatic skeletal muscles damages in rats

J. Siracusa[1], S. Bourdon[1], N. Koulmann[1,2], S. Banzet[1]
[1]Institut de Recherche Biomédicale des Armées, Armed Forces Biomedical Research Institute, Brétigny sur Orge, [2]Ecole du Val-de-Grâce, Paris, France

Skeletal muscle damages can occur in a wide range of situations such as genetic myopathies, physical exercise, or toxic and traumatic injuries. Classical blood markers display high variability. Recently, circulating microRNAs (miRNAs) have been identified as biomarkers of various pathologies or tissue damage. Muscle-specific miRNAs could be biomarkers of muscle dystrophies. However, whether miRNAs can be used as markers of acute and limited muscle damage, the most frequent, is unknown. Our aim was to study plasma miRNAs profiles and kinetics in response to muscle injury in rat, to identify new markers.

Muscle injury was induced in the right soleus muscle of male rats by either notexin injection (NTX) or by crushing (CRUSH). Blood samples were drawn 6 h, 12 h, 24 h, and 48 h post-injury in NTX, CRUSH or sham operated (SHAM) rats and in a control group (CTRL) to measure creatine kinase (CK) and circulating miRNAs. First, a RT-PCR profiling of 752 miRNAs was performed in plasma pools of NTX/CRUSH and CTRL 6 h, 12 h and 24 h after injury. Then, 79 miRNAs were selected on the basis of their detectability, tissue specificity or literature description and analyzed in each sample. Results were normalized with the seven most stables miRNAs.

Plasma CK increased in NTX at 6 h and 12 h post-injury with a return to the baseline at 24 h, no changes were found in other groups. Plasma levels of muscle-specific miRNAs miR-1-3p, miR-133a, miR-133b, miR-206-3p and miR-499-5p were increased in NTX group with a peak value at 12 h compare to CRUSH, SHAM and CTRL. Similar profiles were observed for non muscle-related miR-378a-3p, miR-434-3p and miR-409-3p. These results could be explained by the fact that notexin injection is known to be a more drastic model and is associated with extended muscles damages compared to crush model. MiR-208b was increased in NTX and to a lower extent in CRUSH at 6 h and 12 h. miR-497-5p and miR-93-5p progressively decreased from 12 h to the minimum at 48 h in NTX. Interestingly, miR-122-5p which has been proposed as a markers of liver injury, transiently increased at 6 h in NTX and CRUSH injuries. Whether miR-122-5p was released by injured muscle or by liver is unknown. MiR-126a-3p, highly expressed in endothelial cells, remained stable and cardiac-specific miR-208a, proposed as a marker of cardiac injury, remained undetectable.

In conclusion, we describe new circulating miRNA profiles associated with skeletal muscle injuries. Further analysis will determine how to combine miRNAs measurements to optimize diagnosis.

Reduction of Hepatitis C viral replication through targeting HCV-genotype-4 p7 ion channel by mir-29a in cell replicon

R. A. Helmy, R. Y. Mekky, E. N, A. AI
Pathology and Toxicology Department, German University in Cairo, Cairo, Egypt

P7 is a hepatitis C virus (HCV) protein that is essential for assembly and release of HCV. The crucial role which the P7 ion channel plays in HCV life cycle renders it an attractive therapeutic target. Recent data suggest that effectiveness of P7 inhibitors depends mainly on the amino acid sequence of P7 ion channel which shows significant heterogeneity among the different HCV genotypes. γT827A,T977S vector harboring P7 sequence of genotype 4 HCV. The designed cell replicon was transfected with mimics and antagomirs of mir-29a. Interestingly, It was found that mir29a mimics reduced viral titer by 49% (p = 0.04).

In the present study we endeavored to search for microRNAs that bind to a sequence specific to the P7 protein of genotype 4, in an attempt to investigate a novel therapeutic approach for HCV-genotype 4 infection. We thus performed a bioinformatics analysis, which revealed that mir-29a has 2 binding sites on the P7 ion channel. Using cell culture system, we transfected Huh7 cell lines with in-vitro transcribed pED43/JFH1-

In conclusion, decreasing viral load after forcing expression of mir29a suggests a potential role for this microRNA in targeting HCV P7 ion channel.

Serum micro RNA122 as a prognostic marker in patients with liver cirrhosis

A. Osama
Biochemistry, Assiut, Assiut, Egypt

Chronic liver diseases and cirrhosis are now being recognized as an important cause of morbidity and mortality worldwide. Established cirrhosis has a 10-year mortality of 34–66%. Hepatorenal syndrome and spontaneous bacterial peritonitis are important cause of mortality in cirrhosis. Patients with liver cirrhosis are mostly asymptomatic until decompensation occurs, so it is very difficult to assess the real prevalence and incidence of cirrhosis in the general population. In the liver miR-122 accounts for approximately 70% of all miRs, whereas other organs express much lower amounts of this miR. miR-122 regulates many genes in the liver that control the cell cycle, differentiation, proliferation and apoptosis. In contrast loss of miR-122 in the liver leads to hepatic differentiation with malignant phenotype. The aim of the study was to evaluate miR-122 as a prognostic marker in patients with liver cirrhosis. The study included 100 patients with liver cirrhosis All were subjected to clinical evaluation, abdominal ultrasonography, a group of laboratory investigations and serum miR-122 level by real time PCR. Serum miR-122 level among the studied groups showed significant statistical difference between group I "compensated" and both groups II "ascites" and III "SBP" (P < 0.001), while there was *high* statistical significanct difference between group I "compensated" and group IV "HRS" (P < 0.001). *S*trong negative correlation between serum miR-122 level and MELD score (p = 0.001), and very strong negative correlation between serum miR-122 level and Child score (p < 0.001). Lower serum miR-122 levels are associated with ascites, spontaneous bacterial peritonitis and hepatorenal syndrome. Therefore, serum miR-122 could be considered as a new

MON-065
Silencing of HSP90 affects miRNA profile in monocyte-like cells

S. Dabelić, J. Dumić, S. Šupraha Goreta, J. Pterik, O. Čulić, K. Barišić
Faculty of Pharmacy and Biochemistry, University of Zgreb, Zagreb, Croatia

Heat shock protein 90 (HSP90), a highly conserved chaperone, is crucial for the stability and function of many proteins, including oncogenic proteins involved in tumorigenesis (*e.g.* antiapoptotic proteins, transcription factors, signal-transduction proteins, Tyr-kinase receptors, *etc*.). Inhibition of HSP90 has been shown to be a promising therapy approach with clinical relevance for treatment of specific tumour types. On the other hand, microRNAs (miRNAs), small, non-coding RNAs (20–23 nucleotides) involved in the control of gene expression, are recognised as key players in the pathogenesis of human malignancies, but also as potential biomarkers and therapeutic targets. Yet, there is no data on the effects of the suppression of HSP90 expression on miRNA profile. This is why is this study we investigated the miRNA profile in monocyte-like cells after the exposure to the specific small interference RNA (siRNA) directed to HSP90 mRNA.

The reduction of Hsp90 mRNA expression by 70% and 65% was accomplished following 24 h and 48 h of transfection of human acute monocytic leukemia THP-1 cells with 10 nM siRNA, respectively, as determined by the TaqMan real-time PCR quantification. ApoTox Glo assay revealed that, at the same time, silencing did not affect cell viability, neither showed cytotoxic nor pro-apoptotic effect. The expression patterns of microRNAs were determined using Agilent microRNA arrays on biological duplicate time-courses. Cells transfected with scrambled RNA served as controls.

The obtained data suggest profound changes of miRNA profile in the cells with significantly reduced HSP90 expression; namely, after 24 h, the expression of 3 miRNAs were reduced (miR-195, miR-221, miR-224) while the expression of 20 miRNAs were significantly increased, especially of let-7b and let-7f, miR-15a, miR-4270, miR-769, miR-933. After 48 h, the reduced expression of 14 miRNAs (*e.g.* miR-1, miR-125b, miR133b, miR145, miR-451, miR-517a and b), and increased expression of 10 miRNAs, the most significantly of miR-1234, miR-135a, miR-146a, miR-374, and miR-4298 were observed.

The understanding of biological meaning of the observed changes of miRNA profile after supersession of HSP90 expression as well as molecular mechanisms underlying these events remain to be elucidated. These data could contribute to the better understanding of mode of action of the therapeutic HSP90 inhibitors but also reveal potential new therapeutic targets.
Keywords: HSP90, miRNA.

siRNA loaded chitosomes as an adjuvant therapy in cancer treatment

H. Jagani[1], N. Kasinathan[1], P. K. Shetty[2], S. Reddy[2], V. S. Rao[1]
[1]*Pharmaceutical Biotechnology,* [2]*Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal, India*

The aim of the present study was to study the effect of siRNA loaded chitosomes as an adjuvant in chemotherapy with doxorubicin. siRNA was designed to target anti-apoptotic *Bcl-2* gene. Chitosomes were synthesized by coating liposomes prepared by reverse phase evaporation method using phosphatidylcholine and cholesterol with water soluble chitosan. The effect of process variables on mean particle size, polydispersity index, zeta potential and encapsulation efficiency of prepared chitosomes were studied using factorial design. siRNA loaded chitosomes were evaluated for serum and short term stability studies. Cytotoxicity of siRNA loaded chitosomes and doxorubicin was evaluated by MTT assay on normal and cancerous cells. Expression studies were performed after transfecting siRNA loaded chitosomes to MCF-7 and MDA-MB-453 cells. *In vivo* efficacy of siRNA loaded chitosomes with doxorubicin were tested in Ehrlich Ascites Carcinoma (EAC) tumor bearing Swiss albino mice. Chitosomes were having mean particle size of 220 nm, surface charge +30 mV, PDI 0.18 and encapsulation efficiency of siRNA was 40%. Chitosomes were found to be stable up to 12 weeks at 4 °C. siRNA degradation by serum nucleases was prevented up to 24 h when incubated with 10% FBS. Blank chitosomes were found to be non-toxic. mRNA and protein level of *Bcl-2* was significantly reduced by chitosomes. Chitosomes with half the dose of doxorubicin were found to be effective in improving increase in mean survival time and % increase in life span of tumor bearing mice. Chitosomes loaded with siRNA can be promoted as an adjuvant therapy in cancer treatment to reduce the dose of the chemotherapeutic agent and reduce the toxicity associated with it.

Targeting cancer cell specific by siRNA-peptide complex

N. M. Martucci[1], N. Migliaccio[1], I. Ruggiero[1], C. Palmieri[2], P. Arcari[1], A. Lamberti[1]
[1]*Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples,* [2]*Department of Experimental and Clinical Medicine, University of Catanzaro "Magna Graecia", Catanzaro, Italy*

Despite the clinical response of anticancer treatments, including conventional chemotherapeutic treatments, tumorigenic B-cell lymphomas show an incomplete response to clinical treatments that result in a minimal residual disease (MRD) where few residual neoplastic cells undetected *in vivo*, replenish the cancer cell

© 2014 The Authors. FEBS Journal © 2014 FEBS

reservoir. This scenario, which is also shared with other cancer diseases, requires the development of strategies to advance in novel, selective targeting toward the tumorigenic cells that survive to the anticancer agents. Here, our experimental system takes advantage of the therapeutic properties of an idiotype specific peptide (A20-36) that binds specifically the B-cell receptor (BCR) of murine lymphoma cells (A20 cell line) [1] in the setting of an anticancer strategy, based on the selected delivery of electrostatic-based complex, peptide-siRNA [2]. To this purpose, two engineered, arginine rich, peptides that included the A20-36 targeting sequence (EYVNCDNLVGNCVI) were designed to bind fluorescent-labeled siRNA. One peptide was engineered at C- terminal of A20-36 with 9 Arg (9R-A2036) whereas the other included 5 Arg at the N- and C-terminus, respectively (5R-A2036-5R). A random peptide (SSAYGSCKGPCSSGVHSI) arginine modified has been used as control. Compared to the random peptide-siRNA complexes, both A20-36-siRNA complexes were able to selective deliver of fluorescent-labeled siRNA into A20 cells, as evaluated by cytofluorimetry and confocal microscopy, whereas fluorescent-labeled siRNA alone was not internalized. For potential delivery *in vitro*, the capability of peptides to deliver an anti-GAPDH siRNA in the cells was investigated by evaluating the expression levels of the enzyme. The results suggest that both A2036-9R and 5R-A2036-5R peptides may enable the delivery of siRNA to B cells. Even though we observed a relative modest silencing of GAPDH, with respect to classical transfection procedure, this method should have the great advantage of being based on the specific ligand-receptor interaction delivery of the siRNA [3]. In this setting, the improvement of this strategy is expected to provide a safe and non-invasive approach for the delivery of therapeutic molecules.

The intestinal tract is the largest reservoir of microbes in the human body. The intestinal microbiota is thought to be able to modulate alterations of the gut induced by enteropathogens, thereby maintaining homeostasis. *Listeria monocytogenes* is the agent of listeriosis, an infection transmitted to humans upon ingestion of contaminated food. Crossing of the intestinal barrier is a critical step of the infection before dissemination into deeper organs. Upon infection, the setting up of a contentious dialogue between the bacterium and its host translates into a drastic remodelling of both prokaryotic and eukaryotic gene expression programmes.

Here, we have investigated the role of the intestinal microbiota in the post-transcriptional regulation of the host transcriptome during infection [1]. We highlight a complex interplay between the host cell, the bacterial invader and the microbiota on the regulation of both host genes and microRNAs during intestinal response to listeriosis. We provide a regulatory network defined by the host microRNAs and their target genes during infection, and show that the microbiota plays an important role in modulating microRNA-based regulations. The influence of the microbiota on host gene expression correlates with its property to dampen the infectious process. Our work provides an unprecedented insight into the impact of the intestinal microbiota on host transcriptional reprogramming during infection by a human pathogen.

The role of miRNAs in zebrafish cardiac regeneration

Z. Kontarakis[1,2], D. Stainier[1,2]

[1]*Developmental Genetics, Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany,* [2]*Biochemistry, University of California San Francisco, San Francisco, CA, USA*

Zebrafish exhibit a tremendous ability to regenerate their organs, i.e brain, fin and heart, after injury. miRNAs are small non coding RNAs regulating genes at the post-transcriptional level and they have been implicated in virtually every cellular process so far. It is thus rational to hypothesise that miRNAs play a role during the regeneration process, where the precise regulation of wound closure, necrotic tissue removal as well as production and patterning of new cells into functional tissue is of paramount importance. Complete regeneration is missing from mammals, despite being much needed after cases like heart infarction. We used zebrafish to identify miRNAs that are differentially regulated during heart regeneration after cryoinjury. This miRNA signature could represent functional features missing or failing to be activated in mammals. One of the upregulated miRNAs at 4 days post cryoinjury is miR-15c. Using TALEN technology, we induced a genomic lesion resulting in an 11nt deletion in the mir-15c transcript, removing the seed region and thus theoretically disrupting miR-15c function. The mutant fish do not show an obvious phenotype during development and are viable. Their response to heart injury remains to be tested.

Keywords: miRNAs, regeneration, zebrafish.

Forming a cluster, miR-143 and miR-145 are colocalized at 5q32 and expressed by a bicistronic primary transcript. A well-documented tumor suppressor role has been attributed to miR-143/145 cluster, targeting HRas, KRas, c-Myc, MDM2, IGF1R and

© 2014 The Authors. FEBS Journal © 2014 FEBS

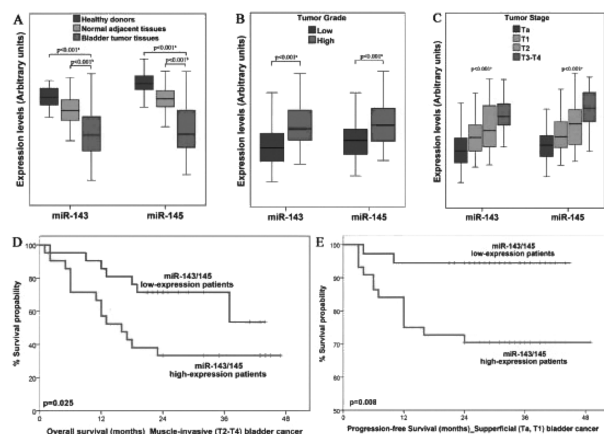

Fig. 1. Evaluation of miR-143/145 cluster clinical significance in bladder cancer. Expression analysis of miR-143/145 in bladder tumors and normal tissues (A), according to tumor grade (B) and stage (C). Kaplan-Meier analysis of the OS of the muscle-invasive (T2-T4; D) and the PFS of the superficial (Ta, T1; E) BlCa patients.

EGFR, in human malignancies, including bladder cancer (BlCa). However, its clinical significance for disease progression and the survival of the patients has been only partially investigated. Total RNA was isolated from separate specimens obtained from bladder tumors and the adjacent normal bladder wall of 140 BlCa patients, as well as from 40 healthy donors. Thereafter, total RNA was polyadenylated and reverse transcribed to cDNA, which was subjected to qPCR analysis. The expression of miR-143/145 was strongly downregulated in BlCa patients compared to healthy donors ($p < 0.001$), while reduced expression revealed in approximately the 80% of the tumors compared to their normal adjacent tissues ($p < 0.001$). An opposite profile was observed in tumor specimens, as elevated miR-143/145 levels were correlated with high-grade tumors and muscle-invasive (T2-T4) BlCa compared to low-grade or superficial (Ta, T1) tumors ($p < 0.001$). A strong unfavorable value of miR-143/145 for BlCa was thereafter revealed as its higher expression was correlated with poor patients' survival. Muscle-invasive BlCa (T2-T4) patients with higher miR-143/145 levels showed significantly shorter overall survival (OS; Kaplan-Meier analysis: $p = 0.025$) compared to those with reduced expression. Additionally, higher risk for disease progression to muscle-invasive BlCa (Cox multivariate analysis: HR= 4.756; $p = 0.016$) and significantly shorter progression-free survival (PFS; Kaplan-Meier analysis: $p = 0.008$) was observed for the superficial BlCa (Ta, T1) patients with elevated miR-143/145 levels, independently from tumor grade and stage. These data clearly highlight the deregulation of miR-143/145 expression in BlCa epithelium and their clinical significance for the prediction of superficial tumors progression to muscle-invasive stage and the survival expectancy of the patients.

Uncovering the interconnectivity between infertility-associated woman diseases

M. Kori[1], K. Y. Arga[2]
[1]Bioengineering, [2]Marmara university, Istanbul, Turkey

Background: Infertility became a major problem worldwide. Nowadays, approximately 50 million couples worldwide are affected from infertility. Infertility is defined as a disease of the reproductive system that impairs the body's ability to perform the basic function of reproduction. The goal of this study is to integrate transcriptomics datasets with biological networks to (i) identify candidate genes, proteins and metabolites that have the potential for being biomarker for infertility-associated woman diseases, and (ii) map the interconnectivities between genetic mechanisms of these diseases.

Method: Nineteen transcriptomics datasets for infertility-associated woman diseases (polycystic ovary syndrome, endometriosis, ovarian, cervical cancer and uterine leiomyomas) were analysed statistically (via RMA and LIMMA methods) to identify differentially expressed genes (DEGs) for each disease. Proteins encoded by DEGs were determined and data was integrated with reconstructed protein-protein interaction network and human Recon2 metabolic model for further analyses (via BioMet toolbox) to identify reporter genes, proteins and metabolites. Enrichment analyses were performed (via DAVID bioinformatics tool) to map the interconnectivities between diseases and biological pathways.

Results:Integrated analyses indicated that (i) samples of same disease obtained from different donors were representing variable gene expression profiles (i.e., 1–25% of the genome was differentially expressed); (ii) the inspected diseases were representing high interconnectivities at protein-protein interaction level; and (iii) several genes and proteins were representing potential for being biomarker for these infertility-associated women diseases.

Conclusion: Analysis of whole genome expression profiles provides a good opportunity for systems level investigation to characterize the interconnectivity between infertility-associated woman diseases and provides hypotheses for further *in vivo* studies to characterize novel biomarker proteins.

Keywords: Biomarker, Infertility, Transcriptomics.

Activation of NMDA receptors causes disruption of the cerebral endothelial cell-constructing tight junction barrier

R.-M. Chen[1], J.-T. Chen[2], Y.-T. Tai[2]
[1]Graduate Institute of Medical Sciences, Taipei Medical University, [2]Department of Anesthesiology, Wan Fang Hospital, Taipei, Taiwan

Background: The N-methyl-D-aspartate (NMDA) receptor is a ligand-gated calcium (Ca^{2+}) channel. Recently, the NMDA receptor (NMDAR) was implicated in blood-brain barrier (BBB) dysfunction. The present study was designed to evaluate the effects of the NMDAR on the cerebral endothelial cell (CEC)-constructed barrier and its possible signal-transducing mechanisms.
Methods: Cultured mouse CECs were used as an experimental model. We performed immunofluorescence, immunoblotting, RT-PCR assays, and an intracellular Ca^{2+} analysis to determine the existence of the NMDAR. After treatment with NMDA, the permeability extents of transendothelial electrical resistance (TEER) and FITC-dextrans were measured. And the occludin structure was immunostained. Levels of occludin, matrix metalloproteinase (MMP) 2 and 9, extracellular signal-regulated kinase (ERK) 1/2, and mitogen-activated/ERK kinase (MEK) 1 were detected and quantified.
Results: The presence of NMDAR subunits was proven at the mRNA and protein levels. Analysis of intracellular Ca^{2+} mobilization demonstrated the functionality of the NMDAR. After exposure to NMDA for 24 h, the TEER value decreased and the structure of occludin became disorganized. Investigations also revealed the occludin protein level significantly decreased. As to the mechanism, NMDA enhanced MMP2 and MMP9 levels in time-dependent manners. Meanwhile, levels of phosphorylated (p) MEK1 and pERK1/2 were augmented following NMDA treatment.
Conclusions: In this study we show that activation of the NMDAR caused dysfunction of the BBB by decreasing the occludin protein level and possibly through a MMP expression and MEK/ERK signaling pathway.
Keywords: cerebral endothelial cells, NMDA receptor, tight junction.

Anxiolytic-like effect of α-asarone from *Acorus gramineus* in a rat model using chronic corticosterone injections

B. Lee, B. Sur, I. Shim, H. Lee, D.-H. Hahm
AMSRC, Kyung Hee University, Seoul, Korea

We investigated the anxiolytic-like activity of α-asarone from *Acorus gramineus* (AAS) in an experimental rat model of anxiety induced by repeated administration of the exogenous stress hormone corticosterone (CORT). The putative anxiolytic effect of AAS was studied in behavioral tests of anxiety, such as the elevated plus maze (EPM) test and the hole-board test (HBT) in rats. For 21 consecutive days, male rats received 50, 100, or 200 mg/kg AAS (i.p.) 30 min prior to a daily injection of CORT. Dysregulation of the HPA axis in response to the repeated CORT injections was confirmed by measuring serum levels of CORT and the expression of corticotrophin-releasing factor (CRF) in the hypothalamus. Daily AAS (200 mg/kg) administration increased open-arm exploration significantly in the EPM test, and it increased the duration of head dipping activity in the HBT. It also blocked the increase in tyrosine hydroxylase (TH) expression in the locus coeruleus (LC) and decreased mRNA expression of brain-derived neurotrophic factor (BDNF) and its receptor, TrkB, in the hippocampus. These results indicated that the administration of AAS prior to high-dose exogenous CORT significantly improved anxiety-like behaviors, which are associated with modification of the central noradrenergic system and with BDNF function in rats. The current finding may improve understanding of the neurobiological mechanisms responsible for changes in emotions induced by repeated administration of high doses of CORT or by elevated levels of hormones associated with chronic stress. Thus, AAS did exhibit an anxiolytic-like effects in animal models of anxiety.

Behavioral and brain-region specific biochemical changes in streptozotocin-induced diabetes

A. G. Kokkosis[1], C. Constantinou[2], K. E. Kypreos[2], M. Margarity[1]
[1]Biology, [2]Medicine, University of Patras, Patras, Greece

Type I diabetes (T1D) is characterised by lack of insulin (Ins) secreting pancreatic β cells while type II diabetes (T2D) by reduced sensitivity of peripheral tissues to Ins. Previous work in experimental animals indicated that T1D may show an association with depression-like behavior, while T2D has been linked to dementia. The aim of the present study was to investigate the effects of streptozotocin-induced T1D on the cholinergic system and on behavioral indices including fear-anxiety, memory-learning, social dominance and depression. We also sought to determine whether Ins administration can reverse these effects in T1D adult male mice. Mice (n = 42) were divided into 3 groups (n = 14). The first 2 groups became diabetic after intraperitoneal (IP) administration of streptozotocin (50 mg/kg body weight/per day), for 5 consecutive days. After 21 days the second diabetic group was given long-acting Ins glargine (6 IU/kg) IP for 6 consecutive days. A euglycemic control animal group was also included in the study. All 3 groups underwent behavioral analysis 2 days following Ins administration in the Ins-treated mice. Fear-anxiety was assessed by using the thigmotaxis test and the elevated plus-maze test. Memory-learning was evaluated by the step-through passive avoidance test. Social dominance was assessed by the social dominance tube test. Depression-like behavior was evaluated by the forced swimming test. In addition to the behavioral tests biochemical analyses, including acetylcholine (ACh) levels, the acetylcholinesterase (AChE) activity in different brain regions (cerebral cortex, midbrain, hippocampus, striatum, diencephalon and cerebellum), plasma glucose, total cholesterol and triglycerides levels, were performed. Correlation coefficients between behavioral indices and glucose levels were also determined. The results showed that T1D engendered anxiogenesis, memory loss,

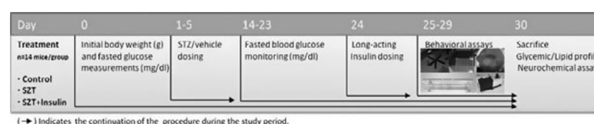

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

social defeat and depression-like behavior in mice. Spearman correlation analysis revealed that the coefficients between the particular behaviors and plasma glucose levels were linearly correlated. In T1D mice, we observed a statistically significant decrease in the ACh levels of the brain regions studied. The AChE activity in both salt-soluble and detergent-soluble fractions was significantly increased in the same brain regions. In the Ins-treated T1D mice both ACh levels and AChE activity were efficiently reversed in a brain region-dependent manner. Additional biochemical and molecular mechanisms involved in cholinergic system adaptation in diabetes are currently under investigation.

Diabetes induces changes in motor proteins distribution in the rat retina: implications for axonal transport

F. I. Baptista[1,2], M. J. Pinto[3,4], F. Elvas[1,2], T. Martins[1,2], R. D. Almeida[3], A. F. Ambrósio[1,2,3,5]
[1]*Centre of Ophthalmology and Vision Sciences, IBILI,* [2]*Pharmacology and Experimental Therapeutics, IBILI,* [3]*CNC-Center for Neuroscience and Cell Biology,* [4]*PhD Programme in Experimental Biology and Biomedicine (PDBEB), Center for Neuroscience and Cell Biology, University of Coimbra,* [5]*AIBILI, Coimbra, Portugal*

Diabetic retinopathy is a leading cause of vision loss and blindness in working-age adults. It has been considered a microvascular disease, but increasing evidence has shown that the neural components are also affected, even before the detection of vascular changes. However, the mechanisms underlying neural dysfunction are not elucidated. Impairment of axonal transport is associated with several neurodegenerative diseases and might also play a role in diabetes-associated disorders affecting nervous system. In this study, we investigated the impact of type 1 diabetes (2 and 8 weeks duration) on KIF1A, KIF5B and dynein motor proteins in the retina. Additionally, since hyperglycemia is considered the main trigger of diabetic complications, we investigated whether prolonged exposure to elevated glucose could affect the content and distribution of motor proteins in retinal cultures.

The immunoreactivity of motor proteins was evaluated by immunohistochemistry in retinal sections and by immunoblotting in total retinal extracts from streptozotocin-induced diabetic and age-matched control animals. Primary retinal cultures were exposed to high glucose (30 mM) or mannitol (osmotic control; 24.5 mM plus 5.5 mM glucose), for seven days.

Diabetes decreased the content of KIF1A at 8 weeks of diabetes as well as KIF1A immunoreactivity in the majority of retinal layers, except for the photoreceptor and outer nuclear layer (ONL). Changes in KIF5B immunoreactivity were also detected by immunohistochemistry in the retina at 8 weeks of diabetes, being increased at the photoreceptor and ONL, and decreased in the ganglion cell layer (GCL). Regarding dynein immunoreactivity there was an increase in the GCL after 8 weeks of diabetes. No changes in the immunoreactivity of motor protein were found in retinal cultures.

The alterations in motor proteins detected in the retinas of diabetic animals suggest that axonal transport may be impaired under diabetes, which might contribute to early signs of neural dysfunction in the retina of diabetic patients and animal models.

Early cranial irradiation alters epigenetics parallel to reduced hippocampal neurogenesis in adult mice

T. Koç[1], E. B. Yılmaz[2], L. Şahin[3], T. Ergenoğlu[3], N. C. Öztürk[1], H. Öztürk[1]
[1]*Anatomy,* [2]*Radiation Oncology,* [3]*Physiology, Mersin University, Mersin, Turkey*

Radiotherapy is an effective tool in the treatment of pediatric malignancies but it is associated with adverse side effects, both short and long term. One of the cardinal late onset effects is cognitive deficits. Exposure of cranial irradiation to the early brain in rodents has been shown to potentially change the hippocampal neurogenesis levels in adulthood. Here, we demonstrated that epigenetics is also altered accompanying with the reduced hippocampal neurogenesis in the adult brain of C57BL6/J mice long after the early cranial irradiation.

For the experimental design, a single dose of 8 Gray (Gy) whole cranial irradiation at postnatal day 14 (P14) (Rad^+ Group) or double doses (Rad^{++} Group) of 8 Gy both at P14 and P21 (total of 16 Gy) were administered to the pups. Additionally, a group of age and body weight matched mice were assigned as sham (anesthetic) or naive controls. Seven months after the cranial irradiation, three main groups of mice (Control, Sham and Rad) were first assigned for Open Field (OF) test to measure the locomotor activity, and afterwards for Morris Water Maze (MWM) paradigm to test the hippocampal dependent spatial learning and long term memory. No significant difference was observed between the groups in OF test. In the MWM paradigm, Rad^+ and Rad^{++} groups displayed significantly weaker cognitive abilities as compared to the controls. Lastly, a significant dose-dependent difference of irradiation was also detected.

Following MWM experiments, we employed immunohistochemical stainings (im) with phenotypic neuronal and epigenetic markers to test the ongoing neurogenesis and epigenetic events in the P230 hippocampi. We found a significant decrease of Doublecortin-im (immature neuron marker) and Neuronal Nuclei-im (mature neuron marker) in the subgranular layer of the dentate gyrus of irradiated mice as compared to the controls. In the same hippocampal regions, there was also significant reduction of DNA methylation determinants (DNA methyl-transferase (DNMT) DNMT1-im, DNMT3a-im and Methyl-CpG Binding Protein 2-im positive cells). Our overall data suggests that exposure of cranial irradiation to the young brain alters not only the neurogenesis but also the epigenetic profile in adult hippocampus which may reflect the cellular base of the weakened cognitive abilities observed in the MWM experiments. All data was analyzed via parametric tests, using SPSS statistical software (V17).

Understanding the mechanism by which ionizing radiation affects epigenetic programming will provide insight into how to develop protection against the potentially harmful risks associated with radiation exposure.

Endogenous human neuromodulators Lynx1 and Slurp1: structure, function and mechanism of action

M. A. Shulepko[1,2], A. S. Paramonov[1], Z. O. Shenkarev[1], K. S. Mineev[1], D. S. Kudryavtsev[1], I. E. Kasheverov[1], M. S. Thomsen[3], A. Arseniev[1], D. A. Dolgikh[1,2], V. I. Tsetlin[1], M. P. Kirpichnikov[1,2], E. N. Lyukmanova[1]
[1]*M.M. Shemyakin & Yu.A. Ovchinnikov Institute of Bioorganic Chemistry,* [2]*Moscow State University, Moscow, Russian Federation,* [3]*Copenhagen University Hospital, Copenhagen, Denmark*

Discovery of endogenous neuromodulators Lynx and SLURP having homology both to Ly6 proteins and three-finger snake α-neurotoxins expressed in the various human tissues provoked much interest to their role in the organism. In contrast to α-neurotoxins, highly specific inhibitors of nicotinic acetylcholine receptors (nAChRs), Lynx and SLURP proteins exhibit their activity only in the presence of a receptor agonist and characterized as allosteric modulators. Lynx proteins are membrane-tethered by a GPI anchor and co-localized near nAChRs in the brain, while SLURPs are secreted proteins and probably play the role of autocrine/paracrine hormones in different non-neuronal tissues.

We developed the effective bacterial expression systems, which allowed us to produce the set of mutant and isotope labeled variants of water-soluble domain of human Lynx1 (ws-Lynx1) and human SLURP1. For the first time ws-Lynx1 and SLURP1 activity against the number of pharmacologically relevant receptors was characterized, and new targets were revealed. We characterized the distribution of Lynx1 at the organ, cellular, and sub-cellular level, and for the first time detected Lynx1 in the cerebrospinal fluid. Spatial structure and conformational plasticity of neuromodulators were studied by NMR-spectroscopy. Contrary to α-neurotoxins having rigid structures, NMR analysis revealed high mobility of the loop regions of ws-Lynx1 and SLURP1. Site-directed mutagenesis identified amino acid residues of ws-Lynx1 important for interaction with muscle-type and α7 nAChR. Computer modeling, based on NMR structures of ws-Lynx1 and SLURP1 and the model of extracellular domain of α7 nAChR, together with mutagenesis data, revealed a possible modes of interaction between neuromodulators and receptor. It was shown that in spite of the high structural homology, Lynx1, SLUPR1, and α-neurotoxins interact with the receptor in different manners and their binding sites overlapped only partially.

ETS proteins Elk-1 and Pea3 and their transcriptional targets in neuronal survival and differentiation

I. Aksan Kurnaz, B. Kandemir, E. Sahin
Genetics and Bioengineering, Yeditepe University, Istanbul, Turkey

ETS proteins are transcription factors that are targeted by the MAPK pathway, and are associated with a wide range of processes including proliferation, survival, inflammation, and differentiation. Although they are known to bind a typical GGAA/T motif, the domain structure, interaction partners, and DNA recognition motirs of the subfamilies of ETS proteins can vary immensely, resulting in a wide range of responses in different tissues. In neurons, Elk-1, a member of the Ternary Complex Factor (TCF) subfamily, was reported in axonal and dendritic structures and to correlate with survival, with *survival of motor neuron (SMN)* as a novel target promoter. On the other hand Pea3 subfamily of ETS proteins, namely Pea3, Erm and ER81, was reported to function in establishing functional motor neuron circuits, although primary transcriptional targets were not thoroughly analyzed. In this study, we have carried out microarray analysis in neuronal model cells transfected with Elk-1, Pea3, Erm and Er81 in an effort to distinguish transcriptional targets of these proteins. Interestingly, quite a large percentage of the genes were found to be repressed in Pea3-transfected cells, including Elk-1; in the case of Pea3 subfamily main groups of genes found to be upregulated were found to be either immune system-related or neuron-related genes, in particular cytoskeletal dynamics-related genes, whereas Elk-1 was found to regulate channel or transport protein coding genes, hypoxia-related genes, putative Pea3 targets, as well as genes related to apoptosis and proliferation. The putative neuronal targets of Elk-1 and Pea3 proteins, as well as potential cross-regulatory loop between them, will be discussed in relation to neuronal survival and differentiation.

Keywords: ETS, Neuronal cell death, Neuronal differentiation.

Evaluation of three novel hydroxypicolinaldehyde oximes as efficient uncharged reactivators of VX-inhibited human acetylcholinesterase

Z. Kovarik[1], M. Katalinic[1], L. Jean[2], P.-Y. Renard[2], J. Renou[2], C. Gomez[2]
[1]*Institute for Medical Research and Occupational Health, Zagreb, Croatia,* [2]*Normandie Univ, COBRA, UMR 6014 & FR 3038, Univ Rouen, INSA Rouen, Mont-Saint-Aignan Cedex, France*

Organophosphates (OP) inhibit acetylcholinesterase (AChE, EC 3.1.1.7), both in peripheral tissues and the central nervous system, causing adverse and sometimes fatal effects due to the accumulation of the neurotransmitter acetylcholine. The currently used therapy, which focuses on the reactivation of inhibited AChE, is limited to peripheral tissues because the commonly used quaternary pyridinium oxime reactivators do not cross the blood brain barrier at therapeutically relevant levels. Three new uncharged oximes **1** [E)-3-hydroxy-6-(4-morpholinobutyl)picolinaldehyde oxime], **2** [(E)-6-(5-(diethylamino)pentyl)-3-hydroxypicolinaldehyde oxime], and **3**[(Z)-3-hydroxy-6-(5-(piperidin-1-yl) pentyl)picolinaldehyde oxime] have been synthesized. These novel compounds exhibited *in vitro* reactivation potencies toward VX-phosphorylated human acetylcholinesterase equal or superior to those of pyridinium oximes (HI-6, 2PAM, etc.), which are currently used as antidotes against nerve agents. The evaluation of individual reactivation constants revealed that the potent reactivation exhibited by oxime **1** referred to its efficient interaction with the phosphonate group of the VX-conjugated AChE through forming a transition state reflected in an up to 2-times faster k_{+2} than HI-6. Interestingly, the binding affinity of the other two oximes was very similar to that of HI-6, meaning that the structural requirements of novel compounds to react with phosphorylated AChE were fulfilled. In conclusion, we obtained potential antidotes for OP-poisoning that could act centrally, reactivating brain OP-phosphorylated AChE.

Keywords: acetylcholinesterase, enzyme kinetics, reactivation.

Excitatory and depressor synaptic processes in neurons of spinal cord and substantia nigra in conditions of Parkinson's disease combined with bilateral ovariectomy and protection by synestrol

H. Stepanyan[1], M. Pogosyan[1,2], N. Hovsepyan[2], A. Minasyan[3], J. Sarkissyan[1]
[1]*CNS Function Compensation,* [2]*L.A. Orbeli Institute of Physiology,* [3]*Yerevan State Medical University, Yerevan, Armenia*

In intact female Albino rats, subjected to bilateral ovaryectomy (OVX) in conjoining with Parkinson's disease (PD) and with protection by Sinestrole (S) after 4-5 weeks the activity registration of spinal cord (SC) L4-L5 segments‘ motoneurons (MNs) to high frequency stimulation (HFS) of hind limbs extensor (P), flexor (G) nerves and subnstantia nigra (SN), as well as SN to HFS of Caudate Putamen (CPu) by means of on-line selection and software mathematical analysis based on depressor and excitatory tetanic and post tetanic (unilateral and mixed) effects revealed the following: In norm noted the prevalence of excitatory tetanic effects, except of those in SN neurons to HFS of CPu, in which along with powerful depressor reaction took place reasonably expressed excitatory, not lower than the above-mentioned. In conditions of OVX combined with PD was found comparatively worse expression of depressor effects in all examined structures, except the SC MNs to HFS of G, while such excitatory effects were increased, especially to HFS of SN and also except SC MNs to HFS of G. However, only in conditions of OVX, compared with norm, in SC MNs to HFS of P and G depression was declined, especially in poststimulus depressor succession and increase of excitability to HFS of P, particularly in the same mixed condition; to HFS of SN depression increased only in unilateral succession, but twice elevated the excitation in such excitatory reactions and finally in SN neurons to HFS of CPu a depression declined or was equal the norm, was not excitatory sequence and slightly increased tetanic potentiation in a mixed sequence. In conditions of S protection on the model of PD with OVX in SC MNs to HFS of P, G and SN it is obvious the significant increase of tetanic depression, except it abrupt decrease in SN neurons. Also fell sharply the tetanic excitation in SC MNs and SN neurons, but with increase the background activity. Thus tetanic excitation in conditions of OVX with PD has experienced an increase and with S – decrease, except SN neurons.

Microarray identification of potential novel targets of Ets-domain transcription factor Pea3

B. Kandemir[1], Y. Kayacan[1], I. M. Durasi[2], B. Bakır Güngör[3], U. Sezerman[2], I. Aksan Kurnaz[1]
[1]*Genetics and Bioengineering, Yeditepe University,* [2]*Natural Sciences, Sabanci University, Istanbul,* [3]*Computer Engineering, Abdullah Gül University, Kayseri, Turkey*

PEA3 subfamily of ETS domain transcription factors act as nuclear targets of signal-transduction pathways, regulating variety of responses including cell proliferation, differentiation, development and apoptosis. Pea3 subfamily, including Pea3, Erm and Er81, has been reported to regulate functional motor neuron circuitry, as well as identify specific motor neuron pools. Pea3's transactivation capacity is known to be regulated by MAPK pathways in response to stimuli, and a number of target promoters involved in breast cancer progression and metastasis have been identified. However, the specific downstream targets of Pea3 in neuronal circuitry are still not clear. In this study, we have used gene expression microarray analysis to determine potential novel target genes in SH-SY5Y model system. To that end, cells were transfected with either Pea3VP16 (constituvely active) expression vector or pCDNA3 (empty vector) and microarray analysis was performed. Microarray data were analyzed by bioinformatics tools and database such as KEGG pathway analysis program and DAVID. Subsequently, promoters of nervous system-related genes were analyzed for presence of a consensus Pea3-binding ets motif. Furthermore, mRNA expression levels of a selected subset of genes were confirmed by using Real-time PCR or RT-PCR.

Keywords: Pea3 transcription factor, Microarray, Identification.

Parasympathetic ganglia derive from Schwann Cell Precursors

C. Picard, I. Espinosa, E. Outin, J.-F. Brunet
Institut de Biologie de l'ENS (IBENS), Ecole Normale Superieure (ENS), Paris, France

Neural crest cells migrate extensively and give rise to most of the peripheral nervous system, including the three types of autonomic ganglia: sympathetic, parasympathetic and enteric. The migration pathways of sympathetic and enteric precursors towards the dorsal aorta or in the walls of the gut, repectively, are well charted, but surprisingly little is known about the way in which parasympathetic ganglia form, at many locations, close to their target organs.

Here, we show that parasympathetic precursors first colonize cranial nerves, where they co-express the pan-visceral transcriptional determinant Phox2b and markers of Schwann Cell Precursors (SCPs). Some of these cells down-regulate Phox2b and give rise to Schwann cells, while others maintain Phox2b expression and go on to form parasympathetic ganglia. Thus, cranial SCPs have a dual neuronal/glial fate and are the source of parasympathetic neurons during normal development. Unexpectedly, cells with a history of Phox2b expression are also found associated with limb nerves, and are even capable of forming at least one ganglion, of unknown function, in the upper limb, showing that the dual Schwann cell/neuron fate is not unique to cranial nerves.

These data imply that the numerous locations of parasympathetic ganglia throughout the head and trunk are specified by the pattern of cranial nerve outgrowths —which carry preganglionic parasympathetic fibers— a parsimonious way of hooking up synaptic partners in development.

Keywords: Neural Crest Cells, Parasympathetic ganglia, Schwann Cells.

MON-087
Profiling imidazolium and benzimidazolium oximes as antidotes in organophosphorus compound poisoning

M. Katalinic[1], N. Macek Hrvat[1], A. Milicevic[1], D. Jelic[2], I. Primozic[3], S. Tomic[3], Z. Kovarik[1]
[1]*Institute for Medical Research and Occupational Health,* [2]*Fidelta Ltd,* [3]*Department of Chemistry, Faculty of Science, University of Zagreb, Zagreb, Croatia*

Organophosphorus compounds (OP) used as pesticides account for more than 3 000 000 accidental or deliberate cases of poisoning registered per year worldwide. Furthermore, OPs developed as nerve agents (soman, sarin, tabun, VX) still present a threat in terrorist attacks and conflicts, such as in the recent case of Syria. The main targets of OP compounds are cholines-

© 2014 The Authors. FEBS Journal © 2014 FEBS

terases (ChEs) of the central and peripheral nervous system: acetylcholinesterase (AChE, EC 3.1.1.7) and butyrylcholinesterase (BChE, EC 3.1.1.8). Upon exposure, OP compounds covalently bind to the specific active site serine after which physiological activity of these enzymes is permanently lost. The antidotal property of the oximes is attributed to their ability to reactivate ChEs inhibited by OPs and thus restore vital functions and reduce the severe consequences for an organism. In the search for more efficient oximes, a better understanding of their interactions with ChEs presents an important step considering the strict criteria set for their *in vivo* applications. For this purpose, we investigated a set of imidazolium and benzimidazolium oximes, presenting a structural shift from the oximes currently used in medical practice. A comprehensive analysis was performed defining all relevant kinetic parameters of reactivation as well as interactions with uninhibited ChEs. Several oximes were pointed out as leads in the development of new antidotes especially in the case of OP-inhibited BChE reactivation. Experimental data were correlated with computational studies including QSAR analysis. We were able to thoroughly describe the characteristic of novel oximes that contribute to favourable interactions with ChEs and should be the basis for further structure refinement. Furthermore, novel oximes were characterised for their cytotoxic profiles on a set of cell lines in order to elucidate all unwanted effects *in vivo* before investigating their further development as potential pharmaceuticals.

Keywords: acetylcholinesterase, butyrylcholinesterase, reactivation.

Promising serum protein marker for early detection of Alzheimer's disease

R. Kumar, A. Gupta, V. Sahu, A. P. Singh, S. Kumar, K. Singh, A. B. Dey, S. Dey
Biophysics, All India Institute of Medical Sciences, New Delhi, India

Sirtuin (SIRT) pathway has a crucial role in Alzheimer's disease (AD). The present study evaluated the alterations in serum sirtuin1 (SIRT1) concentration in healthy individuals (young and old) and patients with AD and mild cognitive impairment (MCI). Blood samples were collected from 40 AD and 9 MCI patients as cases and 22 young healthy adults and 22 healthy elderly individuals as controls. Serum SIRT1 was estimated by Surface Plasmon Resonance (SPR), Western Blot and Enzyme Linked Immunosorbent Assay (ELISA). A significant ($p < 0.0001$) decline in SIRT1 concentration was observed in patients with AD (2.27 ± 0.46 ng/μl) and MCI (3.64 ± 0.15 ng/μl) compared to healthy elderly individuals (4.82 ± 0.4 ng/μl). The serum SIRT1 concentration in healthy elderly was also significantly lower ($p < 0.0001$) compared to young healthy controls (8.16 ± 0.87 ng/μl). This study, first of its kind, has demonstrated, decline in serum concentration of SIRT1 in healthy individuals as they age. In patients with AD and MCI the decline was even more pronounced, which provides an opportunity to develop this protein as a predictive marker of AD in early stages with suitable cut off values.

Keywords: Alzheimer, Mild cognitive Impairment, Sirtuin.

A study on the effects of chaperone fusions on protein folding and activity using firefly luciferase fusions with DnaK and GroEL

E. A. Kalfopoulou, A. T. Chatsisvili, C. H. Panagiotidis, C. A. Panagiotidis
School of Pharmacy, Aristotle University of Thessaloniki, Thessaloniki, Greece

The quantities of proteins required for biotechnological or pharmaceutical applications are often so vast that they cannot be supplied from their natural reservoirs. Modern biotechnology has provided solutions by developing systems for protein overproduction in many organisms, especially the bacterium *Escherichia coli*. However, the potential of *E. coli* as a protein «cell factory» is limited by the inability of many overproduced proteins to fold properly and their subsequent accumulation in the bacterial inclusion bodies. Taking advantage of the normal roles of the major *E. coli* molecular chaperones, DnaK and GroEL, in protein folding, we constructed plasmid vectors that express N-terminal fusions with DnaK or GroEL and showed that such fusions can overcome the solubility problem. To study whether these soluble chaperone fusions have acquired proper conformation and are biologically active, we fused the firefly luciferase (LUC) gene to DnaK or GroEL. LUC overexpression in bacteria, at both 28°C and 37°C, yields little soluble protein, while the vast majority accumulates in inclusion bodies. In contrast, the DnaK-LUC fusion accumulates mainly in the soluble fraction (especially at 28°C) and its solubility increases when co-expressed with DnaJ and GrpE, the two DnaK co-chaperones. GroEL-LUC displays only intermediate solubility. Following IMAC purification of the recombinant LUC and its fused forms under denaturing conditions, we measured the ability of these proteins to remain in the soluble fraction after removal of the denaturant. Following dialysis, the chaperone-luciferase fusions remained predominantly soluble, whereas the majority of the unfused LUC precipitated. *In vitro* protein folding experiments, measuring the regain of luciferase activity after chemical denaturation, showed that DnaK-LUC fusions refold far more efficiently than unfused LUC, even in the absence of ATP. ATP addition to the refolding reactions dramatically improved both the rate and degree of refolding, which was further increased in the presence of DnaJ and GrpE. To verify the specificity of these results, we tested a fusion of LUC to DnaK25, a DnaK mutant with ATP hydrolysis and substrate binding defects and found that its protein folding ability was compromised. These results shed light on the molecular mechanisms involved in the protein folding properties of chaperone fusions. More importantly, they indicate that chaperone fusions can refold with high efficiency *in vitro*, following chemical denaturation and removal of the denaturant. The latter property has significant implications in the production of biotechnologically relevant proteins.

Crystal structures of the γ subunit of the heterotrimeric translation initiation factor 2 of archaeal aIF2 in GTP-bound and GDP-bound forms

E. Dubiez, A. Aleksandrov, C. Lazennec-Shurdevin, Y. Mechulam, E. Schmitt
Laboratoire de Biochimie, Unité mixte de Recherche 7654, Ecole Polytechnique, Centre National de la Recherche Scientifique (CNRS), F-91128 Palaiseau cedex, France

In eukaryotes and archaea, translation initiation begins with the assembly of the ternary complex (TC), consisting of initiator methionyl-tRNA (Met-tRNAi) anchored to the GTP-bound form of the heterotrimeric initiation factor 2 (e/aIF2). GTP hydrolysis and Pi release from e/aIF2 control the correct selection by the initiation ribosomal complex of the initiator tRNA and of the start codon on the mRNA. In eukaryotes, the GTPase activating protein (GAP), eIF5, participates in the control of this checking step. However, archaea have no equivalent of eIF5. Therefore, GTP hydrolysis on aIF2 is likely to occur without GAP assistance.

The catalytic mechanism of the GTP hydrolysis on e/aIF2 remains unknown. In our study, we determined the crystal structures of the wild-type aIF2 γ subunit from Sulfolobus solfataricus bound to GDPNP, and GDP at high resolution (1.4 Å and 2.1 Å, respectively). The structures revealed conformational changes of the protein upon nucleotide binding, in particular in the P-loop and in the switch I and switch II regions. These regions carry catalytically important and conserved residues. In particular, a histidine residue in the switch II region and an aspartate in the GKT loop are conserved in e/aIF2 sequences but also in the sequence of elongation factors. These residues were modified by site-directed mutagenesis. The crystal structures of the mutant proteins bound to GTP were determined. The data give some clues about the mechanism of GTP-hydrolysis by aIF2. New hypotheses are being tested using molecular dynamics simulations.

Effect of Alu RNP and scAlu RNP on transaltion initiation in vitro

A. Ivanov, T. Mikhailova, D. Susorov, E. Sokolova, E. Z. Alkalaeva
Group of Translation Regulation, Enhelgardt Molecular Biology Institute, Moscow, Russian Federation

Human mobile genetic elements present in genome predominantly like Alu repeats.

There was found near 1.3 million ones that form 10% of human genome. Most of Alu repeats are transcribed by RNA pol III generating Alu RNA. Alu RNA tends to degrade to scAlu RNA (small cellular Alu RNA). These ncRNAs specifically bind protein heterodimer SRP 9/14. Alu RNP complexes inhibit translation initiation at uncapped mRNA without 5'UTR in cell-free translation systems. We carried out action of Alu/scAlu RNP to understand mechanism of the inhibition. For this purpose we used cell-free system and reconstituted eukaryotic translation system (RETS). We estimated effect of Alu/scAlu RNP on mRNA with different 5'UTRs in rabbit reticulocyte lysate. The influence of Alu/scAlu

© 2014 The Authors. FEBS Journal © 2014 FEBS

RNP and RNA on initiation complex assembly was detected by toe-print analysis in RETS. We have found that scAlu RNP inhibits mRNA containing IRES's translation in RRL. However Alu/scAlu RNP had no effect on cap-dependent initiation (on mRNA with β-actin and BRCA1 leaders). But uncapped β-actin leader was inhibited by scAlu RNP. Also we have found inhibition of 80S assembling on CrPV leader by Alu RNP in REST but scAlu RNP had no effect. Ribosome assembling on mRNA containing uncapped

β-globin UTR was affected by both Alu and scAlu RNP. We propose that scAlu RNP inhibits any cap-independent loading of mRNA in 40S ribosomal subunit. eIF6-deficient mice exhibit thrombocytopenia due to a defect in polyploidization and maturation of megakaryocytes

S. Ricciardi[1], A. Miluzio[1], L. Costa[1], M. Bonomo[2], R. Aiolfi[3], D. Brina[1], L. Guidotti[3], F. Falciani[2], S. Biffo[1]

eIF6 is a translation factor acting downstream of insulin/PMA stimulation. Herein, we investigated the consequences of *eIF6* deletion in mice on platelets biogenesis and hemostatis. We show that eIF6 deficiency leads to thrombocytopenia, resulting in severely impaired hemostasis, as indicated by prolonged bleeding time upon injury. The reduction in platelets count is the consequence of a defect in platelets production owing to a defect in bone marrow (BM) megakaryopoieis. As a matter of fact, BM eIF6$^{+/-}$-derived megakaryocytes (MKs) exhibit a decrease in mean ploidy level and a delay in the expression of terminal MK differentiation markers, as for instance the glycoprotein Ib (GPIb). It is well accepted that MKs cell size is related to the degree of polyploidization. Interestingly, both cycling (2N/4N) and polyploid (16N) eIF6$^{+/-}$-derived MKs are reduced in size, with a size reduction slightly more pronounced in mature polyploid MKs than in immature ones. Consistent with a failure in terminal MKs differentiation and maturation, analysis of platelet production *in vitro* reveals that fraction of proplatelet forming megakaryocytes is significantly lower in cultured eIF6$^{+/-}$ MKs than in WT cells. This is the first report of a translation factor regulating platelet development. Analysis of differentially regulated genes between eIF6$^{+/+}$ and eIF6$^{+/-}$ MKs will shed more light on the mechanism by which eIF6 regulates megakaryopoiesis.

[1]Bio Assessment Center, KRIBB, Cheongwon-gun, Korea, [2]Rutgers University, [3]Robert Wood Johnson Medical School, NJ, USA

More 26,000 protein coding sequences (CCDS) have been identified in the human genome. Here, we analyzed the codon usage in all these human CCDS and found that there are preferential usage of minor codons for Ala, Pro and Ser in the initial part of CCDS. The usage of GCG out of four Ala codons, CCG out of four Pro codons, UCG out of six Ser codons and ACG out of four Thr codons are significantly higher in the initial 50 codons of CCDS. These codons are most rarely used among their synonymous codons. The gene expression of luciferase-chimeric protein containing five consecutive GCG (rarest used Ala codon) in the initial part of the gene is significantly higher than that containing five consecutive GCC (most frequently used Ala codon). Our results show that the rare codon slow translation and decrease error rate lead to increased translational efficiency reason of because the rare codon may have similar pattern of Kozak sequence, having a strong affinity for ribosome.

Function of the Sec61p Loop 7 in ER protein tranlocation

F. Pereira, K. Römisch
Microbiology, Faculty of Natural Sciences and Technology VIII, Saarland University, Saarbrücken, Germany

The Sec61 complex is a heterotrimeric complex responsible for the translocation of secretory proteins through the endoplasmic reticulum (ER) membrane and also likely for the retrolansloca-tion of misfolded proteins subject to ER-Associated Degradation (ERAD). Sec61p, the pore forming subunit of the channel, is a transmembrane protein with 10 transmembrane domains and a single large luminal loop (L7). This loop is thought to be important for the opening of the channel and due to is position and exposure, a potential point of contact between chaperones and ERAD substrates in the ER lumen and the channel. We are working with a Sec61 mutant lacking L7, which has profound post-translational protein import and soluble protein ERAD defects but no cotranslational protein import defect. Our main objective is to identify possible L7 interacting proteins through chemical crosslinking using isolated ER membranes. Crosslinking with a homobifuctional crosslinker (NH_2-reactive) showed that the absence of the L7 impairs the interaction of Sec61p with the other two subunits of the complex (Sbh1p and Sss1p). In preliminary tests with a heterobifuctional crosslinker (NH_2 and non-specific reactive) we identified several potential interactions with Sec61p that are strongly impaired in the sec61ΔL7 mutant. We are currently trying to identify the unknown interacting proteins by analysis of the complexes with a combination of immunoprecipitation, immunoblotting and mass spectrometry. Our ultimate

© 2014 The Authors. FEBS Journal © 2014 FEBS

aim is to ascertain the role of these interactions in the bidirectional transport through the Sec61 channel.

Function of the Sec61p N-terminus in protein translocation across the ER membrane

F. Elia, K. Römisch
Microbiology, Faculty of Natural Sciences and Technology VIII, Saarland University, Saarbrücken, Germany

Sec61p is a highly conserved polytopic membrane protein characterized by a compact bundle of 10 transmembrane helices spanning the ER membrane. The two halves of the protein form an aqueous pore in the ER membrane and a lateral gate facing the lipid bilayer. Sec61p is the channel-forming subunit of the heterotrimeric Sec61 complex that mediates co-translational import; two single-spanning membrane proteins, Sss1p and Sbh1p, stabilize the channel and mediate interactions with other proteins. In yeast, proteins can also be post-translationally translocated into the ER by the heptameric Sec complex, composed of the Sec61 complex and the heterotetrameric Sec63 complex. The Sec61 channel is also a candidate for the dislocation channel for ERAD substrates. The N-terminus of Sec61p is oriented towards the cytosol and residues 3–21 have the potential to form an amphipathic α-helix; moreover, Sec61p is N-terminally acetylated and the N-terminal acetylation of Sec61p was shown to be important for its function at high temperature (Soromani *et al.*, 2012). In order to gain insight into the function of the N-terminus of Sec61p, we generated two *sec61* variants: one carrying a deletion of the N-terminal residues 4–22, *sec61ΔH1*, and one lacking both the N-terminal acetylation site and the N-terminal residues 4–22, *sec61ΔN21*. Yeast expressing *sec61ΔH1* and *sec61ΔN21* were viable, but their generation time increased approximately 4-fold in YPD and they were tunicamycin-hypersensitive at 24°C. We found that ppαF, a soluble post-translational import substrate, strongly accumulated in the cytosol of *sec61ΔH1* and *sec61ΔN21* cells. In addition, both mutants were defective in ERAD of CPY*, an established soluble ERAD substrate. We are currently testing the *sec61ΔH1* and *sec61ΔN21* mutants for co-translational import and transmembrane protein ERAD defects.

Functional and structural studies of the bacterial toxin ldrD

S. A. Pulido[1], H. M. Rückert[1], C. Göbl[1], F. Falsone[2], H. Meyer[1], K. Zangger[1]
[1]*Chemistry,* [2]*Institute of Pharmaceutical Sciences, Karl Franzens University, Graz, Austria*

Several Toxin/Anti-Toxin (TA) systems have been described in different prokaryotic species including *Escherichia coli*. Kawano and coworkers described in 2002 a genetic element in *E. coli* which acts as a TA system. They called this element LDR (for Long Direct Repeats) [1]. Four repetitive sequences are part of this element. Three of those, *ldrA*, *ldrB*, *ldrC* are clustered in the same locus and present high homology whereas *ldrD* is located in a different locus and presents reduced homology with the other LDR members. *LdrD* codes for two open reading frames of 35 and 28 codons. *LdrD*-35 is a 35 aminoacid peptide which causes growth inhibition and changes in the cell physiology. On the other hand, *ldrD*-28 codes for a complementary mRNA which counteracts the toxic effects of the *ldrD*-35 in a post-transcriptional mechanism [1]. Until now the mode how *ldrD*-35 exerts its toxic effect is unknown; besides, there is no evidence of the expression of the full length *ldrD* peptide although its mRNA is very stable and constitutively expressed under experimental conditions. This information leads to the hypothesis that the events how *ldrD* exerts toxicity to the cell reside during the translation process and might respond to environmental stimulus.

We therefore decided to study the posttranscriptional events coupled to the expression of the *ldrd*-35 peptide in order to understand the mechanism of action in the cell and to elucidate why the peptide is not expressed, we also performed structural studies over the synthetic peptide to gain further hints about the possible targets of the expressed peptide which could lead to the toxic effects exerted by this gene. In this work, by applying cross linking techniques coupled to MS and fluorescence anisotropy studies, we found that the *ldrD* peptide interacts with several ribosomal proteins including the protein L4 in the ribosomal tunnel; we therefore explored the primary structural motifs which could mediate such interactions by mutational studies. The NMR structure of the peptide and CD spectroscopy studies in Tetrafluorethanol (TFE) showed a high helical propensity in the peptide which is a common feature between the so called stalling peptides [2]. Mapping the results of the mutational studies over the NMR structure supports the idea that the secondary structure formed by this peptide is mainly responsible for its activity. We present here the first functional/structural study of *ldrD* and present evidence for proposing *ldrD* as a new ribosome stalling peptide.

HCV IRES involves 18S rRNA in initiation of translation of the viral RNA on the 40S ribosome

A. Malygin[1,2], O. Kossinova[2], I. Shatsky[3], G. Karpova[1,2]
[1]*Novosibirsk State University,* [2]*Institute of Chemical Biology and Fundamental Medicine, Siberian Branch of the Russian Academy of Sciences, Novosibirsk,* [3]*Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University, Moscow, Russian Federation*

Initiation of translation of genomic RNA of hepatitis C virus (HCV) is provided by a highly structured fragment in its 5'-untranslated region, the so-called Internal Ribosome Entry Site (IRES), which upon binding to the 40S ribosomal subunit stimulates formation of the 48S initiator complex without assistance of the AUG codon recognition initiation factors. It was generally accepted that this binding is realized through the interaction of the IRES with ribosomal proteins. Using chemical probing, we have found that the HCV IRES bound to the 40S ribosomal subunit protects the backbone and bases of the triplet CCC in the 18S rRNA expansion segment 7 (ES7) apical loop from attack by chemical probes, indicating complementary base-pairing of this loop with the IRES subdomain IIId apical loop. Furthermore, we have shown that the universally conserved nucleotide G1639 displays enhanced accessibility to hydroxyl radicals when the 40S subunits are complexed with the IRES, the IRES domain II and initiator AUG are together necessary for this enhancement. We proposed that contacts of the HCV IRES with the 18S rRNA ES7 stabilize viral RNA binding on the 40S ribosome. These contacts presumably provide interplay between IRES domain II and the AUG codon close to ribosomal protein S5, which causes a rearrangement of 18S rRNA structure in the vicinity of G1639. As a result, G1639 becomes exposed and the corresponding site of the 40S subunit implicated in tRNA discrimination can select Met-$tRNA_i^{Met}$. Thus, our data demonstrate at nucleotide resolution

Host fitness effects of aminoglycoside resistance 16S rRNA G1405 and A1408 methyltransferases from clinical pathogens and natural antibiotic producers

D. Viducic, S. Obranic, M. Matovina, F. Babic, G. Maravic Vlahovicek
Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

16S rRNA modification by the G1405 and A1408 methyltransferases (MTases) is a protection mechanism in *Actinomycetes* that naturally produce various aminoglycosides, which prevents newly synthesized antibiotic to bind to the ribosome. Unfortunately, these enzymes are found in a growing number of clinical pathogens where they cause a high-level resistance and pose an imminent threat to the successful use of aminoglycoside antibiotics. G1405 and A1408 make part of evolutionary conserved decoding site in the small ribosomal subunit, which is heavily modified by other housekeeping MTases. We and others have found that G1405 and A1408 MTases interfere with housekeeping MTases that act on the neighbouring nucleotides. The effect on the *E. coli* fitness cost has been examined only for three enzymes found in clinical strains in two independent studies based on different experimental systems and results were divergent.

We extended the fitness cost study to 8 enzymes found in both clinical strains and antibiotic producers. We examined how constitutively expressed MTases affect the growth of *E. coli* by measuring the generation time in exponential phase as well as growth rate in growth competition experiments with the parental strain. We tested the translation accuracy by measuring the CUG initiation, UGA read through and −1 frameshifting in β-galactosidase reporter assay. The complete analysis was extended to the *E. coli* strain with inactivated gene for the housekeeping MTase RsmF, whose action was found to be impaired by aminoglycoside resistance enzymes in previous studies.

Our results show that all aminoglycoside enzymes show negative effect on the growth rate of the host in growth competition experiments, but there is a notable difference between the enzymes from the clinical strains *vs.* the ones from the producers. While bacteria expressing MTases from clinical strains completely disappear from the mixed culture after 5–6 days of growth, bacteria expressing enzymes from antibiotic producers still make 20% of the mixed culture even after 10 days. On the other hand, we observed that translation accuracy results vary between the strains expressing different aminoglycoside resistance MTases and depending on the presence of the housekeeping MTase. This suggests that even though the enzymes belong to the same family and have a very similar crystal structure, their binding to the ribosome and their catalytic mechanisms may show subtle differences responsible for the versatile fitness cost effects. It is therefore of great importance to further analyse these differences and consider them for the successful design of new drugs that would overcome aminoglycoside resistance.

How many initiator tRNA genes does *E. coli* need?

L. Samhita[1], U. Varshney[1], V. Nanjundiah[2]
[1]*Microbiology and Cell Biology*, [2]*Molecular Reproduction Development and Genetics, Indian Institute of Science, Bangalore, India*

Multiple copies of a gene require enhanced investment on the part of the cell, and as such, call for an explanation. The observation that *Escherichia coli* has four copies of initiator tRNA ($tRNA_i$) genes, encoding a special tRNA ($tRNA^{fMet}$) required to start protein synthesis, is puzzling particularly because the cell appears to be unaffected by the removal of one copy. However, the fitness of an organism has both absolute and relative connotations. Reasoning thus, we carried out growth competition experiments between *E. coli* strains that differ in the number of $tRNA_i$ genes that they contain. This has enabled us to uncover an unexpected link between the number of $tRNA_i$ genes and protein synthesis, nutritional status and fitness. Wild-type strains with the canonical four $tRNA_i$ genes are favoured in nutrient rich environments and those carrying fewer are favoured in nutrient poor environments. Auxotrophs behave as if they have a nutritionally poor 'internal environment'. A heuristic model that links $tRNA_i$ gene copy number, genetic stress and the growth rate accounts for the findings. Our observations provide strong evidence that natural selection can work through seemingly minor quantitative variations in gene copy number and thereby impact organismal fitness.

Identification and structural studies of human DNA topoisomerases cellular complexes targeted by cancer drugs

C. Bedez[1], C. Batisse[1], J.-F. Ménetret[1], M. Recher[2], A. Wagner[2], V. Lamour[1]
[1]*Integrated Structural Biology, IGBMC*, [2]*Faculté de Pharmacie de Strasbourg, Illkirch, France*

Type 2 DNA topoisomerases (Top2) are essential proteins that regulate DNA topology during cell division, replication, transcription and chromosome replication. The human Top2 is targeted by anti-cancer agents used in chemotherapy. Most of them induce the formation of ternary complexes between Top2-DNA and the drug. These complexes are then converted into DNA breaks leading to cell death. In human cells, two isoforms are encoded by different genes. The α isoform (Top2α) is overexpressed during cell proliferation and is a hallmark in certain types of cancer. The β isoform (Top2β) was discovered later and several studies suggest that this isoform could be involved in the development of secondary malignancy after treatment by anti-topo compounds such as etoposide. The two isoforms share high sequence similarity and a similar structural organization but mostly diverge on their C terminal domain. The structure and the functional role of this domain are not well understood since no structural information is available on this domain alone, or in the context of the full length enzyme.

In addition, the Top2 enzymes are part of large cellular complexes whose role in disease processes are still to be elucidated. The identification of potential drug targets among proteins associated with the Top2 complexes could help to elaborate efficient multi-therapy and decrease side effects of drugs. In this work, we combine the proteomic analysis of the cellular partner of the Top2 enzyme and the structural analysis of these complexes. We

© 2014 The Authors. FEBS Journal © 2014 FEBS

use cryo electron microscopy to analyze the full length Top2α enzyme in complex with DNA and drugs, and a chemoproteomic approach to identify the Top2 cellular complexes targeted by drugs.

We will present here the production in yeast and the purification of the two isoforms of this large enzyme (340 KDa) that are prepared for functional and structural studies, and the analysis of their post-translational modifications. Our recombinant enzyme is used to validate the chemical probes derived from drugs prior to pulldown experiments on cancer cell lines. We will also present our preliminary study on the three dimensional reconstruction of the full length enzyme complex with DNA and etoposide using single molecule reconstruction by cryo electron microscopy. This project is the first step to characterize large complexes centered on the Top2 and targeted by drugs.

[1]Laboratory of Systems Biology, Moscow Institute of Physics and Technology (State University), [2]Laboratory of Proteomics, Shemyakin-Ovchinnikov Institute of Bioorganic Chemestry RAS, [3]Laboratory of Postgenomic Research in Biology, [4]Laboratory of Proteomics, Institute of Physico-Chemical Medicine, Moscow, Russian Federation

It has been revealed that small open reading frames (sORFs, up to 100 codons) have the potential to encode biologically active peptides that have regulatory roles in eukaryotic cells (Kastenmayer et al., 2006), (Kondo et al., 2010), (Andrews et al., 2014). In plants, a number of peptides encoded by sORFs play significant roles in various aspects of plant growth and development (Hanada et al., 2012). However, most *ab initio* gene prediction programs are not well suited for identifying sORFs with coding potential. Moreover, existing standard proteomic approaches poorly suited for the identification of proteins less than 10 kDa.

We used prediction program sORFfinder (Hanada et al., 2012) to find intergenic regions with high coding potential in the genome of the model object moss *Physcomitrella patens*. High-throughput RNA-Seq by SOLiD 4 genetic analyzer (Life Technologies, Applied Biosystems) and identification of native peptides by TripleTOF 5600 LC-MS/MS (ABSciex) has been carried out on gametophore, protonema and protoplast cells of moss *Physcomitrella patens*. Optimal procedure for endogenous peptide extraction and identification has been worked out to demonstrate translation of sORFs.

Using sORFfinder we distinguished 241,228 sORFs within intergenic region with high coding potential. RNA-Seq confirmed transcription of 8,450 sORFs from intergenic region and 16,928 previously known genes of *Physcomitrella patens*. Tandem mass-spectrometry analysis resulted in identification of 18 peptides derived from 12 sORFs within intergenic region, 52 peptides derived from 42 sORFs that were previously thought to be untranslated region of mRNAs and more than 100 peptides from about 100 alternative sORFs within previously known ORFs.

Comparative analyses of sORFs sequences distinguished in moss *Physcomitrella patens* with genomes of other plant species revealed high conservation in terms of synonymous/nonsynonymous substitutions. The report will be discussed further steps to validate the results overexpression and knockout mutants of coding sORFs, functional categorization and expression under stress.

Implementation of a chaperone fusion system for the production of soluble and biologically active chemokines in *E. coli*

A. G. Ntalli, T. D. Bellou, M. T. Karazafeiri, C. A. Panagiotidis
School of Pharmacy, Aristotle University of Thessaloniki, Thessaloniki, Greece

Escherichia coli is widely employed in the production of recombinant proteins for biotechnological and therapeutic use. However, its usefulness as a recombinant protein "cell factory" is hindered by the inability of many recombinant proteins to fold properly when overexpressed. Such misfolding leads to low protein solubility and subsequent accumulation within bacterial inclusion bodies. Several strategies have been employed to alleviate this problem, including the development, in our laboratory, of a chaperone fusion-protein expression system that yields properly folded, soluble recombinant proteins. Here we apply the chaperone fusion system to the production of two biologically important CXC-chemokines, i.e. IP10 (CXCL10) and SDF-1α (CXCL12). While chemokines are considered valuable research/diagnostic and therapeutic tools, due to their biological functions as signaling molecules in immunity and inflammation, their overproduction in bacteria leads to their aggregation and deposition in inclusion bodies. We find that such bacterially overexpressed and aggregated recombinant SDF1α and IP10 are present as covalently linked protein multimers, which revert to monomers upon exposure to a reducing agent. Thus, the observed multimerization can be attributed to the formation of aberrant intermolecular disulfide bonds, instead of the two intramolecular disulfide bonds that normally stabilize the CXC-chemokine structure. Expression of the two chemokines as fusions with DnaK, the *E. coli* Hsp70, resulted in high levels of soluble DnaK-chemokine production, minimal aggregation and negligible formation of intermolecularly linked chemokine multimers. These results cannot be simply attributed to the fusion of a chemokine to a highly soluble protein fusion partner, since chemokine fusions with GroEL (an Hsp60) and glutathione S-transferase displayed greatly reduced or no solubility, respectively. Thus, both the increased solubility of the DnaK-chemokine fusions and their lack of intermolecular disulfide bonds can be attributed to the presence of the specific chaperone fusion partner, i.e. DnaK. The order of the fusion protein partners does not appear to affect protein folding and solubility. The DnaK-chemokine fusions can be readily purified by IMAC under native or denaturing conditions and, unlike the unfused recombinant chemokines, these fusions refold promptly after removal of the denaturant. Furthermore, they are active in chemotaxis assays (wound-healing and cell migration assays). These results provide good evidence that our chaperone-fusion system can be applied in the biotechnological production of both soluble and biologically active chemokines in *E. coli*.

Heterosis, known also as hybrid vigor, refers to the phenotypic superiority of a heterozygous hybrid compared to its homozygous parents. In plants, hybrid vigor is associated with the rate of growth and protein synthesis as well as advanced environmental adaptability. Since the molecular mechanism of this phenomenon has not yet been fully understood, scientists continue to investigate different genetic models. Recent advances in quantitative trait loci (QTL) mapping in *Saccharomyces cerevisiae* have uncovered several targets associated with heterosis. The gene encoding ribosomal protein L39 (*RPL39*) was confirmed as a potential heterosis trait locus (HTL). L39 is an excess non-essential protein found in eukaryotic cells which affects translational fidelity and the rate of peptide bond formation in the 80S ribosome.

Based on these results, we decided to study the potential effect of heterosis on eukaryotic protein synthesis, focusing on the translational mechanism of yeast. The strains used in this study include two parental wild-type strains (6x6 and BYxBY), two hybrids (6xBY and 6xBY6) and a hemizygous strain (Δ6xBY) lacking one of the two alleles of *RPL39*. Following *in vitro* experiments, we tested the translational fidelity, the peptidyl-transferase activity (k_{cat}/K_M), and the ribosomal profile of each strain on sucrose gradient. According to our data, an increased error frequency (EF) of both hybrid strains was observed, compared to their homozygous parents. Moreover, Δ6xBY strain displayed significantly higher EF compared to 6xBY and 6xBY6, exceeding the expected effect caused by the deletion of one of its two alleles. However, the PTase activity of the studied strains did not show any significant difference between parental and hybrid strains ribosomes, as well as their gradient profiles. In conclusion, heterosis which has been associated with cell growth and protein synthesis in yeast, did not exert any effect on the catalytic activity of the ribosomes, but has only a statistically significant effect on translation accuracy.

Keywords: heterosis, ribosome, yeast.

Investigating the role of the poly(A) binding protein (PABP) 1 Lysine-606 modification in regulating post-transcriptional control

T. Blee[1], A. Cook[2], M. Brook[1], N. Gray[1]
[1]*MRC Centre for Reproductive Health, University of Edinburgh,*
[2]*Wellcome Trust Centre for Cell Biology, Michael Swann Building, University of Edinburgh, Edinburgh, UK*

PABP1 is a multifunctional regulator of gene expression which acts as a primary determinant of translation efficiency and stability, regulates the fate of specific mRNAs, and participates in microRNA (miRNA)-mediated regulation and nonsense-mediated mRNA decay (NMD). In relation to this, many PABP1 protein partners have been identified which bind overlapping sites within its C-terminal PABC domain, therefore, it unclear how its different functions are coordinated. Recently, we have found that PABP1 is subject to extensive post-translational modifications (PTMs) including putative lysine acetylation/methylation switches which may affect its interaction with different PAM2 motif-containing proteins. In particular, molecular modelling of the acetylation or methylation of Lys606 within the PABC domain, using available structures of PABC in complex with eRF3a and PAIP2, suggests that modification of this residue, which is critical in PABC-PAM2 interactions, may differentially affect these PABP1 interactions. Thus, we aim to experimentally investigate the role of the Lys606 modification as a molecular switch which dictates PABC-mediated protein-protein interactions thereby co-ordinating different aspects of PABP1 function to control the utilisation/destruction of mRNAs within cells. Novel methods are used for recombinant protein production of site-specifically acetylated/dimethylated PABC domain. This is used to study the interactions of PABC with known PAM2 proteins/peptides in biophysical studies and consequently structural studies. Here, the strategies for the investigation are discussed further and current progress is shown.

Investigation into Pdc behavior upon 14-3-3 binding using NMR, SAXS and Trp fluorescence quenching techniques

M. Kacirova[1,2], J. Novacek[3], L. Zidek[3], V. Obsilova[2], T. Obsil[1,2]
[1]*Department of Physical and Macromolecular Chemistry, Charles University in Prague, Faculty of Science,* [2]*Department of Protein Structure, Institute of Physiology, Academy of Sciences of the Czech Republic, Prague,* [3]*CEITEC – Central European Institute of Technology, Masaryk University, Brno, Czech Republic*

Phosducin (Pdc), a highly conserved 30 kDa phosphoprotein, regulates visual signal transduction by interacting with the beta and gamma subunits of the retinal G-protein. Pdc was also suggested to be involved in transcriptional control, the regulation of transmission at the photoreceptor-to-ON-bipolar cell synapse, and the regulation of the sympathetic activity and blood pressure. The function of Pdc is regulated by phosphorylation at Ser54 and Ser73 in a process that involves the binding of phosphorylated Pdc to the regulatory 14-3-3 protein. The 14-3-3 proteins are highly conserved dimeric molecules that regulate the function of other proteins through a number of different mechanisms. The exact role of the 14-3-3 protein in regulating Pdc function is still unclear, but it is entirely possible that 14-3-3 either sterically occludes and/or affects the structure of Pdc. Both 14-3-3 binding motifs are located within the N-terminal domain of Pdc, which participates in the binding to the beta and gamma subunits of the retinal G-protein as well as contains the SUMOylation site Lys-33.

Our previous study revealed that phosphorylated Pdc and the 14-3-3 protein form a stable complex with 1:2 molar stoichiometry. Complex formation with 14-3-3 affects the structure and reduces the flexibility of both the N- and C-terminal domains of dpPdc, suggesting that dpPdc undergoes a conformational change when binding to 14-3-3. To further investigate this interaction and mainly the 14-3-3 protein-mediated conformational changes of Pdc, we performed structural studies using NMR, SAXS and tryptophan fluorescence whose results are presented here.

Large-effect beneficial synonymous mutations overcome deleterious synonymous changes in an enzyme-coding gene

D. Agashe[1,2], M. Sane[1], K. Phalnikar[1], G. Diwan[1], V. Sahasrabuddhe[1], A. Habibullah[1], W. Polachek[2], C. J. Marx[2]
[1]*National Center for Biological Sciences, Bangalore, India,* [2]*Harvard University, Cambridge, USA*

Synonymous mutations have traditionally been considered to evolve neutrally. However, recent evidence shows that synonymous codon changes may face quite strong selection, although it remains difficult to derive general patterns about the nature and strength of such selection. In previous work with synonymous variants of an enzyme-encoding gene of *Methylobacterium extorquens*, we showed that altering codons could be extremely deleterious. Although the exact physiological mechanism likely depends on the specific sequence, the fitness disadvantage arose from insufficient enzyme production. We now show that during laboratory evolution, these synonymous variants rapidly regain fitness via repeatable and mutant-specific beneficial synonymous mutations in the N-terminal region of the gene. Although none of the mutations caused a reversion to the wild- type codon or altered tRNA genes, all of them increased focal gene and protein expression. Different allele variants found diverse mechanistic solutions during evolution, some alleviating unconventional binding to the anti-SD sequence, and others altering mRNA structure or stability. Our results thus suggest that co-evolutionary dynamics between tRNA copy number and codon use may be unlikely in the short-term, potentially because of the existence of multiple local fitness peaks in the adaptive landscape. Thus, bacteria may find diverse evolutionary solutions to the immediate physiological problems caused by accumulated deleterious synonymous mutations; and tRNA gene copy number changes may gradually fine-tune global protein production in the long term.

Mutational analysis of the ribosomal A site reveals the binding pattern for the 16S rRNA A1408 methyltransferases from the clinical pathogen and a natural producer of aminoglycosides

S. Obranic, G. Maravic Vlahovicek
Department of Biochemistry and Molecular Biology, Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

The aminoglycosides represent a class of antibiotics that are often prescribed for the treatment of various infections caused by both Gram-positive and Gram-negative bacteria. They are natural substances derived from *Streptomyces* spp. or *Micromonospora* spp. or synthesized *in vitro*. Aminoglycoside-producing bacteria have evolved a self-protecting system that inhibits the aminoglycoside binding to their target by methylating specific ribonucleotides in antibiotic-binding sites of the ribosome. Enzymes that are involved in this process are members of 16S rRNA G1405 or A1408 methyltransferase subfamilies and were until recently only been found in the natural producers of aminoglycoside antibiotics. However, a number of occurrences of high-level resistance to aminoglycosides in the clinic has been reported in recent time and a few novel G1405 and A1408 methyltransferases have been isolated from clinical pathogens.

In this work, we studied the ribosomal A site binding pattern of two of the A1408 methyltransferases, KamB from the natural producer of aminoglycosides and NpmA, a novel methyltransferase isolated from a clinical pathogen. Both enzymes confer high-level resistance to aminoglycoside antibiotics by methylating the A1408 nucleotide in the 16S rRNA of the small ribosomal subunit. In our work we used a specialized *E. coli* system, in which all *rrn* operons were inactivated, and ribosomal RNA was transcribed from a vector-based *rrn* operon. We constructed single nucleotide mutations in the part of the operon corresponding to the A site of 16S rRNA. We introduced actively expressing enzymes in these cells and monitored their ability to grow in media supplemented with various concentrations of kanamycin. We determined minimal inhibitory concentration of kanamycin for these cells and analyzed the target nucleotide A1408 methylation with primer extension.

Our results show that some of the point mutations introduced into 16S rRNA reduce the ability of both KamB and NpmA methyltransferases to effectively methylate the target nucleotide, A1408. We also observed a slight difference between the 16S rRNA binding patterns for these enzymes, suggesting that even though they have the same mode of action they might not bind to their substrate in the same manner. Our results presented here will be of great assistance in the development of specific NpmA inhibitors that could restore the potential of aminoglycoside antibiotics.

New insights about S1 binding to the ribosome by NMR

P. Giraud[1], J.-B. Crechet[2], M. M. Uzan[3], F. Bontems[1], **C. Sizun**[1]
[1]*ICSN, CNRS, Gif-sur-Yvette,* [2]*Ecole Polytechnique, Palaiseau,* [3]*IBPC, CNRS, Paris, France*

Ribosomal protein S1 is an essential actor for protein synthesis in *E. coli* since it helps mRNA recruitment by the 30S ribosomal subunit and recognition of the correct start codon during translation initiation. *E. coli* S1 is a modular protein that contains six repeats of an S1 motif, which have distinct functions despite structural homology. Whereas the three central repeats have been shown to be involved in mRNA recognition, the two first repeats that constitute the N-terminal domain of S1 are responsible for binding to the 30S subunit. We solved the structure of these two first repeats by NMR and showed that the first repeat is a degenerate OB-fold whereas the second repeat is associated with two helices that stem from the linkers with the first and third repeats. Based on these structures and on interactions properties with nucleic acids determined by NMR we propose a model for the binding of S1 to the ribosome.

pERp1/Mzb1 – functional characterization of a novel ER protein

A. Chatsisvili, N. Lodder, I. Braakman
Cellular Protein Chemistry, Faculty of Science, Utrecht University, Utrecht, the Netherlands

pERp1/Mzb1 is an endoplasmic reticulum (ER)-resident protein of 18 kDa, exclusively expressed in B cells. It is up-regulated during B cell to plasma cell differentiation and plays a key role in IgM assembly and secretion. pERp1/Mzb1 possesses a thioredoxin-like active site motif CXXC, typical of oxidoreductases. However, until now only a modest oxidoreductase activity of it has been measured in *in vitro* experiments, which is increased by the presence of protein disulfide isomerase (PDI), a well characterized oxidoreductase with chaperone activity. Since, the mechanism of action of pERp1/Mzb1 still remains obscure, we aim to determine its activity *in vivo* and identify if it is affected by other ER oxidoreductases, such as PDI, with which it might act synergistically. Low Density Lipoprotein Receptor (LDLR), a cell-surface receptor that mediates the clearance of LDL particles from blood circulation and regulates plasma cholesterol levels, is used as a model protein, since it has thirty disulfide bonds and a characteristic folding pattern. Using pulse-chase experiments, it was shown that pERp1/Mzb1 increases the homogeneity of disulfide bonds of LDLR, delays its folding and leads to its aggregation. On the other hand, PDI co-expression results in more heterogeneous disulfide bond formation compared to only pERp1 expression. Furthermore, PDI decreases the aggregation of LDLR caused by pERp1/Mzb1 and keeps LDLR mostly in its reduced form. These results shed a light into the activity of pERp1/Mzb1 and show how it affects the folding, aggregation and disulfide bond formation of LDLR.

Keywords: LDL receptor, oxidoreductase activity, pERp1/Mzb1.

Proteome of the venom of hump-nosed pit viper (*Hypnale hypnale*) from Sri Lanka

S. Y. Fung[1], C. H. Tan[2], N. H. Tan[1], S. M. Sim[2]
[1]*Department of Molecular Medicine,* [2]*Department of Pharmacology, University of Malaya, Kuala Lumpur, Malaysia*

The Sri Lankan hump-nosed pit viper (Hypnale hypnale) venom composition was investigated using two main proteomic approaches: (1) shotgun-liquid chromatography-mass spectrometry/mass spectrometry (shotgun-LC-MS/MS); (2) sequential use of reverse-phase high performance liquid chromatography (rp-HPLC), sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and peptide sequencing. Approach (1) revealed 52 venom proteins, 70% of which are toxinologically related variants confined to several protein families. Protein structures conserved in the venoms of phylogenetically related snakes supported the observed cross-neutralization of H. hypnale venom by the Malayan pit viper (Calloselasma rhodostoma) antivenoms. Approach (2) ascertained the venom key components, i.e. zinc-dependent metalloproteases (30%), phospholipases A2 (22%), L-amino acid oxidase (20%), C-type lectins (9%) and serine proteases (7%). These toxins correlate with the venom's principal hematoxic effects and local tissue destruction, indicating the target toxins for immunoneutralization. Interestingly, the findings also revealed the presence of nerve growth factors, aminopeptidases and three-finger toxin-like peptides in low abundances, the occurrence and functions of which require further characterizations. Both the proteomic approaches complement one another in unmasking the H. hypnale venom proteome and its key toxin constituents. The knowledge is essential for elucidating the pathophysiology of H. hypnale envenomation and for optimizing antivenom formulation in the future.

Keywords: Hypnale, proteome.

RACK1 binding to the ribosome is required to regulate the translational efficiency of specific mRNAs

S. Gallo[1,2], S. Ricciardi[1], E. Maffioli[3,4], M. Mancino[1,5], G. Tedeschi[3,4], S. Biffo[1,5]
[1]*INGM – National Institute of Molecular Genetic,* [2]*Vita-Salute San Raffaele University,* [3]*DIVET, University of Milano,* [4]*Filarete Foundation, Milano,* [5]*DiSIT, University of Eastern Piedmont "A. Avogadro", Alessandria, Italy*

Translation is a fundamental cellular process performed by ribosomes and is regulated by several different signaling pathways. In particular, RACK1 is a protein originally characterized as a receptor for activated PKCs and it is present on the 40S ribosomal subunit near the mRNA exit channel. RACK1 is proposed to act as an interface between signaling and ribosome machinery.

To address RACK1 role in translation, we performed *in vitro* translation assays using HeLa lysates downregulated for RACK1. We show that RACK1 depletion impairs the translation of cap-, TOP- and stem loop-regulated mRNAs (but not IRES-dependent translation). The addition of wt exogenous RACK1 is able to rescue this translation deficit.

To define if RACK1 role in translation depends by its binding to the ribosome, we generated a R36D K38E mutant RACK1 with low affinity for the ribosome. On *in vitro* translation, the addition of exogenous mutant RACK1 is unable to restore translation to the levels of wt RACK1. We have purified wt and mutant RACK1 from transfected HEK293 cells and interactors of both proteins are identified. Both wt and mutant RACK1 are shown to interact with wide pools of proteins, sharing several ones such as grp78. Among the interactors specific for wt RACK1, we are focusing on 40S rpSA which is a required component for 40S biogenesis.

We are going to test whether rpSA presence on the ribosome is affected by RACK1 depletion, and possibly if rpSA role can contribute to explain the translation deficits in those conditions.

Keywords: RACK1, ribosome, translation regulation.

Relocalization of translation factor eIF2D to the centrosome in mammalian cells upon stress

D. S. Makeeva[1], P. G. Sinitsyn[1], P. A. Ivanov[2], D. E. Andreev[2], I. M. Terenin[2,3], S. E. Dmitriev[2,3]
[1]*Faculty of Bioengineering and Bioinformatics,* [2]*Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University,* [3]*Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation*

eIF2D (formerly called ligatin) is a mysterious translation factor that is able to facilitate tRNA binding to the P-site of the ribosome in a GTP-independent manner. Its activity requires an AUG codon of mRNA properly positioned in the P-site before the tRNA binding. In a reconstituted system of eukaryotic translation initiation, eIF2D can replace both eIF2 and eIF5B in reactions of 48S and 80S complex formation, respectively. However, in contrast to eIF2-mediated initiation which is limited to Met-tRNAi, this alternative pathway may operate with elongator tRNAs.

© 2014 The Authors. FEBS Journal © 2014 FEBS

The physiological function of eIF2D is yet unknown. In yeast, eIF2D ortholog TMA64 has genetic interactions and expression profile that predict its involvement in control of the cell cycle and adaptation to stress. In addition to translation-related domains (N-terminal PUA and C-terminal SUI1), eIF2D possesses a much less conserved central part with similarity to Kin17_mid and SWIB/MDM2 domains. This feature suggests that eIF2D may be a component of protein complexes that coordinate cell cycle checkpoints in response to stress. To investigate a putative role of eIF2D in such events, we analyzed its localization within cultured mammalian cells under variety of conditions.

We found that under normal conditions eIF2D was diffusely distributed in the cytoplasm. However, upon induction of severe oxidative stress by sodium arsenite, both endogenous eIF2D and transiently expressed GFP-eIF2D formed two clearly defined foci in the cytoplasm in close proximity to the nucleus. These foci were clearly distinct from stress granules that were extensively formed under these conditions and contained several components of translation machinery. They were positively stained with antibodies against gamma-tubulin, the marker of centrosome. Similar localization pattern was observed under a number of stress conditions. The centrosomal localization of eIF2D was determined by the middle portion of the protein. We concluded that upon induction of stress response, eIF2D is relocated to the centrosome to participate in some specific translation events. This spatially restricted activity of eIF2D may be related to control of the cell cycle progression.

The study was partially supported by RFBR (grant 13-04-01121-a).
Keywords: centrosome, eIF2D, translation initiation.

Structures of mRNA have for a long time been described as key elements in the regulation of gene expression. Many bacterial mRNAs adopt structures in their 5' untranslated regions that modulate the accessibility of the 30S ribosomal subunit. Structured mRNAs interact with the 30S in a two-step pathway where the docking of a folded mRNA precedes an accommodation step. Recently, we demonstrated (1) that ribosomal protein S1 endows the 30S with an RNA chaperone activity that is essential for the docking and unfolding of structured mRNAs, and the correct positioning of the initiation codon inside the decoding channel. The rate of the S1-induced RNA melting is slow, suggesting that this step is ratelimiting in the initiation process of structured mRNAs. The first three OB-fold domains of S1 retain all the activities of the protein on the 30S subunit, while the function of the last two remains to be addressed. However, S1 is not required for all mRNAs and acts differently on mRNAs according to the signals present at their 5' ends. Interestingly, the action of S1 on the ribosome is countered by repressor proteins to prevent translation. All in all, S1 confers activities to the ribosome in such a way that the initiation of translation is selectively adapted for unstructured and structured mRNAs.

RNA mimicry by the Fap7 adenylate kinase in ribosome biogenesis

M. Blaud[1], J. Loc'h[1], S. Rety[1], S. Lebaron[1], D. Tollervey[2], P. Deschamps[1], J. Jombart[1], J. Robert-Paganin[1], L. Delbos[1], E. Zhang[1], F. Chardon[1], N. Leulliot[1]
[1]LCRB Université Paris Descartes, UMR 8015 CNRS, Paris, France, [2]Wellcome Trust Centre for Cell Biology, The University of Edinburgh, Edinburgh, UK

Over 200 pre-ribosomal factors are involved in the maturation of ribosomes. Most of these factors are essential to cell survival, but their precise function remains elusive. One of the last steps of maturation of the ribosome small subunit is the cleavage of 20S pre-rRNA in 18S rRNA in the cytoplasm. This cleavage is carried out by the endonuclease Nob1 and also requires the presence of other factors such as the methyltransferase Dim1, and a plethora of NTPases including the Rio protein kinases, Prp43 and its cofactor Pfa1, the Ltv1 GTPase and the Fap7 NTPase.

The function of Fap7 is especially intriguing since the human homologue bears adenylate activity, an enzymatic activity not usually found during ribonucleoprotein biogenesis. In addition, Fap7 regulates Cajal body assembly and cell cycle progression via the p53-MDM2 pathway. Finally, the function of Fap7 is intimately linked to its interaction with the Rps14 ribosomal protein. The Rps14 C-terminal domain is essential for D-site cleavage and is located in proximity to the 18S rRNA 3'-extremity in the mature ribosome. The deletion of this protein causes the 5q syndrome that is phenotypically close to Diamond Blackfan anemia. The link between the enzymatic activity of Fap7 and its role in ribosome biogenesis remains enigmatic.

This work presents the functional and structural characterization of the Fap7-Rps14 complex. We report that Fap7 association blocks the RNA binding surface of Rps14 and, conversely, Rps14 binding inhibits adenylate kinase activity of Fap7. In addition, the affinity of Fap7 for Rps14 is higher with bound ADP whereas ATP hydrolysis dissociates the complex. These results suggest that Fap7 chaperones Rps14 assembly into pre-40S particles via RNA mimicry in an ATP-dependent manner. Incorporation of Rps14 by Fap7 leads to a structural rearrangement of the platform domain necessary for the pre-rRNA to acquire a cleavage competent conformation.

S6 kinases interplay with new partner – adaptor protein TDRD7

O. Skorokhod[1], I. Gout[2], V. Filonenko[1]
[1]Cell Signalling, Institute of Molecular Biology and Genetics NAS of Ukraine, Kyiv, Ukraine, [2]Structural and Molecular Biology, University College London, London, UK

Ribosomal protein S6 kinases (S6Ks) are belong to the AGC family of Ser/Thr kinases and are important players in cellular PI3K/mTOR signalling network, implicated in the regulation of cell size, growth and metabolism. Our recent yeast two hybrid screening using S6K1 as bait allowed us to identify a novel bind-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ing partner of S6K1 – TDRD7, a scaffold protein involved in regulation of cytoskeleton dynamics, mRNA transport, protein translation, piRNAs processing. The aim of current project was to study S6Ks interplay with TDRD7.

First of all we have performed the bioinformatical analysis of TDRD7 primary structure and possible S6K1 sites of phosphorylation on this protein. At the next step six different fragments of TDRD7 were cloned, ovexpresed and purified from bacteria cells. These recombinant proteins were used in a set of pull-down experiments with full-length S6K1. Direct interaction between C-terminal tudor domain of TDRD7 and S6K1 has been shown. This interaction were further confirmed in Far-Western blot on recombinant S6K1 and TDRD7 fragments. Moreover, purified domains of TDRD7 were used as antigens for mouse immunizations and generation of monoclonal antibodies.

The generated antibodies were used for studying S6K1/TDRD7 interaction in mammalian cells *in vivo*. We succeed to detect an interaction between TDRD7 and S6K1 in HEK293 and rat brain lysates. Than, the application anti-TDRD7 and anti-S6K2 antibodies generated previously, allowed us to detect the existence of complexes S6K2-TDRD7 in HEK293. Moreover, the generated anti-TDRD7 antibodies allow us to find several new TDRD7 isoforms in HEK293.

And finally, we have found that S6K1 like S6K2 phosphorylate 3 from 6 fragments of TDRD7 in the *in vitro* kinase reaction.

Confocal microscopy studies suggest possible co-localization of S6K1/TDRD7 and S6K2/TDRD7 within perinuclear region in HEK293, HEPG2 cells and in soma of primary rat hippocampal neurons. And finally, we have detected that C-terminal synthetic peptides of S6K2 with methylated Arg interfere with TDRD7 from HEPG2 lysates. The physiological characteristics of S6K2-TDRD7 interaction and the role of this complex formation need further investigation.

Keywords: TDRD7, S6 kinase, methylation.

Selenoprotein mRNA cap hypermethylation and translation initiation

A.-S. Gribling-Burrer[1], L. Wurth[2], C. Verheggen[3], M. Leichter[1], A. Takeuchi[1], S. Baudrey[1], F. Martin[1], A. Krol[1], E. Bertrand[3], C. Allmang[1]
[1]UPR9002, CNRS, Strasbourg, France, [2]Gene Regulation Programme, Centre for Genomic Regulation and UPF, Barcelona, Spain, [3]UMR 5535, CNRS, Montpellier, France

Mammalian mRNAs are produced from complex and coordinated biogenesis pathways and acquire 5' terminal 7-methylguanosine cap structures that are essential to every aspect of mRNA metabolism, including localization, translation and decay. Selenoprotein mRNAs contain an in-frame UGA selenocystein (Sec) codon, usually sign of the termination of translation, and thus undergo particular translation recoding. Consequently, these mRNAs have to follow dedicated biogenesis pathways involving conserved assembly proteins and chaperon complexes. Our work reveals for the first time in vertebrates that selenoprotein mRNAs bear hypermethylated caps. We show that the acquisition pathway of this cap is common with that of small nuclear and nucleolar ribonucleoprotein particles, involved in RNA maturation processes. Our data also provide evidence that the hypermethylated-capped selenoprotein mRNAs localize to the cytoplasm and are translated but not efficiently recognized by the translation initiation factor eIF4E. These findings suggest that selenoprotein mRNAs may be subjected to a distinctive mode of regulation.

Keywords: mRNA cap hypermethylation, selenoproteins, translation initiation.

Eukaryotic and archaeal translation initiation complexes have in common a functional core containing mRNA, the ternary initiation complex (e/aIF2, GTP, Met-tRNA$_i^{Met}$), e/aIF1 and e/aIF1A bound to the small ribosomal subunit. In eukaryotes, the functional core is extended by many additional factors, most of them being involved in a long-range scanning of mRNA, necessary to decipher the initiation codon. In archaea, long-range scanning does not occur thanks to the occurrence of Shine-Dalgarno sequences or of very short 5'UTR on mRNA. Concomitantly, archaeal translation initiation only requires the core complexes.

We have determined two cryo-EM structures of archaeal translation initiation complexes containing mRNA and initiator tRNA, with either the full set of initiation factors or in the absence of aIF1. Together with toe-printing experiments, the structures reveal how the initiator tRNA in a P_{out} state cooperates with aIF1 to decipher the initiation codon. aIF1 departure allows concerted motions of the head of the 30S subunit and of the tRNA, leading to a complex with the initiator tRNA fully accommodated in the P site resulting in a P_{in} state. These motions induce a close conformation of the 30S subunit, which is stabilized by the C-terminal helical domain of aIF1A. The results provide insights into translation initiation steps that are common to archaea and eukaryotes.

Structural approaches on YIH1: a protein involved in protein synthesis control under starvation conditions

S. Zamora[1], J. Bravo[1], B. Séraphin[2]
[1]Signal Transduction Unit, Instituto de Biomedicina de Valencia, Valencia, Spain, [2]IGBMC, Illkirch, France

Protein synthesis is an essential and complex process that is susceptible to different environmental situations. One of them might be the accumulation of uncharged tRNAs due to starvation, leading to the activation of a cell response that affects general protein synthesis.

The proposed mechanism requires GCN2 binding to GCN1, being this interaction mediated by the GCN2 RWD domain. Once these two proteins have interacted, the complex binds to the ribosome, what is essential for the detection of empty tRNAs; since GCN1 is thought to facilitate the transfer of uncharged tRNAs from the ribosome to the histidyl tRNA synthetase like domain of Gcn2. This signal activates the kinase domain of GCN2, leading EIF2α phosphorylation, which promotes the translation of some determinant transcription activators of amino acid biosynthetic genes and also represses general protein synthesis.

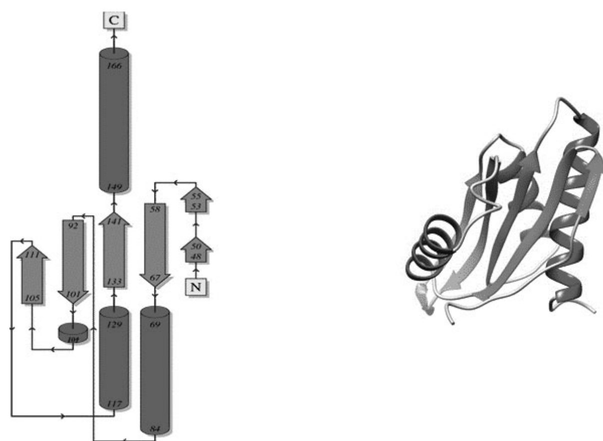

Fig. 1. On the left side we can see the C-terminal topology diagram of Y1H1 fungi homolog obtained from PDBsum. On the right side we show the C-terminal crystal structure of Y1H1 fungi homolog, obtained at 2Å resolution.

YIH1 (yeast IMPACT homolog 1) also contains a RWD domain that interacts with GCN1 through the same region as GCN2, thus competing with GCN2 for GCN1 binding and down-regulating GCN2 activation.

Our aim is to elucidate the crystal structure of the YIH1-GCN1 complex. Here we present the crystallization trials of this complex and also, the C-terminal structure of a fungi YIH1 homolog. This C-terminal belongs to the UPF 0029 group in Pfam with unknown functions described. It is conserved in both procariotes and eucariotes. This domain is organized as beta-alpha-beta-beta-alpha-beta, similar to a ferredoxin like domain (Figure 1)

Structural characterization of the β-propeller domain of Erb1, an essential protein in eukaryotic ribosome biogenesis

M. Wegrecki, J. Bravo
Signal Transduction Unit, Instituto de Biomedicina de Valencia-CSIC, Valencia, Spain

Erb1 (Bop1 in mammals) is a eukaryotic protein essential in ribosome biogenesis. Altogether with Nop7 and Ytm1 it forms a stable complex that participates in early steps of rRNA processing and is necessary for the proper maturation of the 60S ribosomal subunit although its exact implication in the process remains unknown. The amino terminal part of Erb1 harbors a poorly characterized domain (BopNt) which is directly responsible for its function and binding to Nop7 and Ytm1, whereas the carboxy-terminus of the protein contains a big β-propeller domain that is formed by seven WD repeats. It has been postulated that this C-terminal region is not directly involved in the main function of the protein during 60S synthesis; nevertheless it is well conserved within the Erb1/Bop1 family and provides an extensive surface for possible protein-protein and protein-RNA interactions. In total, 22 pre-ribosomal factors contain a β-propeller domain in their structure indicating that it is one of the most common folds that maintain the complex network of interactions required for the 60S assembly.

Here we present the crystal structure of the β-propeller domain of Erb1 from *Saccharomyces cerevisiae* at 1.6Å (residues 417–807) that was obtained as a result of random proteolysis event during crystallization trials of Erb1/Nop7 dimer. The structural information allowed us to exactly define the boundaries of the domain and to describe its particular features, being the presence of a long insertion within the second WD repeat the most distinctive characteristic. This additional segment forms a protrusion on the surface of the propeller and may play an important role in peptide binding. We conclude that the proper folding of the insertion is determined by the neighboring blades of the propeller. The analysis of the electrostatic surface and conserved hot-spot residues allows us to predict the patches that might be involved in protein-protein interactions. At last, we carry out a comparison of the conservation of the WD domain of Erb1 with other known seven-bladed propellers that gives an idea of how this extremely variable sequence produces such a similar fold.

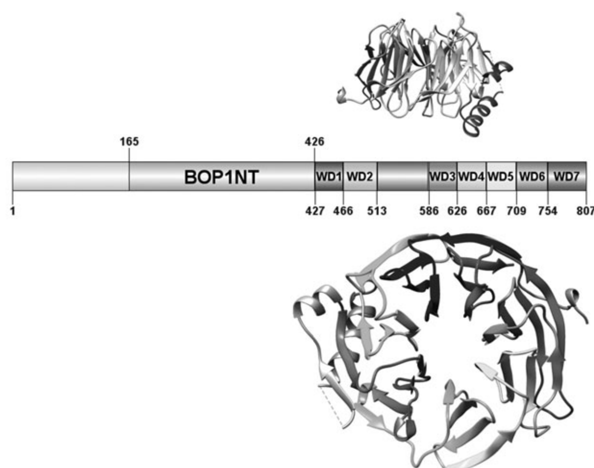

Fig. Diagram showing the domain organization of Erb1 from *Saccharomyces cerevisiae* and the structure of the carboxy-terminal β-propeller (residues 427-807). The coloring of the top-view cartoon representation in the bottom panel corresponds to the seven WD repeats represented on the bar. The position of the insertion on the bar and in the upper panel is highlighted in magenta.

MON-125
Structure of a thiolase like protein from *Mycobacterium smegmatis*

N. Janardan
Molecular Biophysics Unit, Indian Institute of Science, Bangalore, India

Thiolases are enzymes involved in fatty acid metabolism.They occur as either dimers or tetramers. Analysis of the *Mycobacterium smegmatis* genome suggests that it codes for several thiolases and thiolase-like proteins, most of which have not been well studied. We have determined the crystal structure of a thiolase-like protein (type 1) (*Ms*TLP1) from *M. smegmatis* at 2.7Å resolution by the single wavelength anomalous dispersion method. The structure revealed that the N-terminal domain has the thiolase fold. An extra C-terminal domain is also observed. Interestingly, it consists of six β-strands forming an anti-parallel β-barrel. Sequence and structural comparisons with classical thiolases revealed that the residues known to be essential for catalysis in thiolases are not conserved in *Ms*TLP1. Consistent with this observation, activity measurements showed that *Ms*TLP1 does not catalyze the thiolase reaction. Unlike classical thiolases, *Ms*TLP1 is a monomer in solution. This is the first structural report of a monomeric thiolase-like protein. These studies show that *Ms*TLP1 belongs to a new group of thiolase-like proteins of unknown function.

Keywords: Crystal structure, Mycobacteria, Thiolase.

Systematic search for stress-response factors influencing the 100S ribosome formation

H. Yoshida[1], T. Shimada[2], Y. Maki[1], S. Furuike[1], M. Ueta[3], C. Wada[3], A. Wada[3], A. Ishihama[4]

[1]Department of Physics, Osaka Medical College, Takatsuki, [2]Chemical Resources Laboratory, Tokyo Institute of Technology, Tokyo, [3]Bio-informatics section, Yoshida Biological Laboratory, Kyoto, [4]Research Center for Micro-nano Technology, Hosei University, Koganei, Japan

In proteobacteria group gamma including *Escherichia coli*, protein synthesis is suppressed by the formation of 100S ribosomes under stress conditions such as nutrient starvation. The 100S ribosome, a dimer of 70S ribosomes, is formed after association of 70S ribosome monomer with "Ribosome Modulation Factor" (RMF). Upon entry into the stationary growth phase, the 70S ribosomes are converted into 100S dimers, which are functionally inactive in translation. An *E.coli* strain deficient in the *rmf* gene cannot form 100S ribosomes and its lifetime is shorter than that of the wild-type strain, indicating that the transformation of ribosomes is an important strategy for *E.coli* survival under stress conditions. This ribosomal resting state is called the hibernation stage [1]. At present, however, little is known regarding the regulation of stationary-phase-coupled RMF expression.

Recently, we elucidated that cAMP-CRP is involved in transcription regulation of the *rmf* gene and the formation of 100S ribosome [2]. CRP (cAMP receptor protein) is the global regulator of genes for carbon source utilization. In parallel, we also identified that transcription of the *rmf* gene is regulated by ppGpp, an alamone produced under nitrogen starved conditions [3]. These findings indicate that transcription of the *rmf* gene is regulated through several pathways under various stress conditions including carbon and nitrogen starvation. In order to elucidate the pathways, we performed a systematic search for the stress-response factors that influence the 100S ribosome formation. On the basis of these results, we would like to discuss the relationship between the stress response and the 100S ribosome formation.

The collapse of ribosome biogenesis promotes terminal erythroid differentiation

C. Floquet[1], A. Raimbault[1], B. Guyot[2], D. d'Allard[1], O. Kosmider[1,3], F. Morlé[4], P. Mayeux[1], M. Fontenay[1,3]

[1]INSERM U1016, CNRS UMR8104, Institut Cochin, Université Paris Descartes, [2]CGPhiMC CNRS UMR5534, Université Claude Bernard Lyon1, [3]Service d'hématologie biologique, AP-HP, HUPC, Paris, [4]CGPhiMC CNRS UMR5534, Université Claude Bernard Lyon1, Lyon, France

Ribosome biogenesis (RB) is a key event allowing cell growth before division. Defective RB recognized in inherited Diamond-Blackfan anemia, emphasizes the functional importance of ribosome in erythropoiesis. In this study, we aimed at investigating the regulatory role of RB during the erythroid precursor maturation which is characterized by a cell size reduction during 2 to 3 rapid cell divisions (Figure).

We used two *in vitro* systems of expansion and differentiation of erythroblasts (E.) derived of immature hematopoietic progenitors from human mobilized peripheral blood or mouse fetal liver. The expansion step is supported by the Stem Cell Factor (SCF) and the second step depends on erythropoietin (EPO).The structure of the nucleolus was studied by electron microscopy. Compared to immature proerythroblasts (proE), a dramatic size reduction and change in nucleolar structure (*ie*. the disappearance of fibrillar and dense fibrillar components) is observed at the stage of mature polychromatophilic E. suggesting a loss of functionality.

RB was measured by a pulsed SILAC (Stable Isotopic Labeling by Amino acids in Culture cell) proteomic assay that quantified the incorporation of newly synthesized ribosomal proteins in the ribosome. Both in mouse and human models, immature proE expanded upon SCF and EPO demonstrate a maximal RB with a renewal rate of 60% and 50% every 14 h and 24 h, respectively. By contrast, RB rapidly interrupted with the disappearance of proE and basophilic E after the switch to EPO alone. Consistently, the quantities of ribosomal RNA (rRNA) 45S precursor estimated by qPCR are maximal in proE and almost null in orthochromatophilic E. Inhibition of RB at proE stage by RNApol I specific inhibitor (CX-5461) accelerates the onset of terminal erythroid differentiation suggesting that RB is a rate limiting factor for final maturation.

We then hypothesize that degree of signaling intensity in response to SCF and EPO may control the level of RB. To address this question, we investigated the mTORC1 (mechanistic Target Of Rapamycin Complex 1) pathway which is directly involved in RB through its substrate p70S6Kinase. Activation of P-p70S6Kinase and P-Rps6, as well as ribosome renewal, are twice more elevated in response to SCF and EPO than to EPO alone. Furthermore, inhibition of mTORC1/p70S6K/Rps6 pathway by rapamycin disrupts RB and leads to an acceleration of terminal erythroid differentiation.

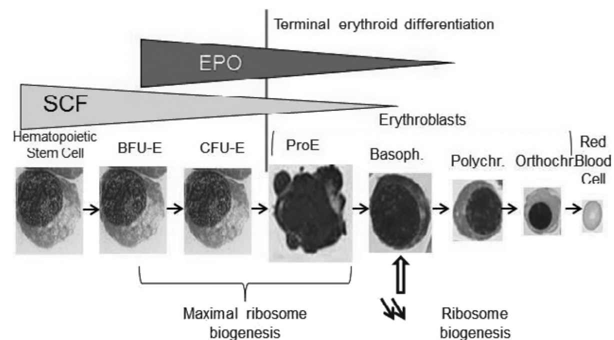

Fig. 1.

This study demonstrates that the collapse of RB promotes erythroid cell terminal maturation and shows the regulatory role of mTORC1 pathway on RB during erythropoiesis.

Keywords: erythroid differentiation, mTORC1, ribosome biogenesis.

TNF receptor-associated protein 1 (TRAP1) is an HSP90 chaperone involved in mechanisms of stress protection and resistance to apoptosis in mitochondrial and extramitochondrial compartments. Remarkably, aberrant deregulation of TRAP1 function has been observed in several cancer types with potential new opportunities for therapeutic intervention in humans. Recent studies by our group identified a previously undescribed localization of TRAP1 in the endoplasmic reticulum and ascribed to this localization novel roles of TRAP1 in quality control of mitochondria-destined proteins through the attenuation of their synthesis and degradation. However, the molecular mechanisms involved in such regulation are still largely unknown. To shed light on the signaling pathway of TRAP1-dependent attenuation of mRNA translation, we analysed protein synthesis regulation in HCT116 and HEK293 and found that in both cell lines TRAP1 silencing enhances cap-mediated translation and increases ratio between cap- and IRES-mediated translation. Consistently, expression levels of p70S6K and RSK1, two translation activating kinases, are increased upon TRAP1 knock down. Furthermore, we show that these regulatory functions affect the response to translational stress and cell migration in wound healing assays, processes involving these kinases. Notably, the regulatory mechanisms controlled by TRAP1 are conserved in colorectal cancer tissues, since an inverse correlation between TRAP1 and p70S6K expression is found in tumor samples, thereby supporting the relevant role of TRAP1 in translational regulation *in vivo*. Taken as a whole, these new findings candidate TRAP1 network for new anti-cancer strategies aimed at targeting the translational/quality control machinery of tumor cells.

The SBP2 protein central to selenoprotein synthesis contacts the human ribosome at expansion segment 7L of the 28S rRNA

O. Kossinova[1], M. Alexey[1,2], A. Krol[3], G. Karpova[1,2]
[1]*Insitit of Chemical Biology and Fundamental Medicine,* [2]*Novosibirsk State University, Novosibirsk, Russian Federation,* [3]*Architecture et Réactivité de l'ARN, Institut de Biologie Moléculaire et Cellulaire, Starsbourg, France*

The amino acid selenocysteine is encoded by UGA, usually a stop codon, thus requiring a specialized machinery to enable its incorporation into selenoproteins. The machinery comprises the $tRNA^{Sec}$, a 3'UTR mRNA stem-loop termed SElenoCysteine Insertion Sequence (SECIS), which is mandatory for recoding UGA as a Sec codon, specialized elongation factor eEFSec, the SECIS Binding Protein 2 (SBP2) and other proteins. SBP2 is a pivotal protein component in selenoprotein synthesis. It binds the SECIS stem-loop in the 3'UTR of selenoprotein mRNA and interacts with both eEFSec and the ribosome at the 60S subunit. Here, SBP2 binding site on the human ribosome was identified. Cross-linking experiments with bifunctional reagents demonstrated that the SBP2 binding site is mainly formed by the 28S rRNA. Direct hydroxyl radical probing of the entire 28S rRNA in the complex of SBP2 with the ribosome revealed that SBP2 protects helix ES7L-E in expansion segment 7. Diepoxybutane cross-linking confirmed the interaction of SBP2 with helix ES7L-E. Additionally, chemical probing showed that the binding of SBP2 to the ribosome led to increased reactivity of a few bases in ES7L-E and in the universally conserved helix H89, indicative of conformational changes in the 28S rRNA in response to SBP2 binding. Altogether, the findings obtained led us to bring new insight into the selenocysteine insertion mechanism in mammals.

The work was carried out in the frame of the Laboratoire International Associé LIA NUCPROT and supported by the Russian Foundation for Basic Research (grant 12-04-93111-CNRSL_a to G.K.).

Visualization of ribosomes in the nucleus of *Drosophila* cells

A. S. Abdullahi, S. Brogna, on behalf of Brogna Laboratory
Biosciences, University of Birmingham, Birmingham, UK

Translation requires correct joining of the small and large ribosomal subunits on the mRNA. Although the 40S and 60S subunits are assembled in the nucleolus in eukaryotes, it is believed that there are mechanisms preventing 80S formation and translation initiation in the nucleus. Contrary to this view, with a novel technique we have recently reported that functional 80S ribosomes are also present in the nucleolus and other nuclear sites (1). Notably, the signal was drastically reduced by Pol II inhibition, suggesting that nuclear 80S are preferentially associated with mRNA or their precursors. Flow cytometric analysis reveals that nuclear 80S is present at all stages of the cell cycle which peaks at the S-Phase. Serum starvation and other forms of cellular stress were found to increase nuclear 80S. At present we are using our 80S visualization technique to analyze the sub-cellular distribution of ribosome in different tissues such as photoreceptor neurons with the aim of understanding whether 80S are present along axons and synapses of active neurons. We will present our latest results at the meeting.

MON-132
1A2 insulator can interact with two promoters in one model system

P. Elizar'ev, D. Chetverina, P. Georgiev, M. Erokhin
Department of the Control of Genetic Processes, Institute of Gene Biology, Russian Academy of Sciences, Moscow, Russian Federation

Insulators are regulatory DNA elements that participate in the modulation of the interactions between enhancers and promoters. An insulator located between enhancer and promoter disrupts enhancer-promoter interactions. One possible mechanism of this is the establishment of direct insulator-promoter interactions that prevent physical contacts between promoter and enhancer. Insulators have the ability to neutralize enhancer action with respect to several promoters in one model system. In the present study it was shown that the 1A2 insulator can interact with promoters of the *hsp70* and *yellow* genes in one model system in *Drosophila melanogaster*. Interactions between insulators and promoters were demonstrated using the assay based on the yeast GAL4 activator. The GAL4 activator fails to stimulate the promoter that is located at the long distance from the corresponding gene; however interacting element (insulator) brings it closer to the promoter allowing such stimulation. Additionally the insulator-promoter interaction was confirmed by chromatin immunoprecipitation (ChIP) assay. It was demonstrated that the insulator protein CP190 is detected on the hsp70 promoter only in the presence of the insulator in the transgene. Thus the insulator-promoter interaction can play an important role in the modulation of the enhancer action.

Keywords: insulator, insulator-promoter interactions.

5-aza-2′-deoxycytidine up-regulates expression of MGAT3 gene in HepG2 cells and causes significant changes in N-glycome of secreted proteins

M. Klasić[1], P. Korać[1], T. Horvat[1], J. Krištić[2], G. Lauc[2,3], V. Zoldoš[1]
[1]*Department of Molecular Biology, Faculty of Science, University of Zagreb,* [2]*Glycobiology Laboratory, Genos Ltd,* [3]*Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia*

Protein N-glycosylation is an important posttranslational modification which affects protein structure and function. Majority of plasma proteins are synthesized in liver and changes in their glycosylation are often associated with different types of liver diseases, including hepatocellular carcinoma (HCC). HepG2 cell line is a hepatocellular carcinoma cell line which secretome is comparable with secretomes of HCC patients. This cell line can serve as a model to study epigenetically induced changes in glycosylation of secreted proteins. Using epigenetic inhibitor 5-aza-2'-deoxycytidine we have induced global hypomethylation in HepG2 cells. A panel of 84 glyco-genes was analysed and around 20% of the genes changed the expression level following the epigenetic treatment. Change in glyco-gene expression level was correlated with preferential appearance of particular glycan structures in the HepG2 secretome. The overexpression of *MGAT3* gene explained the majority of the changes observed in the glycosylation profile. GNT-III, enzyme coded by *MGAT3* gene, is responsible for the addition of bisecting GlcNAc, which prevents further core fucosylation and branching. When methylation and the expression level of *MGAT3* was specifically analysed and correlated with glycome composition from secretome of HepG2 cells following 5-aza-2'-deoxycytidine treatment we were able to detect decrease of glycan structures with core fucose and highly branched structures. Many epigenetic inhibitors are currently explored as part of a therapeutic strategy or are already used in cancer treatment. The present work contributes to our understanding of their efficiency in altering the N-glycan profiles of secreted proteins.

A mechanism for sensing chromatin alterations in mammalian cells

A. Kaidi[1,2], S. Jackson[1]
[1]*The Gurdon Institute, University of Cambridge, Cambridge,*
[2]*Cellular and Molecular Medicine, University of Brsitol, Bristol, UK*

Detection of genomic changes represents a critical step in the cellular response to DNA damage. Here, we show that the protein acetyltransferase KAT5 (Tip60) becomes tyrosine phosphorylated upon DNA damage, which enhances its binding to the histone mark H3K9me3. This in turn triggers KAT5-mediated acetylation of the ATM kinase, promoting checkpoint activation and cell survival. Notably, we also establish that chromatin alterations *per se* can induce KAT5 tyrosine phosphorylation and ATM-dependent signaling, and identify the proto-oncogene c-Abl as the mediator of this modification. These findings thereby define KAT5 as a key sensor for genomic and chromatin perturbations, and highlight a prime role for c-Abl in such events.

Aberrant methylation of HOXA10 in eutopic and ectopic endometrial tissues of women with endometriosis

Y. Samadieh[1,2], M. Shahhoseini[2], R. Favaedi[2], S. Mahdian[3], F. Ramezanali[3], R. Aflatoonian[3]
[1]*Faculty of Basic Sciences and Advanced Technologies in biology, University of Science and Culture,* [2]*Department of Genetics at Reproductive Biomedicine Research Center,* [3]*Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran*

Endometriosis is a benign gynecological disorder which is associated with both infertility and pelvic pain and it is characterized by the presence of endometrium outside the uterine cavity. Although it has been proposed that endometriosis is a genetic disease, but recent studies revealed that endometriosis can be considered as an epigenetic disorder. In this study, we analyzed mRNA expression of *HOXA10* gene parallel to methylation level of its promoter, as a critical gene responsible for uterine organogenesis, endometrial differentiation and cell proliferation through the regulation of hundreds of genes. To achieve this aim, eutopic and ectopic endometrium samples were collected using laparoscopy from 28 women with documented endometriosis, and also endometrial tissues were collected from 18 healthy fertile women

© 2014 The Authors. FEBS Journal © 2014 FEBS

undergoing laparoscopy for tubal ligation surgery as a control group. Ethical approval and informed patient consent was gained for the use of tissue samples. Quantitative expression analysis was performed by real-time PCR technique and methylation detection analysis was performed by Chromatin Immunoprecipitation (ChIP), using anti-MeCP2 antibody. Data showed a harmonious pattern between mRNA expression of *HOXA10* and methylation level of its promoter region. In the way that, *HOXA10* gene expression in eutopic endometrium decreased in secretory phase in comparison to control group, parallel to hypermethylation of the promoter. In contrast, hypomethylation of *HOXA10* in ectopic tissue samples caused a significant increase in mRNA level of the gene, in both proliferative and secretory phase, comparing to control group. Our data suggest that epigenetic aberration of *HOXA10* gene may be associated with the etiology of endometriosis.

Analysis of epigenetic pathways induced by enhancer and insulator in genetic constructs transfected into Drosophila S2 cells

D. Fedoseeva, N. Tchurikov, O. Kretova,
Epigeneticmechanismofgeneexpression group
Epigenetic Mechanism of Gene Expression, Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

Enhancer and insulator are ones of the key regulators of gene expression. We developed a system designed for the study of these elements in transfected genetic constructs. The system prevents the effects coming from other regulatory elements in cis on epigenetic states in different regions of the constructs. Previously we detected in Drosophila cultured S2 cells a promoter-independent bidirectional synthesis of non-coding RNAs in the intergenic region of the constructs induced by enhancer (enhancer RNAs, eRNAs). The synthesis was repressed by a single insulator or a pair of gypsy insulators (Tchurikov et al., 2009).

In this study we want to explore this eRNAs, and investigate epigenetic pathways launched by enhancer and insulator in genetic constructs transfected into S2 cells. With 5' RACE, primer extension and high-throughput sequencing approaches we detected that the most part of TSS of eRNAs are located at about 250 bp distance from the enhancer. We revealed, that enhancer induces the H3K4me3 and H3K18ac in the regions of eRNA synthesis. We observed that insulator acts as antagonist of enhancer, as far as it inhibits both the levels of eRNAs synthesis and H3K4me3 and H3K18ac marks produced by enhancers, and, at the same time, induces H3K4me1 and H3K27ac marks in the same region of the construct. Furthermore, study of insulator proteins binding shows that these proteins bind in different regions of genetic constructs. E.g., dCTCF, mod(mdg4)2.2 and Su(Hw) bind with enhancer and promoter regions in the absence of insulator. Interestingly, the introduction of one copy of gypsy insulator in the genetic construct suppresses this binding, while two copies of gypsy insulators are not as efficient, suggesting the interaction between them. Beside this, using ChIP we observed, that the genomic copies of gypsy and six different insulators from Bithorax Complex interact with nuclear lamina.

These data strongly suggest that enhancers and insulators mainly act indirectly, epigenetically, modulating histone modifications, synthesis of eRNAs, and regulating 3D chromosomal structures.

Analysis of the epigenetic response induced by environmental conditions during seasonal adaptation of *C. carpio* fish

M. Alvarez[1,2], A. Molina[2,3], N. Simonet[1], G. Nardocci[3], I. Araya[3], C. Fernandez de la Reguera[1], R. Fumeron[1]
[1]*Deparment of Biological Science, Universidad Andres Bello, Vina del Mar,* [2]*Interdisciplinary Center for Aquaculture Research, Concepcion,* [3]*Deparment of Biological Science, Universidad Andres Bello, Santiago, Chile*

For the *Cyprinus carpio* (carp) fish, seasonal acclimatization requires implementation of complex molecular and cellular mechanism that coordinates phenotypic plasticity. This process involves a reprogramming of gene expression, which in turn integrates a global homeostatic response. Previously, we have demonstrated that ribosomal genes (rDNA) activity is directly correlated with a change of activity and structure of the nucleolus. Moreover, this trait seems to be based in substantial changes in the number of active rDNA genes during carp acclimatization. Considerable evidence indicates that epigenetic mechanisms are important for regulation of this intricate process. In addition, cells must also have the ability to maintain their functions by constantly sensing and adapting to environmental variations (homeostasis). We are interested in the intersection of these two major cellular functions, namely in the issue of how transcriptional rRNA regulation is coordinated in response to oscillating environmental changes.

In the present work, we present some epigenetic mechanisms contributing to govern the reprogramming rDNA transcription in response to the seasonal adaptation of carp fish. Initially, we have determined the progression of the ratio of active/inactive ribosomal genes during acclimatization. Subsequently, we focused our attention in the rDNA regulation mediated by a molecular axis that involves TTF-I and NoRC chromatin-remodeling complex. Additionally, we have investigated the role of the eNoSC chromatin-remodeling complex during caloric restriction in carp cells. In the first case, we have established that NoRC contributes to silencing of rDNA during cold adaptation season. On the other hand, eNosC displays a compensatory effect that contributes to prevent a drastic cellular energy imbalance during carp acclimatization. Finally, we have studied the role of histones variants mH2A and H2A.Z in the transcriptional regulation of rDNA genes during carp seasonal adaptation. In both cases, we have observed that the activity of rDNA can be seasonally modulated through a dynamic exchange of canonical histones by their variants during the carp acclimatization.

In conclusion, our results demonstrate that epigenetic mechanisms play a central role in the reprogramming of gene expression of rDNA, which emerge as a molecular strategy to implement phenotypic plasticity during carp seasonal adaptation.

ranging from yeast to *Homo sapiens*. SNF2 like family members are further divided into several subfamilies according to the sequence features outside of their ATPase domain. The prominent subfamilies include ISWI, CHD1, SWI/SNF, and INO80 subfamilies.

The previous studies in our lab on human SWI2/SNF2 like protein hINO80 has demonstrated the catalytic and DNA binding activity (Bakshi *et al* 2006). The recent work in our lab has shown essentiality of dINO80 for Drosophila development, as *dIno80* knock-out is late embryonic lethal and these embryos show misexpression of homeotic genes (Bhatia *et al*, 2011). The DNA binding motif of INO80 has been identified by SELEX approach. In order to validate the regulatory role of hINO80 in human cell lines we cloned the INO80 binding motif both upstream and downstream the reporter gene. The strategy involved cloning the sequence having INO80 motif in a reporter vector pGL3 and monitor the expression of the reporter gene in the presence/ absence (knock down) of hINO80. By monitoring the expression of luciferase reporter gene under both conditions the regulatory role of hINO80 has been studied and we hypothesize INO80 to be functionally more diverse than what is known in literature so far.

We have bioinformatically analysed the distribution of INO80 and YY1 binding motif in the sequences upstream and downstream of human protein coding genes. While there are genes with both INO80 and YY1 binding motif, there are also several genes that have INO80 binding motif alone and YY1 motif alone. This raises the possibility of YY1 independent function of INO80. We have validated the binding of INO80 at selected target sites *in vivo* by Chromatin Immunoprecipitation (ChIP). We have also demonstrated the direct and specific DNA binding of hINO80 complex by EMSA. We have shown that INO80 can regulate reporter gene expression through its binding site.

Our results suggest an additional function of INO80 in regulating gene expression perhaps by direct binding to the DNA and acting as a recruiter, through its binding motif. The nature of the INO80 complex that mediates this function remains to be deciphered.

ASXL2 links ERα to histone methylation and determines antiestrogen response in ERα-positive breast cancer

U.-H. Park[1], E.-J. Kim[2], S.-J. Um[1]
[1]Department of Bioscience and Biotechnology, Sejong University, [2]Department of Molecular Biology, Dankook University, Seoul, Korea

Despite the importance of correlations between transcriptional activity and epigenetic regulation of Estrogen receptor α (ERα) in breast cancer, their mechanisms and physiological roles are not clearly understood. Here we demonstrated that Additional sex comb-like 2 (ASXL2) plays pivotal role in ERα-positive (ERα+) breast carcinogenesis through recruiting co-activator complex containing LSD1 and UTX and removing repressive histone codes on ERα-target promoter upon E2 stimulation, supporting cooperation of ASXL2 complex in genome-wide level. ASXL2 expression is strongly correlated with ERa level, showed close association with overall good survival rate of breast cancer patients. Our data suggest that the necessity and majority of ASXL2 on ERα activity and the possibility of ASXL2 as new diagnostic marker and therapeutic target of breast cancer.

Characterizing the zinc finger binding interactions of PRDM9 with the DNA of recombination hotspots

Y. Gravogl, T. Schwarz, I. Tiemann-Boege
Institute of Biophysics, Johannes Kepler University, Linz, Austria

Meiotic recombination events cluster in 1–2 kb regions of the genome termed recombination hotspots. Hotspots have been characterized for a long time, but little is known on how and why a region is targeted for recombination. The histone methyltransferase PRDM9 has been identified as a key trans-regulator of hotspot activity in mammals. It is believed that PRDM9 recognizes specific DNA motifs via its tandem array of zinc fingers and then epigenetically marks the local chromatin by its histone methyltransferase activity. Specific DNA motifs recognized by PRDM9 are a key factor in determining hotspots, yet there are many cases in which motifs are neither necessary nor sufficient to determine a hotspot, and in many instances the motifs are found more often outside than within hotspots. Thus, we still do not fully understand the binding determinants of PRDM9 to DNA. We are therefore analyzing PRDM9 binding affinities to diverse DNA substrates *in-vitro* using Electrophoretic Mobility Shift Assays (EMSAs), as well as more quantitative biophysical techniques. We have confirmed that binding to a specific hotspot sequence is much stronger than to a random DNA sequence or even to the predicted binding sequence (derived by the Persikov algorithms). Moreover, the addition of high amounts of specific or unspecific DNA leads to an increased PRDM9 affinity, suggesting either a cooperativity effect or a change in accessibility to the DNA-binding region. Furthermore, epigenetic modifications such as DNA methylation as well as the nature of the regions flanking the motif have a strong effect on the binding. Our results show that DNA binding motifs recognized by the zinc finger array do not capture all the aspects of the binding site information.

Keywords: Meiotic recombination, PRDM9, Protein-DNA binding assays.

Comparative analysis of methylation/deletion patterns of chromosome 3 in different cancer types using NotI-microarrays

A. A. Dmitriev[1,2], G. S. Krasnov[1], A. V. Kudryavtseva[1,2], A. V. Snezhkina[1], A. V. Gerashchenko[3], E. E. Rudenko[3], E. E. Rosenberg[3], G. A. Puzanov[1], M. A. Puzanov[1], B. Y. Alekseev[2], V. N. Senchenko[1], V. I. Kashuba[3]
[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, [2]P.A. Herzen Moscow Cancer Research Institute, Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, [3]Institute of Molecular Biology and Genetics, Ukrainian Academy of Sciences, Kiev, Ukraine

Cancer is characterized by numerous genetic and epigenetic alterations. NotI-microarrays earlier developed by Dr. Eugene R. Zabarovsky are unique tool enabling simultaneous identification of DNA hypermethylation and deletions – two major reasons of tumor suppressor gene (TSG) inactivation. In the present work, methylation and/or deletion (M/D) frequencies were evaluated in lung (40 samples), ovarian (18), cervical (48), renal (23), breast (47) and colon (24) primary tumors using specific to chromosome 3 NotI-microarrays containing 180 NotI-clones associated with 188 genes. The important role of chromosome 3 in cancer is well known, but large-scale simultaneous analysis of genetic and epigenetic aberrations was not still performed. In this study in each cancer type we identified at least 25 genes with 15% or higher

© 2014 The Authors. FEBS Journal © 2014 FEBS

M/D frequency. These genes include TSGs or TSG-candidates (for example, *VHL*, *CTDSPL*, *ITGA9*, *EPHB1*, and *ALDH1L1*) and genes that were not previously considered as cancer-associated (e.g., *LRRN1*, *GORASP1*, *FGD5*, *TOPAZ1*, and *PLCL2*). In general, patterns of M/D were distinct in different cancer types. Nevertheless, the same genes were altered often. Proteins encoded by identified genes are involved in signaling pathways and biological processes frequently affected during carcinogenesis. However, for a part of the genes, functions of their proteins are still unknown: *LRRN1*, *LRRC3B*, and *TOPAZ1*, for example. In several examined samples at least 20 out of 180 NotI-sites were affected simultaneously. Probably, these samples represent CIMP+ tumor phenotype. Results of the bisulfite sequencing analysis were in concordance with NotI-microarray data and confirmed methylation as a frequent event in examined cancer types. Frequent (>40%) and significant (>4-fold) down-regulation was shown for several genes with high M/D frequency (for example, *CTDSPL*, *ITGA9*, *ALDH1L1*, *LRRN1*, and *FGD5*) using quantitative PCR. Finally, obtained data allowed to suggest potential sets of methylation markers for diagnostics of each studied cancer type and identification of pathomorphological characteristics of tumor.

Comparative chromatin evaluation of human embryonic stem cells and induced pluripotent cells

R. Favaedi[1], M. Shahhoseini[1], S. Molla Mohammad[2], H. Baharvand[2]

[1]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, [2]Department of Stem Cells and Developmental Biology at Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran

Pluripotent cells including embryonic (ESCs) and induced pluripotent stem cells (iPSCs) have extraordinary characteristics originated from their chromatin structure and regulation. One of the regulating levels of chromatin is post-translational modifications (PTM) on histones. PTMs are very important molecular determinants in epigenetic regulatory mechanisms. Also the pattern of PTMs which termed epigenome, has a critical role in regulation of pluripotency, differentiation and the fate of ESCs and iPSCs. Some PTMs such as H3K9ac and H3K9me2 are well known as epigenetic marks which correlate with active and repressive chromatin, other ones like bivalent marks (H3K4me3 and H3K27me3) are characteristic features of pluripotent cells. So, examination of nucleosomes as target of PTMs can be an adequate and rapid way to compare total levels of epigenetic marks on chromatin of ESCs and iPSCs. In this study the chromatin of human ES cells before and after differentiation was analyzed and compared with chromatin of iPS cells originated from differentiated ESCs and also fibroblasts as committed cell line. For this respect, an enzyme-linked immunosorbent assay (ELISA) based method was used for the quantitative evaluation of H3K9ac/me and bivalent marks, as PTMs on intact nucleosomes to compare their patterns on ESCs and iPSCs. Results showed significant changes of all examined epigenetic marks through differentiation of ES cells as well as the pluripotency induction of differentiated cells. Although on the other side, remarkable similarities were seen in PTM patterns of the two pluripotent ESCs and iPS cell. This experiment indicates the association of epiproteomic signature of cells with cellular identity, pluripotency, differentiation and reprogramming state of cells.

Comparison of 5hmC enichment techniques

J. Hunter, J. Thomson, R. Meehan

IGMM MRC HGU, Edinburgh, UK

Epigenetic regulation is the process by which gene expression can be regulated without affecting the underlying DNA sequence. Direct modification of DNA bases and histone tails are 2 ways in which this regulation can occur. One well studied epigenetic mark is that of direct chemical modification to cytosine bases in the dinucleotide "CpG". The most abundant forms of this modification are that of 5-methylcytosine (5mC) as well as the more recently rediscovered 5-hydroxymethycytosine (5hmC) mark. The latter of these marks is of particular interest due to its apparent relationship with transcriptional activity when found in genic regions. The focus of my PhD is on the changes in the epigenetic profiles of cells during both reprogramming and the loss of the DNA methyltransferase responsible for maintaining the methylation pattern of the genome, DNMT1. Analysis has shown that certain epigenetic profiles, such as that of 5hmC, can be used as a good identifier of tissue type and state. As such current 5hmC research is focussed on the distribution of this modification genome wide.

Although several 5hmC enrichment techniques have been described, the majority of work focuses on antibody based enrichment protocols (HmeDIP). However, antibody based techniques may have some limitations and sequence bias. Thus part of the focus of my work has been to compare this widely used and well accepted 5hmC enrichment technique to newer alternative approaches, namely glycosylation based chemical capture techniques and JBP based affinity purification. From this analysis we compared the efficiencies of all three techniques, using genome wide arrays along with qPCR to give a side by side comparison of the results of the protocols. Data from this research has shown that the JBP affinity based approach yields very low levels of enrichment post purification, whilst chemical capture protocols result in comparable 5hmC patterns to those generated using HmeDIP. Nevertheless we do find a number of regions which show a striking yet reproducible difference between the two techniques which could be the result of either antibody bias or a failure in the chemical capture to bind to these regions. Further work has given us a better understanding of the basis of these differences allowing us to determine which protocol or combination of techniques gives the most accurate picture of the epigenetic landscape.

CpG islands promoter methylation the main cause for GNMT gene decreased expression in pancreatic adenocarcinoma

A. Botezatu[1], C. Bleotu[2], A. Nastase[3], G. Anton[1], N. Bacalbasa[4], D. G. Duda[5], S. O. Dima[3], I. Popescu[3]
[1]Viral Genetic Engineering Laboratory, [2]Antiviral Therapy, Romanian Academy "Stefan S. Nicolau" Institute of Virology, [3]Center of General Surgery and Liver Transplantation "Dan Setlacec", Fundeni Clinical Institute, [4]Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [5]Edwin L. Steele Laboratory for Tumor Biology, Massachusetts General Hospital, Boston, MA, USA

Pancreatic cancer remains a major challenge for therapy and biomarkers identification. Many epidemiological and clinical studies had proved the importance of early detection to decrease the mortality caused by pancreatic cancer.

Epigenetic silencing of tumor suppressor genes is a major contributor to neoplastic transformation and is an area of intense research. Identification of genes which undergo cancer-specific CpG island hypermethylation and correlation of these data with tumor stage, progression, and long-term prognosis are becoming increasingly common.

The aim of this study was to identify new factors involved in pancreas oncogenesis.

The results of bioinformatic analysis of microarray data found a down regulation of GNMT gene (glycine N-methyl transferase) in pancreatic adenocarcinoma. GNMT posses CpG islands in the promoter and is an important gene involved in methyl group metabolism and in maintaining a normal methylation status of the genome.

To test the hypothesis that GNMT is epigenetic regulated in PDAC, we evaluated the *GNMT* gene expression and promoter methylation status in 30 paired samples of PDAC and normal pancreatic tissue. We found significantly higher methylation frequencies ($p < 0.001$) in PDACs (2.82–100%, median=36.05%) than in controls (0.28–14.02%, median=4.39%). The *GNMT* gene expression was decreased in PDACs compared to normal pancreatic tissue in 26/30 cases (86.67%). Fold change expression of investigated gene was between −0.02 and −4.55, median = −2.42, suggesting an important role for the downregulation of this gene in PDAC. Furthermore, we show that the treatment with 5-aza-dC increased *GNMT* mRNA expression and decreased viabiliy in PDAC cells. Collectively, these data indicate that *GNMT* is aberantly methylated in PDAC, and may be a major mechanism for gene silencing. Methylation of *GNMT* gene is directly correlated with disease stage and with tumor grade, indicating that these epigenetic effects may be important regulators of PDAC progression, and may serve as prognostic biomarker for PDAC.

The study was supported by POSDRU 89/1.5/S/60746 and PN-II-PT-PCCA90/2012 research grants.

CTCF target sequences within the chicken alpha-globin gene locus

E. Kotova, D. Didych, S. Akopov, L. Nikolaev, E. Sverdlov
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation

CTCF is a highly conserved multifunctional transcription factor of vertebrates. This protein is implicated in diverse regulatory functions, including transcriptional activation/repression, insulation, imprinting, X chromosome inactivation. CTCF role in the global organization of chromatin architecture was supported in a lot of works. CTCF protein binds DNA sequences named insulators. Insulators block influence of regulatory genome elements on genes located on the other side of insulator. Chicken alpha-globin gene domain is an open chromatin domain both in erythroid and nonerythroid cell types. However expression of the most nonglobin genes in domain doesn't change in consequence of the erythroid cells differentiation. We supposed that CTCF binding has a crucial role in alpha-globin genes insulation and domain structure reorganization linked with erythroid cell differentiation. We selected CTCF-binding sequences from fragments of the chicken alpha-globin locus DNA by two dimentional EMSA (Electrophoretic Mobility Shift Assay) in vitro. CTCF binding for some of this sequences was shown in vivo by chromatin immunoprecipitation and ChIP-seq (chromatin immunoprecipitation with massively parallel DNA sequencing) analysis on erythroid and lymphoid chicken cell lines. Some differences in CTCF-binding of this fragments in this cell lines may suggest a role of CTCF protein in alpha-globine gene expression. We compared data get by two dimention EMSA, ChIP-seq analysis and CTCF binding site motifs location. This comparison allow us to suggest, that vertebrate genomes contain a lot of sequences that can effectively bind CTCF in vitro, but don't bind it in vivo. As well DNA fragments that bind CTCF in vivo can have relative weak CTCF affinity in vitro and weak CTCF binding site consensus similarity.

Detection of active promoters in human genome libraries using reporter assay

D. Didych, C. Luibimova, S. Akopov, E. Sverdlov, L. Nikolaev
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation

Promoters are indispensable functional elements in all expression systems used in a wide range of medical and biological research. For many applications strong and cell-type specific expression of genes of interest is needed. Therefore massive functional approach for detection and isolation promoters active in specific cell types may be a very useful technique. For detection of active promoters in genome libraries we obtained sonicated PCR-amplified human library and cloned it between two reporter genes of green and red fluorescent proteins located in "head-to-head" orientations in plasmid vector. Over 400000 DNA fragments with size of 300–1500 bp were cloned and pool of plasmids obtained. After transient transfections of two human cell lines we analyzed green fluorescence using flow cytometer and find that 1% and 7% of true GFP-positive cells in A-431 and 293T cells, respectively. We also inserted in plasmid vector CMV enhancer and cloned library fragments into this construct between two reporter fluorescent protein genes. CMV enhancer increased the number of true GFP-positive cells up to 6% and 18% in A-431 and 293T cells, respectively, and therefore can be used for detection of weak or inactive cell-specific promoters in genome libraries.

Keywords: active promoters, genome libraries, massive functional assay.

DNA methylation alterations in ovarian cancer: impact on cancer initiation, progression and response to therapy

M. Keita[1], Z.-Q. Wang[1], J.-F. Pelletier[1], M. Bachvarova[2], M. Plante[3], J. Gregoire[3], M.-C. Renaud[3], A. Sebastianelli[3], A.-M. Mes-Masson[4], **D. Bachvarov**[1]
[1]Laval University, [2]CRCHU-Quebec, [3]CHU-Quebec-HDQ, Quebec, QC, [4]Université de Montréal, Montreal, QC, Canada

We used methylated DNA immunoprecipitation (MeDIP) in combination with CpG island tiling arrays to characterize at high resolution the DNA methylation changes that occur in the genome of serous epithelial ovarian cancer (EOC) during disease progression. The DNA methylation profiles of five serous borderline, five serous grade 1/stage III/IV, five serous grade 3/ stage I and five serous grade 3/stage III/IV EOC tumors were compared with those of five normal human ovarian tissue samples.

We found widespread DNA hypermethylation at CpG islands in serous tumors that occurs even in less invasive/early stages of ovarian tumorigenesis. This hypermethylation preferentially included key developmental/homeobox genes and is possibly associated with repressive chromatin marks such as Polycomb group proteins-mediated gene silencing. Contrary to DNA hypermethylation, significant DNA hypomethylation was observed only in high-grade (G3) serous tumors. The later observation was further confirmed when comparing the DNA methylation profiles of primary cell cultures derived from matched tumor samples obtained prior to, and following chemotherapy treatment from two serous EOC patients with advanced disease. To our knowledge this is the first report that has shown the presence of massive DNA hypomethylation in advanced serous EOC, associated with the possible induction of a number of oncogenes, implicated in cancer progression, invasion/metastasis and probably chemoresistance. Our data raise the concern that demethylating drugs that are currently being used in advanced EOC disease (representing the majority of serous EOC cases) might have adverse effects due to activation of oncogenes and prometastatic genes. Understanding the relative roles of hypomethylation and hypermethylation in cancer could have clear implications on the therapeutic use of agents targeting the DNA methylation machinery.

Our epigenomic approach has also led to the identification of novel aberrantly methylated gene targets in serous EOC, including hypermethylated genes with potential tumor-suppressor gene function, and hypomethylated genes, involved in disease progression. These genes could represent new therapeutic targets and/or novel biomarkers indicative of EOC etiology.

DNA methylation analysis of selected genes comprised in the epidermal differentiation complex (EDC) during epidermal differentiation

B. Sobiak, A. Graczyk, W. Lesniak
Department of Molecular and Cellular Neurobiology, Nencki Institute of Experimental Biology, Polish Academy of Science, Warsaw, Poland

The epidermal differentiation complex (EDC) incorporates a syntenic and linear cluster of 4 gene families encoding the S100 proteins, the small proline rich proteins (SPRRs), the late cornified envelope proteins (LCE) and the S100-fused type proteins (SFTPs), all involved in keratinocyte differentiation process. We presupposed that epigenetic factors may play a considerable role in the regulation of EDC gene expression. As a research model we employed human epidermal keratinocytes (primary HEKa cells) in undifferentiated and differentiated form (the latter maintained in higher calcium concentration). Methods of real time PCR, genomic DNA isolation, bisulfite conversion and conventional sequencing were applied. First, we examined the expression pattern of several S100 genes during epidermal differentiation. Subsequently, we verified if the observed changes in mRNA level were reflected by changes in DNA methylation pattern. We performed the analysis for S100A6, S100A7, S100A8, S100A13 genes, for the NICE1 gene located within the LCE subcluster, and also for genes encoding involucrin and loricrin - the established markers of keratinocyte differentiation. Additionally, we examined DNA methylation within a recently identified conservative non-coding element endowed with enhancer properties. Gene areas harboring extremely CpG rich regions (defined as CpG islands) along with relatively CpG poor regions were selected for analysis. The analyzed DNA fragments were localized in the immediate proximity of transcription start sites or in both exons and introns. We did not observe distinct changes in CpG methylation in the analyzed gene regions between the initial and final stage of keratinocyte differentiation. Furthermore, the actual methylation state did not preclude the gene expression level. Other EDC fragments are to be investigated to localize differentially methylated regions (DMRs) of potential regulatory significance.

Effect of insertion of anticancer drug 6-thioguanine into DNA on the functioning of mammalian de novo DNA methyltransferase Dnmt3a

E. Gromova, O. Kirsanova, I. Iasko, A. Sergeev
Moscow State University, Moscow, Russian Federation

6-Thioguanine (G^s) is a cytotoxic drug which is widely used for the treatment of acute leukemia. However, the mechanism of G^s cytotoxicity is still unknown. *In vivo* G^s forms 2'-deoxy-6-thioguanosine triphosphate which incorporates into DNA. DNA methylation at CpG sites is an epigenetic modification of the genomes that plays an important role in regulation of many biologic processes including gene regulation. DNA methyltransferase Dnmt3a is involved in establishment of new methylation patterns in genome. The incorporation of G^s into CpG sites may affect the activity of Dnmt3a. Here, we examine the impact of G^s on cytosine methylation mediated by catalytic domain of Dnmt3a (Dnmt3a-CD). 30-mer DNA duplexes containing G^s either in the CpG site or adjacent to it (G^s-DNA) were obtained. Also we designed two-site substrates with G^s replacements. Using two-site substrates we took into account that the active form of Dnmt3a is a tetramer with two catalytic centers.

An introduction of the G^s into the CpG site near the target cytosine led to decrease of methylation as compared to the unmodified substrate. This effect may be due to the perturbation of the contact of Dnmt3a-CD with the 6-oxo group of the guanine which is important for the formation of a catalytically competent complex Dnmt3a-CD/DNA. Occurrence of the G^s opposite the target cytosine or in the CpG flanking sequences virtually has no effect on the methylation efficiency. Importantly, that in the case of two-site substrates incorporation of one or two G^s residues caused approximately equal decrease of the V_0 values. Probably, methylation of both sites by two catalytic centers of

© 2014 The Authors. FEBS Journal © 2014 FEBS

tetramer Dnmt3a-CD occurs interdependently and modification of one of the CpG-sites affects methylation of non-modified neighboring CpG site.

Binding of Dnmt3a-CD to G^s-DNA shows positive cooperativity like in the case of unmodified substrates. The K_d values for G^s-DNA/ Dnmt3a-CD complexes slightly increased regardless of the position of the G^s residue in DNA.

Absorption band of 6-thioguanine is above 300 nm where unmodified DNA and the enzyme are transparent. This allowed us to use G^s residue as spectroscopic probe and to study structural changes of G^s-DNA in complex with Dnmt3a-CD by circular dichroism in the region of 300–400 nm. The local disturbance of stacking interactions of bases in the CpG-site within G^s-DNA/ Dnmt3a-CD complexes were observed probably due to the flipping of the target cytosine out of the double helix.

Taken together, these results showed epigenetic contribution of 6-thioguanine incorporation into DNA via impact on the functioning of Dnmt3a.

This work was supported by the RFBR grant 13-04-00727.
Keywords: DNA methylation 6-thioguanine.

Protein-DNA binding in the absence of consensus motif

A. Afek[1], D. Lukatsky[2]
[1]Chemistry, [2]Ben-Gurion University, Beer-Sheva, Israel

Genome-wide identification of protein-DNA binding preferences of ~100 of *Caenorhabditis elegans* transcription factors (TFs) has revealed that a significant fraction of binding events occur in highly occupied target (HOT) regions where few specific transcription factor binding sites (TFBSs) have been detected. These measurements also revealed that a significant fraction of consensus TFBSs do not bind TFs. Furthermore, *in vitro* measurements of *C. elegans* TFs binding preferences indicate that TFs systematically bind DNA sequences that lack known consensus motifs. These observations strongly suggest that alongside with conventional specific binding, additional recognition mechanisms affect protein-DNA binding preferences.

Here we demonstrate that DNA sequence repeats characterized by certain symmetries, statistically affect protein-DNA binding. Using a simple statistical mechanics model, we compute the nonconsensus protein-DNA binding free energy originating from TFs binding to such sequence repeats in the *C. elegans* genome. We use the term nonconsensus protein-DNA binding in order to emphasize the point that specific, consensus TFBSs do not contribute to this effect. We show that the nonconsensus protein-DNA binding free energy is negatively correlated with the overall TF occupancy genome-wide. In addition, we show that genomic background surrounding specific TFBSs influences specific protein-DNA binding via the modulation of nonconsensus protein-DNA binding.

Finally we will present our recent measurements in which we used high-throughput protein-DNA binding assays to measure the binding levels and free energies of binding for several human TFs to tens of thousands of short DNA sequences with varying repeat symmetries. Based on statistical mechanics modeling, we identify a new protein-DNA binding mechanism induced by DNA sequence symmetry in the absence of specific base-pair recognition, and experimentally demonstrate that this mechanism indeed governs protein-DNA binding preferences.

Epigenetic regulation of piwil2 transcription in testicular tumors

S. Kondrateva, E. Stukacheva, J. Skvortsova, T. Azhikina
Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Science, Moscow, Russian Federation

DNA methylation is a major epigenetic modification with a very important role in regulation of gene expression. During tumor development methylation pattern changes, this process is especially significant for gene regulatory regions and leads to changes in transcription level of appropriate genes. There are four PIWI-like proteins (PIWIL) in humans which are involved in embryonic stem cells development and promote precancerous stem cells proliferation. Many researchers report *piwil* genes transcription level changes in neoplasias, in particular, in testicular tumors.

We studied the influence of *piwil2* CpG island (CGI) methylation on its promoter activity in transiently transfected Tera-1 (testicular embryonic carcinoma) and A549 (lung adenocarcinoma) cell lines. The luciferase assay has showed a notable reduction of methylated promoter activity in both cell lines. Demethylation of CGI by 5-aza-2'-deoxycytidine and trichostatin A restored *piwil2* transcription inTera-1 other then A549 cell line.

Additionally, *piwil2* CGI methylation level was measured by methylation-sensitive high resolution melting (MS-HRM) analysis in testicular tumors (11 samples) and adjacent to tumor normal tissues. Also, *piwil2* transcription levels were determined in the same samples. There was no correlation between these two parameters in tumor and normal tissues. Absence of pronounced epigenetic regulation of *piwil2* transcription in testicular tumors could be due to expression of mRNA isoforms from alternative promoters, distant from CGI region.

In vivo and *in vitro* data obtained points to high tissue-specific manner of *piwil2* transcription: promoter demethylation appears to be a necessary but not sufficient condition for transcription. Probably, there is another expression regulation mechanism for *piwil2*, which is not connected with methylation level of CpG-rich promoter region.

The work was supported by RFBR grant 14-04-32314 and "Molecular and Cellular Biology" Programme of the Presidium of the Russian Academy of Sciences.
Keywords: epigenetics, methylation, CGI.

Epigenetic role of the nuclear factor NF-Y on inhibitor of DNA binding (ID) helix-loop-helix family genes in human embryonic carcinoma cells

M. Shahhoseini, F. Moeinvaziri, R. Favaedi, H. Gourabi
Department of Genetics, Royan Institute for Reproductive Biomedicine, Tehran, Iran

Epigenetic mechanisms such as incorporation of histone variants/ substitutes have been shown to play key roles in regulation of gene transcription. Among them, NF-Y (Nuclear Factor Y) is a helix-loop-helix histone substitute protein which specifically binds to the CCAAT box of the target genes and causes their regulation. The CCAAT box is one of the cis-regulatory elements present in eukaryotic promoter regions of numerous genes such as basic helix-loop-helix ID (Inhibitor of DNA binding) factors. The ID regulatory proteins have important roles in development, by inhibiting differentiation and stimulating proliferation. Regarding the critical roles of *ID* genes in development, the potential role of NF-Y transcription factor on these NF-Y-regulated genes was aimed in this study. For this respect, we looked

© 2014 The Authors. FEBS Journal © 2014 FEBS

into expression levels of *ID* genes in a human embryonic carcinoma cell line, named NT2/NTera2, before and after 7 days-induction of differentiation. Afterwards, NF-Y incorporation on the regulatory regions of *ID* genes was evaluated quantitatively using chromatin immunoprecipitation (ChIP) coupled with real-time PCR on chromatin extract of NTera2 cells before and after differentiation. The results showed a significant incorporation of NF-Y on the CCAAT regulatory regions of *ID* genes before induction of differentiation, whereas a reduction was observed in the midst of induction term. In addition, the coordination in gene expression profile of *ID* genes with NF-Y incorporation during proliferation and differentiation implies for the first time that the NF-Y transcription factor might play a central role in transcriptional regulation of *ID* genes in embryonal development.

Functional analysis of H2A ubiquitination in Polycomb repression

A. R. Pengelly, R. Kalb, J. Mueller
Chromosome and Chromatin Biology, Max Planck Institute of Biochemistry, Munich, Germany

To directly investigate the function of histone post-translational modifications in a metazoan, we use a system that permits the conditional replacement of the endogenous canonical histone proteins with mutated histone proteins in *Drosophila*. We investigated the role of histone modifications in Polycomb repression and recently showed that cells containing a histone H3-K27 point mutation fail to repress transcription of genes that are normally repressed by PRC2, the methyltransferase that modifies H3-K27. Here, we present our analysis on the role of histone H2A monoubiquitination in Polycomb repression. Unexpectedly, we found that repression of Polycomb target genes is maintained in cells containing mutant versions of H2A or H2Av that can no longer be ubiquitinated by PRC1-type complexes. This suggests that H3-K27 methylation but not H2A monoubiquitination is critical for maintaining Polycomb repression in Drosophila. We are currently investigating why H2A monoubiquitination is nevertheless essential for completion of embryogenesis and viability.

Keywords: development, histone modifications,, polycomb silencing.

Global DNA methylation evaluation and DNMT1 gene expression in thyroid neoplasia

I. V. Iancu[1], A. Plesa[1], A. Botezatu[1], I. Huica[1], G. Anton[1], D. Manda[2], A. Brehar[3], C. V. Badiu[3]
[1]*Molecular Virology, "Stefan S. Nicolau" Institute of Virology,* [2]*Research Laboratory,* [3]*Department of Endocrinology, "CI Parhon" National Institute of Endocrinology, Bucharest, Romania*

Introduction: Thyroid carcinoma is the most common endocrine malignancy worldwide. Thyroid cancer initiation and progression occurs through gradual accumulation of various genetic and epigenetic alterations. DNA methylation is an epigenetic modification which is catalyzed by DNA cytosine-5-methyltransferases (DNMTs) and occurs at the 5-position (C5) of the cytosine ring, within CpG dinucleotides. DNMT1 is responsible for the maintenance of DNA methylation patterns in mammals and plays a crucial role in the epigenetic control of gene expression. Recently many studies have reported the implications of global DNA hypomethylation in several cancer types but little is known about this epigenetic event in thyroid neoplasia. Study aims to investigate the relationship between global DNA methylation status and DNMT1 expression levels in several types of thyroid tumors.

Methods: For this purpose 26 patients who underwent thyroidectomy were enrolled and divided into the following three groups acording to histopathologically exam: 1–10 subjects with papillary thyroid carcinoma (PTC); 2–8 patients with follicular adenoma (FA) and 3–8 patients with nodular goiters (NG). DNA and total RNA were extracted from tissue samples (26 matched tumoral and their adjacent normal tissue as controls) using commercial kits. DNA global methylation levels were assesed in patients samples by measuring 5-methylcytosine (5-mC) levels using ELISA. DNMT1 mRNA levels were quantified by qRT-PCR (ABI). Statistical analysis was performed with GraphPad Prism 5.0.

Results: The obtained data showed that for all 3 groups the global DNA methylation levels were lower than that of controls. Moreover a significant lower level of 5-mC was found in PTC patients compared with adjacent normal tissue. ($P < 0.007$) Results did not reveal significant differences between groups regarding DNMT1 gene expression levels. For PTC samples DNMT1 mRNA levels were found decreesed compared with controls, a positive correlation between DNMT1 expressions and global DNA methylation was noted for this group of patients.($P < 0.001$) Global DNA hypomethylation may play a important role for thyroid neoplasia but more studies are needed in order to elucidate the involvement of this epigenetic modification in thyroid tumorigenesis.

HDAC inhibitors are potential regulators of tumor growth and tumor microenvironment

M. Maleszewska, A. Steranka, B. Kaminska
Laboratory of Molecular Neurobiology, Nencki Institute of Experimental Biology, Warsaw, Poland

Glioblastoma (GB) is one of the most difficult human malignancies to treat due to frequent dysfunctions of tumor suppressors and oncogenes, epigenetic aberrations, diffusive growth and changes in the tumor microenvironment. GB are abundantly infiltrated by microglia and peripheral macrophages that instead of developing anti-tumor immune responses, polarize into an anti-inflammatory phenotype and support invasion, angiogenesis and suppress the adaptive immunity. Recent evidence points to deregulation of histone modifying enzymes and aberrant epigenetic histone modifications in GB. The altered expression of histone deacetylases (HDACs) was detected in glioblastoma, but there was no systematic studies of neither expression or impact of selected HDAC inhibitors (HDACi) on glioma cells and microglia exposed to glioma.

Using immunofluorescence and Western blotting we found that VPA (valproic acid) and TSA (trichostatin A) increase histone H4 acetylation both in glioma and microglial cells. Treatment with TSA, but not VPA, affected viability of glioma cells. HDACi at non-cytoxic concentrations inhibited glioma-induced morphological changes of microglia, however only TSA inhibited upregulation of gene expression in activated microglia. The analysis of various HDAC gene expression revealed changes in the level of HDAC class II mRNAin microglia stimulated by glioma. These results suggest the role of HDAC class II in glioma pathology. We demonstrate the inhibitory effect of HDAC inhibitor on glioma growth and polarization of microglia into the proinvasive phenotype that points to a new prospect of therapeutic strategy based on direct modulation of tumor cells and its microenvironment.

Highly conserved ENY2/Sus1 protein binds to *Drosophila* CTCF and is required for barrier activity

A. Bonchuk, O. Maksimenko, O. Kyrchanova, V. Stakhov, A. Parshikov, P. Georgiev
Institute of Gene Biology, Moscow, Russian Federation

ENY2/Sus1 protein is highly conserved multifunctional protein that is component of the deubiquitinylation module of SAGA histone-acetyltransferase complex involved in transcription regulation and of TREX-2 complex involved in the mRNA export. Structures of ENY2/Sus1 within these complexes suggest that this protein serves as adaptor molecule, binding to either Sgf11 (in SAGA) or Sac3 (in TREX-2) using the same surface for these interactions and so cannot bind both partners simultaneously. Also the Drosophila homologue of ENY2/Sus1 protein interacts selectively with the zinc-finger domains of Su(Hw), this interaction is required for barrier activity of Su(Hw)-dependent genomic insulators (that prevents spreading of heterochromatin in the genome). Other *Drosophila* insulator protein dCTCF marks active promoters and boundaries of many histone H3K27 trimethylation domains associated with repressed chromatin. In particular, dCTCF binds to such boundaries between the parasegment-specific regulatory domains of the *bithorax* complex. In this study we demonstrate that the Drosophila ENY2 protein is recruited to the zinc-finger domain of dCTCF and is required for the barrier activity of dCTCF-dependent promoters and insulators. Inactivation of ENY2 by RNAi in BG3 cells leads to the spreading of H3K27 trimethylation and Pc protein at several dCTCF boundaries. Homologous model of Drosophila ENY2 protein structure has been created based on known structures of human and yeast homologues. Using molecular docking we found several possible conformations of interaction between ENY2 and dCTCF zinc-finger domain and confirmed this using GST-pulldown assay in vitro. According to protein docking results this interaction utilizes the same interface of ENY2 protein as its known partners Sgf11 and Sac3. We tested this proposition using coexpression of tagged ENY2 and Sgf11 together with dCTCF zinc-finger domain. Copurification assays revealed that these interactions are mutually exclusive, suggesting that ENY2 protein might not be involved in recruitment of the SAGA-complex, which is known to promote formation of the transcriptionally-active chromatin. The results suggest that evolutionary conserved ENY2 is responsible for the recruitment of an as yet unidentified complex that is essential for establishing a barrier between active and silenced chromatin domains.

Keywords: chromatin boundaries, chromatin insulator, polycomb silencing.

Histone deacetylase inhibitors as differentiation agents in breast cancer cells

H. Ismail[1], M. Bail[1], D. Laperrière[1], S. Mader[1,2]
[1]*Institute for Research in Immunology and Cancer, University of Montreal,* [2]*Biochemistry Department, University of Montreal, Montreal, QC, Canada*

Approximately two thirds of breast tumours overexpress estrogen receptor alpha (ERα) at the time of diagnosis. Antiestrogen therapy has been effective in blocking the proliferative effects of ERα, but unfortunately a significant proportion of patients will relapse due to resistance. Histone deacetylase inhibitors (HDACis) are a new class of anticancer agents with anti-proliferative activity. *In vitro*, HDACis have been shown to suppress ERα expression and are currently being tested in clinical trials in combination with antiestrogens for treatment of ERα-positive breast tumours. Here, we report that the HDACis Trichostatin A (TSA) and suberoylanilide hydroxamic acid (SAHA) abrogate expression of several luminal lineage transcription factors including ERα, FOXA1 and GATA3, all of which are known to regulate estrogen signaling and cell proliferation in MCF-7 breast cancer cells. As knockdown of FOXA1 reduces the expression of both ERα and GATA3, its suppression by TSA might contribute to loss of these transcription factors. Using gene expression microarrays, we observe that TSA treatment does not lead to increased expression of basal-like markers or of transcription factors controlling epithelial to mesenchymal transition. On the other hand, several markers of lactogenic differentiation, including the SREBF1-driven cholesterol biosynthesis pathway, are induced by TSA treatment *in vitro*. Consistently, we show reduced protein expression of ER, FOXA1 and GATA3 during lactation in the mouse mammary gland. In addition, markers of neuronal differentiation were also increased. We further show that chemical inhibition of the histone acetyltransferase P300 prevents the induction of SREBF1 expression and reverses the effects of TSA on ERα, GATA3 and FOXA1. This indicates that the effects of TSA are mediated via increased acetylation of protein substrates. Our study suggests that treatment of ERα-positive mammary cells by HDACis used in the clinic induces features of several differentiation pathways and contributes to its antiproliferative activity.

Histones acetylation modulates differentiation and neovascularization potential of fetal stem cells

F. Iordache[1], A. Constantinescu[1], E. Andrei[1], C. Curutiu[2], A. M. Grumezescu[3], G. Voicu[3], H. Maniu[1]
[1]*Fetal and Adult Stem Cell Therapy, Institute of Cellular Biology and Pathology "Nicolae simionescu",* [2]*Microbiology-Immunology, Faculty of Biology, University of Bucharest,* [3]*Faculty of Applied Chemistry and Material Science, Politehnica University of Bucharest, Bucharest, Romania*

The process of neovascularization is a complex process involving a series of interconnected steps leading to the formation of new blood vessels when vascular lesions occur in adult bodies. The major steps involved proliferation, chemotaxy, migration, adherence and differentiation of endothelial progenitor cells (EPCs) to the target situs, and their organization in vascular networks. Recent analysis of epigenetic changes showes that histone acetylation regulates pluripotency of EPCs and their differentiation capacity by controlling the expression of genes and transcription factors that are required for differentiation and neovascularization. To investigate the role of histone acetylation in regulation of neovascularization we used VPA (Valproic acid), a histone deacetylases (HDACs) inhibitor that mentained histone in an acetylated state. DNA intercalation with acridine orange and western blot analysis revealed that in the presence of VPA, histone H3 is acetylated at lysine 9, suggesting an acetylated state of chromatine. qRT-PCR data indicated that the expression of molecules involved in EPCs differentiation VE-cadherin, eNOS, VEGFR2, vWF and CD31 were decreased significantly after treatment with VPA. Furthermore flow cytometry assay revealed that at protein level the expression of surface markers CD31,

© 2014 The Authors. FEBS Journal © 2014 FEBS

CD105, VE-cadherin and VEGFR2 were inhibited whereas the expression of CD34 and CD45 remained unchanged, demonstrated that HDACs are involved in endothelial differentiation of progenitor cells. The proliferation of EPCs assesed by mesurements of telomerase activity and western blot analysis of PCNA showed a decreased proliferative potential, as well migration capacity assesed by wound-healing assay. Adherence capacity was also influenced by VPA, starting 12 hours after stimulation VPA has led to a decreased in adherence of EPCs. EPCs chemotaxis to anigogenic factors such as angiopoietin, VEGF, and SDF1α mesured in real time with xCELLigence system was stimulated by VPA. *In vitro* angiogenesis assay using Matrigel showed that in the presence of acetylated histones the number of capillary-like networks was reduced by up to 75%. Scanning electon microscopy photomicrographs showed that in the presence of VPA, EPCs lose the ability to form capilary networks on colagen scafolds, suggesting that histone acetylation inhibits the neovascularization process *in vitro*. Discovering the involvment of epigenetic mechanisms that regulate human vasculature development and differentiation will provide us greater insights into a variety of disorder, where the need of vasculatization is essential.

Identification of *Arabidopsis* KUMONOSU gene involved in DNA methylation and heterochromatin-associated silencing

Y. Ikeda[1,2], C. Becker[3], L. López González[1], M.-N. Pouch-Pélissier[1], R. Pogorelcnik[1], D. Weigel[3], O. Mathieu[1]
[1]*CNRS UMR6293 – INSERM U1103 – GReD, Aubiere, France,* [2]*Institute of Plant Science and Resources, Okayama University, Kurashiki, Japan,* [3]*Max Planck Institute for Developmental Biology, Tübingen, Germany*

In plants, multiple layers of epigenetic regulators are required for heterochromatin-associated silencing, including many repetitive sequences and transposable elements (Regal and Mathieu, Biochim Biophys Acta., 2011). However, the control mechanism of tissue specific heterochromatic silencing is still unknown.

Here, we report the new *Arabidopsis* gene affecting heterochromatin-associated silencing, *KUMONOSU* (*KUN*). We isolated *kun* mutant from the screening affecting transgene silencing. In *kun* mutant, not only transgene, many endogenous repetitive sequence and transposable elements were activated. Moreover, the expression of specific genic regions was also affected and DNA methylation level of many target genes was slightly decreased in the mutant. Interestingly, release of silencing of the reporter transgene was observed specifically in vascular tissues of *kun* mutant, which may indicate possible tissue-specificity in the regulation of heterochromatin silencing.

Impact of glucose and O-GlcNAc transferase on expression of Polycomb genes in breast cancer cells

E. Forma, P. Jozwiak, M. Brys, A. Krzeslak
Department of Cytobiochemistry, University of Lodz, Lodz, Poland

Cancer is not only genetic disease but it can arise also from epigenetic abnormalities. The results of epidemiological studies indicate that obesity or hyperglycemia may increase the risk of some cancers, including breast cancers. Moreover, high blood glucose seems to be an important factor of cancer progression. Recent studies suggest that O-GlcNAcylation which consists in addition of N-acetylglucosamine on serine or threonine residues of proteins may play a key role in the regulation of the epigenom in response to cell metabolic status. Two enzymes are responsible for cyclic O-GlcNAcylation: O-GlcNAc transferase (OGT), which catalyzes the addition of the GlcNAc moiety to target proteins and O-GlcNAcase (OGA) which, removes the sugar moiety from proteins. The results of recent studies suggest that OGT may link cell metabolic status with transcriptional repression caused by Polycomb proteins. Abnormal OGT expression and O-GlcNAcylation are features of breast cancer cells but their role in Polycomb-dependent gene regulation remains to be elucidated. In this study we investigated the effect of hipo- normo- and hiperglycemia conditions on expression of O-GlcNAc cycling enzymes, expression of Polycomb genes, i.e. EZH2, SUZ12, RING1B and BMI-1 as well as histone modification levels in breast cancer cells (MCF7, MDA-MB-231 and Hs578t) and non-tumorigenic epithelial mammary cell line (MCF10A). Moreover, the impact of glucose and OGT down-regulation by RNAi on expression of several Polycomb target genes involved in cell differentiation and epithelial mesenchymal transition was analyzed. The results showed significant glucose-dependent changes in mRNA and protein level of OGT, OGA, EZH2 and BMI-1 in breast cell lines. Significant glucose-dependent increase in EZH2 protein expression was especially evident in poorly differentiated breast cancer cells MDA-MB-231 and Hs578t, which show high invasive phenotype. Cells grown in high glucose showed decreased BMI-1 protein and H2A ubiquitinylation levels compared to cells grown in low glucose. OGT down-regulation caused decreased O-GlcNAcylation in cells and was correlated with reduced EZH2 protein level but not BMI-1 level. OGT interference influence expression of some Polycomb target genes. There was increased expression level of FOXC1 and CDH1 and decreased level of HOX10A in cells with OGT depletion. The results of our preliminary studies suggest direct link between aberrant O-GlcNAcylation which is a nutrient-responsive modification and EZH2-dependent repression in breast cancer cells.

MON-162
Impact of surfactants on soft wheat meiosis

A. Zhussupova, N. Omirbekova, Z. Zhunusbayeva
Molecular Biology and Genetics, Al-Farabi Kazakh National University, Almaty, Kazakhstan

Surfactants are broadly used in the national economy as active components of detergents, and in release of the products, based on synthetic and natural fibers. Oil and chemical industries, manufacture of construction materials also serve as important consumers.

A number of works is available on various biological effects and violations of structure and functions of organisms under synthetic surfactants, most of which depict biochemical changes. However, there is absolutely no data available on the possible genetic consequences.

The objective of our study is the comparative analysis of genetic toxicity of surfactants varying in their chemical nature at the level of chromosome violations in soft wheat microsporogenesis.

Kazakhstanskaya 3 and Shagala soft spring wheat varieties were used as the study material. The following non ionogenic surfactants: Triton X-100, Triton X-305, Twin 85, Twin 65 and Twin 20, frequently used in biological research, were chosen in a 1% concentration (with five hours treatment prior to sowing in the field). Seeds, processed by the distilled water, served as control. Pollen mother cells were temporally fixed in Carnoy solution, washed three times with 70% ethanol solution. Acetocarmine staining was used for estimation of chromosome aberra-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tions in wheat microsporocytes. Chromosome violations were considered in 13,280.00 cells under the light microscope with appropriate statistical processing.

The maximum number of chromosome violations in Kazakhstanskaya 3 is caused by Twin 85, Triton X-305, Twin 65, and Triton X-100 (29.2 ± 0.9%, 25.7 ± 0.9%, 25.6 ± 0.8% and 32.5 ± 0.7% respectively), rather than Twin 20 (19.54 ± 0.7%), with the difference reliable at 99% probability level and similar for Shagala; with up to 16 times higher general frequency in compare with the spontaneous level.

Mutations at metaphase I are represented by multi-, univalents, clumping of chromosomes (pycnosis), shift of the metaphase plate division spindle and overflowing of nuclear matter, anaphase I – lagging chromosomes, bridges and fragments, anaphase II – bridges with fragments, asynchronous fission, and nucleus free cells. At tetrad stage violations of both nuclear (dyads, triads, pentads and hexades) and cytoplasmic (changes of tetrad walls and absence of cytokinesis) nature are found.

It is possible that the increasing frequency of the aberrant cells in wheat gametes is associated with the surfactants collision of physiological processes occurring in a cell, resulting in disturbed enzymatic system, which in turn leads to the accumulation of chromosomal defects. Spindle violation might be caused by uneven growth of its fibers, due to which fast-growing threads form bends, resulting with the chromosomes delay in the equatorial part of the cell or impaired formation of daughter cells.

Keywords: meiosis, surfactants, wheat.

In silico study of drought and salt tolerance in wheat

A. Fujah-Yusuf[1,2], M. Labhilili[1], S. Cherkaoui[2]
[1]*Molecular Biology, National Institute of Agricultural Research,*
[2]*Biology, Mohammed V University-Agdal, Rabat, Morocco*

The in silico study of genes is an important step because it helps guide the interpretation of experimental results and suggest new experiments. Salt-tolerant candidate genes in wheat and other cereals include HKT, NHX, SOS, and HAK genes. Drought-tolerant candidate genes are DRG, DHN, DRF, DREB, etc. These genes were searched, identified and downloaded from the NCBI database. Comparative studies and analyses such as search for candidate genes' functions, search for protein domains, multiple sequence alignments, and phylogenetic tree construction as well as primers design were carried outusing bioinformatics tools. The RT-PCR primers associated with the candidate genes for the studied traits were designed as molecular markers to assist theprogram for improvement in cereals precisely in wheatvia marker-assisted selection.

Inhibition of DNA methylation alters chromatin organization, nuclear positioning and activity of 45S rDNA loci in cycling cells of *Q. robur*

V. Zoldos[1], V. Vičić Bočkor[1], T. Horvat[1], D. Barišić[2], Ž. Maglica[3]
[1]*Faculty of Science, Univeristy of Zagreb, Zagreb, Croatia,*
[2]*Friedrich Miescher Institute for Biomedical Research, Basel,*
[3]*Ecole Polytechnique Fédéral de Lausanne, Lausanne, Switzerland*

In *Quercus robur* there are two rDNA loci, the major (NOR-1) and the minor (NOR-2) locus. We aimed to deduce the transcriptional activity of the two rDNA loci in root tip cycling cells by

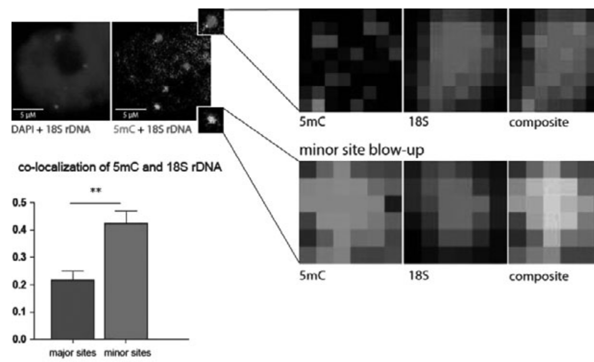

Fig. 1.

exhamining the position of rDNA loci in respect to the nucleolus, organizational patterns (topology) of rDNA chromatin in metaphases and interphases using light and electron microscopy, silver staining of NORs, epigenetic signatures of rDNA chromatin and the expression levels of 18S rRNA genes before and after treatment of root tips with the DNA methylation inhibitor 5-aza-2'deoxycytidine (5-aza-2'-dC). Our data indicates that in normal physiological conditions of *Q. robur* cells, a situation resembling nucleolar dominance is present where only rRNA genes within the NOR-1 locus are transcriptionally active and participate in the formation of the nucleolus. To investigate the role of the other, transcriptionally inactive NOR-2 locus, we induced its reactivation by treatment with 5-aza-2'-dC. We observed that a decrease in levels of DNA methylation at NOR-2 locus and an increase in total level of rRNA transcripts do not affect the contribution of this locus in nucleolar formation, suggesting its loss of function. In addition, we propose a correlation between rDNA chromatin topology, location of different rDNA fractions related to the nucleolus, epigenetic signature and the activity of rRNA genes within the active NOR-1 locus.

Keywords: DNA methylation, rDNA locus, transcriptional activity.

Integrative genome-wide analysis reveals novel pathways and transcription factors involved in non-small cell lung cancer drug resistance

D. Li
School of Life Science and Technology, Tongji University, Shanghai, China

Background: The mechanism of acquired drug resistance in non-small cell lung cancers (NSCLC) is poorly understood. The transcriptome and epigenetic signature associated with drug resistance, in particular, are not well-defined. We performed an integrative genome-wide analysis with the aim of identifying unique gene expression patterns, pathways, transcription factors (TFs), DNase I hypersensitive sites (DHSs), and enhancers involved in drug resistance.

Methods: We conducted RNA-sequencing (RNA-Seq) to examine differentially expressed genes and pathways, DNase I sequencing (DNase-Seq) to identify DHSs and infer TFs binding sites, and chromatin immunoprecipitation sequencing (ChIP-Seq) to locate H3K4me2 histone modification across enhancers in the gefitinib-resistant NSCLC cell line PC9R and its gefitinib-sensitive parental cell line, PC9.

Results: We discovered several genes and pathways, many of which are related to the epithelial-mesenchymal transition (EMT). We also identified differential distributions of both DHSs and enhancers and inferred TFs, which are closely associated

© 2014 The Authors. FEBS Journal © 2014 FEBS

with gene up-regulation in NSCLC gefitinib-resistant cells. Finally, we showed that drug-resistant cells exhibit an increased invasion ability and an up-regulation of EMT markers found in gefitinib-resistant lung cancer patients.

Conclusion: This integrative genome-wide analysis of genes, pathways, DHSs, enhancers, and TFs that are associated with acquired drug resistance may deepen our understanding of the mechanism underlying NSCLC drug resistance.

MATH-BTB domain protein AtBPM1 directly interact with DMS3, important component of RNA-directed DNA methylation in plants

N. Bauer[1], D. Leljak-Levanic[1], R. Vukovic[2], G. Razdorov[1]
[1]University of Zagreb, Zagreb, [2]University of Osijek, Osijek, Croatia

In *Arabidopsis thaliana*, the MATH-BTB (BPM) proteins comprise a small family of six members. BPMs act as substrate-binding adaptors for the Cullin3-based ubiquitin E3 ligase, and interect with a broad range of Ethylene response factor/apetala2 transcription factors and with homeodomain-leucine zipper transcription factor ATHB6 affecting fatty acid metabolism and abscisic acid signaling. We showed previously that AtBPM1, localizes predominantly in nucleolus of plant cells indicating a Cullin3 independent function. To further elucidate the molecular function of AtBPM1, we identified AtBPM1 binding and functional partners using tandem affinity purification and mass spectrometry. Different stress-related proteins were identified in AtBPM1 protein complexes such as Catalases CAT2 and CAT3, Nucleoside diphosphate kinase III, Glycine-rich RNA-binding proteins GRP7 and GRP8, MLP-like protein 423, Polyketide cyclase/dehydrase and lipid transport superfamily protein. Moreover, we have identified a set of DNA repair and chromatin remodeling proteins, such as Nucleosome assembly protein NAP1, Tudor-SN proteins, DNA-damage-repair/toleration protein DRT102, WD-40 repeat family protein/beige-related, Chromatin remodeling 34, DNA mismatch repair protein Msh6-1 as well as a known components of RNA-directed DNA methylation, defective in meristem silencing 3 DMS3 and RNA-directed DNA methylation 1 RDM1. Furthermore, direct interaction of AtBPM1 and DMS3 was confirmed by yeast two hybrid and pull down assays and DNA methylation in plants overexpressing AtBPM1 was reduced. These results, for the first time, links MATH-BTB proteins with DNA methylation and related mechanisms.

Keywords: chromatin remodeling, protein-protein interactions, RNA-directed DNA methylation.

Methylation analysis of selected genes associated with carcinogenesis: downregulation of APC, AR, GPX3, PTGS2, TIMP2, RASSF1 and DKK3 genes expression is regulated by hypermethylation

M. A. Lewandowska[1], K. H. Kaminska[1], J. Kowalewski[2]
[1]Molecular Oncology and Genetics, The F. Lukaszczyk Oncology Center, Department of Thoracic Surgery & Tumors, L. Rydygier Collegium Medicum, Nicolaus Copernicus University, Poland, [2]Department of Thoracic Surgery & Tumors, L. Rydygier Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

PNC (perinucleolar compartment), is a subnuclear structure forming in cancer cells. PNC prevalence (a percentage of cells containing at least one PNC) is correlated with higher grade and stage of breast cancer - is potential cancer biomarker. Previous studies have shown that increasing PNC prevalence positively correlates with PTB expression, the main component of the PNC structure. Therefore we hypothesized that the expression of other genes whose proteins are part of the PNC structure, and general tumor suppress genes may also vary in the cell lines PNC prevalence high vs. low cells.

Aim: Our first aim was to analyze the expression of several tumor suppressor genes including: APC, AR, DKK3, GPX3, PTGS2, RASSF1, TIMP2 Secondly, we evaluated whether DNA methylation is involved in regulating their expression.

Methods: We have evaluated gene expression using 2 fluorescence detection systems: SYBRGreen dye-based assay (reference gene MRPL19) and hydrolysis probe assays (reference genes PBGD and GAPDH). Methylation analysis for 16 tumor suppressor genes in prostate cancer cell lines with low (PC3), and high (PC3-M, PC3-M LN4) PNC prevalence and fibroblasts was performed using EpiTectMethylII PCR system based on detection of remaining input DNA after cleavage with a methylation-sensitive and /or methylation dependent restriction enzyme.

Results: We evaluated gene expression and methylation of 7 tumor suppressor genes. Interestingly, DKK3 expression was 20-fold lower respectively in PC3M, PC3MPro4 and PC3MLN4 compared to PC3 line and suitably more than 100-fold compared to fibroblasts. These lines are also characterized by increased level of methylation of the gene DKK3 (over 90%) as compared to PC3 and fibroblasts (below 1%). In addition, PTGS2 and RASSF1 expression was minimum 7.5 fold higher and 10-fold higher in VH10 versus all 4 prostate cancer cell lines and correlated with methylation below 1.5% in VH10 and 99% in PC3M for both gene. APC and AR gene expressions were both 2-fold lower in prostate cancer cell lines versus VH10. Methylation results are consistent with theirs expression ones: APC and AR were methylated in average 0.3% and 8.4%, respectively in VH10, whereas in PC3 LN4 and PC3M cells lines methylation for both genes was above 65% .

Methylation of glycosylation genes in cancer

A. Vojta[1], I. Samaržija[1], G. Lauc[2,3], V. Zoldoš[1]
[1]Department of Molecular Biology, Faculty of Science, University of Zagreb, [2]Genos Glycobiology Laboratory, [3]Department of Biochemistry and Molecular Biology, Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

Aberrant protein glycosylation is a well-documented and universal feature of malignant transformation as well as tumor progression. The intricate network of enzymes that carry out protein glycosylation is controlled by epigenetic mechanisms, which under physiological conditions integrate information from the environment and fine tune cellular metabolism. Glycosylation affects the function of extracellular and membrane proteins by incorporating sugars into their structure, making the carbohydrate moiety an integral part of the glycoprotein, which affects its function. Since glycoproteins are positioned at the interface between the cell and its surroundings, their involvement in all steps of tumor progression is unsurprising. We focused on the changes of epigenetic control in glycosylation-related genes, both the enzymes which directly modify protein molecules and regulatory proteins such as HNF1A, the master regulator of plasma protein antennary fucosylation. Publicly available methylation data was used to compare the epigenetic regulation of glycosylation-associated genes in cancer cells, matching healthy tissue and, when applicable, matching cell lines. Remarkably complete datasets involving hepatocellular carcinoma and lung cancer enabled us to identify the key differences between normal and malignant cells in the pattern of regulation of glycosylation, while the data on melanoma progression gave insight into the role of glycosyla-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tion in metastasis. This study will guide our further experimental work involving direct glycan analysis in liver tissue, which will be aimed to confirm the effect of epigenetic regulation of glycosylation genes on observed glycan structures.

Pediatric high-grade gliomas (pHGG) are histologically similar to high-grade gliomas of adults (aHGG), however they have different characteristics and molecular mechanisms involved in the progression and gliomagenesis.

Chromatin remodeling is of primary importance in regulating gene expression, apoptosis, DNA replication and repair. Dysfunctions in chromatin-remodeling mechanisms have been associated with disease development, and particularly, alterations in chromatin structure can lead to deregulated expression of tumor suppressor genes or oncogenes and cancer initiation.

Our analysis was focused on 3 molecular factors involved in chromatin remodeling pathway: H3.3, ATRX and DAXX. These three proteins colocalize in pericentric eterochromatin and the ATRX-DAXX complex is involved in the deposition of the H3.3 variant at heterochromatic regions of the genome and cooperate providing stability to the telomeres. Loss of ATRX or DAXX gene promote tumorigenesis through altered gene expression and genomic instability; in particular, their absence can lead to telomere instability and elongation of chromosomal endings, even in the absence of telomerase, and then through an alternative mechanism of telomeres' elongation (ALT).

The study was conducted on 83 pHGG cohort, with age range of 0–16, including: Glioblastomas (GBM), Peripheral Neuroectodermic Tumors (PNET), Pylocit Astrocytomas (AP) and Anaplastic Astrocytomas (AA).

ATRX, DAXX and H3.3 expression has been investigated at protein level by Immunohistochemistry (IHC), at genomic level through the analysis of messenger RNA by reverse transcription polymerase chain reaction (RT-PCR) followed by sequencing and mutational analysis for H3F3A and H3F3B. Furthermore, presence of ALT has been investigated by the Quantitative Fluorescence in situ Hybridization (Q-FISH) analysis.

In this work we evaluated the components of chromatin remodeling in high grade pediatric glial neoplasms to define a possible correlation between the presence of alterations of ATRX dAXX and H3.3 genes and histology, grading (WHO) and age at onset.

Novel regulatory elements of the 9p21 region: the role in breast cancer development

M. F. Baietti[1,2], J. Crowther[1,2], M. Fiers[1], A. Sablina[1,2]
[1]Center for the Biology of Disease, VIB, [2]Center for Human Genetics, KU Leuven, Leuven, Belgium

The 9p21 region, harboring the ARF/CDKN2A/B tumor suppressor locus, is known to be frequently deleted in breast cancer.

Integrated analysis of copy number alteration-expression revealed that 9p21 loss-of-heterozygosity (LOH) does not affect expression levels of the 9p21 tumor suppressor genes. This could be explained by the fact that all three genes are epigenetically silenced in breast cancer patients. On the other hand, the analysis of The Cancer Genome Atlas (TCGA) breast cancer dataset revealed that loss of the 9p21 region is associated with poor survival. Further interrogation of ENCODE data has revealed a disproportionate number of regulatory elements within the 9p21 region, suggesting their potential role in tumor suppression.

By applying circular chromosome conformation capture (4C), we examined the network of long range chromosomal interactions in primary human mammary epithelial cells and two breast cancer cell lines, MCF7 and MDA-MB134-VI. We identified chromosomal regions that physically interact with 9p21 regulatory elements. This allowed us to create a catalogue of genes, in which expression may be modulated by regulatory elements located in the 9p21 region. Strikingly, gene set enrichment analysis (GSEA) revealed that the identified set of genes significantly overlap with genes that are differentially expressed in breast cancer patients with 9p21 LOH. Using genome editing techniques we are generating isogenic cells targeted with a 9p21 deletion. These models will allow us to confirm the contribution of 9p21 regulatory elements to the regulation of the identified genes. Among the genes that become abnormally up-regulated due to loss of the 9p21 regulatory regions, we will also search for genes involved in known cancer-related pathways.

This study will provide an opportunity to unravel the link between genomic architecture, gene regulation and function to determine the role of regulatory elements in cancer development.
Keywords: 9p21, breast cancer, chromatin organization.

Nucleosome rearrangement as a feedback mechanism between DNA methylation and transcription factor binding

V. Teif[1], D. A. Beshnova[2], Y. Vainshtein[1], C. Marth[1], J.-P. Mallm[1], T. Höfer[1], K. Rippe[1]
[1]German Cancer Research Center, Heidelberg, [2]EMBL, Hamburg, Germany

During differentiation of embryonic stem cells, chromatin reorganizes to establish cell type specific expression programs. Here, we have dissected the linkages between DNA methylation (5mC), hydroxymethylation (5hmC), nucleosome repositioning and binding of the transcription factor CTCF during this process. By integrating MNase-seq and ChIP-seq experiments in mouse embryonic stem cells (ESC) and their differentiated counterparts with biophysical modeling, we found that the interplay between these factors depends on their genomic context. The mostly unmethylated CpG islands have a reduced nucleosome occupancy and are enriched in cell type-independent binding sites for CTCF. The few remaining methylated CpG dinucleotides are preferentially associated with nucleosomes. In contrast, outside of CpG islands most CpGs are methylated and the average methylation density oscillates so that it is highest in the linker region between nucleosomes. Outside CpG islands binding of TET1, an enzyme that converts 5mC to 5hmC, is associated with labile, MNase-sensitive nucleosomes. Such nucleosomes are poised for eviction in ESCs and become stably bound in differentiated cells where the TET1 and 5hmC levels go down. This process regulates a class of CTCF binding sites outside CpG islands that are occupied by CTCF in ESCs but loose the protein during differentiation. We rationalize this cell type dependent targeting of CTCF with a quantitative biophysical model of competitive binding with the histone octamer in dependence of the TET1, 5hmC and 5mC state.
Keywords: chromatin, DNA methylation, nucleosome.

Protective effect of lithium chloride on cytotoxicity of lead nitrate in non-adherent bone marrow cells

S. M. Banijamali, A. Rabbani-Chadegani
Biochemistry, Institute of Biochemistry and Biophysics, Tehran, Iran

The harmful effects of lead nitrate on the body have been well documented. It has been show that Lithium chloride, as an element that is used for clinical purposes, has significant protective effect on the cells treated with lead. Lead can damage all type of tissues especially blood and hematopoietic stem cells. Bone marrow is the most important tissue that hematopoiesis occurs in it. Therefore any toxic substance that disturbs this process can lead to various diseases such as anemia and cancers. In this study the protective effect of lithium against lead-induced cytotoxicity in mouse non-adherent bone marrow cells are investigated.

The cells were prepared from mouse femurs and cultured in the absence and presence of various concentration of lithium chloride or lead nitrate. Cell viability was quantified using trypan blue and MTT assays. Also Histones and high mobility group B (HMG B) proteins were extracted and analysed on SDS-PAGE and immunobloted. When the cells were first treated with 160 μM of lithium chloride for 3 h and then exposure to different concentrations of lead nitrate, lead-induced cytotoxicity was overcome. With exposure of non- adherent bone marrow cells to lead nitrate the content of HMG B and histone H1 on the gel was decreased as metal concentration increased. However, pretreatment of the cells with lithium chloride prevented proteins reduction. Western blot analysis against HMGB and histone H1 antibodies confirmed the results. This study suggests that we could take advantage from lithium chloride potential for medical purpose in reduction of lead undesirable effects.

Keywords: chromatin proteins, Cytoprotective effect, lithium chloride.

MON-174
Protein-DNA binding in the absence of specific base-pair recognition

D. Lukatsky
Chemistry, Ben Gurion University of the Negev, Be'er-Sheva, Israel

Until now, it has been reasonably assumed that specific base-pair recognition is the only mechanism controlling the specificity of transcription factor (TF)-DNA binding. Contrary to this assumption, here we show that nonspecific DNA sequences possessing certain repeat symmetries, when present outside of specific TF binding sites (TFBSs), statistically control TF-DNA binding preferences. We used high-throughput protein-DNA binding assays to measure the binding levels and free energies of binding for several human TFs to tens of thousands of short DNA sequences with varying repeat symmetries. Based on statistical mechanics modeling, we identify a new protein-DNA binding mechanism induced by DNA sequence symmetry in the absence of specific base-pair recognition, and experimentally demonstrate that this mechanism indeed governs protein-DNA binding preferences.

Keywords: Protein-DNA interactions, transcription regulation.

RARβ gene methylation in primary glioblastomas

E. I. Atli[1], R. Kalkan[2], S. Artan[3]
[1]Molecular Biology and Genetic, Acibadem University, Istanbul, Turkey, [2]Molecular Biology and Genetic, Near East University, Nicosia, Cyprus, [3]Eskişehir Osmangazi University Medical Genetic Department, Eskişehir, Turkey

Background: In our study, patients who have received a diagnosis of GBM response to treatment and survival the relationship between of the tumor suppressor gene methylation pattern RARβ is aimed to reveal. Other is the objective of our study, yet you find new areas of application MS-HRM method for use in the determination of the GBM samples. According to our information rarbeta for GBM patients in the literature that there is only one paper. So our group of patients RARβ methylation frequency in GBM world literature will form the basis.
Results: In our study, GBM was diagnosed 40 cases related to the tumor samples were studied Eskisehir Osmangazi University Faculty of Medicine, Neurosurgery Department by the operated and the Department of Pathology by histopathological examining.
Conclusions: GBM in 24 cases of 40 patients (60%) proportions of different quantitative methylation was determined of RARβ gene. Examples of 24 cases of the methylation rate according to our assessment of samples 3 of which 25% methylated, 5 were 50% methyl, 4-one 75% methylated and 12 cases 100% RARβ gene hypermethylation demonstrated. The mean survival time of the patients with methylation RARβ period of 19 months, and 15 months of nonmethylated is calculated as cases. Our case study 28 patients received treatment, the remaining 12 cases were not specified in the patient files of any treatment protocol. When statistically evaluated patients who received treatment with chemotherapy and radiotherapy of patients with a 25 month survival was determined. Patients who received radiotherapy alone or no treatment protocol was applied in cases between 15 and 20 months, a significant difference in survival has been observed. On the other hand, in response to retinoic acid mediated marker for chemotherapy to be RARβ. Chemotherapy, which may be important for resistance to retinoids.

Recognition of 5-methylcytosine and 5-hydroxymethylcytosine by methyl-directed restriction endonucleases

G. Sasnauskas, E. Zagorskaitė, V. Siksnys
Institute of Biotechnology, Vilnius University, Vilnius, Lithuania

DNA methylation is a covalent DNA modification that is abundant in most forms of life. 5-methylcytosine (5mC) and the recently discovered 5-hydroxymethylcytosine (5hmC) are involved in the epigenetic regulation of gene expression in eukaryotes. Bacterial methyl-directed restriction endonucleases (MD-REases) are promising molecular tools for the studies of 5mC and 5hmC distribution in eukaryotic genomes. Understanding the mechanism of modified DNA recognition by these enzymes might open new avenues for the design and improvement of methylation profiling tools.

We have focused on elucidating of molecular mechanisms of modified DNA recognition by two groups of MD-REases:

1 MspJI family enzymes that are specific for 5mC and 5hmC in various sequence contexts;
2 PvuRts1I family enzymes that recognize two 5hmC or glucosylated 5hmC nucleotides separated by ˜20 base pairs.

Structural comparison of DNA-binding domains of MspJI, AspBHI (both belong to the MspJI family), and PvuRts1I with known protein structures revealed similarities to the eukaryotic SRA (set and ring associated) domains that interact with 5mC and 5hmC-containing DNA. In the crystal structures the SRA domains flip out the modified cytosine base from the DNA duplex and position it within a protein pocket. MspJI, AspBHI and PvuRts1I endonucleases also have similar protein pockets, but direct evidence for base flipping by these enzymes is still missing.

We have employed chemical modification-based assays to detect base flipping by MD-REases and have performed mutational analysis of protein loops that may be involved in recognition of DNA nucleotides adjacent to the modified base. Our results indicate that DNA recognition mechanism employed by eukaryotic SRA domains is conserved among MspJI and PvuRts1I-like restriction enzymes: all these proteins employ similar structural elements for DNA binding and use base-flipping for the recognition of modified cytosine.

RNA mediated trans-activation: its therapeutic potential in anaplastic thyroid cancer

W. Arancio[1], S. I. Genovese[2], G. Pizzolanti[1], C. Giordano[1]
[1]*DiBiMIS, University of Palermo,* [2]*Palermo, Italy*

RNA mediated Trans-Activation is a proposed mechanism involved in the setting of the epigenetic state of chromatin.

It has been studied first in *Drosophila melanogaster* where it seems that at least some transcribed loci are marked as transcriptionally active by their own transcripts. This effect acts *in trans* and in some cases could give rise to a transgenerational paramutational-like effect.

This work studies the RNA mediated trans-activation in the light of one of its possible applications, specifically its use as a therapeutic strategy for the incurable and highly aggressive ATC (Anaplastic Thyroid Cancer). We explore the possibility to reactivate the Thyroid specific NIS (Natrium-Iodide Symport) via the expression of ncRNAs with sequence homology with transcripts from the NIS coding locus itself. The reactivation of NIS in ATC would make them susceptible to treatment with radioiodine. Preliminary data strongly suggest that we reached our goal.

This work suggests that RNA trans-activation is a conserved mechanism and it may be used in human to manipulate the gene expression.

Role of histone methylation in transcriptional repression of Ras-association domain family tumor suppressor, RASSF8

I. Pratha, A. Kumarasamy, S. Mahalingam
Department of Biotechnology, Indian Institute of Technology Madras, Chennai, India

Ras proteins are well-known for its critical role in cell proliferation. "Ras-association domain containing family" (RASSF) proteins are non-enzymatic Ras effectors which comprises of ten members. RASSF members are predominantly identified as tumor suppressors and downregulated by promoter hypermethylation in cancers. One such member, RASSF8 is involved in maintenance of adherent junctions. It is interesting to note that the downregulation of RASSF8 was observed in many cancers despite insignificant promoter hypermethylation suggesting a novel mechanism regulating RASSF8 function. Hence, we aimed to understand the mechanism by which RASSF8 is downregulated in cancers. Treatment of MCF-7 cells with 5-aza deoxycytidine, a demethylating agent results in unaltered the RASSF8 expression which indicated the possibility of other epigenetic marks regulating RASSF8 expression. Interestingly, BIX-01294, an inhibitor of G9a, a histone methyltransferase increased the RASSF8 expression in MCF-7 cells. G9a is a histone methyltransferase (HMT) which catalyse mono- and di-methylation of Histone H3 at Lysine9 residue. Subsequently, a well-known member of HMT, SUV39H1 catalyse trimethylation of H3K9 leading to chromatin condensation resulting in transcriptional repression. Over-expression of G9a and SUV39H1 downregulates RASSF8 promoter activity. Experiments with RASSF8 promoter deletion constructs using reporter assays identified the region between −350 and −266 to harbour the repressor element. Further Chromatin immunoprecipitation confirmed the occupancy of Histone H3, H3K9me2, and H3K9me3 in the same region in RASSF8 promoter. Together, our data implicates histone methylation independent of DNA methylation in transcriptional regulation of RASSF8.

Role of Sp1 in butyric acid-induced HIV-1 gene expression

K. Imai, K. Ochiai
Microbiolog, Nihon University School of Dentistr, Tokyo, Japan

The ability of human immunodeficiency virus-1(HIV-1) to establish latent infection and its re-activation is considered critical for the progression of HIV-1-associated diseases. Accumulating evidence has indicated that histone acetylation and deacetylation regulates HIV-1 gene expression. The bacterial metabolite butyric acid has been shown to be a potent inhibitor of histone deacetylases (HDACs), leading to transcription of HIV-1

© 2014 The Authors. FEBS Journal © 2014 FEBS

proviruses. We previously demonstrated that butyric acid-producing bacteria in the vaginal and oral cavities and gut can strongly induce histone acetylation and HIV-1 replication from latently infected cells by inhibiting HDAC; thus, [Editor1] co-infection with anaerobic bacteria is an important risk factor for progression of AIDS. However, the molecular mechanism by which butyric acid activates HIV-1 gene expression is not well understood. In this study, we found that Sp1 binding sites are considerably involved in butyric acid-mediated activation of HIV-1 gene expression as indicated by the results of a luciferase assay using HIV-1 long terminal repeats (LTRs) of various mutants. Sp1 knockdown by small interfering (si) RNA and the Sp1 inhibitor mithramycin A inhibited the effects of butyric acid. Furthermore, we observed that cAMP response element-binding (CREB)-binding protein (CBP) was involved in butyric acid-induced Sp1-dependent HIV-1 gene expression. A chromatin immunoprecipitation assay analysis revealed that Sp1 and HDAC1 are present in the HIV-1 LTR promoter in TZM-bl cells and dissociate from the promoter concomitantly with the association of acetylated histone H3 and CBP upon butyric acid stimulation. Furthermore, siRNA knockdown of Sp1 resulted in decreased recruitment of CBP to the promoter. These results suggest that butyric acid stimulates HIV-1 promoter activity through the inhibition of Sp1-associated HDAC activity and recruitment of CBP to the Sp1 sites on HIV-1 LTR. Our findings suggest that Sp1 should be considered as a therapeutic target in new anti-viral therapies against HIV-1 infection aggravated by butyric acid-producing bacteria.

Keywords: HIV/AIDS, butyric acid, HDAC.

Sequences proximal to the HCF-1 cleavage site are novel binding sites for O-GlcNAc transferase to facilitate HCF-1 glycosylation and proteolysis

T. Bhuiyan, V. Kapuria, P. Waridel, W. Herr

Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland

O-GlcNAc transferase (OGT) is a cellular glycosyltransferase that modifies a large number of proteins by the addition of a sugar molecule, N-Acetylglucosamine, to serine or threonine residues in the form of O-linked-beta-N-acetylglucosamine (O-GlcNAc). One of the most extensively glycosylated proteins is the human Host cell factor-1 (HCF-1), a transcriptional co-regulator of cell cycle progression.

We have recently shown that OGT not only glycosylates, but also proteolytically cleaves HCF-1 at six sites during protein maturation. OGT's unusual dual role for HCF-1 is believed to link cellular nutrient levels to cell cycle progression. However, how these two post-translational modifications –glycosylation and proteolysis– are regulated and coordinated with each other, is currently unknown.

We have performed mutational analyses of sequences proximal to the HCF-1 cleavage site and combined mutants of OGT in our cellular or in vitro assays. We have identified an HCF-1 sequence that contains a cluster of novel glycosylation sites. This sequence has a high affinity for OGT and augments substrate glycosylation and proteolysis. A dissection of the two OGT activities further shows that glycosylation of the OGT–binding sequence is not required for proteolysis. Thus, we provide evidence for a novel OGT–binding sequence that efficiently recruits OGT to facilitate glycosylation and proteolysis of HCF-1.

Keywords: Epigenetics, Glycosylation, O-GlcNAc transferase.

Significance of DNA methylation in regulation of hypoxia-inducible factor -3α expression in colorectal cancer

A. Rawuszko-Wieczorek[1], K. E. Bujnicka[1], K. Horbacka[2], P. Krokowicz[2], P. P. Jagodziński[1]

[1]Biochemistry and Molecular Biology, Poznan University of Medical Sciences, Poznan, [2]Department of General and Colorectal Surgery, Poznan University of Medical Sciences, Poznań, Poland

Introduction: Colorectal cancer (CRC) is the most frequent gastrointestinal malignancy. The development of solid tumors, including CRC, is associated with hypoxic conditions as a result of immense proliferation of tumor cells. Main adaptive response that allow cells to adjust to changed environment is hypoxia-inducible factor -α (HIF-α), which is an oxygen-sensitive component of the HIF-1 transcription factor. There are three isoforms of HIF- α subunit: HIF- 1α, HIF- 2α and HIF- 3α. HIF- 1α and HIF- 2α share similar protein structure and may bind together with HIF-β subunit to activate HIF-dependent gene transcription. HIF3- α, on the other hand, act as a weak transcription factor and is reported to suppress HIF-1α or HIF-2α-mediated gene expression. Relatively little is known about regulation of *HIF-3α* gene expression in CRC. Presence of CpG island within promoter region of *HIF-3α* prompted us to investigate it role in colorectal tumorigenesis. DNA hyper or hypomethylation of gene regulatory sequences alter expression of cancer related genes in CRC.

Materials and Methods: Using real time PCR and western blotting we determined *HIF3-α* expression in primary colorectal cancer and histopathologically unchanged colorectal tissue from the same one hundred patients with respect to patient survival. DNA methylation level within promoter region of analyzed gene was evaluated using bisulfite sequencing and high-resolution melting analysis (HRMA). We also assessed the effect of DNA methyltransferase inhibitor, 5-Aza-2'-deoxycytidine (5-dAzaC), on *HIF-3α* in HCT116 and DLD-1 colon cancer cells under hypoxic and normoxic conditions.

Results: We found significantly lower HIF3-α mRNA and protein level in primary colorectal tissue than in histopathologically unchanged colorectal tissue. Moreover, Kaplan-Meier analysis revealed a benefit of high HIF-3α protein level in cancerous tissue in patient survival compare to low HIF-3α protein level. The reduced *HIF3-α* expression was also preliminary correlated with increased DNA methylation in the CpG island of the *HIF3-α*. Additionally we observed that 5-dAzaC significantly increased *HIF3-α* expression level in HCT116 cancer cells under hypoxic conditions, whereas under normoxic neither DNA methylation nor changes in expression level were observed.

Conclusions: Our findings present that *HIF-3α* is decreased in CRC and high HIF-3α protein level in cancerous tissue might be prognostic factor for CRC. Additionally, initially observed methylation-induced epigenetic silencing of *HIF3-α* may facilitate better understanding the mechanism of hypoxia response.

SMRT sequencing defines the sequence requirements for the positioning of base J into DNA

H. van Luenen[1], P. A. Genest[1], W. Zhao[1], S. Jan[1], L. Baugh[2], T. Clark[3], S. Turner[3], J. Korlach[3], P. Myler[2,4,5], **P. Borst**[1]
[1]The Netherlands Cancer Institute, Plesmanlaan 121, 1066 CX Amsterdam, The Netherlands, [2]Seattle Biomedical Research Institute, 307 Westlake Ave N, Seattle, WA 98109-5219, USA, [3]Pacific Biosciences, 1380 Willow Road, Menlo Park, CA 94025, USA, [4]Departments of Medical Education & Biomedical Informatics, [5]Global Health, University of Washington, Seattle, WA 98195, USA

Some T's in nuclear DNA of trypanosomes and *Leishmania* are hydroxylated and glucosylated to yield base J (β-D-glucosyl-hydroxymethyluracil)(Gommers-Ampt et al., Cell, 1993). Base J replaces 1% of T in the Leishmania genome and is only found in telomeric repeats (99%) and in regions where transcription starts and stops (1%) (Van Luenen et al., Cell 2012). This highly restricted distribution must be co-determined by J-Binding Proteins (JBPs) 1 and 2 that catalyze the initial step in J synthesis, the hydroxylation of selected T-residues in DNA. To determine the DNA sequences recognized by JBP1/2, we used SMRT sequencing of DNA segments inserted into plasmids grown in *Leishmania tarentolae*. We show that SMRT sequencing recognizes base J in DNA and that the signal generated is characteristic and DNA context dependent. *Leishmania* DNA segments that normally contain J also pick up J when present in the plasmid, whereas control sequences do not. Even a segment of only 10 telomeric (GGGTTA) repeats is modified in the plasmid. This modification requires JBP2, as it does not occur in JBP2 null cells. We show that J spreads from the plasmid insert into adjacent plasmid sequences. We find a consensus sequence for J insertion of T-(N)12-A and infer that JBP1 is able to bind to J and then hydroxylate a T at position +13 (but not −13) on the complementary strand, explaining the unusual modification of the (GGGTTA)n repeats in which only the second T is modified and the unusual kinetics of JBP1 binding to J-DNA (Heidebrecht et al., JACS, 2012). We present a speculative model for the *de novo* J insertion and spreading involving G-quadruplets.

Keywords: DNA modification, Telomeres, TET/JBP1.

Solubilization of huntingtin aggregates: success lies with a combinatorial effort, rather than a singular target

A. K. Bhadra, I. Roy
Biotechnology, National Institute of Pharmaceutical Education & Research (Niper, S.A.S.Nagar), S.A.S.Nagar, Mohali, India

Protein misfolding is a common motif recurring in many neurodegenerative disorders. Proteins containing long, homopolymeric stretches of glutamine are especially prone to misfolding which results in their aggregation, causing diseases like Huntington's disease (HD) and various ataxias. Increased oxidative stress, cellular toxicity and impairment of many cellular pathways have been well documented in HD. Strategies like the use of osmolytes, ubiquitination and activation of autophagy have shown some success in inhibiting aggregation of mutant huntingtin (mhtt). A better understanding of the various players will help in devising a more rational and comprehensive solution. Here, we show that glycerol3-phosphate dehydrogenase (Gpd1), a key enzyme in the glycerol synthesis pathway, plays a unique and pivotal role in regulating the expression of silent information regulator-2 (Sir2), a major histone deacetylase, in a yeast model of HD. Absence of Gpd1 showed significant increase in Sir2 expression, which could not be reversed even on supplementing these cells with Gpd1. Increased expression of Sir2 correlated with solubilization of mhtt. Gene expression analysis showed marginal upregulation of chaperones and High-osmolarity glycerol (HOG) pathway genes in Δ*Gpd1* cells. Interestingly, even when Sir2 activity was inhibited by nicotinamide, solubilization of mhtt remained high in Δ*Gpd1* cells. This led us to discover the third component of this multifactorial response, viz. tailless complex polypeptide (Tcp1), one of the subunits of cytosolic chaperonin Tcp1-ring complex (TRiC). The expression of Tcp1 was found to be significantly higher in Δ*Gpd1* cells, where Sir2 expression and solubility of mhtt were high. It has been reported that prior acetylation and methylglyoxal (MGO) mediated glycation of αA-crystallin enhances its chaperone activity {*Biochim Biophys Acta* 1832; 195–203 (2013)}. Coimmunoprecipitation of Tcp1 with acetylated lysine and MGO antibodies showed Tcp1 to be hyperacetylated as well as glycated in Δ*Gpd1* cells. This increased its chaperonin activity, leading to higher solubilization of mhtt. Thus, in addition to Sir2 activity, enzymatic and non-enzymatic modifications of Tcp1 are responsible for increased solubilization of mhtt. As expected, oxidative stress level and toxicity were reduced in these cells. Overall, we propose a novel role for Gpd1 in regulating Sir2 expression and its downstream effectors like Tcp1, by facilitating the enzymatic and non-enzymatic modifications of the chaperone.

Keywords: chaperonin, glycation, protein aggregation.

Spatial interaction of CpG islands in the interphase nucleus

A. Gavrilov[1], E. Gushchanskaya[1], S. Ulyanov[1], O. V. Iarovaia[2], A. Artemov[3], S. V. Razin[2]
[1]Group of Genome Spatial Organization, [2]Laboratory of Structural and Functional Organization of Chromosomes, Institute of Gene Biology RAS, [3]Faculty of Bioengineering and Bioinformatics, Lomonosov Moscow State University, Moscow, Russian Federation

Using 4C-seq, we characterized the genome-wide patterns of spatial contacts of several CpG islands (CGIs) located on chromosome 14 in cultured chicken lymphoid and erythroid cells. We observed a clear tendency for the spatial clustering of CGIs present on the same and different chromosomes regardless of the presence or absence of promoters within these CGIs. Accordingly, we observed preferential spatial contacts between the Sp1 binding motifs and other GC-rich genomic elements, including the DNA sequence motifs capable of forming G-quadruplexes. On the contrary, an anchor placed in a gene/CGI-poor area formed spatial contacts with other gene/CGI-poor areas on chromosome 14 and other chromosomes but not with GC-rich elements. These results corroborate the two-compartment model of the spatial organization of interphase chromosomes and suggest that the clustering of CGIs constitutes an important determinant of the 3D organization of the eukaryotic genome. Using ChIP-seq, we mapped genome-wide the CTCF deposition sites in the chicken lymphoid and erythroid cells that were used for the 4C analysis. We observed a good correlation between the density of CTCF deposition sites and the level of 4C signals for the anchors located in CGIs but not for an anchor located in a gene desert. It is thus possible that CTCF contributes to the clustering of CGIs observed in our experiments.

This work was supported by the Russian Science Foundation (grant 14-14-01088).
Keywords: 4C, CpG island, genome 3D organization.

Specific epigenetic code in crested newt spermatogenesis

L. Buribasa
University of Bucharest, Bucharest, Romania

An exciting challenge in developmental biology field is to decipher the molecular mechanisms involved in cellular differentiation and to understand the processes that control and regulate genes expression. The study of nuclear molecular architecture during gametogenesis represents one approach toward deciphering the molecular organization and function of the eukaryotic chromatin. As spermatogenesis progresses, there is a widespread reorganization of the haploid genome followed by extensive DNA compaction. It is becoming increasingly evident that the dynamic composition of chromatin plays an important role in the activities of enzymes and in the processes that act upon it.

In order to gain an insight into mechanisms controlling histone hyperacetylation/histone replacement during spermiogenesis, we have investigated in vivo effect of TSA on *Triturus cristatus* spermatogenesis. We focused our investigations on the dynamics of chromatin structure after treatment with trichostatin A (TSA), a histone deacetylase inhibitor. Ultrastructural and molecular analysis of the newt testicular tissue after TSA treatment indicated a major chromatin remodelling in sperm nuclei, evidenced by chromatin decompactation and the absence of sperm-specific proteins. Thus, histone deacetylation could be interpreted as an early signal of histone replacement by highly basic sperm-specific proteins a process tightly linked to nuclear condensation. The analysis of the electrophoretic profiles of DNA restricted with MspI/HpaII isoschisomere enzymes showed a global DNA demethylation in the TSA-incubated testicular tissue. ChIP assay and Immunocytochemistry (ICC) with specific antibodies to histones modifications (H4 hyperacetylation, H2A ubiquitination, H3K9 methylation) evinced a modulation of the chromatin structure during spermatogenesis that requires changed patterns of histone proteins and histone modifications which contribute to restructuring of chromatin. Some of these epigenetic modifications are involved in genomic imprinting.

Stearoyl-CoA desaturase regulates sirtuin 1 activity in skeletal muscle

A. Dziewulska[1], P. Dobrzyn[2], A. Pyrkowska[1], J. M. Ntambi[3], A. Dobrzyn[1]
[1]Laboratory of Cell Signaling and Metabolic Disorders, [2]Nencki Institute of Experimental Biology, Warsaw, Poland, [3]Departments of Biochemistry Nutritional Sciences, University of Wisconsin-Madison, Madison, WI, USA

Recent studies indicate that epigenetic modifications such as histone methylation and acetylation are essential for the regulation of lipid-mediated metabolic pathways and energy metabolism. The introduction of such modifications and the balance between acetylation and methylation are crucial for gene expression. NAD-dependent deacetylase sirtuin-1 (SIRT1) affects histone H3 lysine 9 acetylation status and therefore contributes to epigenetic gene silencing. The aim of our study was to elucidate whether stearoyl-CoA desaturase 1 (SCD1), an important control point in lipid and insulin signaling, affects the activity of SIRT-1 in skeletal muscle. Our study showed that the level of histone H3 K9 acetylation is significantly reduced in skeletal muscle with diminished Scd1 expression and increased in muscle with Scd1 overexpression. Opposite results were obtained when methylation profile of H3K9 was analyzed. The level of Sirt1 gene expression was decreased in skeletal muscle of mice with muscle-specific overexpression of Scd-1 (mSCD-1 Tg). Also, SIRT1 protein content was affected in SCD-1 knockout mice. Importantly, skeletal muscles of SCD-1 KO mice are extremely insulin sensitive and have high metabolic rate. Muscle-specific overexpression of SCD-1 severely impairs glucose tolerance in mice fed high-fat diet compared to wild-type mice. Our results show that SCD1 influences histone H3 acetylation/methylation ratio via SIRT1 activity and suggest that modifications in H3K9 may contribute to insulin sensitivity regulation in skeletal muscle and susceptibility to insulin resistance development.

Terminin protein DTL/MOI and trimethylguanosine synthase TGS1 are required during *Drosophila* oogenesis

G. P. Grezal[1], I. M. Boros[1,2]
[1]Department of Biochemistry and Molecular Biology, Szeged University, [2]Institute of Biochemistry, Biological Research Center, Hungarian Academy of Sciences, Szeged, Hungary

The Drosophila CG31241 is a bicistronic gene, which encodes a telomere protein DTL/MOI and the RNA trimethylguanosine synthase TGS1, required for sn/snoRNA biogenesis. Telomere protection and sn/snoRNA 5' cap hypermethylation are essential processes in Drosophila. In the absence of DTL chromosome ends become the targets of DNA break repair enzymes and form fusions which will lead eventually pupa lethality. The absence of the TGS1 protein causes failures in TMG cap modification of the sn/snoRNAs and results in small disc phenotype and late L3 larval lethality.

Despite the sever disturbance of these basic functions, the DTL/TGS1 double mutants are able to survive until the late L3 larval stage, which raises the possibility that the maternal product could rescue the animals so far. Using transgenic animals, carrying somatic line specific DTL or TGS1 expression system, we examined the role of DTL and TGS1 in the germline. Loss of TGS1 resulted in decreased fecundity and fertility, dysfunctional production and maturation rate of the eggs. Additionally, the dorsal appendage and the length of the eggs were decreased. In the ovary, higher occurrence of apoptosis at the 8th developmental stage, and aberrant nurse cell nuclear morphology was detected.

In germline specific DTL mutant ovaries, the number of the nurse cells was altered, ring channels showed aberrant morphology and the developing cyst could not leave the germarium. These morphological observations showed unstable penetrance as expected from the stochastic nature of the uncapped telomere behavior.

Our observations suggest that both DTL and TGS1 are necessary for proper oogenesis. Our data suggest that similarly to somatic cells in the germline DTL is involved in chromosome end protection. On the other hand the phenotype of TGS1 mutants suggests that its function is required for proper chromatin formation.

The developmental dynamics and disease potential of random monoallelic gene expression

A.-V. Gendrel[1], M. Attia[1], C.-J. Chen[1,2], P. Diabangouaya[1], N. Servant[2], E. Barillot[2], E. Heard[1]
[1]Genetics and Developmental Biology Unit, [2]Bioinformatics, Biostatistics and Computational Systems Biology of Cancer Unit, Institut Curie, Paris, France

The majority of autosomal genes in mammals are believed to be expressed from both alleles. However a number of imprinted genes exist and an increasing number of loci may be expressed monoallelically in a random fashion, similarly to the X chromosome in females where one of the two Xs is randomly chosen for inactivation. Classical examples of random monoallelic expression (RME) include members of large gene families, such as immunoglobulins and odorant receptors. Single copy genes have also been reported to show RME but the *in vivo* relevance and underlying mechanism of this pattern of expression remain poorly understood. We have identified a series of RME genes in clonal neural progenitor cell lines derived from highly polymorphic male and female mouse embryonic stem cells. We show that RME occurs during differentiation and, once established, the monoallelic state can be highly stable and DNA methylation does not always account for this extremely stable epigenetic state. We also demonstrate that RME of single copy genes can occur even in the absence of DNA sequence polymorphism *in vivo*. Several of the genes we identify play important roles in development and have been implicated in human autosomal dominant disorders, including the *Eya* genes and the BOR syndrome. We propose that monoallelic expression of such genes might contribute to the fine-tuning of the regulatory pathways they control during development, but in the context of a mutation on one allele, this may predispose such genes to loss of function in a proportion of cells and thus contribute to disease.

The histone composition in neutrophils of patients with community-acquired pneumonia and chronic obstructive pulmonary disease

L. Muravlyova, V. Molotov-Luchanskiy, D. Klyuyev, R. Bakirova, D. Ludmila, E. Kolesnikova
Biochemistry, Karaganda State Medical University, Karaganda, Kazakhstan

The aim of the work was to study the histone composition in neutrophils of patients with community-acquired pneumonia and chronic obstructive pulmonary disease (COPD). Patients were divided into 3 groups. 29 patients with COPD, moderate severity, mixed form (emphysematous and bronchial), exacerbation, respiratory insufficiency of grade 2 were included in first group. 20 patients with community-acquired pneumonia and COPD were included in second group. 16 patients with community-acquired pneumonia were included in 3-d group. The control group consisted of 32 healthy persons. All patients and healthy subjects had received the full information on probable inconveniences at the blood sampling before giving their written informed consent.

For neutrophils separation we used the standard procedure. Purity and viability were assessed by trypan blue dye exclusion. The samples of >85% neutrophilic leukocytes with >90% viability were obtained. In neutrophils of all subjects the composition of histone H1, H2A, H2B, H3, H4 were detected following the protocol of L.Markusheva et al (2000).

The results obtained have demonstrated the significant increasing of H1 histone (by 88%, $p < 0.05$), total fraction of H2A, H3,H4 histones (by 61%, $p < 0.05$) and H2B histone (by 56%, $p < 0.05$) in neutrophils of COPD patients in comparison with healthy persons.

The increasing of H1 histone (by 36%, $p < 0.05$), total fraction of H2A, H3, H4 histones (by 2 times, $p < 0.001$) and H2B histone (by 5.5%, $p < 0.001$) was determined in neutrophils of patients with community-acquired pneumonia in comparison with healthy persons.

The decreasing of total fraction of H2A, H3,H4 histones (by 82%, $p < 0.05$) in neutrophils was established in patients with community-acquired pneumonia and COPD in comparison with healthy persons.

Our results have demonstrated opposite changes of histone composition in neutrophils of patients with community-acquired pneumonia and COPD in comparison with results of first and second groups of patients. Such kind of histone decomposition could be connected with different epigenetic mechanisms.

Keywords: Histones, neutrophils, pneumonia.

The RSC remodeling complex as essential component of the remodeler network for chromatin remodeling at the yeast PHO5 promoter

S. Musladin[1], D. Hlevnjak[1], N. Krietenstein[2], P. Korber[2], **S. Barbaric**[1]
[1]Laboratory of Biochemistry, Faculty of Food Technology and Biotechnology, Zagreb, Croatia, [2]Molecular Biology, Adolf-Butenandt-Institut, University of Munich, Munich, Germany

The yeast *PHO5* promoter was the first and still is one of the best characterized examples of a massive chromatin transition that is an absolute prerequisite for transcription activation. The comprehensive search for involved cofactor(s) revealed a complex network of five remodelers from all four major subfamilies in yeast. We showed recently that RSC, the only remodeling complex essential for viability in yeast, is a major component of this network. In continuation we wished to fully clarify the role of RSC, especially if it is essential for *PHO5* promoter opening. We applied new strategies for more complete RSC ablation than the previous inactivation of its catalytic subunit Sth1 by the temperature sensitive degron allele $Sth1^{td}$. First, we combined the deletion of *RSC2*, encoding a subunit of a major RSC complex isoform, with inactivation of $Sth1^{td}$ during *PHO5* induction at the nonpermissive temperature (37 °C). Second, we constructed a double mutant containing a Tet-Off-promoter driven *STH1* gene and the *rsc2* deletion allele and examined chromatin remodeling upon physiological induction at 30 °C. In contrast to the $sth1^{td}$ single mutant, both double mutants achieved no appreciable *PHO5* promoter opening even after prolonged induction suggesting an essential role of RSC complex. The same was true for a *PHO5* promoter variant activated by the non-physiological activator Gal4, i.e. the RSC effect is not specific for induction through PHO signaling nor for promoter activation by the native activator Pho4. We also demonstrated that RSC activity is not only essential for opening but also for the maintenance of open chromatin at the *PHO5* promoter.

Keywords: chromatin remodeling, gene transcription, yeast PHO5.

The SUMO-specific isopeptidase SENP3 regulates the SET1/MLL methyl transferase complex and controls fate of human mesenchymal stem cells

A. Nayak[1], S. Viale-Bouroncle[2], C. Morsczeck[2], S. Müller[1]
[1]Institute of Biochemistry II, University Hospital Building 75, Goethe University Medical School, 60590 Frankfurt am Main, [2]Universitätsklinikum Regensburg, Regensburg, Germany

Cellular differentiation processes critically rely on the control of gene expression programs. The ubiquitin-like SUMO system regulates gene expression, but the molecular insights in this process are incomplete. Here we show that the SUMO-specific isopeptidase SENP3 controls H3K4 methylation by regulating histone-modifying SET1/MLL complexes. SET1/MLL complexes are composed of a histone methyltransferase and the regulatory components WDR5, RbBP5, Ash2L and DPY-30. MLL1/2 complexes are particularly important for the activation of *HOX* genes and contain menin as an additional component. We demonstrate that SENP3 is associated with MLL1/2 complexes and catalyzes deSUMOylation of RbBP5. This is required for activation of a subset of *HOX* genes, including the developmental regulator *DLX3*. In the absence of SENP3, the association of menin and Ash2L with the *DLX3* gene is impaired leading to decreased H3K4 methylation and renders chromatin less permissible for transcription as was evident by reduced recruitment of active RNA polymerase II. Importantly, the SENP3-DLX3 pathway dictates osteogenic differentiation of human mesenchymal stem cells thus delineating the importance of balanced SUMOylation for the epigenetic control of gene expression programs. This study also esbalished novel molecular mechanism that governs the associataion of of histone methyl transferase complex to its target gene.

MON-193
The transcriptional co-repressor Ski localizes in the pericentromeric region of mitotic chromosomes, regulating the expression of targeted genes at the early G1 phase of the cell cycle

C. Cappelli[1], U. Urzua[1,2], J. Toro[1], E. Cassanova[1], C. Vargas[1], G. Donoso[1], S. Rivas[1], K. Orostica[1], R. Verdugo[1,2], R. Armisen[1,2], **K. Marcelain**[1,2]
[1]Biomedical Sciences Institute, Faculty of Medicine, Universidad de Chile, [2]Center for Cancer Research and Treatment, Facultad de Medicina, Universidad de Chile, Santiago, Chile

Ski is a nuclear protein that is part of transcriptional co-repressor complexes containing histone deacetylase activity. Ski is expressed throughout the cell cycle, reaching its highest levels in mitosis. In order to establish the role of Ski during mitosis, a detailed characterization of Ski localization during this stage of the cell cycle in mouse embryonic fibroblasts (MEFs) was performed. It was observed that Ski was forming pairs of well defined dots in the pericentromeric region of some mitotic chromosomes. Giving that Ski is a transcriptional co-repressor, we hypothesized that during mitosis, Ski was targeting pericentromeric genes for silencing after mitosis is completed, i.e., early G_1. Thus, we compared overall gene expression in MEFs knock out for Ski (*Ski-/-*) and MEFs *Ski-/-* expressing an ectopic protein (Ski-/-_hSKI), synchronized at early G_1. Total RNA was extracted and Cy3/Cy5 labeled cDNA was hybridized to a mouse exonic oligonucleotide array (MEEBO). The analysis revealed that 265 genes were differentially expressed in the presence of Ski at G_1. Among these, 161 were repressed and 104, overexpressed. Although there was a homogeneous coverage of the probes on the different chromosomes and along each chromosome, 75 (47%) out of 161 repressed genes were located in the first 50 Mb of chromosomes and 65% of them on chromosomes 9, 13 and 17. The most repressed genes corresponded to three pericentromeric genes (*mmp-3, mmp-10, mmp-13*) located in a cluster at chromosome 9. Microarray results were validated by real-time RT-PCR assays and the occupancy of Ski on the promoter of *MMP3* gene was confirmed by a chromatin immunoprecipitation (ChIP) assay. The presence of Ski correlated with a decrease in H3Lys9 acetylation and an increase in H3Lys9-3me levels in mitotic and G_1 cells, and at chromosome level, acetylation of histone H3 at Lys9 (H3Lys9) was decreased in regions that co-localized with Ski. These results suggest that Ski direct the mitotic bookmarking of pericentromeric genes, repressing the expression of those genes at the beginning of the next cell cycle (early G_1). Supported by National Counseling of Science and Technology (CONICYT) Grant FONDECYT 1120222 and Chilean Ministry of Education Grant STIPAS MECESUP 0717.

The yeast HMG proteins Hmo1 and Nhp6 exert a differential stimulatory effect on ATP-dependent nucleosome remodeling activity

M. Hepp, R. Amigo, **J. L. Gutierrez**
Bioquimica y Biologia Molecular, Universidad de Concepcion, Concepcion, Chile

ATP-dependent chromatin remodeling activity plays a relevant role in several aspects of DNA metabolism, including transcriptional regulation. Several protein complexes harboring this activity have been described, with the yeast SWI/SNF (switching defective/sucrose non-fermenting) as the founding member. These complexes can facilitate the access of DNA-interacting proteins to their cognate sequences by transiently exposing stretches of nucleolsomal DNA, by mobilizing histone octamers in *cis* (sliding) or evicting them towards naked DNA stretches or histone chaperones. A number of elements have been described as factors stimulating or affecting ATP-dependent nucleosome remodeling, such as certain histone modifications, DNA sequences and also High Mobility Group (HMG) proteins. Little is known about the influence of HMG proteins on the activity of these complexes and no studies have addressed the influence of different types of yeast HMG proteins on the activity of complexes such as ySWI/SNF. In order to gain insight into these aspects we performed different types of *in vitro* nucleosome remodeling assays, observing that the yeast HMG proteins Nhp6A, Nhp6B and Hmo1 are able to stimulate SWI/SNF sliding activity. However, only Hmo1 stimulates other biochemical outcomes of ySWI/SNF activity and binding of this complex to the nucleosome. Different experimental approaches were used to explore the mechanism by which Hmo1 stimulates ySWI/SNF acitivity. These stimulatory effects exerted by Hmo1 appear to be dependent on the C-terminal tail of this protein, as a deletion mutant of this protein, lacking the last 35 residues, is not able to stimulate SWI/SNF activity nor binding to the nucleosome. Stimulation of SWI/SNF action by Hmo1 was also observed *in vivo*. In a *hmo1* deletion mutant of *Saccharomyces cerevisiae*, changes in mRNA levels of SWI/SNF target genes were observed. In the absence of Hmo1, nucleosome positioning on promoter regions of these genes and physical association of ySWI/SNF to these regions were also affected. Supported by grant CONICYT, FONDECYT/Regular 1130818.
Keywords: chromatin remodeling, HMG proteins, SWI/SNF.

Theoretical study of DNA methylation in nucleosome

I. Ivani[1], G. Portella[2], M. Orozco[1]
[1]IRB Barcelona, Barcelona, Spain, [2]Department of Chemistry, Cambridge University, Cambridge, UK

Cytosine methylation in DNA is a major epigenetic signal, and plays a central role in propagating chromatin status during cell division, regulation of gene expression, transcriptional regulation, maintenance of genomic stability and in the development of cancer (1). However the mechanistic links between DNA methylation and histone methylation are poorly understood.

We have performed biased molecular dynamics (MD) simulations and free energy and mesoscopic calculations of the base flipping on histone-bound DNA, free DNA (linker DNA) and curved DNA of the same sequence. By using umbrella sampling techniques we were able to calculate the energy of flipping cytosine base on different positions on histone-bound DNA and compare it with experimentally observed values (2). The simulation results give us an atomistic view on the methylation favourable spots, energetics involved and the influence of DNA binding to the histone protein.

Free energy calculations indicate that methylation disfavours cytosines, which are placed in the region of the minor groove that is pointing away from histones, while it favours CpG step placed in the region with the major groove pointing away from the protein. This confirms the proposed mechanism of methylation of a CpG step with base flipping done in the major groove (1). These findings also correspond with recent study done in our group on nucleosome binding affinity and cytosine methylation (3).

The study of nucleosome-like curved DNA suggested that the curvature of DNA is responsible for energetically more favourable base flipping at a CpG step in the nucleosome rather than in the linker DNA of the same sequence. Our results suggest that physical properties of DNA might play a significant role in epigenetic regulatory mechanisms and might influence nucleosome formation.

VHH-based universal histone binding domains: novel tools for a different look on and manipulation of chromatin

D. Jullien[1,2], J. Vignard[1], Y. Fedor[1], A. Olichon[3], M. Crozatier[4], B. Salles[1], B. Ducommun[2], G. Mirey[1]
[1]Research Centre in Food Toxicology, Toxalim UMR1331, INRA & Université Paul Sabatier Toulouse 3, [2]Institut des Technologies Avancées du Vivant USR3505, CNRS, [3]Centre de recherche en Cancérologie de Toulouse, INSERM, [4]Centre de Biologie du développement, Université Paul Sabatier Toulouse 3, Toulouse, France

The engineering of histone binding domains, non-endogenously encoded by the genome, therefore without intrinsic cellular functions, constitutes a major issue in the epigenome editing and visualization. Using an immune library of VHHs (or nanobodies®), the monomeric antigen-binding domain of camelidae heavy chain antibodies, we made several rounds of phage display affinity selection against histone H2AX extracted from chromatin. Among the selected clones, we identified several VHHs, referred to as chromatibodies, presenting the unique ability to specifically recognize chromatin, from human to yeast, in cell immunostaining. In vitro, chromatibodies bind core histones, exhibiting a marked preference to the H2A-H2B dimers compared to the histone monomers and the H3-H4 tetramer. Expressed as a GFP fusion in human cells or in drosophila, chromatibodies retain their ability to specifically bind chromatin, and similar to conventional core histone-GFP probes, allow non-invasive live chromatin imaging. However, unlike H2B-GFP, fluorescent chromatibodies exhibit a high exchange mobility on chromatin, as revealed by FRAP experiments. By varying the nature and the number of chromatibodies modules linked to GFP, we have been able to modulate the mobility and specificity of the probe to chromatin. We therefore have developed a family of genetically encoded affinity reagents to chromatin that potentially have the ability to carry any modifying activities to the nucleosomes, a capability which could be used to manipulate epigenetic marks at the scale of the whole genome.

A new pathway for embryo implantation: the uterine LEFTY2/AKT/SGK1 axis

M. Salker[1,2], F. Lang[1], J. Brosens[2]
[1]*Department of Physiology, Eberhard-Karls-University of Tübingen, Tübingen, Germany,* [2]*Reproductive Health, Warwick Medical School, Coventry, UK*

Background: Pregnancy requires attachment of the embryo to a receptive endometrium followed by implantation. Endometrial SGK1 is rapidly induced in response to the post-ovulatory rise in progesterone but expression is transiently down-regulated during the window of implantation. Previous analysis of mid-secretory endometrial samples revealed that SGK1 is deregulated in unexplained infertility, although the underlying mechanisms are not understood.
Methods: AKT inhibitor screening & functional analysis *in vitro* and *in vivo*, protein analysis, qRT-PCR, embryo transfer and histological assessment uterine sections.
Findings: In endometrial cells, an increase in SGK1 activity is reciprocated by a decrease in AKT phosphorylation, pointing towards a homeostatic mechanism that balances the activities of these related kinases. To test this hypothesis, we screened 9 AKT inhibitors in Ishikawa cells, an endometrial epithelial cell line, and identified 2 AKT inhibitors (INH-III and V) that strongly enhanced endometrial SGK1 phosphorylation. Transient flushing of the non-pregnant uterus in mice with AKT inhibitors INH-III or V strongly upregulated SGK1 phosphorylation. Moreover, AKT inhibition *in vivo* down-regulated the E3 ubiquitin-protein ligase Nedd4-2, thereby enhancing epithelial sodium channel (ENaC) expression on the luminal epithelium. To assess the impact of AKT inhibition on implantation, uteri of pseudopregnant female mice were flushed with INH-III or vehicle prior to embryo transfer. Ten cultured blastocysts were transferred to a single uterine horn and the implantation sites counted after 3 days. We show that transient exposure of the uterus lumen to INH-III prior to embryo transfer significantly reduced the number of implantation sites compared to vehicle control. Finally, we demonstrate that recombinant LEFTY2, an important inhibitor of the NODAL signalling pathway produced by decidualizing stromal cells, induces a reciprocal increase and decrease SGK1 and AKT phosphorylation, respectively; and is sufficient to block implantation in mice.
Conclusion: We provide evidence that the activities of SGK1 and AKT are homeostatically balanced in the endometrium of human and mice. LEFTY2-dependent AKT inhibition enhances SGK1 phosphorylation and abolishes embryo implantation by perturbing uterine fluid handling. Our results indicate that the LEFTY2/AKT/SGK1 axis is a promising target for fertility control as well as for the prevention of implantation failure, especially in the context of assisted reproductive technologies.

A set of LRR-RLK genes quantitatively regulate root growth under iron-limited conditions in Arabidopsis

S. Satbhai, W. Busch
Gregor Mendel Institute of Molecular Plant Biology, Vienna, Austria

Plant development is highly plastic and is profoundly influenced by the environment. The sessile life style of plants has led to the development of diverse mechanisms required for the perception and response to fluctuating environments. Drought, changing temperatures, lack of sufficient nutrients, exposure to toxic minerals, and soil compaction are just a few examples of the environmental constraints that roots are exposed to during plant growth and to which they respond by altering their developmental program. We used a geographically diverse set of 450 natural accessions of *Arabidopsis thaliana* to identify genes that quantitatively regulate root growth responses to Iron (Fe) deficiency using genome wide association mapping. We identified more than 20 genomic loci that were statistically highly significantly associated with changes of root growth rate upon iron deficiency. Among genes in proximity of these associations, a cluster of 3 *Leucine-rich repeat receptor-like protein kinases* (*LRR-RLK*) genes and a kinase gene showed strong signatures of epistatic interactions. Each of the single mutant lines of these signaling genes displayed a significant root growth rate reduction on iron deficient media but not on full media, showing that this gene cluster is involved in growth regulation under iron limited conditions. Due to their tissue specific expression pattern, we hypothesize that these 4 genes are coordinating growth responses in different tissues of the root. We are currently testing this hypothesis and exploring the epistatic interactions of these genes and their alleles.

A two loci genetic incompatibility leads to offspring respiratory deficiency within the Saccharomyces cerevisiae species

J. Hou, A. Friedrich, J. Schacherer
Université de Strasbourg/CNRS, Laboratoire de génétique moléculaire, génomique et microbiology UMR 7156, Strasbourg, France

Understand the molecular basis of how reproductive isolation evolves within a same species offers great insight into the patterns of genetic differentiation as well as the onset of speciation. Previously, we examined the landscape of post-zygotic reproductive isolation within the *Saccharomyces cerevisiae* species by analyzing a large number of crosses among genetically diverse strains, and identified chromosomal rearrangements as the major cause leading to the observed cases of reduced offspring viability. By contrast, genetic incompatibility results from epistatic interactions between diverged genes remained undetected, indicating that this type of mechanism is probably rare and might have a modest effect to the offspring viability under permissive laboratory con-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ditions. To further our understanding of the prevalence of genetic incompatibility relative to the onset of reproductive isolation in this species, we selected 30 crosses that are compatible (offspring viability >90%) on standard laboratory media (YPD), and scored their offspring viability in the presence of different conditions (e.g. carbon sources, temperature, chemicals). One cross between a clinical isolate and the laboratory reference strain S288c was found to be incompatible, showing reduced offspring viability of 75% on media containing non-fermentable carbon sources (e.g. glycerol and ethanol). Using bulk segregant analysis strategy, we mapped the regions and genes that are involved in the incompatibility. We performed allele replacements and confirmed that interactions between incompatible alleles result in respiratory deficiency. This study demonstrates the first example of genetic incompatibility related to specific ecological environment in the *S. cerevisiae* species.

Additional sex comb-like 1 and Nmyc controls alveolar epithelial cell formation during mouse embryonic development by Retinoic acid signaling

S. T. Moon, S. J. Um
Mollecular Biology, Sejong University, Seoul, Korea

Retinoic acid (RA) plays a pivotal role during lung development at late gestation. RA plays important roles in cell-to-cell communications. Asxl1 has been identified as an interacting protein of RA receptor (RAR) and functions as either co-activator or repressor in a cell type-specific manner. To investigate physiological functions of Asxl1, we generated Asxl1-null mice. Homozygous Asxl$^{-/-}$ embryos died shortly after birth, respiratory failure and remarkably decreased the expression levels of several epithelium markers. To identify how Asxl1 might regulate lung epithelial cell, we compared mRNA expression profiles in lung from E18.5 Asxl1$^{-/-}$ mice and wild-type littermates. One of the altered up regulation genes is Nmyc, which encodes a factor that down regulate by RA. Furthermore, there is an overlap in gene expression in the Asxl1$^{-/-}$ mcie and Nmyc overexpression TG mice lung. To identify as these data, Nmyc and target gene expression validate at E18.5 lung samples. To demonstrate that the Nmyc induction upon Asxl1 knock down, we performed the Asxl1 knock down in human lung carcinoma cell lines A549 in normal medium condition. In this cancer cell line, knock down of Asxl1 resulted that increased Nmyc expression. Additionally, we found that RARa repressed the transcription activity of Nmyc promoter. Overall, our data suggest that RA combined with Asxl1 is essential for lung epithelial cell development, which may be critical for air breathing at birth.

Adverse glucocorticoid effect on angiogenesis is associated with Akt/mTOR pathway in vitro

E. T. Korgun[1], A. Ozmen[1], G. Unek[1], D. Kipmen-Korgun[2], Z. Avcil[2], I. Mendilcioglu[3]
[1]*Histology and Embryology,* [2]*Department of Biochemistry,* [3]*Department of Obstetrics and Gynecology, Akdeniz University Medical School, Antalya, Turkey*

Glucocorticoids have been used during pregnancy for several reasons but overexposure to glucocorticoids may have adverse effects. Despite the widespread use of dexamethasone and other steroids in clinical practice, it's still not known how proangiogenic factors and their receptors are affected from glucocorticoid exposure. Therefore, we aimed to investigate the effect of glucocorticoid exposure on VEGF, PIGF, VEGFR1 and VEGFR2. We also investigated whether glucocorticoid effect on angiogenesis mechanisms is Akt/mTOR pathway dependent or not. HUVECs were incubated with synthetic glucocorticoid, Triamnicinolone Acetonide (TA). TA administration led to a decrease in VEGF and VEGFR1 expression at mRNA and protein levels and an increase in VEGFR2 protein expression. PIGF protein expression was unaffected by TA treatment but mRNA expression levels were decreased dose dependently at 48 and 72 hours incubation. Phospho-Akt expression was unaffected, but phospho-p70S6K and phospho-4EBP1 expression was decreased time and dose dependently. According to Matrigel analysis, vascular network forming capacity was decreased time and dose dependence of TA. In summary, we observed that glucocorticoids have negative effects on angiogenesis mechanisms, which was dependent on the alterations of cellular and soluble angiogenic protein and mRNA levels and their respective vascular network forming capacities in an Akt/mTOR pathway dependent manner.

Keywords: Akt/mTOR, angiogenesis, glucocorticoids.

An unique N-glycosylation in Drosophila BMP-type ligand Screw contributes to a robust BMP morphogen gradient in embryogenesis

P. Tauscher, O. Shimmi
Institute of Biotechnology, University of Helsinki, Helsinki, Finland

Nature exhibits an amazing variety of species. However, despite this immense diversity of animals, their development is controlled by common genetic mechanisms, which are widely conserved among metazoan phyla. One very well studied example for such highly conserved molecules are Bone Morphogenetic Proteins (BMPs), which belong to the TGF-β family. Three BMP-type ligands have been identified in *Drosophila* – Screw (Scw) and Glass bottom boat (Gbb), which are BMP5-8 type ligands, and Decapentaplegic (Dpp), a BMP2/4-type ligand. It has been considered that the *scw* gene evolved by gene duplication from *gbb*, and that it is exclusively found in higher Diptera [1]. Both, Scw as well as Gbb form a functional unit with Dpp [2, 3]. While Scw:Dpp heterodimer is the primary ligand for dorsal-ventral patterning in the early embryo [2], Gbb:Dpp heterodimer is crucial for crossvein development of the pupal wing [3]. Additionally, in both contexts a conserved kind of transport mechanism is acting, which is crucial for proper signalling outcome [2–4]. A further indication for the conserved mechanism during embryogenesis and crossvein formation is that Scw can rescue *gbb* mutant phenotypes in the wing. Intriguingly, *vice versa*, Gbb is not able to recover *scw* mutant phenotype in the early embryo [1]. Taken together, these facts raise the question of what is the fundamental difference that causes the differing signalling outcome of Scw and Gbb?

In the course of this study we are focusing on the differential N-glycosylation of highly conserved signalling molecules and how these modifications might be utilized for species- and context specific signalling.

Analysis of human and rabbit metallothioneins by Brdicka reaction and mass spectrometry

M. Zalewska[1], S. Krizkova[2,3], E. Sieradzka[1], K. Tmejova[2,3], M. A. Merlos Rodrigo[2,3], D. Hynek[2,3], V. Adam[2,3], R. Kizek[2,3], H. Milnerowicz[1]
[1]Department of Biomedical and Environmental Analysis, Wroclaw Medical University, Wrocaw, Poland, [2]Central European Institute of Technology, Brno University of Technology, [3]Department of Chemistry and Biochemistry, Faculty of Agronomy, Mendel University in Brno, Brno, Czech Republic

Metallothioneins (MTs) form a large family of evolutionarily conserved low-molecular-weight proteins (~6 kDa), found in practically all life forms, in vertebrates, invertebrates, fungi and even in plants. MT plays a special role in maintaining the homeostasis of metals essential for the proper functioning of the human body, including Zn, Cu. MT is also responsible for detoxification of heavy metals such as Cd and Hg and removal of free radicals. Mammalian MTs were separated into two charge-separable isoforms, designated as MT fractions 1 and 2. The six amino acids of rabbit MT sequence show marked differences compared with the sequences of other mammalian MTs. The biological significance for this difference remains unclear.

The present study demonstrates an analytical approach of employing two detection techniques: Brdicka reaction and matrix-assisted laser desorption/ionization - mass spectrometry analysis (MALDI-MS) to characterize MTs from human and rabbit liver.

By MALDI-MS, rabbit and human MT were identified and additionally to monomers of MTs (~6 kDa), which are the major peaks in mass spectrum, small signals from the dimers of MTs were also observed, which are present both in human and rabbit MT.

During MT analysis by Brdicka reaction, changes in signals - RS_2Co (−1.25V which represents current response of MT complex with components of Brdicka electrolyte), Cat1 (−1.35V) and Cat2 (−1.48V) correspond to hydrogen evolution from the supporting electrolyte catalyzed by the MT - were observed. Concentrations of MT – 0.025, 0.5 and 0.1 mg/ml were analyzed. With decreasing MT concentration, RS2Co and Cat signals decreased and shifted to more positive potential. Signals Cat1 and Cat2 are more exposed with decreasing MT concentration. Character of the mentioned MT signals changed with different MT concentrations. The best signal for human MT was observed in concentration 0.025 mg/ml and for rabbit MT in concentration 0.05 mg/ml.

Methods used in this report allow MTs identification, permit to quantify the purity and content of its isoforms, and allow studying its quantification and polymerization.

Brk regulates wing disc growth in part via repression of Myc expression

N. Doumpas[1,2,3], M.-R. Romero[3], E. Blanco[3], B. Edgar[1], M. Corominas[3], A. Teleman[2]
[1]ZMBH, [2]DKFZ, Heidelberg, Germany, [3]IBUB, Barcelona, Spain

The biological and molecular mechanisms, which regulate tissue size, represent an essential but unresolved problem in developmental biology. The main question is how developing growing tissues know when they have reached their correct final size and therefore should stop growing. The developing wing of Drosophila melanogaster is one model system that has been extensively used to address this question. One signaling pathway that strongly influences wing tissue size is the TGFß pathway, which is activated by Dpp – a gradient morphogen member of the TGFβ family growth factors. Flies lacking Dpp in the wing have extremely small wings, whereas overactivation of the Dpp pathway leads to excessive tissue overgrowth, clearly indicating that Dpp signaling is required to support tissue growth and also that the size of the wing correlates with the activity of the Dpp pathway. Dpp promotes growth via repression of the transcription factor Brinker. Although the transcriptional targets of Brinker that control the patterning of the wing, like vg, salm and omb, are known, the transcriptional targets and processes for cell growth and proliferation are not yet fully elucidated. In this project, a genome-wide approach was used to identify Brinker transcriptional targets, performing a ChIP-Seq of endogenous Brinker from wing imaginal discs. I identified the growth regulator Myc as a target of Brinker and showed that myc together with the microRNA bantam explain a significant fraction of the growth inhibition caused by Brinker. This work sheds light on the mechanisms by which Dpp signaling controls tissue growth.

Cell cycle analysis of neural progenitors in the developing ferret neocortex

M. Turrero García, W. Huttner
Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

The evolutionary expansion of the neocortex reflects an increase in neurogenesis, which in turn is due to increased numbers and rounds of cell division of cortical progenitors. The length of the cell cycle is known to be an important parameter determining the proliferative versus neurogenic potential of cortical progenitors. Here, we have studied the length of the individual cell cycle phases of the various progenitor populations in the developing neocortex of a gyrencephalic mammal, the ferret (*Mustela putorius furo*), in order to gain further insight into possible causes underlying neocortical expansion.

Progenitor types were identified by immunofluorescence for Pax6 and Tbr2. These two transcription factors are sequentially expressed by cortical progenitors, in correlation with their progressive restriction towards a neurogenic fate. We identified an abundant progenitor population positive for both of these markers, found in all germinal zones during neurogenesis. We propose these progenitors to be capable of transit-amplification and to include proliferative intermediate progenitors. These Pax6- plus Tbr2-positive progenitors would thus have the potential to expand the progenitor pool and the total number of neurons of gyrencephalic brains.

The length of each cell cycle phase of the four different cortical progenitor populations (Pax6+Tbr2−, Pax6+Tbr2+, Pax6−Tbr2+, Pax6−Tbr2−) was determined by cumulative EdU labeling of postnatal day 1 (P1) ferrets. The greatest difference between these

© 2014 The Authors. FEBS Journal © 2014 FEBS

progenitor types was in the length of their S phase, suggestive of differences in their proliferative versus neurogenic potential. Unexpectedly, and in contrast to previous observations in other animal models, we found little variation in G1 phase length.

In addition, to complement the EdU labeling data, a live imaging method in ferret organotypic brain slice culture was established. Cells in the developing neocortex were labeled with a GFP-expressing adenovirus in order to follow their cell cycle and cell division and to study different progenitor types and their lineages.

MON-207
Characterization of second heart field cardiac progenitor cells in the developing heart

M. Rammah, R. Kelly
IBDML, Marseille, France

Cardiac progenitor cells of the second heart field (SHF) contribute to the poles of the elongating embryonic heart. Failure or perturbation of second heart field development leads to congenital heart defects. Recent studies have provided initial evidence of how distinct regions of the definitive heart are pre-patterned in the progenitor cell population. In particular, the myocardium at the base of the aorta and pulmonary trunk were shown to be prefigured in the outflow tract (OFT), where *Tbx1* has been demonstrated to be crucial for the population of progenitor cells giving rise to subpulmonary myocardium. On the basis of this observation, we investigated the molecular and genetic mechanisms underlying heterogeneity in cardiac progenitor cell population, in particular the *Tbx1*-independent subpopulation that give rise to the future subaortic myocardium. Using the *A17-Myf5-nlacZ-T55* (*T55*) enhancer trap transgene which is expressed in the superior wall of the OFT and the future subaortic myocardium, we investigated the differences in expression pattern, signaling inputs and spatio-temporal pre-patterning of the future subaortic and subpulmonary myocardial progenitors. Our results indicated that the *T55* transgene defines a distinct sub-domain of progenitors within the SHF, specifically in the anterior part of the SHF. We demonstrated that this subpopulation is mainly not derived from the *Hoxb1*-expressing progenitors that contribute to the inferior wall of the OFT and subsequently to the myocardium at the base of pulmonary trunk. We also showed that part of the *T55* sub-domain, located in the most cranial region of the anterior SHF, does not express TBX1, thus most likely being the subaortic myocardial progenitors. Moreover, our preliminary results revealed that *Tbx1*-dependent and independent subpopulations of progenitor cells are characterized by different transcriptional signature and temporal specification; where cells from subaortic myocardial progenitors differentiate earlier than the subpulmonary myocardial progenitors. The molecular mechanisms underlying such differences are currently under investigation. Altogether, this study will provide insights into how cardiac progenitor cells are pre-patterned to prefigure clinically important regions of the definitive heart.

Colour pattern formation in zebrafish

A. Singh, U. Schach, C. Nüsslein-Volhard
Genetics, Max Planck Institute for Developmental Biology, Tübingen, Germany

Colour patterns are a striking feature of animals; they evolve rapidly and play an important role in natural as well as sexual selection. It has been proposed that colour pattern formation in

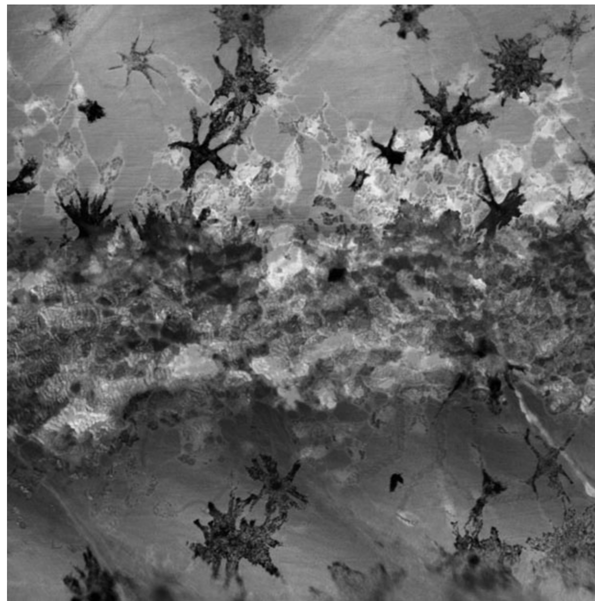

Fig. 1.

adult vertebrates depends on Turing-type interactions between pigment cells, however little is known about the actual developmental mechanisms underlying the complex and prolonged ontogeny of this important adult feature. Zebrafish (*Danio rerio*) owe their name to a repetitive pattern of dark stripes and light interstripes parallel to the anteroposterior body axis which develop during juvenile stages. By inducible Cre/loxP-mediated recombination in neural crest-derived progenitors, we created labelled clones of skin pigment cells that were imaged over several weeks in juvenile and adult fish. Metamorphic iridophores arise from postembryonic stem cells located at the dorsal root ganglia (DRGs) of the peripheral nervous system. They emerge in the skin at the horizontal myoseptum to form the first interstripe and proliferate while spreading bidirectionally along the dorsoventral axis. Patterned aggregation of iridophores during their dispersal generates a series of interstripes that define the stripe regions. Melanophore progenitors appear *in situ* in the presumptive stripe region where they melanise and expand in size to form compact stripes. Thus, although depending on mutual interactions between different pigment cells, stripes and interstripes are formed by a completely different cellular route.

Comparative analysis of the adult and embryo major yolk proteins in the sea urchin

J. Robinson, S. Dev
Biochemistry, Memorial University of Newfoundland, St John's, NL, Canada

The major yolk protein, MYP, is localized to the egg and coelomic fluid of the adult sea urchin. While the egg-localized protein has been extensively studies, relatively little is known about the coelomic fluid-localized form of the MYP. We have conducted a comparative biochemical analysis of these proteins. Sucrose density gradient fractionation revealed unique elution profiles for these proteins. V8 peptide mapping revealed that both species had very similar primary structures while circular dichroic and endogenous tryptophan fluorescence analyses revealed unique

© 2014 The Authors. FEBS Journal © 2014 FEBS

secondary and tertiary structural features. Both proteins exhibit unique responses to calcium suggesting differing requirements for calcium-dependent binding to membranes and protein-dependent, membrane-membrane interactions. We discuss the functional implications arising from these structural differences.

Comparison of several molecular processing approaches of ancient DNA from medieval human remains in Latvia

L. Pliss[1], E. Zole[1], A. Ščėsnaitė-Jerdiakova[1], I. Pole[1], J. Kimsis[1], G. Gerhards[2], E. Petersone Gordina[2], I. Jansone[1], **R. Ranka**[1]
[1]Latvian Biomedical Research and Study Centre, [2]Institute of Latvian History, University of Latvia, Riga, Latvia

In the work with ancient DNA (aDNA) within human evolution studies a complete recovery of genetic material preserved in the sample together with avoiding of contamination with modern DNA are the most important issues. The aDNA usually is present in small amounts and is in various states of degradation. In addition, the archeologic material may contains PCR inhibitors which can be co-purified with aDNA sample. Therefore numerous aDNA extraction methods have deen developed.

In this study, two different aDNA extraction approaches, i.e. commercial-kit based and the protocol of Rohland & Hofreiter (Nature protocols, 2007), were compared. aDNA was isolated from samples of medieval human skeletal remains dated by 15th – 17th centuries, Latvia, followed by PCR amplification of two genetic markers for sex determination. Simultaneously, in order to control contamination, blank samples were included in each experiment of aDNA isolation. The results show that PCR amplification was successful for a set of samples regardless of the extraction method used. In contrast, two samples failed for the PCR amplification in the case of both approaches. These results indicate that different aDNA methods can be used in archeological research and rather the initial DNA degradation level or conditions that may influence the sample preservation should be considered.

Computational and experimental sequence analysis of Y-nups

K. R. Katsani[1], M. Irimia[2], C. Karapiperis[3], Z. G. Scouras[3], B. J. Blencowe[4], V. J. Promponas[5], C. A. Ouzounis[4,5,6]
[1]Molecular Biology & Genetics, Democritus University of Thrace, Alexandroupolis, Greece, [2]Donnelly Centre for Cellular & Biomolecular Research, University of Toronto, Toronto, ON, Canada, [3]Department of Genetics, Development & Molecular Biology, School of Biology, Faculty of Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece, [4]Donnelly Centre for Cellular & Biomolecular Research, University of Toronto, Toronto, ON, Canada, [5]Bioinformatics Research Laboratory, Department of Biological Sciences, University of Cyprus, Nicosia, Cyprus, [6]Chemical Procegineering Research Institute, Centre for Research & Technology, Thessaloniki, Greece

Nuclear pore complexes are composed of 30 evolutionarily conserved proteins or nucleoporins (nups) assembled into sub-complexes. The Y-shaped Nup84/Nup107-160 sub-complex (Y-complex) forms the outer ring scaffold of the pores and is composed of 9 key subunits (Y-Nups) in vertebrates (7 in yeast) with common structural features yet elusive sequence similarities. We deployed computational and experimental sequence analysis involving extensive sequence comparisons, and protein domain detection using the *Drosophila melanogaster* Y-Nups, as queries and augmented the limited set of known protein associations for Y-Nups across eukaryotes. Using established protocols for low-complexity masking, sensitive iterative sequence profile searches, automated sequence clustering and visualization of sequence similarity, we assigned the detected homologies into nine Y-Nup families. Our analysis increased the compendium of known Y-Nups by more than 63% with the resulting multiple sequence alignments sharing as low as <10% identity between certain members and their homologs. In the above alignments using an adaptive length threshold we were able to detect 27 novel multi-domain architectures for Y-Nups that were further validated by genomic sequence comparisons, as well as, their presence in multiple species. RNA-seq expression data revealed that Y-Nups associated with a subset of the discovered domains are found to be under tight coordinated regulation across diverse human and mouse cell types and tissues, implying that they function in conjunction with the nuclear pore. Six (out of the 27) detected cases were strongly supported by the three set criteria (by genome, by expression, by frequency) and point to moonlighting roles of Y-Nups, outside of the pores related to DNA-RNA metabolism and mitotic control and warrant further experimental analysis.
Keywords: nucleoporins, sequence analysis.

MON-212
Conformational changes of intrinsically disordered otolith matrix macromolecule-64

M. Poznar, P. Dobryszycki
Biochemistry, Wroclaw University of Technology, Wroclaw, Poland

Otoliths in fishes and their homologues otoconia in higher vertebrates are part of gravity and linear acceleration detection system. The structures are biominerals composed of calcium carbonate and a small fraction of organic component including proteoglycans, glycoproteins, collagens and noncollagenic proteins. Despite of the low content of organic molecules in the otolith, they play a crucial role in biomineralization by controlling the shape, size and polymorph of crystals.

Otolith matrix macromolecule – 64 (OMM-64) is one of the protein involved in biomineralization control. It was identified by screening a cDNA library of rainbow trout inner ear. OMM-64 is a constituent of high-molecular-weight aggregates (HMWAs) along with otolin-1, heparan sulfate glycosaminoglycans and other unidentified component. It has been demonstrated that the HMWAs control the morphology and polymorph of calcium carbonate. In the presence of HMWAs aragonite crystals are formed, whereas OMM-64 and otolin-1 itself induce vaterite and calcite respectively. Till now it is not known whether the presence of these two proteins is sufficient to form aragonite or another HMWA constituent is necessary. To understand biomineralization process separation and structural and functional analyses of each HMWAs component is absolutely imperative. That is why the first stem of our study is investigation of structural properties of OMM-64.

It has been previously shown that OMM-64, like many others proteins involved in biomineralization, belongs to intrinsically disordered proteins (IDPs). IDPs are very flexible, can interact with multiple partners, gain transient structures and even undergo disorder-order transition. The aim of our work was to investigate whether OMM-64 is able to adopt ordered structure.

© 2014 The Authors. FEBS Journal © 2014 FEBS

In this study conformational behavior and unique response of OMM-64 to environment conditions are presented. Increasing the content of ordered secondary structure in the presence of TFE detected by far UV CD spectra indicated that OMM-64 has tendency to gain ordered structures. Decrease of Stokes radius in the presence of counter ions: Na^{+}, K^{+}, Mg^{2+}, Ca^{2+} was observed implying existence of squeezed partially collapsed conformation. The strongest effect was observed in the presence of calcium ions, which are ligand for the protein. The effect of temperature, pH and chemical denaturant was also investigated. 'Turned out' response to heat and changes in pH was demonstrated. Cooperativity of denaturant induced unfolding was not observed. In low concentration of guanidium chloride (GdmCl) OMM-64 was more compact than without or in high concentration of denaturant.

Acknowledgment: This work was supported by a statutory activity subsidy from the Polish Ministry of Science and Higher Education for the Faculty of Chemistry of Wroclaw University of Technology.

Conservativeness and features of pre-nervous serotonergic signaling system in early embryonic development

D. A. Nikishin[1], Y. V. Khramova[2], S. V. Kremnyov[2], Y. B. Shmukler[1]
[1]Institute of Developmental Biology RAS, [2]Lomonosov Moscow State University, Moscow, Russian Federation

Neurotransmitters, such as serotonin, catecholamines and acetylcholine have numerous non-neuronal functions in addition to classic one. These signaling molecules exist in eggs and early embryos of a wide variety of animal groups and are functionally active during early embryonic development, long before the appearance of the nervous system. It is suggested that the primary function of these substances was humoral regulation of the functional state of the cell, and neurotransmitter function arose secondarily in nerve cells.

Non-neuronal functions of serotonin were most intensively studied since the beginning of the researchers in this field. This biogenic amine is commonly occurring in embryos at early stages of development. Pharmacological experiments on embryos of sea urchins have shown that serotonin is functionally active during the period of cleavage and is required for cell cycle regulation and blastomere interactions. Using molecular genetic techniques, we investigated the composition of the serotonergic system of early embryos three model objects belonging to different phylogenetic groups - sea urchin *Paracentrotus lividus*, clawed frog *Xenopus* and mouse.

Enzymes of serotonin synthesis are expressed at early stages of development, and it is the neural form of tryptophan hydroxylase that is presented in early embryos. Early embryos of all three species have a membrane transporter SERT performing the uptake of serotonin from the extracellular environment to the cytoplasm. Vesicular monoamine transporter VMAT is also expressed during early development of mice and frogs that is required for the accumulation of serotonin in the excretory vesicles and further intercellular signaling. It is interesting that in the early stages of development *Vmat2* gene is expressed, which is typical for the nervous system.

Receptors are the key components of the serotonergic signaling system. In all species investigated several serotonin receptors were expressed simultaneously at early developmental stages. This may be associated with multifunctionality of serotonin at this stage of development. In the case of mice and frogs, receptors that are expressed on the early stages of development influence the same second messenger system (adenylate cyclase) in the opposite way. This fact may indicate a sensitive concentration-dependent serotonergic regulation of early development or its complex spatio-temporal organization.

Our results suggest that the mechanisms of serotonergic signaling in early embryogenesis are generally similar to those in the nerve cells. However, the multiplicity of possible mechanisms of action is one of the characteristics of pre-nervous embryonic serotonergic system.

Keywords: development, neurotransmitter, serotonin.

Defining cell type-specific transcriptomes in the early plant embryo

J. Palovaara, S. Saiga, J. Wendrich, P. van Schayck, D. Weijers
Biochemistry, Agrotechnology and Food Sciences, Wageningen, Netherlands

Multicellular land plants (Embryophytes) develop as a result of the continuous formation of tissue layers and organs made possible by the establishment of diverse cell types and their specification, in space and time, during embryogenesis. A fundamental difference between plants and animals is the cellular and physiological constraints that prevent migration of plant cells. Plants and animals each developed independently from unicellular ancestors and, consequently, plants depend on their own cellular and molecular mechanisms to form their multicellular body. In seed plants, embryogenesis establishes the basic body organization of an apical-basal and radial pattern while the remainder of the plant body develops through the activity of the meristems – stem cell niches in which pluripotent stem cells continuously divide to produce differentiated cells for organ formation. These stem cells are prevented from differentiation by the so-called organizer cells and, while active throughout plant life, they are first specified during embryogenesis. A key unanswered question in plant biology is how these cell types are specified in the early embryo. The embryo of the plant *Arabidopsis thaliana* is a perfect model to study these processes, as most cell divisions are highly invariable and well characterized and therefore highly predictable. During embryogenesis a distinct developmental stage can be discerned (early-globular stage) in which precursor cell types of the future root apical meristem, including the first stem cells and the organizer cell, are being specified. Recently, important insights concerning cell fates have been gained through cell-specific transcriptomics during post-embryonic development in plants. In the present study our aim has been to determine the transcriptome of the first stem cells, the organizer cell and precursors of the root apical meristem to characterize the underlying genetic network responsible for their specification during embryogenesis. To accomplish this we have adapted a genome-wide approach that allows single cell transcriptomic studies in the embryo.

Discovery of a novel zebrafish calponin homology-domain containing transcript using systematic search of RNA sequencing data

L. Vesterlund[1], J. Wang[1,2], J. Kere[1,2,3,4], H. Jiao[1,2]
[1]Biosciences & Nutrition, Karolinska Institutet, Huddinge, [2]Science for Life Laboratory, Stockholm, Sweden, [3]Department of Medical Genetics, Hartman Institute, University of Helsinki, [4]Folkhälsan, Institute of Genetics, Helsinki, Finland

Early development is a complex process which may be governed in part by gene transcripts either specific for this time in development or by specific isoforms of transcripts that continue to be present during later time points. With the introduction of massive parallel RNA sequencing, whole transcriptome investigations became possible through assembling entire transcript from overlapping sequencing reads. Zebrafish (Danio rerio) is an established vertebrate model within developmental biology research. However, the current version of the zebrafish transcriptome annotation is not complete and there are still novel transcripts to be found. We developed a bioinformatics pipeline for systematically searching massive parallel RNA sequencing data for the presence of novel transcripts, aiming at discovering novel transcripts which could be involved in early development. By using data from massive parallel RNA sequencing of early zebrafish embryos we identified a number of putative novel transcripts. Among five fragments from two putative genes chosen for proof-of-principle validation we found a calponin homology (CH)-domain containing transcript. The identified transcript differs from the previous known zebrafish transcript originating from gene located on chromosome 20. In addition, this novel zebrafish gene displays similarity with the human CLMN gene. The CH-domain is found in cytoskeletal and signal transduction proteins, including actin-binding proteins. When transiently knocking down the transcript using morfolinos early development is affected. In summary we have developed a bioinformatics pipeline for systematically searching RNA-seq data after novel transcripts and by using this pipeline we have identified and characterized a novel CH-domain containing gene expressed during early development in zebrafish.

Dynamics of proteomic spectrum of amniotic fluid during different periods of intrauterine ontogenesis

V. Gunko, T. Pogorelova, V. Linde
Rostov Scientific-Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russian Federation

Background: Prenatal development period, which is important for ontogenesis, is connected with deep biochemical transformations in the mother-placenta-fetus system, where amniotic fluid (AF) plays an important role. The ability of this biological environment to react quickly by the modification of its composition to all changes arising in the indicated system allows to use the study of its proteomic spectrum to receive objective information about the character of gestation course and condition of a fetus.

The objective of this study is the analysis of proteomic spectrum of AF during normal and complicated pregnancies.

Methods: The investigation was performed in women with physiological pregnancy (n = 24) and placental insufficiency (PI, n = 20). AF was obtained in the 2nd trimester (23–24 weeks) by means of transabdominal amniocentesis due to medical reasons and during amniotomy in the 1st stage of labor (39–40 weeks). The proteomic analysis of AF was carried out using the two-dimensional electrophoresis (1st dimension: IPG-strip, pH 3–10, 17 cm; 2nd dimension: 8–16% polyacrylamide gel) with the subsequent silver staining of protein and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry of peptides extracted from gel. Proteins were identified using the Mascot program, Swiss-Prot and NCBI data bases.

Results: The dynamics of AF proteomic spectrum in physiological pregnancy are characterized by up-regulation of 3 proteins in the 3rd trimester: transthyretin, calgranulin A and calgranulin B, which were not revealed in the 2nd trimester. During the pregnnacy complicated by PI, regardless of its term, 6 proteins are down-regulated (epidermal fatty acid-binding protein, plasma retinol-binding protein, chorionic somatomammotropin hormone, haptoglobin, peroxiredoxin-2, insulin-like growth factor-binding protein-1 (IGFBP-1)) and 5 proteins are up-regulated (zinc-α-2-glycoprotein, NKG2D ligand 2, fragment IGFBP-1, fibrinogen β chain, putative CDC37-like protein). In the 2nd trimester in case of PI the proteins, which are specific for this period of gestation, are up-regulated: hippocalcin-like protein 1 and α-1-microglobulin/bikunin precursor.

Conclusion: The determined modification of protein production can have both compensatory character aimed at the prolongation of gestation and negative consequences. The results of the present study allow to expand our understanding of the formation of AF protein spectrum during intrauterine ontogenesis and molecular mechanisms of PI development. The revealed proteins of AF difference may be used as markers of this obstetric pathology.

Keywords: Proteins; proteomic spectrum; intrauterine ontogenesis.

Effects of in utero Di-n-hexyl phthalate and Dicyclohexyl phthalate exposure on fetal testicular development in rats

M. Aydoğan Ahbab[1], N. Barlas[1], **C. Güven**[2]
[1]Biology, Faculty of Science, Hacettepe University, Ankara, Turkey, [2]Biophysics, Faculty of Medicine, Adıyaman University, Adıyaman, Turkey

The aim of the study is to investigate the effects of di-n-hexyl phthalate (DHP) and dicyclohexyl phthalate (DCHP) on the male reproductive development *in utero*. Pregnant rats were exposed to DHP and DCHP at doses of 0 (vehicle), 20, 100 and 500 mg/kg/day, by gavage, on gestational days (GD) 6–19. A significant decrease in the anogenital distance (AGD) of male fetuses was observed at all doses of DHP and DCHP. The AGD/cube root of body weight ratio in male fetuses was also significantly reduced compared to control group. The litters with resorption, percentage of resorption and inhibin B levels increased in treatment groups. Despite this, testosterone and MIS/AMH levels in treatment groups decreased. Although FSH and inhibin B levels of male pups exposed to DHP and DCHP increased, FSH/inhibin B ratio decreased in treatment groups. Reduced testosterone production in response to DHP and DCHP exposure appeared to be related to changes in testosterone metabolism, as shown by decreased 3β-HSD immunoexpression. The increased percentages of large Leydig clusters were observed after exposure to DHP and DCHP *in utero*. Histopathological examination of the testis on GD20 revealed changes at all doses. Relative integrated immunodensities of 3β-HSD, MIS/AMH, PCNA and AR decreased after DHP and DCHP exposures. Altered fetal Sertoli cell development and function may caused by disrupted PMC function revealed by reduced AR production in these cells in treatment groups. In conclusion, DHP and DCHP may affect on the fetal testicular development as an anti-

© 2014 The Authors. FEBS Journal © 2014 FEBS

androgen. AGD, litters with resorption, resorption percentages and Leydig cell clusters may also reveal that embryotoxicity of DCHP is more potent than DHP.

Tissue Morphogenesis, Max Planck Institute for Molecular Biomedicine, Muenster, Germany

Blood vessel growth in the skeletal system and osteogenesis seem to be coupled, suggesting the existence of molecular crosstalk between endothelial and osteoblastic cells. Understanding the nature of the mechanisms linking angiogenesis and bone formation should be of great relevance for improved fracture healing or prevention of bone mass loss. Here we show that vascular growth in bone involves a specialized, tissue-specific form of angiogenesis. Notch signalling promotes endothelial cell proliferation and vessel growth in postnatal long bone, which is the opposite of the well-established function of Notch and its ligand Dll4 in the endothelium of other organs and tumours. Endothelial-cell-specific and inducible genetic disruption of Notch signalling in mice not only impaired bone vessel morphology and growth, but also led to reduced osteogenesis, shortening of long bones, chondrocyte defects, loss of trabeculae and decreased bone mass. On the basis of a series of genetic experiments, we conclude that skeletal defects in these mutants involved defective angiocrine release of Noggin from endothelial cells, which is positively regulated by Notch. Administration of recombinant Noggin, a secreted antagonist of bone morphogenetic proteins, restored bone growth and mineralization, chondrocyte maturation, the formation of trabeculae and osteoprogenitor numbers in endothelial-cell-specific Notch pathway mutants. These findings establish a molecular framework coupling angiogenesis, angiocrine signals and osteogenesis, which may prove significant for the development of future therapeutic applications.

Keywords: angiogenesis, bone growth, osteoprogenitors.

Epigenetic control of L1 retrotransposition contributes to skeletal muscle cell differentiation

V. Orlando
BESE, Environmental Epigenetics Research Program, King Abdullah University of Science and technology KAUST, Thuwal, Saudi Arabia

Regulation, evolution and impact of repetitive elements in human genome function is largely unknown. Recent reports indicate that LINE-1 (L1) occurs in brain cells, and stem cells, contributing to neuronal plasticity and somatic diversification. Defects in their mobilization are associated with neurological disorder, as Rett syndrome or Schizophrenia. However, whether somatic L1 retrotransposition regulation could positively contribute to cellular differentiation program is still unexplored. We investigated L1 epigenetic regulation and retrotransposition activity during differentiation of human primary muscle cells, finding that skeletal myogenesis supports a MyoD-dependent and Dystrophyn-nNOS dependent activity of this class of repetitive elements that results in the acquisition of additional L1 copies in differentiated cells.

Such mechanism is impaired during differentiation of muscle cells derived by patients affected by Duchene muscular Dystrophy, being HDAC2 aberrantly recruited at L1 promoter and their transcription repressed. Notably, functional restoration of dystrophin-nNOS-HDAC2 signaling and fiber functionality by HDAC inhibitors or dystrophin re-expression by exon-skipping could restore normal L1 expression levels and CNV either in the *mdx* mice and in DMD primary muscle cells.

We further prove that impairment of L1 mobilization by reverse transcriptase pharmacological inhibition reduces the differentiation ability of normal human primary muscle cells, specifically interfering with sarcolemma and muscle fibers correct formation. In this regard, L1-RC-seq (L1-retrotransposon–capturing and sequencing) revealed muscle site specific L1 insertions in the genome, recurrent in different individuals, with an enhanced CNV during control differentiation, and not in DMD patients where transcriptome program and muscle fiber formation is impaired.

We propose that L1 repetitive elements are positive players in cellular differentiation and cell identity, and their epigenetic deregulation a key trait in muscular dystrophy manifestation.

Keywords: Epigenetics, Retrotransposons, Cell Differentiation.

Evaluation and analysis of different distance measure in context of stabilizing gene content method of phylogenomics as source of phylogenetic analysis

N. Khemka, S. Sinha, A. M. Lynn
School of Computational and Integrative Science, Jawaharlal Nehru University, New Delhi, India

With the advancement of technology and novel cost effective sequencing methods during the recent times, the number of organisms having whole genome sequences has increased exponentially. This huge chunk of high throughput data can be used in many different ways. Besides all the others use of the high throughput data, one of the very common question is to answer correctly the evolutionary history of the organism. There are various methods for the prediction of the evolutionary tree of organisms but the method based on whole genome content is believed to be a better solution to the problem due to consideration of all the genes of the organism. Moreover, consideration of orthologs as a measure of gene content is also quite reasonable due to the presence of better and efficient algorithms for orthologs prediction. Many recent works compare the different distance measure, some well known and some not so familiar ones, on the orthologs data set which can be used as a measure of similarity between the different datasets. In the present study we have compared the different similarity measures like Jaccard similarity index, Dollo evolutionary distance, Dice, Simpson, and Hamming similarity measure.

The study was done on the ortholog dataset of fungal species having whole genome sequence taken from KEGG database. The results show that Jaccard and Dollo distance measures show the most significant results which are also in compliance with the 16S rRNA phylogeny.

Keywords: Orthologs, Phylogenomics, Phylogeny.

Evolution of Prdm genes in animals: insights from comparative genomics and gene expression studies

P. Kerner, D. Meulemeester, **M. Vervoort**
Institut Jacques Monod, Université Paris Diderot - CNRS, Paris, France

Prdm genes encode transcription factors with a PRDI-BF1 and RIZ homology (PR) domain and a variable number of zinc finger motifs. These genes show a wide variety of functions. In particular, several *Prdm* genes, such as *Prdm1* (also known as *Blimp1*) and *Prdm14*, have been shown to have important roles in somatic pluripotent stem cells and in primordial germ cells. Other genes, such as *Prdm8*, *Prdm12*, and *Prdm13*, are expressed in specific neural populations and are required for the proper development of these neural cells. Whereas the functions of *Prdm* genes have been carefully studied in some vertebrates, especially mouse, little is known about the evolution of this gene family. We have searched for *Prdm* genes in the fully-sequenced genomes of 91 different animal species representative of all the main animal lineages. We identified a total number of more than 900 *Prdm* genes in these species, the number of *Prdm* genes per species ranging from 2 to 19 depending on the species. To better understand how the *Prdm* gene family has evolved in metazoans, we performed phylogenetic analyses using the large set of *Prdm* genes we have identified. These analyses allowed to define 14 different subfamilies of *Prdm* genes and to establish that 11 of them are ancestral to bilaterian animals. Detailed analysis allowed to define the gene duplication and gene loss events that occurred in the different animal lineages. By studying a large number of non animal genomes, we also defined the most likely evolutionary origin of this gene family. To get insight into the evolution of the functions of these genes in bilaterian animals, we cloned the full set of *Prdm* genes from the emerging model species, the annelid *Platynereis dumerilii*, a slow-evolving species that is distantly related to both vertebrates and arthropods. Expression patterns of the cloned genes will be reported. Together, our data provide new insights in the evolution of this important family of transcription factors.

Keywords: annelids, neurogenesis, stem and germ cells.

MON-222
Evolution of regulatory properties of fructose-1,6-bisphosphatase

A. Dżugaj[1], M. Jaskolski[2], D. Rakus[1], J. Barciszewski[2]
[1]*Institute of Experimental Biology, Wrocaw University, Wrocaw,* [2]*Institute of Bioorganic Chemistry PAS, Poznan, Poland*

Muscle and liver fructose-1,6-bisphosphatase (FBPase) isozymes are present in mammalian tissues. Both isozymes catalyze the hydrolysis of fructose-1,6-bisphosphate to fructose-6-phosphate and orthophosphate in the presence of divalent cations such as Mg^{2+}, Mn^{2+} or Zn^{2+}. Both are activated by NH_4^+ and K^+ but inhibited by fructose-2,6-bisphosphate, AMP and Ca^{2+}. However, in contrast to muscle FBPase, the liver isozyme is significantly less sensitive to inhibition by AMP and Ca^{2+}, which allows the liver isozyme to play a regulatory role in gluconeogenesis. The role of muscle FBPase is more complex: the muscle isozyme particpates in glycogen synthesis from carbohydrate precursors in striated muscles, but it is also engaged in the protection of mitochondria against stress stimuli and in the regulation of cell cycle progression.

Initial research was focused on the kinetic and structural properties of the liver isozyme and its role in glucostasis. However, comparison of all known primary structures of FBPase from microorganisms and invertebrates through lower vertebrates to birds and mammals – has revealed that the muscle isozyme is an ancestral form of vertebrate FBPase and that the low sensititivity of the liver isozyme to the inhibitors has evolved as an adaptation of vertebrates to hypo- and hyperglycemia. This raised the question of which changes in amino acid residues resulted in this low susceptibility of liver FBPase toward AMP and calcium.

Our studies demonstrated that E69 is essential for the high sensitivity of muscle FBPase to inhibition by calcium ions and that a point mutation, E69Q, desensitizes the muscle isozyme toward inhibition by Ca^{2+}.

The results of our studies also showed that the N-terminus of FBPase functions in the mechanism of allosteric inhibition of the enzyme by AMP. It turned out that the N-terminal region of muscle FBPase contributes to the hight susceptibility of the muscle isozyme to AMP and regulates its interaction with aldolase .

However, differences in the N-terminal sequence between the two FBPase isozymes only partially explained the large difference in their sensitivity to AMP. Thus, we hypothesized that these differences must be related to different conformation of the two isozymes.

As a follow-up of our previous study, we have crystallized human muscle FBPase to compare its structure with that of the human liver isozyme. The structural results demonstrate that while the inactive T conformation of both isozymes is practically the same, their active R-state differs essentially. Studying the crystal structures of FBPase in the T and R form we found a unique R-to-T conversion of human muscle FBPase, which explains its high sensitivity to AMP and the lower affinity of the liver isozyme to this inhibitor.

Evolution of spider toxin diversity in *Cheiracanthium* and *Oxyopes*

M. Y. Sachkova[1], A. A. Slavokhotova[2], E. V. Grishin[1], A. A. Vassilevski[1]
[1]*Neuroreceptors and neuroregulators, Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry,* [2]*Plant Genetics, N.I. Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation*

In the course of evolution living organisms acquired diverse adaptations enabling them to occupy a variety of ecological niches. Venoms of spiders promoted these animals in hunting insects. Most arachnid venoms are based on peptide toxins composing natural combinatorial libraries, i. e. complex mixtures of several groups of homologous toxins. The most probable mechanism underlying the generation of toxin diversity is multiple gene duplications followed by rapid diversifying evolution.

An analysis of two cDNA libraries from venom glands of *Cheiracanthium punctorium* and *Oxyopes takobius* spiders was performed. Translated *O. takobius* library contains precursors of toxins belonging to several structural classes: linear cytolytic peptides, neurotoxins with the inhibitory cystine knot fold (ICK, or knottin) maintained by 3, 4 or 5 disulfides, and chimeric two-domain toxins built from linear and knottin domains. One- and two-domain knottin toxins with 4 or 8 disulfide bonds are characteristic of *C. punctorium* cDNA library.

Nonsynonymous to synonymous nucleotide substitution ratio in the cDNA sequences encoding toxins reflects the tendency to positive/negative selection acting on the toxin genes. Many animal toxins undergo positive selection. In spiders two groups of knottin neurotoxins with 3 disulfide bonds were shown to undergo positive selection. We performed selection analysis in each structural

© 2014 The Authors. FEBS Journal © 2014 FEBS

group using the Nei-Gojobori and Goldman-Yang methods. Surprisingly, it turned out that evolution of most *O. takobius* and *C. punctorium* toxins is driven by negative selection. Diversifying selection affects only one-domain knottins containing 3 disulfide bonds. Thus, among the considered groups some undergo fast evolution, while others are more conserved. Probably the tendency to negative selection acting on most *O. takobius* and *C. punctorium* toxins is due to several factors: the ancient evolutionary age of spiders, non-specific mechanisms of toxin action, and the relatively high molecular mass of the toxins.

Evolutionary origin of the Mycobacterial plasmid pAL5000 replication proteins RepA and RepB

S. K. Das Gupta, S. Chatterjee, A. Basu
Microbiology, Bose Institute, Kolkata, India

The Mycobacterial plasmid pAL5000 has been used extensively for the genetic engineering of Mycobacteria. The replication region of this plasmid comprises two open reading frames encoding the replication proteins RepA and RepB. Replication is initiated by the binding of RepB to the origin of replication located upstream of the *repA-repB* operon. Although the essential elements have been defined the precise mechanism of pAL5000 replication is not fully understood. The objective of this study is to investigate the function as well as evolutionary origin of the pAL5000 derived replication proteins RepA and B.

Plasmids similar to pAL5000 can be found in various Actinobacteria. In all plasmids of the pAL5000 family, RepA and RepB orthologs are found. However while the RepAs are well conserved, RepBs were found to be divergent. The phylogenetic affinities of these two replication proteins were also found to be different, indicating that the *repA-repB* operon was created by random breaking and joining events. However these two Rep proteins function together as indicated by the observation that their synthesis is tightly coupled. Moreover a RepA-RepB fusion was found to be fully active in supporting replication, which further confirms that they function as a pair. The ColE2 plasmids of Gram-negative bacteria are distantly related to pAL5000. These plasmids replicate using a single replication protein (Rep). However in the C-terminal region of ColE2 Rep, a RepB like domain can be found. It appears that the ColE2 Rep must have evolved through the fusion of pAL5000 like RepA and RepB domains.

RepB is a single domain Helix-turn-helix (HTH) family protein which shares considerable homology with region 4 of Extra Cytoplasmic Function (ECF) family of Sigma factors. The involvement of a domain, usually associated with transcription, in a replicative process indicates that early in evolution replication and transcription factors may have utilized same or similar DNA binding domain(s) for sequence specific recognition of DNA. While RepB, the origin binding factor, is a HTH family protein, RepA is related to primase-polymerases (prim-pol) class of ancient proteins which are known to function both as primases as well as polymerases. Previously RepA of ColE2 has been demonstrated to have primase activity. In our investigation it has been shown for the first time, that RepA of pAL5000 which is a ColE2 Rep homolog, can act as a DNA polymerase. Both RepA and RepB therefore represent ancient replication proteins and hence it is proposed that the pAL5000 replication system is of ancient origin.

Extensive mouse regulatory DNA landscapes reveal global principles guiding cis-regulatory evolution

J. Vierstra, E. Rynes, R. Sandstrom, J. Stamatoyannopoulos
Genome Sciences, University of Washington, Seattle, WA, USA

To gain a detailed perspective on the evolutionary dynamics of regulatory DNA, we performed DNase I hypersensitivity mapping in 45 mouse cell and primary tissue types, and systematically compared these with human DHSs from orthologous cell and tissue types. While we identified a small core mammalian regulon comprising DHSs with preserved cell activity patterns that densely encode recognition sites for most known developmental and cell lineage regulators, the mouse and human genome have undergone extensive cis-regulatory rewiring via both innovation and functional repurposing (cell lineage switching) of DHSs driven by acquisition and interconversion of recognition sites for regulators of alternative cell fates. However, despite the weak conservation of individual recognition elements, the density of recognition sequences for cell-specifying master regulators is nearly identical in orthologous tissues. This finding suggests that the evolution of the cis-regulatory compartment is guided directly by a conserved program of spatiotemporal transcription factor activity patterns and indicates that evolutionary selection is preferentially occurring on the overall composition of of the cis-regulatory compartment versus individual cis-regulatory elements. Collectively, these data indicate that the limited regulatory DNA repertoire encompassed by mouse-human shared DHSs with preserved tissue selectivity may function as a scaffold around which diverse potential regulatory programs with convergent outcomes can be constructed with relative facility.

Keywords: chromatin organization, evolution, regulatory DNA.

Genes involved in horizontal gene transfer across different environments

I. Bošnjak[1], D. Babić[2], T. Šegvić-Bubić[3], S. Babić[4], A. Bielen[1]
[1]Laboratory for Biology and Microbial Genetics, Department of Biochemical Engineering, Faculty of Food Technology and Biotechnology, Pierottijeva 6, Zagreb, Croatia, [2]Byte Lab, Dragutina Golika63, Zagreb, Croatia, [3]Laboratory for Aquaculture, Institute of Oceanography and Fisheries, Šetalište Ivana Meštrovića 63, Split, Croatia, [4]Division of Materials Chemistry, Ruđer Bošković Institute, Bijenička cesta 54, Zagreb, Croatia

Horizontal gene transfer (HGT; also named lateral gene transfer) enables the acquisition of new genes between closely or distantly related organisms and it occurs within and between all three domains of life (Eukarya, Bacteria and Archaea). This process can help microbes to adapt to different environments by allowing molecular innovations to be traded within ecological niches. The extent of HGT in natural populations from different environments remains largely unknown and existing data are mostly limited to particular habitats. We compared the extent of HGT from various natural populations using available metagenomic data. Since metagenomes represent total DNA from all microbes present in particular environment, they represent genetic profile of particular sample much better than traditional culture-dependent analyses (it is estimated that over 99% of bacteria living on Earth today cannot be grown in laboratory). We analyzed frequency and diversity of genes involved in HGT mechanisms in metagenomes from wide variety of environments: water (salt and fresh), soil, drainages, gut content, etc. MG-RAST database was used as a major source of

© 2014 The Authors. FEBS Journal © 2014 FEBS

different metagenomes and the abundance of total HGT as well as the abundance of six HGT subcategories: gene transfer agents (GTA), pathogenicity islands (PAIs), phages and prophages (PP), transposable elements (TE), plasmid related functions (PRF) and integrons (I), were determined. Finally, a detailed statistics analysis was used to present the obtained differences in HGT gene content in selected various environments.

Keywords: Horizontal gene transfer (HGT); metagenome, environment.

Genetical analysis of human norovirus in underground water in South Korea

J. S. Lee, I. S. Joo, S. J. Hwang, Y. J. Kim, K. A. Kang, S. H. Kim, K. S. Park
Food Microbiology Division, National Institute of Food and Drug Safety Evaluation, Cheongwon-gun, Korea

Noroviruses (NoV) are important pathogenic viruses that cause foodborne and waterborne gastroenteritis in human. From January to September 2013, we obtained water samples from 550 geological locations in South Korea. Six out of five hundred fifty water samples showed positive result for human NoV by reverse transcription-polymerase chain reaction (RT-PCR). The amplified genomes of ORF 1-2 junction region of NoV from 6 positive samples were then sequenced, genotyped and analysed for sequence alignmnet with reference NoV strains. Approximately 1% (6/550) of the water samples was positive for NoV GI and GII. The genotypic distribution of the 6 NoV strains was as follow: GII-4, 50% (n = 3); GII-11, 16.7% (n = 1); GII-14, 16.7% (n = 1); GII-17, 16.7% (n = 1). The obtained genetic data can be used for prevention and control of foodborne NoV outbreak.

Keywords: foodborne, Norovirus, underground water.

Glycans – the third revolution in evolution

G. Lauc[1], V. Zoldos[2]
[1]*Faculty of Pharmacy and Biochemistry, University of Zagreb,* [2]*Department of Molecular Biology, University of Zagreb Faculty of Science, Zagreb, Croatia*

The development and maintenance of a complex organism composed of trillions of cells is an extremely complex task. At the molecular level every process requires a specific molecular structures to perform it, thus it is difficult to imagine how less than tenfold increase in the number of genes between simple bacteria and higher eukaryotes enabled this quantum leap in complexity. It is generally assumed that the appearance of self-replicating nucleic acids (the first revolution in evolution) provided the basis for the development of early life. Nucleic acids then recruited amino acids to create proteins, which are still the main effectors of life at the cellular level (the second revolution). However, the integration of different cells into a complex multicellular organism required an additional layer of complexity. The invention of protein glycosylation, through its inherent ability to create novel structures without the need to alter genetic information, enabled the entire new level of complexity. Contrary to proteins and nucleic acids, which are made from a direct DNA template, glycans are product of a complex biosynthetic pathway affected by hundreds of genetic and environmental factors. Therefore glycans enable adaptive response to environmental changes and, unlike other epiproteomic modifications, which act as off/on switches, significantly contribute to protein structure and functions. The importance of glycosylation is evident from the fact that nearly all proteins invented after the appearance of multicellular life are composed of both polypeptide and glycan parts.

HAND2 regulates the transcriptional circuits that compartmentalize the early mouse limb bud

M. Osterwalder[1], D. Speziale[1], M. Shoukry[2], R. Mohan[3], R. Ivanek[1], M. Kohler[4], C. Beisel[4], V. Christoffels[3], A. Visel[2], R. Zeller[1], **J. Lopez-Rios**[1]
[1]*Department of Biomedicine, University of Basel, Basel, Switzerland,* [2]*Genomics Division, Lawrence Berkeley National Laboratory, Berkeley, CA, USA,* [3]*Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [4]*ETHZ Department for Biosystems Science and Engineering, Basel, Switzerland*

The genetic interactions and networks that govern limb bud patterning and outgrowth have been studied extensively, while much less is known about the relevant trans-acting factors, target genes and *cis*-regulatory modules. Using a mouse allele in which we have inserted a 3xFLAG epitope-tag into the endogenous HAND2 protein, we identify the genome-wide range of HAND2-binding regions in mouse embryos. By combining this approach with genetic analysis, we uncover a network of HAND2 target regulators that define a proximal limb compartment and are required for morphogenesis of proximal skeletal elements. Simultaneously, HAND2 orchestrates the transcriptional interactions that control the establishment of an anterior and posterior limb bud compartment. While HAND2 directly regulates *Gli3* transcription, is also needed to activate the TBX3 transcriptional repressor, which is essential to position the posterior *Gli3* boundary. This combination of cross-regulation with transcriptional relay provides HAND2-controlled circuits with robustness in defining limb bud compartments prior to activation of SHH signaling.

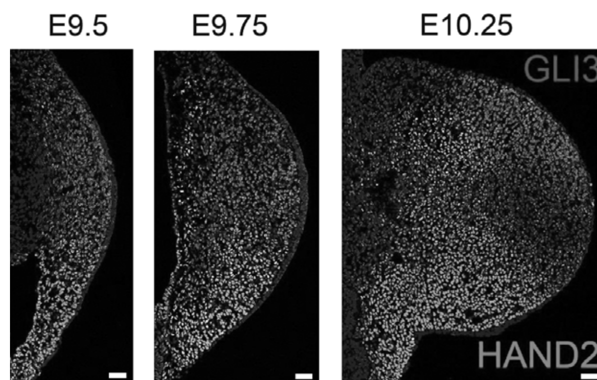

Fig. 1.

Co-immunolocalization of HAND2 (green) and GLI3 (red) in wild-type forelimb buds at E9.5 (25–26 somites), E9.75 (28–29 somites) and E10.25 (33–34 somites). Scale bars: 50 μm.

Keywords: ChIP-seq, Hand2, limb bud.

Identification and structure-function analyses of an Elk-1 antecedent in a primitive triploblastic deuterostome

J. Saxton, D. Tooth, Z. Ferjentsik, A. D. Johnson, P. E. Shaw
School of Life Sciences, University of Nottingham, Nottingham, UK

Gene expansion in early metazoans gave rise to multiple ETS paralogues with overlapping or indiscriminate biological functions. Elk-1, one of three mammalian ternary complex factors, is a well-conserved, ETS domain-containing transcriptional regulator of mitogen-responsive genes. Nonetheless, the *elk-1* gene could be deleted from the mouse genome apparently without adverse effect.

To gain insight into the biological role of Elk-1 through evolutionary conservation, we identified potential antecedent Elk-1 genes in extant early metazoans using database searches and sequence alignments. We then performed biochemical studies to determine whether sequences present in a putative Elk protein of the acorn worm *Saccoglossus kowalewskii*, a primitive hemichordate, were functionally orthologous to characteristic domains of human Elk-1. Our findings link the appearance of a structurally and functionally recognisable Elk-1 to the advent of triploblastic metazoans, implying an ancestral role for Elk-1 during the specification of mesoderm.

Keywords: ETS protein, mesoderm, transcription factor.

MON-234
In vitro reconstitution of a P granule-like phase

S. Saha, L. M. Jawerth, A. A. Hyman
Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

It is well known that cells use membranes to spatially separate biological activities in specialized compartments e.g. nucleus, endoplasmic reticulum, Golgi bodies, mitochondria, lysosomes. On the other hand, compartmentalization is also possible in the absence of a membrane separating the compartment from its surroundings. Such membrane-less compartmentalization is observed in cellular structures containing both proteins and RNA, for instance nucleolus, Cajal bodies, P bodies, promyelocytic leukemia nuclear bodies, stress granules. One such membrane-less compartment in the germ-line cytoplasm of the nematode *Caenorhabditis elegans* is P granule. RNA and more than forty proteins concentrate in P granules. Deficiencies or mutations of P granule proteins result in problems with germ-line development and sterility. The molecular mechanisms of how P granules facilitate normal germ-line development remain remarkably unclear. Further, insight into how compartmentalization occurs and sustains in the absence of membrane is lacking. In order to address these issues, we are attempting to reconstitute *in vitro* a P granule-like compartment from purified components. We will present our progress in this direction.

Keywords: *C. elegans*, P granules, phase separation.

Intrinsically disordered regions in calponin-like Chd64 from *Tribolium castaneum*

A. M. Tarczewska[1], M. Kozowska[1], M. Jakób[1], M. Kaus-Drobek[2], K. Szpotkowski[3], A. Ożyhar[1]
[1]*Biochemistry, Wroclaw University of Technology, Wroclaw,* [2]*Institute of Biochemistry and Biophysics, Polish Academy of Science, Warsaw,* [3]*Institute of Bioorganic Chemistry, Polish Academy of Science, Poznań, Poland*

20-hydroxyecdysone (20E) and juvenile hormone (JH) signalling pathways interact to mediate insect development but the mechanism of their interaction is poorly understood. Recently, two proteins, a calponin-like Chd64 and an immunophilin FKBP39 have been found to play a pivotal role in cross linking these two signalling pathways. GST pull–down and yeast two-hybrid assays revealed that Chd64 and FKBP39 can interact with each other and some nuclear proteins including proteins forming functional receptor for 20E: EcR and Usp and probable receptor for JH a Met protein. Importantly, Chd64 and FKBP39 were shown to bind JH response element (JHRE) in *Drosophila melanogaster*. Nevertheless, the molecular bases of the multiple interactions of the Chd64 and the FKBP39 with various partners remain unknown. We expect to elucidate the function of the Chd64by exploring its biochemical and biophysical properties. Researches on Chd64 from *D. melanogaster* are already carried out in our laboratory and we decided to extend them to a more generic arthropod *Tribolium castaneum. In silico* analyses predicted the existence of intrinsically disordered regions (IDRs) on both termini of the Chd64. Next, a protocol for overexpression and purification of Chd64 had been developed. Obtained recombinant was a subject for intensive biochemical and biophysical studies which aimed to reveal its structural organization. Hydrodynamic properties determined by means of analytical size-exclusion chromatography and analytical ultracentrifugation revealed the Chd64 has elongated, asymmetrical shape and it was further confirmed by small angle X-ray scattering (SAXS). The location of disordered regions was mapped by hydrogen deuterium exchange mass spectrometry (HDX MS). This technique reveled that Chd64 possesses two IDRs: one on the N- and one on the C- terminus, whereas the core of the protein is globular. Since disordered tails are often involved in diverse interactions, it is highly possible that in Chd64 they serve as platforms for multiple interactions with various partners and constitute the foundation for their regulatory function.

MON-236
Investigating Prrx1 cis-regulation during limb development

M. Marinic, Y. F. Chan
Friedrich Miescher Laboratory of the Max Planck Society, Tübingen, Germany

Paired related homeobox 1 gene (*Prrx1*) encodes for a transcriptional coactivator critical for skeletal development, particularly in the limbs, craniofacial region and the inner ear. An enhancer element located upstream of *Prrx1* was shown to drive the expression of the reporter gene in the limb mesenchyme. The replacement of the mouse enhancer by the orthologous region from bats caused the elongation of mouse forelimbs, suggesting that variations in *Prrx1* regulation may play a role in the evolu-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tionary differences between the mouse and the bat limbs. However, this enhancer alone does not account for the entire *Prrx1* expression pattern and little more is known about its regulation. To decipher *Prrx1 cis*-regulation, we cloned individual enhancer candidates based on limb-specific p300 sites and histone modification marks upstream of a *lacZ* reporter gene driven by a minimal β-globin promoter. We plan to improve the existing transgenic reporter assay in the mouse by using *phiC* integrase-mediated site-specific integration at the *Hipp11* locus. Site-specific integration eliminates variations arising from positional effects and transgene copy number. In parallel, we will examine large genomic regions by testing *lacZ*-tagged mouse- and bat-derived bacterial artificial chromosomes (BACs) within the *Prrx1* topological domain. Additionally, we have access to DNA from multiple individuals of two related bat species, the Greater and the Lesser mouse-eared bats (*Myotis myotis* and *Myotis blythii oxygnathus*). Taking advantage of the available genomic data on mouse fore- and hindlimb-specific active chromatin marks and transcription factor binding profiles, we will perform deep sequencing of the homologous regions in bat to identify sequence differences between mouse and bat in putative limb regulators. We will carry out further transgenic reporter assays on limb enhancers showing major sequence dissimilarities between bats and mice, especially those near *Prrx1*, to determine if such mutations lead to expression variations. In summary, the results of transgenic experiments will shed light on the *cis*-regulation of *Prrx1*, while the data obtained from the deep sequencing may indicate how such differences could have evolved. This will in turn open a way to better understanding of how *cis*-regulation of genes is achieved and modulated during the evolution of various morphological forms.

Lauryl-poly-L-lysine: a new antimicrobial agent?

L. Vidal[1], M. Geffard[2]
[1]Analytical and Project Development, [2]Chief Scientific Officer, Gemac, St Jean d'Illac, France

The development of antibioresistance is a major worldwide health problem. The antimicrobial peptides are defined as cationic peptides, generally described by a substantial portion of hydrophobic residues. Here, we describe new tools, whose mechanisms of action differ from current antibiotics.

Thanks to Gemac's know-how in chemistry, our team has synthesized an active product with different satured and insatured fatty acid (FA) covalently linked to a polypeptide, Poly-L-lysine (PLL). These PLL compounds were studied by using specific analytical methods. The linkage of FA to a carrier is largely reported to increase the antibacterial effect of the linked FA, in comparison with free FA, free PLL or a mixture of both (FA free + PLL free). The compounds from C6 to C18 FA linked to PLL were assessed in vitro to evaluate their antibacterial activity. Some FA-PLLs showed a good ability to fight multiresistant bacteria. This bacterial evaluation was shown an optimum compound, Lauryl-PLL. The specificity of linkage lauric acid to the epsilon-NH2 lysyl of the PLL was studied in vitro with another carrier, such as poly-L-ornithine. A screening of Lauryl-PLL against a broad variety of bacteria was realized with Lauryl-PLL, in respect of clinical strains from patients. The determination of the minimum inhibitory concentration of Lauryl-PLL were 250 microM (concentration in small molecules linked) for Staphyloccocus aureus, 125 microM Pseudomonas aeruginosa, and 1000 microM for Escherichia coli. The kinetic activity of Lauryl-PLL was allowed highlight this bactericidal activity against S. aureus and P. aeruginosa strains. This product was found to be the most active product against Gram-positive bacteria, such as S. aureus and Streptoccocus pneumoniae, Gram-negative bacteria, E. coli and P. aeruginosa.

Individual linkage to PLL offers significant advantages, among other aspects, for stabilizing the linked fatty acids. Regarding the hydrophobic part of PLL compounds, the activities of PLL compounds are considered to be more efficacious against Gram-positive than against Gram-negative bacteria. The Lauryl-PLL compound, having an amphiphilic character, might show a better ability to destabilize the bacterial cell wall. Lauryl PLL, which is more hydrophobic than free PLL, could increase interactions with bacterial membranes. According to the literature, the antimicrobial cationic peptides interact with the negatively charged cell membranes of bacteria.

Thus, the Lauryl-PLL compound is a new and promising antimicrobial agent. The treatment of these strains with a very low quantity of product is devoid of undesirable side effects. This strategy opens new perspectives in anti-infective therapeutic strategies.

Keywords: biochemistry, fatty acids, polypeptide conjugated.

Lineage tracing demonstrates multipotency of premigratory and migratory neural crest cells in vivo

A. Baggiolini[1], S. Varum[1], J. M. Mateos[2], D. Bettosini[1], N. John[1], U. Ziegler[2], L. Dimou[3], M. Götz[4], H. Clevers[5], R. Furrer[6], L. Sommer[1]
[1]Institute of Anatomy, [2]Center for Microscopy and Image Analysis, University of Zurich, Zurich, Switzerland, [3]Ludwig-Maximilians-Universität München, Munich, Germany, [4]Institute for Stem Cell Research, Ludwig-Maximilians-Universität München, Munich, Germany, [5]Hubrecht Institute, KNAW and University Medical Center Utrecht, Utrecht, Netherlands, [6]Institute of Mathematics, University of Zurich, Zurich, Switzerland

The neural crest (NC) belongs to the lineages with the broadest developmental potential, generating cell types as diverse as peripheral neurons, myelinating Schwann cells, and pigment cells. However, it is highly controversial whether *in vivo* this diversity is achieved by lineage segregation from multipotent mother cells or by differentiation of distinct lineage-restricted progenitors coexisting in the dorsal neural tube (dNT). Here, we performed *in vivo* fate mapping of single trunk NC cells both at pre-migratory and migratory stages using the *R26R-Confetti* mouse model. We combined quantitative analysis with mathematical evaluation to show that the NC population consists of only few fate-restricted cells, while the majority of NC cells are multipotent. Moreover, multipotency is maintained in migratory NC cells even after their emergence from the NT. Finally, our findings suggest the existence of multipotent neural crest stem cells (NCSCs) *in vivo*.

Keywords: Confetti mouse, Lineage tracing, Neural Crest Cells.

LRRC1 and SCRIB, two polarity genes from the LAP family, genetically interact during embryogenesis

N. Bertrand[1], M. Sebbagh[2], S. Zaffran[1], J.-P. Borg[2], **M. J. Santoni**[2]
[1]Medical Genetics and Functional Genomics, UMR_S910 Inserm, Faculté de Médecine de Marseille 27, Bd Jean Moulin, 13385 Marseille Cedex 05, [2]Cell Polarity, Signalling and Cancer, Centre de Recherche en Cancérologie de Marseille, CRCM, UMR 1068 INSERM, UMR 7258 CNRS, Institut Paoli-Calmettes, Aix-Marseille Université. 27, bd Leï Roure BP 30059, 13273 Marseille Cedex 09, France

This work is focused on the functional study of LAP (LRR And PDZ) scaffold proteins which form an evolutionary conserved family involved in cell polarity. Among them, we are especially interested in Scrib functions. We have contributed to highlight Scrib role in the vesicular recycling pathway as well as in cell migration both involving interactions and regulation of the bPIX/GIT1 complex (Audebert *et al.* 2004; Nola *et al.* 2008). We cloned an atypical LAP member: *Lano* (LRR and no PDZ) / *LRRC1* (Saito *et al.* 2001). Phylogeny and characterization studies have demonstrated that *Lano* has an expression restricted to vertebrates and is a *Scrib* paralogue (Santoni *et al.* 2002).

During *Drosophila* development, *Scribble* (the invertebrate *Scrib* and *Lano* orthologue) inactivation leads to profound defects in the apico-basal (AB) cell polarity associated to uncontrolled cell proliferation (Bilder *et al.* 2000). Interestingly, this phenotype was partially rescued by the expression of a Scribble deletion mutant closely related to Lano (Zeitler *et al.* 2004), suggesting that Lano might be involved in the regulation of the AB cell polarity during the vertebrates development. In contrast to *Drosophila*, *Scrib* mouse invalidation does not affect AB cell polarity but gives rise to a massive defect in the neural tube closure linked to a disruption in convergence extension and planar cell polarity (Murdoch *et al.* 2001). This discrepancy leads us to investigate the function of its paralogue, *Lano*. For this purpose, we engineered mouse models invalidated either for *Lano* or for *Lano* and *Scrib* to evaluate a possible genetic interaction between them.

Mammalian cells, differentiated tissue cells and microorganisms renewal

D. K. Nadiradze
President, Association for Farmers Rights Defense, AFRD, Tbilisi, Georgia

Our research interests encompass cell engineering, tissue engineering and metabolic engineering also Bio Banking (in vitro, in vivo, in situ, ex situ, in farm) and Biopreservation. The emphasis is on the application of systems analysis to biochemical and cellular systems and on the incorporation of physiological insight into the quantitative modeling of biological reactions. The systems employed include mammalian cells, differentiated tissue cells and microorganisms. Current research efforts emphasize employing genomic and proteomic tools in those research projects and exploring novel modeling approaches for quantitative description of cellular processes. A research project on mammalian cell culture focuses on the relationship between physiological regulation and global gene expression. Our research has allowed us to control Energy metabolism to reduce waste metabolite accumulation and to increase the productivity and Product quality. Currently, genomic and proteomic tools are used to unveil the control of cellular structure and physiological characteristics important to process. Metabolomics requires the unbiased identification and quantification of all of the metabolites present in a specific biological sample (from an organism or in vitro). Metabolites are generally labile species, by their nature are chemically very diverse, and often present in a wide dynamic range. For analysis of mRNA and proteins one 'only' needs to know the genome sequence of the organism and exploit thisinformation using nucleic acid hybridization or protein separation followed by MS. We tested and validated four different mathematical models of RNA interference by quantitatively fitting models'parameters to best capture the in vitro experimental data. We show that a simple model is the most efficient way to model RNA interference. Our experimental and modeling findings clearly show that the RNAi-mediated degradation of mRNA is subject to saturation effects. Work on tissue engineering encompasses stem cell renewal and the development of adult and embryonic stem cells to liver cells. Focuses are on the in vitro formation of liver tissue-like spheroids from stem cell derives liver cells and on the regulation of stem cell renewal and differentiation.

Mitochondrial DNA lineage, genetic diversity and population structure of two pre-hispanic Maya populations

M. I. Ochoa Lugo, G. Pérez Ramírez, M. Moreno Galeana, M. D. L. Muñoz
Department of Genetics and Molecular Biology, Center for Research and Advanced Studies of IPN, D.F., Mexico

The Mayan civilization began to settle in the Yucatan area of what is now Mexico. The maximum splendor of this civilization was during the Classic period and had the maximal expansion at the beginning of Postclassical period. The population from the archeological site El Rey Quintana Roo became a relevant city between 1300 to 1550 C.E. and Palenque is an ancient Maya city located at the base of the northern of Chiapas. Palenque was rich natural resources allowed this site a long occupation from the 200 to 900 CE. Because the importance of this civilization we study, maternal lineage, genetic diversity and population structure through the analysis of the sequences comprising the Hypervariable Region I of the mtDNA. The maternal lineage of Mayan pre-Hispanic populations showed the haplogroups C, D, and A with a frequency of 57.1%, 28.6% and 14.3% respectively. These results are different from those reported for populations of ancient Maya from Copan, Honduras that showed frequencies of 89% and 11% for haplogroups C and D respectively. Studies of genetic diversity index and neutrality test, suggested that the population from archeological site El Rey, Quintana Roo was a stable population due to the similarity of the values $\theta\pi$ and θs, and the Tajima D value of zero. In addition, we found significantly negative Fu's Fs values which can be interpreted as a signal of expansion. The pre-Hispanic population from Palenque Chiapas showed no signal of expansion. The phylogenetic analysis by network base on sequences from the ancient populations and contemporary sequences from the NCBI database showed the relationship among these populations and the contemporary Maya populations. In conclusion, we are suggesting that the Maya population pertain to the same culture but have a different genetic origin. We will enrich this study increasing the number of samples and comparing the sequences with those of contemporary populations.

Keywords: PRE-HISPANIC MAYA, Haplogroup, mitochondrial DNA.

Molecular analysis of beta amyrin 11-oxidase (Cytochrome P450 88D6) among *Glycyrrhiza* species grown in Turkey

Ö. Çetin[1], E. Dündar[2], A. Duran[1]
[1]Biology, Selcuk University, Konya, [2]Biology, Balıkesir, Balıkesir, Turkey

The genus *Glycyrrhiza* L. (Fabaceae) is represented with about 20 taxa worldwide and with six species in Turkey. *Glycyrrhiza* species have been used as medicinal plants and natural sweetener for many centuries. *Glycyrrhiza* extracts have been reported to have antimicrobial, antibacterial, antiviral, anticoagulant, hepatoprotective and antidiabetic activities. Glycyrrhizin which is a triterpene saponin is one of the major compounds of *Glycyrrhiza* roots and rhizomes. Glycyrrhizin is about 50 to 100 times sweeter than table sugar. Because of the economical value of glycyrrhizin, genes having key roles in glycyrrhizin biosynthesis are very important. The aim of this study was to conduct molecular characterization of Beta amyrin 11-oxydase which has a key function in glycyrrhizin production. With this respect, genomic structure along with intron and exon polymorphism of Beta amyrin 11-oxidase among *Glycyrrhiza* species grown in Turkey were determined. Studied specimens were collected from different localities in Turkey between 2009 and 2013. Beta amyrin oxidase fragments from genomic DNA and cDNA samples were amplified via nested primers designed for this purpose. The amplified fragments were sequenced using same primers used for amplification. Alignment of the cDNA and DNA sequences was achieved using BioEdit program. The phylogenetic trees were also constructed with the same software. According to molecular analysis, *Glycyrrhiza* taxa were divided into two groups. The first group included *Glycyrrhiza asymmetrica* and *G. flavescens*. The other group included *G. glabra*, *G. echinata* and *G. aspera*. In conclusion, the molecular analysis of beta amyrin 11-oxidase revealed that the gene has polymorphic intron along with polymorphic exons which displayed a correlation with the glycyrrhizin properties of *Glycyrrhiza* taxa. These results can be utilized to device beta amyrin 11-oxydase as a genetic marker to differentiate among *Glycyrrhiza* taxa for their glycyrrhizin production potentials.

Molecular composition of the nucleolus-associated bodies in mouse fully-grown oocytes: extended cytochemical, immunocytochemical and fish analysis of their proteins and RNAs

O. Zatsepina, E. Lavrentyeva, K. Shishova
Laboratory of Structural Biochemistry, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation

It is well known that fully-grown mammalian oocytes, instead of typical nucleoli, contain prominent, but structurally homogenous bodies called 'nucleolus-like bodies' (NLBs). NLBs accumulate a vast amount of material, but their biochemical composition and thus functions still remain undefined. To shed light on these problems we have devised an assay to detect internal oocyte proteins with fluorescein-5-isothiocyanate (FITC) and applied two fluorescent RNA-binding dyes, acridine orange and pyronin Y, to examine whether NLBs accumulate RNAs. Our results unequivocally show that similar to typical nucleoli, proteins and RNAs are major constituents of functionally active (or non-surrounded) NLBs as well as of functionally silent (or surrounded) NLBs. We have also shown, by exposure of fixed oocytes to a mild proteinase K digestion, that the interior of NLBs of both types sequesters nucleolar proteins, which are involved in all major steps of ribosome biogenesis, including rDNA transcription (UBF), early pre-rRNA processing (fibrillarin), late rRNA processing (NPM1/nucleophosmin/B23, nucleolin/C23) and ribosome assembly (RPL26) but neither of the nuclear proteins tested, including SC35, NOBOX, topoisomerase II, HP1α, and H3. In order to learn whether NLBs accumulate ribosomal RNAs (rRNAs), we applied fluorescence *in situ* hybridization technique and antisense FAM-conjugated oligonucleotide probes to 45S pre-rRNA, 18S and 28S rRNAs. The results show that, in contrast to somatic-like nucleoli of preantral oocytes, mature and immature rRNAs are hardly detectable within NLBs of fully-grown oocytes. These observations can be explained either by migration of rRNAs from transforming nucleoli to other oocyte locations (e.g., to cytoplasmic lattices, Monti et al., 2013) or by additional compactization of rRNA within NLBs that makes it inaccessible to the hybridization probes. Overall, our study suggests several novel cytochemical and immunocytochemical approaches that allow researchers to examine composition of 'nucleoli' in fully-grown mammalian oocytes. It also provides the first evidence in favor of an NLB role in the storage of major nucleolar proteins that may explain the requirement of the NLB material for the initial stages of early embryo development in mammals.

Molecular phylogenetic and karyomorphological data about some Turkish *Teucrium* (Lamiaceae) taxa

T. Ozcan[1], F. Altınordu[2], T. Dirmenci[1], E. Martin[2]
[1]Biology Education, Balıkesir University, Balıkesir,
[2]Biotechnology, Necmettin Erbakan University, Konya, Turkey

Teucrium L. genus belongs to Lamiaceae family (subfamily Ajugoideae) and is one of the largest genera at this family. *Teucrium* has about 260 species at all over the world and 250 species of them distributes around the Mediterranean basin.

Chromosome cytology is important when attempting to evaluate relationships and deduce phylogenetic sequences in angiosperms. The use of karyomorphological and karyosymmetrical parameters as characters for the reconstruction of phylogenetic relationship is valid. These parameters include chromosomal characters such as chromosome number, ploidy level and karyologic characters such as total haploid length of the chromosomes and satellite situation. Also karyotype symmetry indices such as A index, A1 and A2 indices which derive from karyomorphology of species are important characters for reconstruction of phylogenetic relationships too. In addition, DNA sequence comparison has been using to determine phylogenetic relationships of the organisms. However, using of DNA sequences is more controversial than using morphological characters. On the other hand, the accuracy of the molecular data can't be ignored. Using different gene regions (nrDNA, cpDNA, mtDNA) are facilitating the identification of the phylogenetic relationships.

In this study, some trees created using DNA data and karyomorphological data. The main purpose of this study is to ascertain molecular phylogeny (using DNA datas) and karyomorphological relationship within some *Teucrium* members using different trees. *Teucrium* genus has 47 taxa growing in Turkey and 12 of them were utilized for molecular phylogenetic and karyo-

morphological trees. trnL-F gene region (cpDNA) were used for molecular data and sequences were processed using BioEdit and Clustal W. Phylogenetic tree was obtained utilizing MEGA 6.0. In addition, six important quantitative traits which are about karyomorphology were used for cluster analysis. All data were processed using NTSYS-pc Version 2.10. The standardized matrix was processed using the Interval Data of Similarity subroutine to obtain the EUCLID matrix. The Unweighted Pair Group Method with Arithmetic Mean (UPGMA) clustering method of the Clustering subroutine SAHN was used to construct the dendrogram in operational taxonomic units. Consequently, molecular phylogenetic and karyomorphological trees basically support each other. But as trnL-F trees have about 820 characters (820 nucleotides) karyomorphological trees have six important characters. Improving to these characters is very important for the next studies.

Keywords: Karyomorphology, Teucrium, trnL-F.

Network inference of serial gene regulation during *D. melanogaster* AP pattern formation

S. Aburatani, H. Toh
Computational Biology Research Center, National Institute of Advanced Industrial Science and Technology, Tokyo, Japan

In systems biology field, revealing the genetic control system during embryogenesis is one of important tasks, and various factors are considered to be regulators of serial events during embryonic development. To elucidate the mechanism of those developmental events, the regulatory relationships between the regulatory factors and specific expressed genes behind the phenomenon should be uncovered.

In this study, we applied one statistical method based on Structural Equation Modeling (SEM), combined with factor analysis, to expression profiles which were measured in embryogenesis. Since SEM can include not only the observed variables but the latent variables within the constructed network model, we can infer the causal relationships between genes and regulatory factors. Furthermore, we improved a new method by combination of cross-correlation and partial correlation to construct an initial model for SEM calculation. We applied our approach to estimate the regulatory network for Antero-Posterior (AP) pattern formation in *D.melanogaster* embryogenesis. In the inferred model, specific transcription factor genes were regulated by not only the other genes' expressions, but also the estimated factors. Since the each factor regulated the same type of genes, those factors were considered to be involved in maternal effects or spatial morphogen distributions. The interpretation of the inferred network model allowed us to reveal the regulatory mechanism for the patterning along the head to tail axis in *D.melanogaster*.

Notch and retinoic acid signaling are required for the spatiotemporal distribution of prune2 mRNA in the zebrafish embryonic development

S. Maddirevula, M. Anuppalle, A. Kumar, M. Rhee
Biological Science and Biotechnology, Chungnam National University, Daejeon, Korea

PRUNE2 is identified as a susceptible gene for Alzheimer's disease. Isoforms of Prune2 regulate various cellular processes, such as neuronal cell differentiation and synaptogenesis. Although *prune2* is known to be expressed in the murine brain, its detailed expression pattern along embryonic development remains to be defined. Here we showed expression profiles of *prune2* transcripts in the zebrafish embryos. *prune2* exhibits low expression level in the early embryogenesis and in later stage embryos, larvae and adult zebrafish brain whereas it is predominantly expressed in the telencephalon, epiphysis cluster, nucleus of the tract of the post optic commissuare, spinal cord neurons, cerebellum, tegamentum, anterior lateral line ganglion, posterior lateral line ganglion and in the rhombomeres 2 to 5. In order to study details expression pattern, we performed two color whole-mount *in situ* hybridization (WISH) with a postmitotic neuron specific marker, *huC* to reveal that *prune2* is expressed in the post mitotic neurons. In addition, we demonstrated that *prune2* transcripts are significantly increased in the Notch signaling homozygous mutant, *mib* (mib^{ta52b}) suggesting that Notch signaling governs the transcription of *prune2* in the zebrafish embryos. Interestingly retinoic acid (RA) signaling modulates the *prune2* expression pattern in the zebrafish embryos. Currently we are addressing the functional roles of Prune2 in the zebrafish neurogenesis.

Keywords: prune2, CNS, post mitotic neurons, Notch, Retinoic acid.

MON-248
Optimal growth schedule of holometabolous insects

K.-I. Hironaka, Y. Morishita
Center for Developmental Biology, RIKEN, Kobe, Japan

In holometabolous insects, adult organs develop as imaginal discs within the growing larvae. Once larvae pass the critical size, juvenile hormone (JH) titers decline and imaginal discs begin to grow rapidly. The subsequent rise in ecdysteroid titers causes the larva to stop feeding and wander away from its food to find a place to metamorphose. The period between attainment of the critical size and ecdysteroid secretion is called the terminal growth period (TGP). Although all holometabolous insects are thought to have the critical size for metamorphosis, the mechanisms for nutritional regulation of the critical size and the TGP differ between species. For example, in Manduca sexta, low nutrition reduces the critical size and has no effect on the duration of the TGP, whereas in Drosophila melanogaster, low nutrition lengthens the duration of the TGP and has no effect on the critical size.

To study the ecological causes of the diversity in the mechanisms for nutritional regulation, we develop a resource allocation model of a holometabolous insect and analyze it with the Pontryagin's maximum principle with free-final-time. A typical optimal growth schedule is biphasic (the so-called bang-bang control): all nutrition is devoted to growth of a larval body until some switching time, after which point all nutrition is devoted to growth of an imaginal disc until the end of development. Regarding the larval body size at the switching time and the second phase as 'the critical size' and 'the TGP', we investigate how these values depend on nutrition for different fitness functions.

Considering that the fitness is proportional to the size of an imaginal disc at the end of development, the combination of a constant TGP and a nutrition-dependent critical size is optimal. On the other hand, the combination of a nutrition-dependent TGP and a constant critical size is optimal if the time to obtain a mature imaginal disc (fixed size) is minimized. These optimal strategies are in accord with the pattern observed for Manduca sexta and Drosophila melanogaster, respectively.

Keywords: Growth regulation, Holometabolous insects, Mathematical modeling.

MON-249
Origin of 35delG mutation in the Belarus population: Where did it come from?

O. Shubina-Oleinik[1], E. Merkulava[2], M. Siniauskaya[1], A. Levaya-Smaliak[3], N. Danilenko[1]
[1]*Institute of Genetics and Cytology, National Academy of Sciences,* [2]*Belarusian Medical Academy of Post-Graduate Education,* [3]*National Centre of Otorhinolaryngology, Minsk, Belarus*

Deletion *35delG* in GJB2 gene is the main cause of congenital hearing loss(HL) in many populations worldwide. It's account up to 70–90% of all GJB2 mutation among the European population. *35delG* is recessive leading to HL in homozygous state. There are regional differences in *35delG* mutation carrier rate even within Europe, where the prevalence is higher in southern (Greece 3.54%, France 3.35%, Italy 4%) and lower in northern European countries (except Estonia 4% and Belarus 5,6%). Moreover, the carrier frequency in Belarus is one of the highest in Europe. The average frequency of *35delG* among the European countries is 2%. The origin and spread of *35delG* among Europeans is attributed to the 'founder effect' and possible heterozygote advantage. It is considered that the *35delG* mutation appeared about 14 000 years ago in the territory of ancient Greece and then spread to Europe.

The goal of our study was the reconstruction of the possible ancestor haplotype linked to the *35delG* mutation among Belarus patients.

We genotyped 96 Belarus patients with HL homozygous for the *35delG* mutation, as well as 144 residents of the country with normal hearing for 4 single nucleotide polymorphisms (SNP) and 2 microsatellite markers (STR) inside or flanking the GJB2 (D13S175 and D13S141).

According to the obtained results, the most frequent 2 STR and 1 SNP variants in studied patient cohort is: 105 (90%) for the marker D13S175, 127 (76%) for the marker D13S141 and (96%) for SNP 1. The frequency of other STR and SNP variants among Belarusian patients is insignificant. The most wide–spread haplotype linked to the *35delG* mutation among Belarus patients is the following: 105–127– SNP 1 (D13S175– D13S141– SNP 1). This haplotype is also frequent among other European populations, as well as in Greece– estimated «homeland» of *35delG* mutation. The data obtained shows that *35delG* mutation was introduced on the territory of Belarus with Neolithic migration from Mediterranean area and spread with high frequency throughout the territory of the country. The hypothesis about the common founder of GJB2 mutation for Europeans was confirmed.

Keywords: 35delG mutation, Belarus, haplotype.

MON-250
Ovarian follicle culture in 2D and 3D systems

Y. V. Khramova, M. Filatov, L. Tatiana, M. Semenova
Embryology, Lomonosov Moscow State University, Moscow, Russian Federation

Search for methods to maintain and restore the ovarian reserve is one of the most important directions of research in the field of experimental embryology due to the fact that the occurence of a cancer in women of reproductive age and girls who have not reached puberty increases. Currently systems and methods of the ovarian tissue and the individual follicles culture in order to obtain mature follicles competent for fertilization and further development are evolved actively. We have compared the results of primary ovarian follicles obtained from the ovaries of C57BL/6J × CBA/J F1 hybrid mice, cultivation in 2D and 3D-systems during 12–14 days. To create the 3D-environment follicles have been encapsulated in alginate hydrogel droplets of different densities or cultured in the 'hanging drop' (both individually and co-culturing with stromal cells of the cortical layer of the ovary). The latter model have been used to study the influence of the presence of ovarian stromal cells in the cultural system on the growth of primary follicles. During the ovarian follicle cultivation on the adhesive Petri dishes the abnormality of follicle structure took place due to theca cells eviction and following migration of granulosa cells on the surface of the theca cells. Follicle structure abnormality has led to a loss of contacts between oocyte and corona radiata cells and the further death of oocyte. Thus, the follicle culture in 2D-system can not be used to obtain oocytes competent for further *in vitro* fertilization. In 3D-culture system an increase of follicle diameter was observed, sometimes *in vitro* ovulation took place, but no antral cavity formation has been observed. In both cultivation systems there were 3 groups of ovulated oocytes: MII – the polar body fully formed, AI – early stage of the polar body formation, MI – no polar body. It was turned out that during *in vivo* ovulation all three types of oocytes were observed. Oocytes from the culture had smaller diameter and more grained cytoplasm than oocytes in natural cycle. Cultivation of the follicles during 7–14 days did not influence on the follicles viability. Staining with the fluorescent dyes that detect live and dead cells showed that dead cells were only in peripheral zone of the follicles. Possibly it was occurred due to a mechanical injury during the follicle isolation. Co-cultivation of the ovarian stromal cells with the follicles in the 'hanging drop' led to a formation of aggregates consisted of the stromal cells and the follicle. Time-lapse microscopy visualization was used to precise the results. In the cases when follicle was dead stromal cells did not form aggregates. Thereby it is possible to get the viable oocytes in the 3D-cultural systems, but their functional condition is the aim of further studies.

Phylogenetic relationships of some *Teucrium* (Lamiaceae) taxa growing in Turkey based on ITS region

T. Ozcan[1], T. Dirmenci[1], F. Coşkun[2]
[1]*Biology Education,* [2]*Biology, Balıkesir University, Balıkesir, Turkey*

Teucrium L. (Lamiaceae) is a cosmopolitan genus and most of the members of the genus distribute around the Mediterranean basin (almost 95% of all the taxa). In Turkey, *Teucrium* has about 34 species or 47 taxa with sixteen of these being endemic to Turkey. The genus *Teucrium* has traditionally been divided into the sections distinguishable by the calyx shape and the inflorescence structure in Turkey. The species growing in Turkey are classified into eight sections: *Teucrium* Benth., *Chamaedrys* (Mill.) Schreb., *Polium* (Mill.) Schreb., *Isotriodon* Boiss., *Scorodonia* (Hill) Schreb., *Stachyobotrys* Benth., *Scordium* (Mill.) Benth. and *Spinularia* Boiss. ITS4 and ITS5A primers were used for the amplification of ITS region. Standard PCR techniques were applied for this study. After the visualization of amplified samples on an agarose gel electrophoresis, they were sequenced using automated methods. In this study, some members of the eight sections were studied. Some *Ajuga, Nepeta, Satureja,* and *Origanum* taxa were chosen as different outgroups as well. Molecular data resulted in support of some morphological findings. The Sect. *Scordium* and the Sect. *Chamaedrys* displayed a close relationship to each other than the other sections of *Teucrium*. Besides, the members of the Sections *Scordium, Chamaedrys*, and *Teucrium* formed monophyletic groups. On the other hand, Sect. *Stachyobotrys* seems polyphyletic. Our data may solve some sys-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tematic problems of the genus. In addition, this study will contribute to the revision of the genus in Turkey.

Pou3f4 is required for normal development of otic capsule and modiolus of mouse inner ear

L. Wu[1], J. Y. Choi[1], J. Bok[2]
[1]Department of Otorhinolaryngology, [2]Department of anatomy, Yonsei University, Seoul, Korea

Pou3f4, encoding a POU domain transcription factor, is the major gene responsible for DFNX2 (DFN3), an X-chromosome linked nonsyndromic deafness in human. It has been shown that *Pou3f4* is expressed in the peri-otic mesenchyme during embryonic inner ear development and consistently, the lack of Pou3f4 function led to defects in bony structures surrounding and within the inner ear such as otic capsule and modiolus, respectively. Inner ear bones are formed by two distinct processes; otic capsule by endochondral ossification and modiolus by intramembranous ossification. To better understand the role of *Pou3f4* in inner ear bone development, we examined the inner ears of *Pou3f4del-J* mouse, a spontaneous mutant with a deletion in the *Pou3f4* locus.

The *Pou3f4*-deficient cochlea displayed abnormalities in the otic capsule and a loss of modiolus. Spatial and temporal expression patterns of chondrocyte markers such as *Sox9* and *Aggrecan* were relatively normal in the developing mutant cochlea. However, expression of hypertrophic chondrocyte marker such as *Col10a1* was slightly delayed, and subsequent bone maturation in the otic capsule appeared to be defective assessed by abnormal expression patterns of *Col1a1* and *Osteocalcin*. These results suggest that Pou3f4 function is required for normal hypertrophic chondrogenesis and bony maturation, but not for early chondrogenesis, during otic capsule formation. Consistent with the lack of modiolus in the mutant cochlea, a bone marker *Osteocalcin* was absent, but instead, *E-cadherin*, which is known to play a role in mesenchymal to epithelial transition, was ectopically expressed. This result suggests that the loss of modiolus in the *Pou3f4*-deficient cochlea is due to an epithelial transition of the mesenchymal tissues in the modiolar region.

Together, our observations suggest that mesenchymal expression of *Pou3f4* during inner ear development is crucial for normal development of both otic capsule and modiolus.
Keywords: bone, inner ear, pou3f4.

Primary characteristics of cytochromes P450 of the CYP74 family of *Selaginella moellendorfii*

E. V. Smirnova[1], S. Gorina[2], Y. Toporkova[1], L. Mukhtarova[2], Y. Gogolev[1], A. Grechkin[2]
[1]Laboratory of Molecular Biology, [2]Laboratory of Oxylipins, Kazan Institute of Biochemistry and Biophysics, Kazan, Russian Federation

Enzymes of lypoxygenase signaling system (including the members of the CYP74 family of cytochrome P450 – allene oxide synthases (AOSs), hydroperoxide lyases (HPLs) and divinyl ether synthases (DESs)) play important role in the regulation of response to stress. Among these groups of enzymes DES are less studied. Previously characterized enzymes are mainly found in Solanaceae plants. They utilize 9-hydroperoxides of fatty acids. There are only two characterized 13-specific DESs of garlic and flax. However, divinyl ethers were found in plants of the different taxons: for example, Ranunculaceae – Dicotyledonous, Iridáceae and Asparagaceae – Monocotylidonous.

Selaginella moellendorfii is the unique object, because there are a lot of various divinyl ethers in tissues of this plant. There are six genes in its genome, which possibly encode DESs. They have a low degree of similarity with the CYP74 enzymes of other subfamilies, that's why they were organized into the new subfamilies – CYP74L and CYP74M. Genes *CYP74M1*, *CYP74M2* and *CYP74M3* were cloned and corresponding enzymes were characterized. These enzymes are not similar isoforms, which catalyze the formation of one group of products, but clearly different enzymes which are responsible for formation of extended diversity of oxylipins. Structures of these compounds have been determined by GC-MS, NMR and UV-spectroscopy. Meaning of such variability of formed oxylipins for plants's life is still unknown.

The work is supported by the following grants RFFI 12-04-01140-a, 12-04-97087-r and 12-04-97059-r, MK-4886.2013.4 and SS-1890.2014.4.

Regional difference of gene expression in bluefin tuna musculature

A. Onishi[1], H. Koyama[2], S. Kinoshita[1], G. Kaneko[1], S. Asakawa[1], S. Watabe[2], H. Ushio[1]
[1]Aquatic Bioscience, The University of Tokyo, Tokyo, [2]Marine Bioscience, Kitasato University, Kanagawa, Japan

Bluefin tuna *Thunnus Olientaris* has anatomically and biochemically a unique muscle composition. In fish myotomal muscle, fast and slow muscles are anatomically separated, where fast muscle occupies the majority of trunk region and slow muscle forms thin layer beneath the skin (superficial slow muscle). In addition to these muscles, bluefin tuna has a large slow muscle lying near the vertebrae, called deep slow muscle. This characteristic muscle is involved in endothermy, the most representative biological feature of tunas. However, the molecular basis on the development of such unique musculature system is completely unknown. Myosin heavy chain (MYH) is a key molecule in the muscle contraction. MYH is encoded by the multi-gene family and spatial expression of MYH genes (*MYHs*) determines morphological, functional and metabolic features of muscle. In various fish species, the composition of *MYHs* shows a clear segregation between fast and slow muscles, although expressional patterns of *MYHs* in tuna muscle has not been proven yet. The present study aims to reveal molecular mechanisms involved in development of bluefin tuna musculature by analyzing spatial differences in the expression of *MYHs* and related genes.

One *MYH*, named *myhf1*, was cloned from fast muscle and its full-length cDNA sequence determined. Phylogenetic analysis based on deduced amino acid sequences showed that *myhf1* belongs to an adult fast-type. Interestingly, functionally important surface loops of myhf1 had characters to those of MYHs from tropical fish, suggesting the adaptation of bluefin tuna muscle to its endothermy. Quantitative real-time PCR and *in situ* hybridization showed a dominant expression of *myhf1* in fast muscle, whereas it was also expressed marginally in superficial and deep slow muscles. Two paralogues of *Sox6*, a known transcriptional repressor of slow muscle-specific genes, were cloned from fast muscle. Unexpectedly, two paralogues were expressed not only in fast but also in slow muscle. Taken together with expression of the adult fast-type *myhf1* in slow muscle, fast muscle fibers in slow muscle of bluefin tuna.

We also characterized the whole transcripts in bluefin tuna muscle by RNAseq analysis. cDNA libraries were constructed from fast, superficial slow, deep slow, and cardiac muscles, and sequenced using an Ion PGM sequencer. A total of 445 Mb

© 2014 The Authors. FEBS Journal © 2014 FEBS

sequences data were obtained from 4 libraries. Among the obtained 118,259 contigs, 32, 275, 106, and 233 contigs were specifically detected in deep slow, superficial slow, fast, and cardiac muscles, respectively. Especially, deep slow muscle-specific contigs are interesting, since they are possibly involved in the formation of this unique musculature.

Keywords: MYH, transcriptome, tuna.

Regulation of WD40-repeat protein 62 by Aurora A- Insights into the maintenance of the mitotic spindle during neurogenesis

N. R. Y. Lim[1], D. C. H. Ng[2]

[1]Biochemistry and Molecular Biology, Bio21 Institute, The University of Melbourne, [2]Biochemistry and Molecular Biology, Bio21 Insitute, The University of Melbourne, Melbourne, Australia

Mammalian neurogenesis occurs during embryogenesis and persists in specific regions of the adult nervous system. Neurogenesis is multidimensional - waves of cell proliferation interspersed with lineage determination and migration events. Understanding such a complex process can be facilitated by dissecting the mechanisms leading to disease that arise during neurodevelopment.

Autosomal recessive primary microcephaly (MCPH) is a neurodevelopmental disorder characterised by decreased brain volume and severe cerebral defects. Recently, mutations in *WD-repeat protein 62 (WDR62)* were found to underlie MCPH. The resultant clinical manifestations suggest that WDR62 is key to cell proliferation and migration in the developing brain. Recent studies showed that WDR62 localised to the spindle pole during cell division. Knocking down WDR62 led to abnormal spindle formation, and premature differentiation of neuroprogenitor cells led to reduced brain volume in mice.

Containing WD-repeats structurally favourable for important scaffolding functions, we hypothesise that WDR62 complexes act as important nodes conferring signalling specificity or provide platforms mediating the subcellular localisation of its binding partners.

Here, the composition of immunoprecipitated WDR62 complexes was elucidated by high performance liquid chromatography-tandem mass spectrometry, revealing distinctive interaction partners of WDR62 in interphase and mitosis. Upon mitotic entry, WDR62 was found to interact with the mitotic regulator, Aurora Kinase A (AURKA). AURKA plays key roles in mitosis - regulating spindle formation and architecture, and mitotic progression. Depleting WDR62 resulted in mitotic spindle deformities, consistent with the phenotype observed upon AURKA inhibition. Strikingly, the inhibition of AURKA led to the loss of WDR62 localisation at the spindle pole, and the biochemical basis of this relationship was further characterised in cultured cell models. While the association of WDR62 with microtubules was regulated by AURKA activity, WDR62 was in turn important for the localisation of AURKA to microtubules. Loss of WDR62 localisation at the spindle pole consequentially results in the impediment of its mitotic functions.

The revelation of WDR62-AURKA interaction and the further characterisation of their relationship will provide important insights into mitosis and mammalian neurogenesis. Interestingly, WDR62 was recently found upregulated in certain cancers. As an inhibitor of AURKA is in clinical trials for cancer, the characterisation of this mitotic interaction will further improve molecular understanding of their contribution to cancer progression.

Retrortansposon-based molecular markers for genetic diversity analysis in genus *Linum*

N. V. Melnikova[1], A. V. Kudryavtseva[1], A. V. Zelenin[1], V. A. Lakunina[1], O. Y. Yurkevich[1], A. A. Dmitriev[1], M. S. Belenikin[1,2], A. S. Speranskaya[1,3], N. V. Kishlyan[4], T. A. Rozhmina[4], O. V. Muravenko[1]

[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, [2]Research Institute of Physico-Chemical Medicine, [3]Department of Higher Plants, Lomonosov Moscow State University, Moscow, [4]All-Russian Research Institute for Flax of the Russian Academy of Agriculture, Torzhok, Russian Federation

SSAP (Sequence-Specific Amplified Polymorphism) method was used to study the genetic diversity of 22 *Linum* species from sections *Linum*, *Adenolinum*, *Dasylinum*, *Stellerolinum*. The SSAP method is based on DNA restriction, ligation of adapters to the restriction sites, and amplification of the DNA fragment with primers complementary to the adapter sequences and the selected conservative region of the retrotransposon.

For investigation of species of genus *Linum* we chose retrotansposons *FL1a*, *FL1b* and *Cassandra*. In total 223 polymorphic bands were scored. Nine groups could be distinguished on the basis of SSAP fingerprint similarity: group ‘A’ included different species of sect. *Adenolinum* (syn. *L. perenne* group); group ‘B’ consisted of *L. hirsutum* subsp. *hirsutum* accessions and group ‘C’ – of *L. hirsutum* subsp. *pseudoanatolicum* and *L. hirsutum* subsp. *anatolicum*; Groups ‘D’, ‘E’, ‘F’ and ‘G’ included species accessions of sect. *Linum*: *L. marginale; L. narbonense, L. decumbens* and *L. grandiflorum* respectively. Group ‘H’ included accessions of *L. angustifolium* and *L usitatissimum* (sect. *Linum*); group ‘I’ – *L. stelleroides* accessions (Figure Neighbor-joining dendrogram for SSAP markers. 1, 2, 5, 6, 7, 8 *L. perenne*; 3 *L. altaicum*,; 4 *L.* komarovii; 9 *L. leonii*; 10, 11 *L. pallescens*; 12, 13 *L. mesostylum*; 14,15 *L. lewisii*; 16, 17, 18, 19, 20 *L. austriacum*; 21 *L. amurense*; 22, 23, 24, 25 *L. hirsutum*; 26 L. *marginale*; 27, 28 *L. narbonense*; 29, 30 *L. decumbens*; 31, 32 *L. grandiflorum*; 33, 34, 35, 36, 37, 38 *L. angustifolium*; 39 *L. usitatissimum* subsp. *biene*; 40, 41 *L. usitatissimum* convar. *crepitans*; 42, 43, 44, 45 *L usitatissimum*; 46, 47 - *L. stelleroides*.). Each group contained at least one group-specific marker. Species clusterization on the bases of

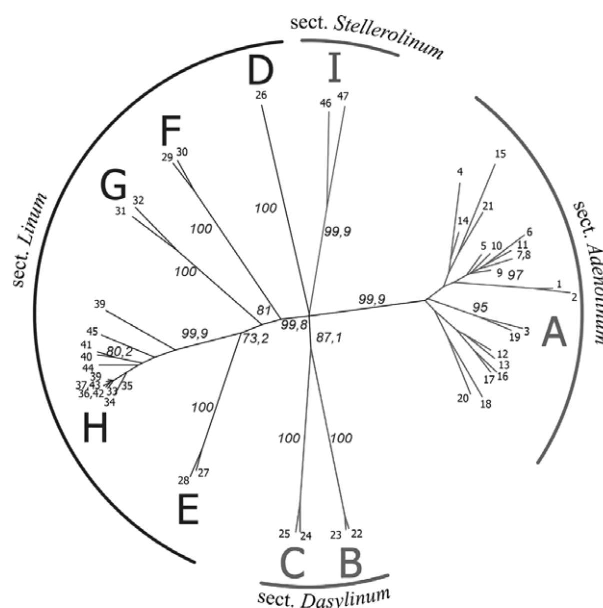

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

SSAP markers was in concordance with their taxonomic division into sections *Dasylinum, Stellerolinum, Adenolinum* and *Linum*. All species of sect. *Adenolinum* clustered apart from species of sect. *Linum*. The data confirmed the accuracy of the separation in these sections. Members of section *Linum* are not as closely related as members of other sections, so taxonomic revision of this section is desirable. *L. usitatissimum* accessions genetically distant from the modern flax cultivars were revealed in our work. These accessions are of particular interest for flax breeding and introduction of new resistances and other useful traits into flax cultivars.

The work was financially supported by grants MK-6205.2012.4, RFBR 12-04-01469 and RFBR 13-04-01770.

SCN1A gene polymorphisms in patients with drug-resistant epilepsy

M. S. Belenikin[1,2], **A. A. Slavokhotova**[3], N. Bryukhanova[1], T. Mescheryakova[1], S. Zhilina[1], G. Mutovin[2]
[1]*Research Center for Children Medical Care,* [2]*Pirogov Russian National Research Medical University,* [3]*Vavilov Institute of General Genetics, Moscow, Russian Federation*

Epilepsy is a life-shortening neurological disorder affecting approximately 1–2% of the worldwide population. Among the genes known to be involved in epilepsy, the SCN1A gene represents one of the most commonly mutated human epilepsy genes. The SCN1A gene codes for the a-subunit of the voltage-gated sodium ion channel. To date about one thousand mutations a reported at SCN1A gene. SCN1A has 26 exons and elucidations for polymorphisms that are most associated with epilepsy is actual task.

An intronic SCN1A IVS5-91G>A polymorphism (rs3812718) is associated with susceptibility to epilepsy [1,2]. Across the studies the strongest association with epilepsy was was found for rs3812718: odds ratio (OR) = 0.85 for allele G (p = 0.0009) and 0.73 for genotype GG versus AA (p = 0.003) [1]. rs2298771 is also associated with susceptibility to epilepsy [1].

Using 454 GS Junior we have performed high-throughput sequencing for exon and important intron regions of SCN1A gene for 42 patients with drug-resistant epilepsy and controls older than one year. For coupled samples the results was verified by Sanger sequencing.

Excluding a few rare mutations of SCN1A gene from this analysis, we have identified and analysed four polymorphisms: rs2298771 (c.3166G>A, exon 16), rs6432860 (c.2259T>C, exon 13), rs7580482 (c.1212A>G, exon 9), rs3812718 (c.603-91G>A, IVS5-91G>A).

We first identified the strong correlations between genotypes for rs2298771, rs6432860 and rs7580482 polymorphisms. Finally, we have found the next associations for polymorphisms:

rs2298771 GG / rs6432860 TT / rs7580482 AA / rs3812718 GG - 5 cases

rs2298771 GA / rs6432860 TC / rs7580482 AG / rs3812718 GA -16 cases

rs2298771 GA / rs6432860 TC / rs7580482 AG / rs3812718 GG - 1 cases

rs2298771 AA / rs6432860 CC / rs7580482 GG / rs3812718 AA - 14 cases

rs2298771 AA / rs6432860 CC / rs7580482 GG / rs3812718 GA - 5 cases

rs2298771 AA / rs6432860 CC / rs7580482 GG / rs3812718 GG - 1 cases

MON-258
Semi-rational engineering of *Neisseria polysaccharea* amylosucrase towards the synthesis of novel oligosaccharides for carbohydrate-based vaccines

A. Verges[1], E. Cambon[1], S. Barbe[1], S. Tranier[2], L. Mulard[3], M. Remaud-Simeon[1], I. Andre[1]
[1]*Université de Toulouse, INSA, CNRS, INRA; Laboratoire d'Ingénierie des Systèmes Biologiques et des Procédés,* [2]*Université de Toulouse, CNRS, UPS; Institut de Pharmacologie et de Biologie Structurale, Toulouse,* [3]*Institut Pasteur, CNRS; Unité de Chimie des Biomolécules, PARIS, France*

Chemical synthesis of complex oligosaccharides still remains critical. Enzymes have emerged as powerful tools to circumvent chemical boundaries of glycochemistry. However, natural enzymes do not necessarily display the required properties and need to be optimized by molecular engineering. Combined use of chemistry and tailored bio-catalysts may thus be attractive for exploring novel synthetic routes.

Within the frame of the development of synthetic routes to provide antigenic oligosaccharides entering in the composition of multivalent vaccines to prevent shigellosis, we have developped a semi-rational engineering strategy to create enzymes displaying

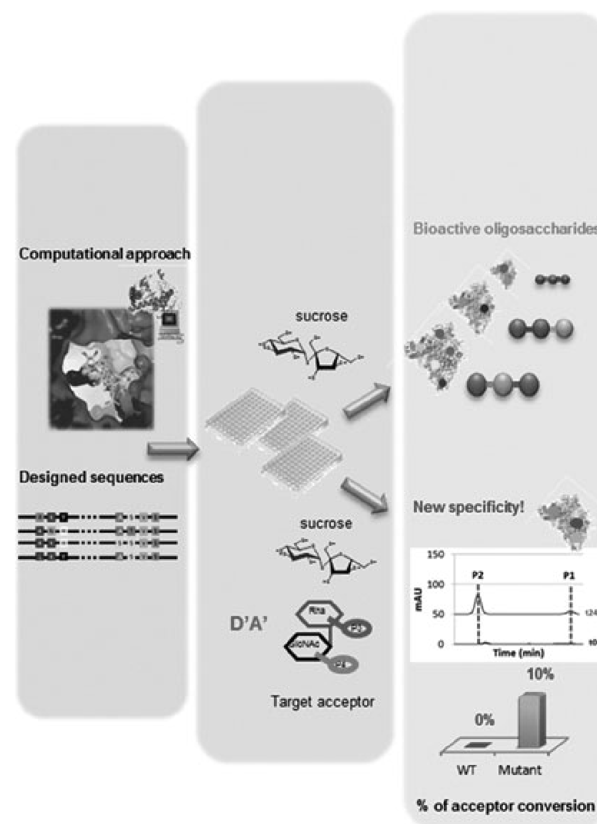

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

the requested specificity toward a non-natural substrate, a chemically protected disaccharide which is a key intermediate in the synthesis of *S. flexneri* serotype 1b repeating unit.[1]

Following a computer-aided design strategy, a focused library of ~16.8 x10^4 mutants of amylosucrase from *Neisseria polysaccharea* (*Np*AS), a sucrose-utilizing a-transglucosidase, was constructed. Upon screening for their ability to utilize sucrose as donor substrate, 55 improved variants were identified. They were subsequently assayed for their aptitude to glucosylate the target non-natural acceptor.[2, 3, 4]

As a result, one mutant containing 7 mutations introduced in the catalytic site, was isolated with a totally novel ability to recognize and glucosylate with the requisite regiospecificity a disaccharide acceptor, which is not recognized at all by the parental wild-type enzyme. Moreover, 4 additional mutants displaying original product profiles or enhanced sucrose activity compared to the wild-type enzyme were identified and characterized in more details at both biochemical and structural levels.

Altogether, these results will hopefully help to improve our comprehension of the sequence-structure-function relationships of this class of enzymes with the view of providing new insights to guide the design of tailor-made enzyme libraries.

Serum protein profile analysis by SELDI-TOF in caveolin-1 transgenic mice

D. I. Popescu, E. Codrici, S. Mihai, A. Nita, R. Albulescu, C. Tanase

Biochemistry-Proteomics, 'Victor Babes' National Institute of Pathology, Bucharest, Romania

Introduction: A caveolin-1 null (CAV-1$^{-/-}$) mouse model was created, to assess the role of caveolin-1 in biogenesis, endocytosis, cell proliferation, signaling pathways and other molecular mechanisms of diseases. Recent studies highlight an important role of caveolin-1 in the regulation of different protein expression. In this content, the aim of our study was to estabilish the serum protein profile for cav-1 transgenic mice versus control, using SELDI TOF – MS (1).

Methods: Serum from transgenic mice Cav-1$^{-/-}$ (Cav-1 KO: Cav1^{tm1Mls}/J) and Cav-1$^{+/+}$ (B6129PF2/J) (The Jackson Laboratory) as control were analyzed. After optimization of protocol selection, the serum protein profiling study was performed on CM10 protein chips using SPA (sinapinic acid) as matrix on a SELDI-TOF personal edition system (Bio-Rad).

Results: Experimental parameters specific to the ProteinChip, including spot protocols (laser intensity and detector sensitivity) were optimized to peak detection variance. Optimal instrument settings, regular calibration along with controlled sample handling and processing nearly doubled the number of peaks detected and intensity variance. The protein profiles were analyzed with the ProteinChip Data Manager Software 3.0.7. The proteomic spectra obtained were compiled, normalized, and mass peaks identified with mass-to-charge ratios between 2000–6000 Da, 10000–19000 Da and between 25.000–40.000 Da. Comparative analysis of protein profile revealed that there were a total of 18 different expressed peptide peaks with statistical significance in the molecular range of 2000–40000 Da. Among which, the expressions of 8 proteins were up-regulated and that of 10 proteins were down regulated in transgenic mice.

Conclusions: The monitoring of protein profiles in caveolin-1 transgenic mice, may allow us to understand the involvement of these mutations in the molecular mechanisms of diseases. SELDI-TOF MS technology represents a proteomics approach that can rapidly identify tens of thousands of proteins. However, it is challenging work to validate, prioritize, and select the best targets from those candidate proteins.

Site-specific genome mutagenesis using the CRISPR/Cas9 system in *C. elegans*

C. A. Umbricht, M. Walser, A. Hajnal

Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland

Background: The CRISPR/Cas9 system has become an efficient technique to generate mutations in the genome of a variety of model organisms. The system consists of a nuclease (Cas9) which is guided by a single guide RNA (sgRNA). The Cas9-induced targeted double strand breaks are subsequently repaired by non-homologous end joining (NHEJ) or homology-directed repair (HDR). Specifically designed donor templates can trigger HDR and thereby lead to insertions of transgenes at specific locations of the genome. Consequently, the CRISPR/Cas9 system is a precise and effective tool for tailored genome editing.

Observations: We applied the CRISPR/Cas9 system to introduce point mutations into the *C. elegans* genome by using the Cas9 nuclease expressed under different germline promoters. In addition, we used varying concentrations of the nuclease, sgRNA and donor template to optimize the efficiency of the system. Furthermore, we developed a single-step approach to clone sgRNAs. After gonadal injection of young adult hermaphrodites, we tested a variety of screening techniques to detect NHEJ- and HDR-events with a special emphasis to identify single amino acid substitutions.

Conclusions: We optimized the sgRNA cloning procedures and screening techniques to identify animals containing engineered inserts in the genome. Our data show that the CRISPR/Cas9 system can be used in combination with a donor template to insert tailored changes into the genome of *C. elegans* in a fast manner and at low cost.

Structural and signalling function of b-catenin during cardiogenesis

O. Piven, O. Palchevska, L. Mazcewich, L. Lukash

Institute of Molecular Biology and Genetics, Kyiv, Ukraine

Beta-catenin is an armadillo protein family member and has dual function being an essential component of the Adherence junction mediating cell-cell contact and acting as a transcriptional co-activator of the T-cell factor/lymphoid enhancer factor complex. In this study we have addressed the role of β-catenin during cardiogenesis, namely we have analyzed how b-catenin haploinsufficiency reflected on embryonically heart development. For this

© 2014 The Authors. FEBS Journal © 2014 FEBS

purpose we induced embryonic β-catenin in heart using Cre-mediated technique. To generate cardiac-specific deletion of β-catenin β catflox/+, a-myosin heavy chain (aMHC)-Cre mice were mated with β catflox/flox mice and embryos were recovered from timed pregnancies. Yolk sac tissues after embryo recovery were used for genotyping. Morphological analysis of embryos hearts were performed with HE and IM staining using. Signalling function of β-catenin during cardiogenesis was analyzed with qPCR using. Gene expression was represented by the ΔC_T value normalized to the reference gene GAPDH. The $\Delta\Delta C_T$ value of each target gene was then calculated by subtraction of the average ΔC_T from the control group. Finally, the n-fold difference was calculated by using the formula $2\Delta\Delta^{CT}$. In our experiment we studied the level of TCF-4, β-catenin, β-MHC, α-MHC, ANP, BNP, cFos and cMyc. For all morphological and molecular biological analysis we have used newborn mice and embryos at E10.5, E12.5 and E14.5. When mice harboring a Cre recombinase transgene under control of an aMHC-Cre promoter were crossed with mice containing a floxed β catenin allele, the embryos appeared morphologically normal at embryonic stages E10.5 and E14.5. To confirm that Cre-mediated deletion of β-catenin gene produces a null phenotype. Immunohistochemical analysis confirmed the absence of β-catenin in the developing myocardium of mutant mice and also demonstrated that N-cadherin was not affected in β-catenin-deficient cardiomyocytes. Thus, the absence of β-catenin does not perturb N-cadherin expression in the embryonic heart, probably due to functional redundancy between β-catenin and plakoglobin in the formation of AJ formation. Interesting that genotyping of β-catenin newborn mice after similar crosses revealed that aMHC-Cre+, β-cateninflox/flox mice were under-represented, suggesting that some mice were dying in utero, probably at late gestation. Thus, only 10% of mice born had a genotype of aMHC-Cre+, β-cateninflox/flox, and one of the mutants died shortly after birth. Additionally in our work we registered some violations of β-catenin signalling and perturbation of β-catenin target genes expression at all analyzed embryos and newborn mice.

Studies on subcellular localization of the germ cell-expressed protein from *Drosophila melanogaster*

B. Greb-Markiewicz[1], N. Banaś[1], D. Sadowska[1], J. Godlewski[2], J. Dobrucki[3], A. Ożyhar[1]
[1]*Biochemistry, Wrocaw University of Technology, Wrocaw, Poland,* [2]*Neurosurgery, Harvard Institute of Medicine, Boston, MA, USA,* [3]*Department of Cell Biophysics, Jagiellonian University, Kraków, Poland*

Juvenile hormone (JH) and 20-hydroxyecdysone have prominent roles in regulating insect development. There is an accumulating evidence that the antimetamorphic function of JH involves Methoprene-tolerant (MET), so MET becomes a putative JH receptor protein. MET belongs to the family of bHLH-PAS transcription factors. The bHLH-PAS proteins are critical regulators of the gene expression networks that are responsible for many essential physiological and developmental processes. In contrast to other insects that depend on MET for survival, *Drosophilids* posses a MET paralog Germ cell-expressed (GCE). While neither mutation of single protein is lethal, mutants missing both paralogs die as prepupae, suggesting that MET and GCE have some redundant functions in vivo. The bHLH-PAS transcription factors functional activity is often correlated with shuttling between nucleus and cytoplasm, according to the masking and unmasking by interacting partners, signals directing these proteins to nuclear or cytoplasmic compartment of the cell.

Recently we identified Nuclear Localization Signals (NLSs) and Nuclear Export Signals (NESs) for MET (Greb-Markiewicz *et al.*, 2011). In order to determine the sequences of NLSs and NESs in GCE, series of deletion and point mutants tagged by yellow fluorescence protein (YFP) were prepared by cloning into EYFP-C1 vector, expressed in mammalian cells and observed with confocal microscopy system.

Contrary to nuclear localization of MET, full lenght GCE we could observe both in nucleus and cytoplasm of the cell. Our results show that dominant NLS from MET is lacking in GCE. We have detected presence of active NLSs in bHLH, hinge region, PAS B and C-terminal fragment of GCE. Active NESs motifs are present in PAS A and PAS B. We found additional factors influenzing localization pattern of deletion mutants and full lenght GCE in absence and presence of JH. We conclude that GCE similarly to MET is a cytoplasm-nucleus shuttling protein with a complicated control system of localization, which vary between proteins.

Study of genetic diversity of green toads (*Pseudepidalea viridis*) populations in Warsaw using msDNA

R. K. Weglinska[1,2,3], M. Gonciarz[3], H. Panagiotopoulou[4], M. Czarnocka-Cieciura[1], A. Stankovic[3,4]
[1]*College of Inter-Faculty Individual Studies in Mathematics and Natural Sciences,* [2]*The Student Society of Genetics and Epigenetics,* [3]*Institute of Genetics and Biotechnology, Faculty of Biology, University of Warsaw,* [4]*Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland*

In the structure of urban agglomeration, small artificial lakes in parks and squares are often inhabited by amphibians like smooth newts and green toads. These habitats are separated and confined by the busy roads and lacking of green areas housing estates. It may affect a high degree of populations isolation, interrupt functional connectivity and genetic structure of species.

The high level of isolation could lead to such negative phenomena as inbreeding depression and decreased in genetic diversity. It may also increase the probability of extinction risk of the local populations. All of these effects could be the result of random population size fluctuations and environmental changes including climate changes. On the other hand, occurrence of common alleles and similar frequency in subpopulations from different study sides may suggest the presence of certain rate of the gene flow.

The aim of the project is to investigate the genetic and demographic structure of the green toad (*Pseudepidalea viridis*) population, species present inter alia in the urban environment of Warsaw, the capital city of Poland. Samples were collected in 2012 and 2013 from five neighboring districts. DNA was extracted directly from eggs and fragments of dead individuals collected near each of studied reservoirs. We used 13 polymorphic microsatellite markers developed for the European green toad. We assessed genotypes for 72 individuals and thus described the genetic characteristic of local populations.

Our results shows high level of inbreeding in studied populations, however some gene flow between close populations can be observed. Those results indicate that migration in urban environment is very difficult for amphibians, nevertheless it is not impossible. That's suggest, a little help applied from humans could significantly increased genetic diversity and population fitness

© 2014 The Authors. FEBS Journal © 2014 FEBS

through facilitating migration. We also confirmed that using 13 polymorphic microsatellite markers is enough to study landscape genetics of green toad populations.

System analysis of cells peptidome of the Phiscomitrella patens

R. Khazigaleeva, I. A. Fesenko, V. Govorun
Institute of Bioorganic Chemestry, Moscow, Russian Federation

Cells within an organism must communicate over both short and long physiological ranges to ensure proper patterning and functional connections. There are several ways to achieve this in plants, including phytohormones, mobile transcription factors, noncoding RNAs, and small signaling peptides.

Peptides are key regulators of many physiological processes in animals, including defense reactions and hormonal, neurohumoral and signaling functions.

As in animals, peptide signals regulating plant growth and development act as ligands of receptor-like kinases.

Peptide pools of the two life forms as well as of the protoplasts of Physcomitrella patents moss were studied by tandem mass spectrometry analysis.

Using tandem mass spectrometry analysis we identified about 4000 gametophore peptides that were fragments of 761 precursor proteins. In protonema cells, we identified about 4000 peptides derived from 855 precursor proteinsthe pool of endogenous peptides and carried out transcriptional profiling of gametophores, protonemata and protoplasts of the P. patens moss.

Transcriptome profiling of the three moss cell types showed that genes of peptide precursors are expressed at higher levels that the rest of the genes We demonstrated significant differences between the peptidomes of protoplasts, protonemata and gametophores and found that the transcriptional level of many gametophore- or protonema- specific peptide precursor proteins tends to be higher in the corresponding tissue.

Telocytes versus fibroblasts and endothelial cells: a proteomic approach

D. Cretoiu[1,2], Y. Zheng[3], S. M. Cretoiu[1,4], L. M. Popescu[1,5], X. Wang[6,7]
[1]*Division of Cellular and Molecular Medicine, Carol Davila University of Medicine and Pharmacy,* [2]*Department of Molecular Medicine, Victor Babeş National Institute of Pathology, Bucharest, Romania,* [3]*Department of Respirology, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China,* [4]*Department of Ultrastructural Pathology,* [5]*Division of Advanced Studies, Victor Babeş National Institute of Pathology, Bucharest, Romania,* [6]*Department of Pulmonary Medicine, Fudan University, Zhongshan Hospital, Shanghai Respiratory Research Institute,* [7]*Fudan University Center for Clinical Bioinformatics, Shanghai, China*

Telocytes (TCs) are newly described interstitial cells characterized by the presence of small cellular bodies and a variable number of very long and thin extensions named telopodes. Telopodes are defined by a length of ~100 micrometers and an uneven caliber given by a succession of very thin segments - podomers and dilations named podoms. TCs were morphologically characterized by light, fluorescence, transmission and scanning electron microscopy, but their proteome was not analyzed. Therefore, we examined by 2D Nano-ESI LC-MS/MS the differentially expressed proteins in lung TCs by comparison with fibroblasts and microvascular endothelial cells. Based on the bioinformatics analysis, proteins extracted from primary cultures of these cells were analyzed and screened by two-sample t-test ($P < 0.05$) and fold change (>2). We identified hundreds of proteins up- or down-regulated, respectively, in TCs as compared with fibroblasts and microvascular endothelial cells. TCs proteins were classified into different categories based on their molecular functions and biological processes. While the proteins identified in TCs are mainly involved in catalytic activity and as structural molecular activity, the proteins in FBs are involved particularly in the synthesis of collagen and other extracellular matrix components. The up-regulated ECs proteins e.g. cell surface glycoprotein MUC18 and von Willebrand factor are considered as hallmarks for these cells. In conclusion, we report here the first extensive identification of proteins from TCs using a quantitative proteomics approach, suggesting that TCs might play specific roles in: a) intercellular signaling b) mechanical sensing and mechanochemical conversion task, c) tissue homoeostasis and remodeling/renewal, d) anti-oxidative stress and anti-cellular aging mechanisms; e) cancer cell proliferation through the inhibition of apoptosis.

The CYP74 family in evolution of cytochromes P450

Y. Toporkova[1], Y. Gogolev[1], A. Grechkin[2]
[1]*Laboratory of molecular biology,* [2]*laboratory of oxylipins, Kazan institute oa biochemistry and biophysics, Kazan, Russian Federation*

Lipoxygenase cascade is one of the most important signaling cascades. Its functioning results in formation of physiologically active derivatives of polyenoic fatty acids – oxylipins. Oxylipins have been found in anim als, proteobacteria, brown and red algae and all land plants. Crucial enzymes of lipoxygenase cascade providing diversity of oxylipins are lipoxygenases and cytochromes P450 of the CYP74 family. Lipoxygenases catalyze oxygenation of fatty acids into hydroperoxides, and the CYP74 enzymes are responsible for their further conversions.

Based on phylogenetic analysis of the CYP74 family and the P450 superfamily one could conclude that the CYP74 enzymes are the most ancient among all P450s. It is confirmed by the following facts. Unlike classic cytochromes P450 which are monooxygenases, the CYP74 enzymes don't need redox partners or molecular oxygen for functioning. Thereby sites conservative for monooxygenases P450 are absent in the CYP74 sequences. Besides, the CYP74s' oxygen-binding domain is substituted by the I-helix central domain involving in catalytic action. And haem-binding domain of the CYP74s contains additional nine amino acids. Evolutionally deletion of motif and simple reaction are more likely than insertion and complex reaction, respectively.

Appearance of the CYP74 enzymes correlates with accumulation of molecular oxygen in the atmosphere. It results in necessity to save cell from membrane fatty acids oxygenated by active forms of oxygen. We suppose that the CYP74 enzymes catalyzed

© 2014 The Authors. FEBS Journal © 2014 FEBS

conversion of oxygenated fatty acids into various compounds – oxylipins which later began to function as signal molecules. It is confirmed by the fact that structure of the CYP74 enzymes is similar to the structure of some catalases. And there are some catalases which possess activities similar to the CYP74s. Thus, one could conclude that the CYP74 enzymes are ancestral for the whole P450 superfamily.

The diatom-derived aldehyde decadienal affects ERK signaling during metamorphosis of the ascidian *Ciona intestinalis*

I. Castellano, E. Ercolesi, G. Romano, A. Ianora, A. Palumbo
Stazione Zoologica Anton Dohrn, Naples, Italy

Diatoms are photosynthetic unicellular organisms playing key roles in the transfer of energy through marine food chains. During grazing by their predators, diatoms can produce polyunsaturated aldehydes, such as decadienal, which have been shown to induce deleterious effects on embryonic and larval development of benthic organisms [1,2]. These effects are mediated by the physiological messenger nitric oxide in the sea urchin *Paracentotus lividus* [3]. Here, we investigate the effect of decadienal on larval development and metamorphosis of the ascidian *Ciona intestinalis*. After hatching, the mobile larva is transformed into a fixed juvenile through a remarkable regression of the tail. At the molecular level, *C. intestinalis* development is regulated by different events, sometimes cross-talking together. These events include: NO production/diffusion, ERK and JNK activation and apoptosis mediated by capsase 3 activation [4,5]. In a previous study we reported that NO mediates a nitro-oxidative stress pathway during *Ciona* larval development resulting in ERK nitration and that increasing NO levels induce the acceleration of metamorphosis [6]. Recently, we have also shown that the increase of NO levels contributes to maintain ERK activation through the down regulation of the MAPK phosphatases, MKP1 and MKP3 [7]. Now we show that larvae exposed to increased levels of decadienal encounter a significant reduction in NO levels during development, resulting in a delay in metamorphosis. Moreover, we show that this event is related to ERK inactivation as demonstrated also by the effect on the downstream ERK gene transcription. Finally, we analyzed the expression of several genes involved in redox homeostasis and we observed that some genes involved in glutathione metabolism are up-regulated upon treatment with decadienal, thus suggesting a fine regulation of glutathione levels. We hypothesize that larval developmental delay induced by decadienal may represent a defense mechanism of the organism to overcome the negative effects of the toxin until the larva attaches to the substrate for metamorphosis into the adult. Overall these results give new insights into the molecular pathways targeted by decadienal, affecting key decisions in biphasic life cycle transition from vegetative to reproductive stages.

The effect of transferrin sialylation on foetal development during pregnancy

M. Wrześniak[1], M. Zalewska[1], M. Królik[2], A. Bizoń[1], H. Milnerowicz[1]
[1]*Department of Biomedical and Environmental Analyses, Medical University,* [2]*Rex Company Polish Genetic Centrum, Wroclaw, Poland*

Transferrin (Tf) is glycoprotein which sialylation is considered to take part in iron transporting. Changes in number of sialic acid residues are thought to have an impact on iron transport and foetal development.

Capillary electrophoresis (Beckman Coulter PA 800plus) was used to separate glycosylated subfractions of transferrin. Electrophoresis was conducted by commercial test for Carbohydrate-deficient Transferrin analyzing with modification. Exposure to tobacco smoke was measured by cotinine level using ELISA test. Iron parameters were determined by colorimetric methods.

Patients were divided in terms of: stage of pregnancy (1st, 2nd and 3rd trimester of pregnancy), health status (ID-iron deficiency and women with proper iron stores as control group) and smoking status (smoking and non-smoking). Relative level of 5-sialoTf during pregnancy was rising while 3-sialo and 4-sialoTf relative level were decreasing in both: ID and control (no-ID and non-smoking) group. 6-sialoTf relative level was rising during pregnancy only in the control group. In the group with ID positive correlation between: 5-sialoTf level and AC (abdominal circumference) ($r = 0.431$; $p < 0.05$) 6-sialoTf level and BPD (biparietal diameter), HC (head circumference), AC and FL (femur length) ($r = 0.450$, $r = 0.496$, $r = 0.508$, $r = 0.423$; $p < 0.05$ respectively) was shown and negative correlation between 3-sialoTf level and BPD, HC, AC and FL ($r = -0.514$, $r = 0.579$, $r = -0.538$, $r = 0.590$; $p < 0.05$ respectively) occurred. Similar observation in the control group was detected.

More-sialylated Tf isoforms positively correlated with foetal biometric parameters and lowered iron stores what may suggest that high content of Tf sialic acid residues protect foetus from lower iron delivery.

Keywords: foetal development, sialylation, transferrin.

The evolutionary conserved LIM homeodomain protein LIM-4/LHX6 impose dual neurotransmitter identity of a *C. elegans* motor neuron-type

J. J. Yeon[1], J. Kim[1], Y. Huh[2], Z. Fang[1], C. Li[3], K. Kim[1]
[1]*Department of Brain Science, DGIST, Daegu,* [2]*Division of Electron microscopic research, Korea Basic Science Institue, Daejeon, Korea,* [3]*Department of Biology, City College of the City University of New York, New York, NY, USA*

The expression of specific transcription factors dictates the differentiated features of postmitotic neurons. However, the mechanism of how specific molecules determine or specify neuronal cell fate during development is not fully understood. In *C. elegans*, the cholinergic and peptidergic SMB neurons consist of four motor neurons that innervate muscle quadrants in the head, send processes posterior down the sub-lateral cords (White et al., 1986), and monitor the amplitude of sinusoidal movement (Gray et al., 2005). To identify the factors that specify the neuronal cell fate of SMB, we performed genetic screens and isolated several *lim-4* mutant alleles, in which *flp-12* neuropeptide gene expression was completely abolished only in the SMB neurons. Previously, it was shown that the LIM-4 LIM homeobox protein has a major role in specification of

© 2014 The Authors. FEBS Journal © 2014 FEBS

AWB chemosensory neuron identity (Sagasti et al., 1999). We found that the expression of other SMB markers, *odr-2* (GPI-Anchored protein), *cho-1* (choline transporter), and *unc-17* (synaptic vesicle acetycholine transporter), were also abolished in *lim-4* mutants and LIM-4 maintains its own expression by autoregulation in the SMB neurons. To investigate the molecular mechanism of *lim-4*, we did promoter analyses and bioinformatics searches with the SMB marker genes and identified several *cis*-regulatory motifs including putative LIM-4 binding sites. We confirmed that these regulatory elements were sufficient to drive the expression of a non-SMB marker gene in the SMB neurons. In addition, we expressed *lim-4* cDNA under the control of the heat shock promoter which not only fully restored *flp-12* gene expression in *lim-4* mutants, but induced the ectopic expression of *flp-12* in other cell-types. Since *lim-4* is evolutionary well-conserved throughout different species, we also expressed the LIM-4 human orthologue, LHX6 and LHX8 cDNA under the control of heat shock promoter in *lim-4* mutants, and found that *lim-4* mutant phenotypes were fully rescued. Furthermore, we are currently expressing the human LHX6 or *C. elegans* LIM-4 in the human neuroblastoma cells to test if expression of these genes could induce the cholinergic cell fate. Taken together, LIM-4 appears to be necessary and sufficient to promote specification of the cholinergic and peptidergic SMB motor neuron fate.

The influence of biological and environmental factors on MT1/MT2 ratio

K. Kowalska, A. Bizoń, H. Milnerowicz
Department of Biomedical and Environmental Analysis, Medical Univeristy, Wroclaw, Poland

Metallothionein (MT) is a protein presents mainly in 4 isoforms: MT1, MT2, MT3, MT4. MT1 and MT2 are most prevalent in the human body. The concentrations of these two isoforms, and consequently MT1/MT2 ratio, are regulated by many factors, including metals, cytokines, glucocorticoides and free radicals. These factors are determined by such aspects of human biology as gender, pregnancy, as well as by environmental factors including the use of oral contraceptives and cigarette smoking, all which may affect the MT1/MT2 ratio in the body.

The investigations were performed in healthy subjects ($n = 128$), who were in similar age (26 ± 5 years). The concentrations of MT1 and MT2 were determined in erythrocyte lysate by ELISA Kit (ref. No. E91119Hu for MT1, E91868Hu for MT2, Uscn Life Science Inc., China). The MT1/MT2 ratio was calculated. The data concerning cigarette smoking were verified by determination of plasma cotinine, metabolite of nicotine, using the commercial Cotinine ELISA test (ref. No.: EIA-3242, DRG International, Inc., USA). MT1 and MT2 concentrations were analyzed in the following groups: group A (female non-smokers not taking oral contraceptives, $n = 36$), group B (female non-smokers taking oral contraceptives, $n = 26$), group C (female smokers not taking oral contraceptives, $n = 15$) group D (pregnant women in third trimester, $n = 30$) and group E (male non-smokers, $n = 21$).

The groups B and E had significantly higher MT1/MT2 ratio (3.75 ± 1.52 and 4.23 ± 1.58, respectively) when compared to the group A (2.65 ± 0.95), while the differences in MT1/MT2 ratio between groups A and C (2.63 ± 1.08) and between groups A and D (3.27 ± 1.34) were not observed.

The gender and oral contraceptives can cause higher MT1/MT2 ratio.

MON-272
The lipoxygenase cascade in several species of brown algae

V. Ermilova[1], Y. Toporkova[1], L. Mukhtarova[2], Y. Gogolev[1], A. Grechkin[2]
[1]*Laboratory of Molecular Biology*, [2]*Laboratory of Oxylipins, Kazan Institute of Biochemistry and Biophysics, Kazan, Russian Federation*

Plants lack an immune system in the sense that it exists in animals, but they possess mechanisms that recognize potential pathogens and initiate defense responses. It has become evident that various types of oxygenated fatty acids, collectively termed «oxylipins», are involved in responses to biotic and abiotic stress factors. These compounds are similar to the eicosanoids formed from arachidonate in animals, which have so many various functions, especially in the inflammatory processes. The existing diversity of oxylipins is provided by nonclassic cytochromes P450 of the CYP74 clan. The CYP74 clan includes hydroperoxide lyases (HPLs), allene oxide synthases (AOSs), divinyl ether synthases (DESs) and the most poorly studied epoxy alcohol synthases (EASs). Despite differences in product specificities, they all metabolize 9- and/or 13-hydroperoxides as substrates, which are produced as a result of the oxygenation of polyunsaturated fatty acids by the action of lipoxygenases (LOXs).

The CYP74 clan members have been found in a wide variety of organisms including animals, plants, bacteria but not algae. Despite this fact oxylipins were detected in different algae species. We analyzed patterns of endogenous oxylipins in several species of brown algae: *Undaria pinnatifida, Sargassum miyabei, Sargassum pallidum* and *Saccharina cichorioides*. Different isomers of epoxy alcohols, ketols, hydroxy and trihydroxy acids were detected. The structures of all compounds have been resolved using GC-MS, HPLC and NMR.

Analysis of genome data of brown alga *Ectocarpus siliculosus* with open reading frames revealed 12 sequences which have homology with cytochromes P450 of higher plants. One of them has similarity with the CYP74 enzymes. We obtained corresponding recombinant protein using *E. coli* expression system. Affinity-purified protein EsCYP74 was incubated with model substrates – 9- and 13-hydroperoxides of linoleic acid. Incubation resulted in formation of a number of epoxy alcohols and dihydroxy acids. Thus, the described enzyme EsCYP74 is the first member of the CYP74 clan detected in algae, and it belongs to one of the most poorly studied groups of the CYP74 enzymes – epoxy alcohol synthase. Detection of the CYP74 enzyme in brown alga complements the common scheme of the CYP74 catalysis and confirms our hypothesis of the CYP74 clan origin and evolutional history of the P450 superfamily.

The role of Otx2 in the correct positioning of the midbrain-hindbrain barrier

B. Fant, T. Lamonerie
CNRS-INSERM, UMR7277, Nice, France

During embryonic development, the neural plate is regionalized anteroposteriorly into several domains with their own individual identities and fates. A correct positioning of the boundaries between those domains is crucial for a normal development of the nervous system. In order to study the mechanisms underlying this boundary positioning, we focused on the establishment of

© 2014 The Authors. FEBS Journal © 2014 FEBS

the midbrain-hindbrain barrier (MHB), an already well-studied structure in which a small number of genes have been shown to play a role (Wurst, 2011). During normal embryonic development, the interplay between these genes, most notably the Otx2 and Gbx2 homeogenes, leads to the correct expression and positioning of the signaling molecule Fgf8. Fgf8 in turns confers to the MHB a role as a self-regulating organizing center for the surrounding domains, known as the isthmic organizer. The regionalization of the midbrain and hindbrain therefore depends on the correct location of the MHB. Mutual repression between the anteriorly expressed Otx2 and the posteriory expressed Gbx2 was thought to be the earliest phenomenon determining the position of the MHB. The expression of those two genes indeed abut each other at the MHB, and experiments where the limit of expression of either Otx2 or Gbx2 was artificially shifted led to a global shift of the MHB gene expression network towards the new limit (Broccoli, 1999). However, using a conditional knock-in strategy for Otx2, we were able to shed a light on the shortcomings of this model: the position of the MHB and the correct development of the midbrain and hindbrain do not only depend on a mutual repression between Otx2 and Gbx2. When we triggered an ubiquitous expression of Otx2 in mutant mice, we observed that, contrary to the posterior shift forecasted by the current model, the MHB was set in place in an anterior position, and that it lacked in sharpness. We are now trying to understand what functions as yet unexplored those homeogenes could control that could further explain their role in the regionalization of the midbrain and hindbrain. One possibility is that Otx2 and Gbx2 may drive the expression of other adhesions molecules, thus giving rise to two cell populations with different adhesive properties, which would then segregate according to the homeogene they are expressing. Another possibility is that the ectopic Otx2 expression modifies the retinoic acid signalling pathway activity through direct interaction with some of its actors, which would result in a modification of hindbrain patterning.

The *Schistosoma mansoni* protein SmShb interacts with and regulates SmVKR1 signalling

M. Morel[1], M. Vanderstraete[1], S. Hahnel[2], K. Cailliau[3], C. G. Grevelding[2], C. Dissous[1]
[1]*CIIL-U1019 UMR CNRS 8204, INSERM, Lille, France,* [2]*Institute for Parasitology, University of Giessen, Giessen, Germany,* [3]*EA 4479 IFR147, Université Lille 1, Villeneuve d'Ascq, France*

Venus Kinase Receptors (VKRs) are invertebrate Receptor Tyrosine Kinases (RTKs) formed by an extracellular Venus Fly Trap (VFT) ligand binding domain and an intracellular tyrosine kinase domain. These receptors were initially discovered in the parasitic platyhelminth *Schistosoma mansoni,* then identified in many invertebrates (Ahier *et al*., 2009; Vanderstraete *et al*., 2013).

Quantitative RT-PCR on various stages and isolated organs of the sea urchin and various insects (Ahier *et al*., 2009), together with recent studies in the parasite *S. mansoni* (Vanderstraete *et al.,* 2014), argued for a role of VKRs in embryonic development and in reproduction. To better understand the cellular functions of VKRs, *S. mansoni* interacting partners of SmVKRs were identified by yeast-two-hybrid (Y2H) screening and SmVKR signalling pathways were characterized in *Xenopus* oocytes (Vanderstraete *et al.,* 2014).

The protein SmShb was shown to interact specifically with the phosphorylated form of SmVKR1. SmShb is an SH2 domain-containing protein, homologous to members of the Shb adaptor family known to transduce signals induced by activated RTKs. Its interaction with phospho-SmVKR1 occurs between its SH2 domain and the phosphotyrosine residue (pY979) located in the juxtamembrane region of SmVKR1. This interaction activates in *Xenopus* oocytes specifically the JNK signaling pathway. *SmShb* and *SmVKR1* transcripts were detected by *in situ* hybridization in mature oocytes and testes of adult schistosomes.

To further analyze the potential importance of SmShb/SmVKR1 signalling in germinal cells, we focussed on the determination of SmShb interacting partners by Y2H screening of a *S. mansoni* adult cDNA library using SmShb as a bait. Among the various potential SmShb partners, we identified two homologs of RhoU and TcTex-1, already known for their respective functions in cell migration and sperm motility.

Preliminary data have shown that the knockdown of SmShb by RNA interference in adult *S. mansoni* results in an accumulation of mature sperm in testes.

Together, these data suggest a role of SmVKR1/SmShb pathway in maturation and migration of germinal cells.

What changes matter? A genomic approach to human evolution

N. Rohner[1], M. Zody[2], D. Reich[1], S. McCarroll[1], D. Lieberman[3], C. Tabin[1]
[1]*Harvard Medical School, Boston,* [2]*Broad Institute,* [3]*Harvard University, Cambridge, MA, USA*

We humans and our closest living relatives, the chimpanzees differ only in 1–2% of our genomes. Despite this genetic similarity we vary in many anatomical and behavioral traits. Upright walking and larger brains are just two prominent examples amongst many others that allowed us to adapt to new environments (compare image). Although full genome sequences are now available for humans, chimpanzees and other primates, surprisingly little is known about the genetic basis underlying these traits. One reason being, that even within the 1–2% difference lie many genetic changes potentially driving human evolution. Because open reading frames of genes tend to be very similar between the great apes, it has been argued that the majority of significant evolutionary changes affect cis-regulatory sequences. To identify the regulatory changes specific to the human lineage we undertook a whole genome approach focusing on the potential regulatory regions that are altered in the human lineage. We aligned human, chimp, macaque, and mouse genomes and concentrated on human-specific drastic changes in otherwise conserved non-coding regions. For simplicity reasons we limited our search criteria to deletions larger than a 100 bp and unique to the human genome. We identified 298 such human- specific deletions, that potentially alter regulatory functions in the human genome. We used a mouse transgenic approach to test if the deletions affect enhancer activity *in vivo*. Out of the 12 tested elements, 4 showed tissue-specific expression at diverse developmental stages. We focused on two human-specific deletions for further study. The first removes an enhancer element near the gene *OSR2,* and the observed expression pattern argues for a role in craniofacial development. The second deletion removes a regulatory element in the gene *ACVR2A*. The transgene expression and the phenotype of a full knockout of *ACVR2A*, suggest a role in the

© 2014 The Authors. FEBS Journal © 2014 FEBS

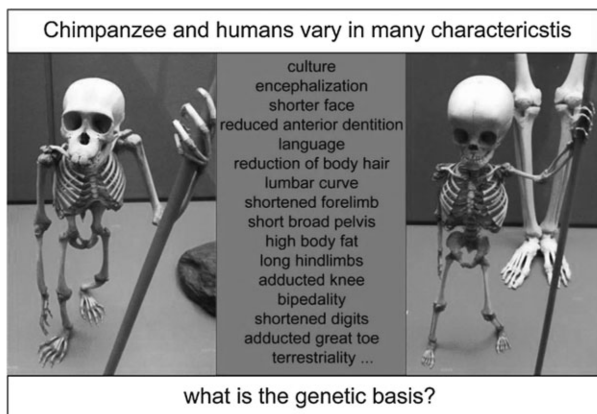

Fig. 1.

human-specific shortening of digit 2–5 and smaller size of upper incisors. Importantly, and in contrast with previous studies, we have mirrored the human situation in a mouse model by removing the enhancer element from the mouse genome, which is causing a down regulation of the nearby gene. We are currently analyzing the mouse model for human-like phenotypes using 3D reconstruction of the skull and the cranial base on micro-computer-tomography generated images.

Zelda: an essential transcription factor in the *Drosophila* development

P. Giannios, S. G. Tsitilou
Biochemistry & Molecular Biology, University of Athens, Athens, Greece

The *Drosophila* zinc finger transcription factor Zelda (Zld)-Zygotic early *Drosophila* activator- appears to play a major role as a regulator of genome activation in the earliest stages of *Drosophila* development. Zld binds to a sequence motif referred to as a TAGteam site and functions as a key transcriptional activator during the maternal-to-zygotic transition – MZT. Zld has been shown to mark regions that are later bound by zygotically expressed transcription factors, suggesting that it can also be part of the machinery that controls the sequence of events following the MZT. It has also been proposed that Zelda ensures coordinated gene expression during embryonic development, either by increasing chromatin accessibility for several other transcription factors, or by being involved in the RNA polymerase II pausing mechanism. Zelda has been shown to be expressed in larval, pupal and adult stages, indicating a possible involvement in the regulation of molecular events throughout the developmental process. However, no data exist to date regarding its potential function in post embryonic development.

Our studies show that overexpression or knock down of Zld in larval wing discs, resulted in strong impaired phenotypes, an indication of its essential role in wing growth. Zld's study of expression in the developing larval wing discs and other larval tissues revealed the presence of novel alternatively spliced transcripts and a protein isoform with possibly different molecular function. Moreover, ChIP assays using larval wing discs revealed that Zelda binds to an intronic region of the optomotor-blind gene, a downstream target of the Dpp pathway. The immunohistochemical stainings of larval wing discs and the expression levels of several selected genes and protein products, showed altered expression of target molecules with key roles in more than one signaling pathways, when Zld was either knocked down or overexpressed. In these terms, the paradigm of Zelda function during embryogenesis where it coordinates the activity of many genes could also apply later in development. Furthermore, recent reports suggest that a prominent link exists between zygotic gene activation and pluripotency control in vertebrates. Thus, the elucidation of the exact role of a transcription factor with distinct functions in zygotic gene activation and patterning processes throughout the development of a simple model organism, could prove extremely valuable for any future study concerning similar and related mechanisms in higher organisms.

3-mercaptopyruvate sulfurtransferase-derived hydrogen sulfide regulates calcium-induced mPTP opening in adult and old rat hearts

N. Strutynska[1], S. Chorna[1], O. Semenykhina[1], L. Mys[1], V. Dosenro[2], V. Sagach[1]
[1]Blood Circulation, [2]General and Molecular Pathophysiology, Bogomoletz Institute of Physiology, Kyiv, Ukraine

Hydrogen sulfide (H_2S) is a biologically active gasotransmitter, which regulates a lot of important physiological functions in the body. In the cardiovascular system H_2S de novo synthesis in belongs to pyridoxal-5-phosphate-dependent enzymes – cystathionine-β-synthase (CBS), cystathionine-γ-lyase (CSE) and 3-mercaptopyruvate sulfurtransferase (MPST). The modulation of endogenous H_2S generation in the cardiovascular system and other tissues and the functional consequence of this modulation are not clear. The formation of non-selective calcium-dependent cyclosporin-sensitive permeability transition pore (mPTP) between the outer and inner mitochondrial membranes is the basis for induction of the cell death by apoptosis. The aims of this study were to elucidate the mechanisms underlying the cardioprotective effects of H_2S in aging rats. Exogenous hydrogen sulfide in physiological concentrations depressed Ca^{2+}-induced mPTP opening in a dose-dependent fashion in adult and rat heartsl. Preincubation of isolated mitochondria with the inhibitor of mitochondrial ATP-dependent potassium channels (K_{ATP}-channels) 5-hydroxydecanoate (10^{-4} mol/l) reduced the protective effect of NaHS (10^{-5} mol/l), indicating the possible involvement of mitochondrial K_{ATP}-channels in inhibition by hydrogen sulfide of Ca^{2+}-dependent pore opening. To clarify the role of endogenous H_2S in the regulation of mPTP opening in the adult and old rats heart, in vitro experiments were carried out using propargylglycine (PG), a specific blocker of the enzyme CSE, and o-(carboxymethyl)hydroxylamine (O-CMH) (10^{-5} to 10^{-3} mol/l), a blocker of MPST. It is interesting to note that only inhibition of MPST by O-CMH causes significantly increase of Ca^{2+}-dependent mitochondrial swelling in adult and old rat heart. PG at any concentration, when added directly to the medium, had no effect on the swelling dynamics. We observed up regulation of mRNA expression of MPST in 2,3-fold in old rat heart compared with adult animals. Under condition of both PG and L-cysteine introduction to adult and old rats was shown that mRNA expression of MPST increased in 8,2-fold and 2,5-fold respectively compared to control. It has been shown that: 1) endogenous H_2S synthesized by enzyme MPST in mitochondria can be involved in the regulation of Ca^{2+}-induced mPTP opening in both adult and old rat hearts; 2) dramatic decrease in H_2S synthesis in old rat heart mitochondria was followed by an increased sensitivity of mPTP opening to Ca^{2+}; 3) the opening of K_{ATP}-channels in the heart muscles plays a significant role in the protective mechanisms of H_2S. These data provide clear evidence for the cytoprotective actions of MPST-derived H_2S in cardiac pathologies.

Keywords: heart, hydrogen sulfide, mitochondrial permeability transition pore.

A 'Floating Boat Bridge' of cytochrome c molecules in plant respirasome

B. Moreno-Beltrán[1], K. González-Arzola[1], A. Díaz-Quintana[1], A. Velázquez-Campoy[2], M. Á. De la Rosa[1], I. Díaz-Moreno[1]
[1]Instituto de Bioquímica Vegetal y Fotosíntesis, cicCartuja, Universidad de Sevilla - CSIC, Sevilla, [2]Institute of Biocomputation and Physics of Complex Systems (BIFI) - Joint Unit BIFIIQFR (CSIC), Universidad de Zaragoza, Zaragoza, Spain

In plants, cytochrome *c* participates in channeling electrons rather than in simply shuttling them between complexes III and IV [1]. However, the mode cytochrome *c* behaves inside a supercomplex such as the respirasome, formed by complexes I, III and IV, remains veiled from a structural point of view. Here, we report *ab-initio* Brownian Dynamics calculations and NMR-driven docking computations showing two well-defined binding sites for cytochrome *c* at the head soluble domain of cytochrome c_1, namely a non-productive (or *distal*) site with a long heme-to-heme distance and a functional (or *proximal*) site with the two heme groups close enough as to allow electron transfer. As inferred from Isothermal Titration Calorimetry experiments, the two binding sites exhibit different equilibrium dissociation constants, for both reduced and oxidized species, that are all within the micromolar range, so revealing the transient nature of such a respiratory complex. Although the docking of cytochrome *c* at the *distal* site occurs at the proximity to the interface between cytochrome c_1 and the Rieske subunit, it is fully compatible onto the complex III structure. In our model, the extra *distal* site in complex III could indeed facilitate the functional channeling of electrons towards complex IV by building a 'floating boat bridge' of cytochrome *c* molecules (between complexes III and IV) in plant respirasome.

Assessing PAT-induced mitochondrial redox status and apoptosis via mitochondria-mediated pathway

M. Boussabbeh[1], I. Ben Salem[1], A. Prola[2], A. Salah[1], C. Lemaire[2], H. Bacha[1], S. Abid-Essefi[1]
[1]Laboratory Research on biologically compatible compounds, University of Monastir, Monastir, Tunisia, [2]INSERM UMR S-769, Paris-Sud 11 University, Châtenay-Malabry, France

Patulin (PAT) is a toxic metabolite produced by several filamentous fungi of the genera of *Penicillium*, *Aspergillus* and *Byssochlamys*, principally by *Penicillium expansum*. Several studies indicate there is a risk associated to the PAT intake, through the consumption of purees and apple juices. The gastrointestinal lumen is thus directly exposed to PAT. In this study, we tried to understand cell-death pathway on human colon carcinoma cells (HCT-116).

Using specific probes in flow cytometry, we assess mitochondrial redox status in terms of mitochondrial transmembrane potential (ΔΨm) and mitochondrial superoxide (mtO2·) production.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Treated cells by PAT exhibit a loss of DYm and a downstream generation of O2·. We also demonstrated that PAT induces apoptosis in HCT-116. There has an increase in caspase3 activity following the use of NucView caspase3 substrate. The resistance of cells deficient in pro-apoptotic proteins (Bax and Bak) to treatment by PAT showed that this mycotoxin promotes the apoptosis through a mitochondria-dependent pathway. Then, to understand whether PAT-induced stress is a cause or consequence, we pretreated cells with N-acetylcysteine (Nac) and we showed that Nac restores cell viability and reduce significantly PAT-induced damages for all tested markers. It be concluded that PAT-induced oxidative stress is the major cause of cell death.

Keywords: apoptosis, Mitochondria membrane potential loss, mycotoxin.

Beneficial metabolic changes induced by glycogen phosphorylase inhibitor treatment

L. N. Nagy[1], T. Docsa[1], A. Tóth[2], L. Somsák[3], T. Fodor[1], P. Gergely[1], P. Bay[1,4]

[1]Department of Medical Chemistry, [2]Division of Clinical Physiology, Institute of Cardiology, [3]Department of Organic Chemistry, [4]MTA-DE Cell Biology and Signaling Research Group, University of Debrecen, Debrecen, Hungary

Glycogen metabolism is regulated by two antagonistic enzymes: glycogen phosphorylase (GP) and glycogen synthase. Glycogen phosphorylase is responsible for the breakdown of glycogen, hence it has major role in hepatic glucose production (HGP). Consequently, it is likely that GP inhibition would reduce blood glucose levels in type II. diabetes.

We evaluated the metabolic properties of novel glucose-based GP inhibitors KB228 (N-(3,5-dimethyl-benzoyl)-N'-(β-D-glucopyranosyl)urea, Ki = 937 nM) and BEVA335 (3-β-D-glucopyranosyl-5-(2-naphtyl)-1,2,4-triazole, K_i = 0.411 nM). In vivo, single i.p. injection of KB228 enhanced glucose sensitivity in chow-fed and high fat diet-fed, insulin resistant (C57/Bl6J mice on 60% fat hypercaloric diet for 3 months) mice that depended on glucose excursion to the liver. KB228 increased oxygen consumption suggesting enhanced mitochondrial function which was presumably linked to the overexpression of uncoupling protein-2 (UCP2). These unexpected changes were observed in animal and cellular models (HepG2) under both normoglycemic and hyperglycemic conditions. In addition, KB228 induced mammalian target of rapamycin complex 2 (mTORC2) which may take an active part in glucose influx and increased glycogen deposition in the cells.

Furthermore, our data demonstrate that such inhibitors do not only reduce glucose levels but enhance glucose-induced insulin release in mice, therefore we investigated these effects on cellular model of pancreatic β-cells, MIN6 cells. KB228 and BEVA335 induced mitochondrial activity, insulin production and facilitated insulin secretion in MIN6 β-cells after two-day treatment. Simiarly to the liver, mTORC2 activity was enhanced in MIN6 cells too by GP inhibitor treatment. KB228 and BEVA335 treatment induced MIN6 proliferation which mirrored in the pancreas of C57/Bl6J mice (chow-and HFD-fed) treated with KB228 (90 mg/kg).

We have described hereby several unexpected, though beneficial metabolic effects of glucose-based GP inhibitors that can be exploited in the future.

Ca2+-dependent fusion pore induced by α,ω-dioic acids as a possible mechanism of the mitochondrial permeability transition

M. Dubinin[1], V. Samartsev[1], K. Belosludtsev[2]

[1]Mari State University, Yoshkar-Ola, [2]Institute of theoretical and experimental biophysics RAS, Pushchino, Russian Federation

Recently we found that the α,ω-dioic acids (among them α,ω-hexadecanedioic acid (HDA) was most effective) are able to induce the opening of the 'non-classical' cyclosporin A (CsA)-insensitive pore in the liver mitochondria loaded with Ca^{2+} or Sr^{2+}. It has been suggested that such permeability is based on the formation of a pore in the membrane of organelles which has lipid nature. In this paper, in order to clarify the molecular mechanism of this process, we studied the effect of HDA on the Ca^{2+}-dependent permeability of artificial membranes using the model of large unilamellar liposomes (LUV) loaded with the fluorescent dye sulforhodamine B (SRB). It was shown that HDA, like palmitic acid (PC), is able to induce permeability of LUV for SRB in the presence of Ca^{2+}. However, the kinetics of SRB release upon the induction of Ca^{2+}-dependent permeability of LUV by HDA and PC is different. Furthermore, it was found that HDA is inferior to PC in ability to induce LUV permeability for SRB. Under the same conditions, α, ω -tetradecanedioic acid which acyl chain is 2 carbon atoms shorter than HDA is less effective. Consequently, the effectiveness of these α,ω-dioic acids as inducers of pore opening is sharply reduced with decreasing number of carbon atoms in their acyl chain, which may be associated with a decrease in their ability to dissolve in lipids. It was established that HDA/Ca^{2+}-induced SRB release from LUV is also dependent on the pH of the surrounding solution. The maximum release of SRB from LUV induced by HDA/Ca^{2+} complex formation was observed at alkaline pH (pH 9.0–10.0). Using the method of ultrasonic interferometry it's shown that HDA, unlike PC, doesn't induce a chemotropic phase transition in the lipid bilayer of membrane in the presence of Ca^{2+}, which as was shown earlier underlies the permeability of lipid membranes induced by Ca^{2+} and PC. Thus, it can be assumed that the Ca^{2+}-dependent permeability of the LUV, induced by HDA and PC occurs by different mechanisms. The method of dynamic light scattering showed that the addition of Ca^{2+} to HDA-modified LUV induces their fusion. We believe that the process of LUV fusion may be accompanied by partial SRB release from LUV due to the formation of fusion pores.

We assumed that the process of membrane fusion may underlie the previously described HDA/Ca^{2+}-induced nonspecific permeability of the inner membrane of liver mitochondria. It is possible that HDA and Ca^{2+} induce fusion of inner and outer mitochondrial membranes in the field of contact sites where the membranes are close together, with subsequent formation of fusion pore resulting in swelling of the mitochondria. This study was supported by the Ministry of Education and Science of Russia (No 1365).

CDK4 and CDK5 inhibition prevents the Drp1-dependent mitochondrial fission and neuron death induced by MPP+

C. Y. Huang, C. Y. Hsieh, J. I. Chuang

Department of Physiology, National Cheng Kung University, Tainan, Taiwan

Mitochondrial dysfunction is an early event of cell death in the neurodegenerative diseases, such as Parkinson's disease (PD).

© 2014 The Authors. FEBS Journal © 2014 FEBS

Mitochondrial function is closely linked to its morphological dynamics, fusion and fission (fragmentation). Aberrant mitochondrial fission controlled by mitochondrial fission protein of dynamin-related protein 1 (Drp1) may result in cell death. Our previous results have showed the involvement of Drp1-dependent mitochondrial fission in a 1-methyl-4-phenylpyridinium (MPP^+)-induced parkinsonian model. Recent studies also demonstrated that mitochondrial dynamics change at different stage of cell cycle and cyclin-dependent kinase 5 (CDK5) is involved in the regulation of mitochondrial fission during neuron apoptosis. Herein, we investigated whether CDK inhibition protects postmitotic and terminally differentiated neurons from MPP^+ intoxication by reducing the Drp1-dependent mitochondrial fission. We found that neurons overexpressed dominant negative $Drp1^{K38A}$ or the treatment of selective inhibitor of CDK4 (CDK4I) or CDK5 (roscovitin) inhibit MPP^+-induced mitochondrial fission as early as 4 h after the treatments in primary cortical neurons. There is no nuclear fragmentation at 4 h after MPP^+ treatment; however, the co-treatment of CDK4I or roscovitin significantly reduced the number of neurons with condensed nucleus and neuron death. The MPP^+-induced upregulation of mitochondrial Drp1 protein expression was significantly attenuated with more pronounced after the treatment of CDK4I than roscovitin. In the cortical neurons overexpressed wild type Drp1, the prevention of CDK4/5 inhibition in MPP^+-induced mitochondrial fission was blunted. These results reveal that CDK4 and CDK5 inhibition prevents Drp1-dependent mitochondrial fission to protect the neurons against MPP^+ toxicity.

Characterization of Mcl-1 isoforms and their impacts on cell growth and survival

U.-I. Chen[1], Y.-K. Chen[1], J. J.-Y. Yen[2], H.-F. Yang-Yen[1]
[1]Institute of Molecular Biology, [2]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan

The Bcl-2 family proteins, which regulate many cell survival and death pathways, play a critical role in a variety of cellular processes under physiological as well as pathological conditions. Mcl-1 belongs to the anti-apoptotic subfamily of the Bcl-1 family protein, which is widely expressed in many cell types in the vertebrate. Mcl-1 has long been noticed to exist as two major isoforms with different gel-mobility. By extensive biochemical characterization, we demonstrated that the slow mobility (SM) isoform is a full-length protein targeted to the outer membrane of mitochondria (MOM), whereas the fast-mobility (FM) isoform is an N-terminally truncated product generated inside the mitochondrial matrix via an MPP-mediated cleavage reaction. The 33 amino acid residues at the N-terminus of the Mcl-1 protein turn out to serve both as a mitochondrial targeting and processing signal. Interestingly, unlike the full-length protein located at MOM, the mitochondrial matrix-localized isoform failed to interact with BH3-only proteins and manifested a greatly attenuated anti-apoptotic activity. To gain further insights of the Mcl-1 functions in the mitochondrial matrix, we generated Mcl-1 knock-in mutant mice (the 3RG mutant) that are defective in producing the matrix isoform. The phenotype of the 3RG mutant mice will be presented at this meeting.

Comparison of the effects of riboflavin and ascorbic acid on orofacial and plantar formalin induced pain

C. R. Bohotin[1], A. Luca[1], A. Dondas[2], T. Alexa[1], R. Iliescu[3]
[1]Pathophysiology, [2]Cardiovascular Surgery Clinic, [3]Pharmacology, University of Medicine and Pharmacy 'Gr.T.Popa' and Centre for the Study and Therapy of Pain, Iasi, Romania

Background: There are evidences that mitochondria play an important role in pain processing by modulating radical oxide species production as well as ATP. It is also documented that vitamin B_2 (riboflavin), a prophylactic drug in migraine therapy, is an ultimate precursor in the biosynthesis of flavin mononucleotide (cofactor in mitochondrial complex I) and that the vitamin C (ascorbic acid) is a vitamin with mitochondrial transport and functions acting as antioxidant as well as pro-oxidant.

Aim of the Study: To investigate if a single dose of the above mentioned vitamins, modulate pain perception from orofacial (OFT) and plantar (PFT) formalin tests in mice.

Methods: The experiments were done in BALBc mice and each group had at least 8 animals per group. Mice received intraperitoneally riboflavin-vitB2 (100 mg/kg), ascorbic acid-vitC (500 mg/kg) or saline-NaCl (0.1 ml/10 g b.w.) and were thereafter divided into 6 groups: OFT_{vitB2}, $OFT_{vitC,}$ $OFT_{NaCl,}$ $PFT_{vitB2,}$ $PFT_{vitC,}$ $PFT_{NaCl.}$ The nociceptive score was determined by recording the number of seconds animals spent grooming the injected area and expressed as mean ±SEM separately for the 2 phase of the formalin test, the neurogenic (first) respective inflammatory (second) phase. Data was analyzed using ANOVA and the Post-hoc comparisons between groups was determined using the Bonferroni-test.

Results: The B_2 and C vitamins significantly modified pain perception in both phases of OFT and the second phase from PFT. When compared with control group (148 ± 9s), only the riboflavin had analgesic effect on the second phase of OFT (81 ± 15s, $p = 0.025$). By contrary both riboflavin (36 ± 9s, $p < 0.001$) and ascorbic acid (81 ± 18s, $p = 0.013$) had analgesic effect on the second phase of PFT when compared with saline group (145 ± 12s). No significant statistical differences between the vitamins analgesic effect were recorded in PFT.

Discussions: By the use of riboflavin and ascorbic acid we expect to transitory modulate mitochondrial function and thus the ATP and/or ROS production. In our study a single dose of B_2 and C vitamin modulate pain perception in both models of pain. Although B2 vitamin acts on both OFT and PFT, vitamin C modifies only the PFT. Thus, we can hypothesize, that mitochondrial ATP is more important in pain modulation then ROS production or that the pain from OFT and PFT have different mechanisms.

Taken together, our study demonstrates that ascorbic acid and riboflavin modulate pain perception after a single dose, but the mechanisms that could be linked to mitochondrion modulation require further investigation.

Cox26 – a novel component of the cytochrome c oxidase required for proper enzymatic function

M. Levchenko[1], M. Wissel[1], L. Juris[1], M. Vukotic[2], M. Deckers[1], P. Rehling[1,3]
[1]*Insitute for Cellular Biochemistry, University Medicine Goettingen, Göttingen,* [2]*Institute for Genetics, University of Cologne, Cologne,* [3]*Max-Planck Institute for Biophysical Chemistry, Göttingen, Germany*

Cellular respiration is a basic mechanism for energy conversion. Oxidative phosphorylation (OXPHOS), which is carried out in the mitochondria of eukaryotic cells, provides energy in the form of ATP. The protein complexes constituting the OXPHOS machinery are located in the inner mitochondrial membrane. Complexes I to IV comprise a respiratory chain, transferring electrons in a series of redox reactions. The electron transfer is coupled to proton pumping across the inner membrane, and thus establishes a proton gradient, which is then used by complex V (ATP synthase) to generate ATP. The respiratory chain complexes form higher oligomeric structures called supercomplexes or respirasomes to promote efficient electron transport.

Cox26, a protein of a yet unknown function, is a constituent of respiratory chain supercomplexes in yeast *Saccharomyces cerevisiae*. We have identified Cox26 as a novel subunit of the cytochrome c oxidase (COX), the terminal enzyme of the mitochondrial respiratory chain. Yeast cells lacking Cox26 are affected in cytochrome c oxidase function and exhibit a decrease in COX enzymatic activity. Furthermore, the absence of Cox26 influences respirasomes formation and leads to a decreased association of the cytochrome c oxidase with supercomplexes.

Keywords: cellular respiration, cytochrome c oxidase, mitochondrial electron transport chain.

Cross-talk between the PINK1/Parkin pathway and the ER-mitochondria interface: role in the regulation of mitochondrial physiology

Z. Erpapazoglou[1], C. Gautier[2], A. Brice[1], O. Corti[1]
[1]*Brain and Spine Institute,* [2]*Diverchim, SA, Hopital Pitie-Salpetriere, Paris, France*

The kinase PINK1 and the E3 ubiquitin ligase Parkin, products of two genes responsible for familial Parkinsonism, participate in the same mitochondrial quality control mechanism. Upon depolarization of the mitochondrial membrane, the PINK1/Parkin pathway gets activated, leading to increased fission, outer membrane rupture and finally complete elimination of damaged organelles by mitophagy. Our team has identified the TOM (Translocase of the Outer Membrane) complex as a molecular switch in the pathway. Upon $\Delta\psi$ collapse, Parkin is recruited by PINK1 to the TOM machinery and preferentially interacts with the TOMM70 receptor. Further proteolytic destabilization of TOM core components primes mitochondria for mitophagy.

There is growing evidence that ER-mitochondria contacts, responsible for lipid and Ca^{2+} exchanges between the two compartments, play a crucial role in Parkin-dependent mitochondrial clearance. Furthermore, our own recent results suggest that the ER-mitochondria interface is regulated by the PINK1/Parkin pathway.

More precisely, we have observed both by confocal and electron microscopy that the ER-mitochondria interface is significantly enhanced in Parkin-deficient cells. This alteration is most likely at the origin of the mitochondrial Ca^{2+} overload observed in these cells. Though we were not able to detect Parkin at ER-mitochondria contacts, using a subcellular fractionation-based approach, we demonstrated the presence of PINK1 and TOM subunits, including TOMM70, at this interface. In parallel, we showed that the ER-mitochondria tether Mfn2 is increased in abundance in tissue from Parkin-deficient mice, specifically at the ER-mitochondria interface, suggesting that it is a central target of Parkin at this interface, possibly responsible for the observed perturbations in Parkin-deficient cells.

We are currently using fluorescence microscopy and Ca^{2+} imaging in order to elucidate the involvement of the PINK1/Parkin pathway in the regulation of ER-mitochondria contacts and their function. These studies should give new insight into how PINK1 and Parkin regulate mitochondrial physiology and how loss of their function contributes to the development of Parkinsonism.

Fast redox exchange within the photosynthetic electron transport chain relies on short-lived nature of the complexes between cytochrome b_6f and its acceptors, namely plastocyanin and cytochrome c_6. This complex must conciliate its ability for a swift intermolecular electron transfer and a rapid dissociation and, hence, a limited specificity. To dig into this issue, we have studied the interaction between cytochrome c_6 and the soluble fragment of cytochrome f from the cyanobacterium Nostoc sp. PCC 7119 by NMR spectroscopy. To avert redox exchange, the low potential M58C variant of cytochrome c_6 was used instead of the wild-type protein to characterize the complex with cytochrome f by chemical shift perturbation and paramagnetic relaxation NMR experiments. Notably, the interaction is highly dynamic, as expected from a pure encounter complex, without any dominant conformation. Ensemble docking computations and Monte-Carlo simulations suggest a model in which charge–charge interactions pre-orient cytochrome c_6 with its haem edge facing cytochrome f, still yielding a wide assortment of conformations. Hydrophobic contacts between both cytochromes bring the two haem groups close enough to allow a fast electron transfer. The resulting balance between non-polar and electrostatic interactions along the lifetime of the complex is responsible for its dynamics and avoids any high-energy transition state barrier to slow down the dissociation process.

Cytosolic and intramitochondrial cAMP produced by soluble adenylyl cyclase control in mammalian cells the subunits turnover and activity of the respiratory chain complex I

D. De Rasmo[1], A. Santeramo[2], M. Larizza[2], P. Lattanzio[1], S. Papa[1], A. Signorile[2]
[1]Institute of Biomembranes and Bioenergetics (IBBE), Bari, Italy, CNR, [2]SMBNOS, University of Bari, Bari, Italy

In mammalian cells the nuclear-encoded subunits of complex I are continuously imported into mitochondria, where are incorporated together with mitochondrial-encoded subunits to form the mature complex or separately exchanges with pre-existing copies in the complex. The results of our work show that both the cytosolic cAMP, produced by plasma membrane adenylyl cyclase, and intramitochondrial cAMP, produced by the soluble adenylyl cyclase, modulate at post-translational level the concentration of nuclear-encoded subunits of the mitochondrial exposed catalytic moiety of the complex and consequently its NADH-ubiquinone oxidoreductase. The cytosolic cAMP/PKA promote the mitochondrial import/maturation of these subunits, the intramitochondrial cAMP stabilizes the mitochondrial level of the subunits adequate for their assembly in the functional complex by preventing their degradation by mitochondrial Lon protease.

Diagnostic value of activity of mitochondrial enzymes activity in children with the hepatic form of glycogen storage disease

O. Kurbatova[1], A. Surkov[1], L. Miroshkina[1], S. Polyakova[1], T. Izmailova[1], G. Semenova[1], I. Samokhina[2], E. Kapustina[1], R. Zakirov[1], S. Petrichuk[1]
[1]Scientific Centre of Children Health, RAMS, Moscow, [2]Научный центр здоровья детей РАМН, Москва, Russian Federation

Glycogen storage disease (GSD) are a group of inherited diseases, accompanies with carbohydrate metabolism disorders, when the type of disease I, III and VI, enzyme deficiency implements in glycogen accumulation in liver. This errors leads to others metabolic ways errors, which lead to disturbance in mitochondria function.

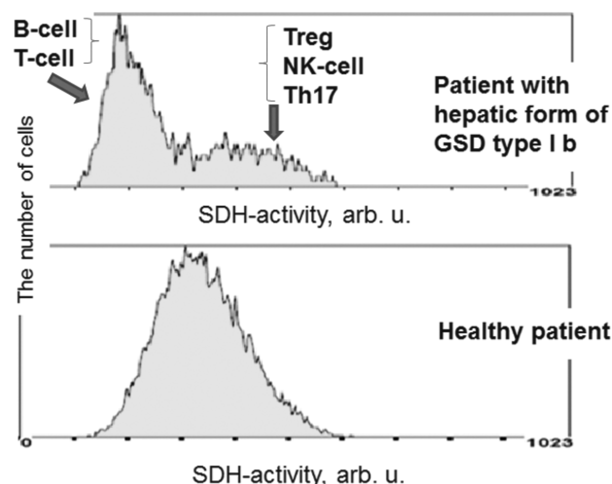

Fig. 1. The heterogeneity of the SDH activity in the whole lymphocyte populations.

Aim: To evaluate the diagnostic value of the mitochondrial enzymes activity in children with the hepatic form of GSD.

Patients and methods: We examined 106 children with hepatic form of GSD at age from 1 to 17 years. The distribution by sex was 36 girls, 70 boys. Control group consisted of 34 healthy children.

Lymphocytes enzymes activities (succinatedehydrogenase (SDH) and NADH-dehydrogenase(NADH-H) are respiratory chain enzymes (complex I and complex II respectively), moreover SDH is also the Krebs cycle enzymes, that catalyzed the oxidation succinate to fumarate) were measured using the quantitative cytochemical method with a help cytodensitometry (Videotest, Russia) and SDH activity in lymphocytes subsets was measured by flow cytometry (Beckman Coulter FC500 (USA)).

Results: We found SDH activity decrease, along with NADH-D activity increase in children with hepatic form of GSD. SDH/NAH-D index was decrease in GSD-patients compared with the control group. The most significant alterations were found in type-I of GSD.

We found the heterogeneity of the SDH activity in the whole lymphocyte populations. SDH activity was decreased in B-cells and T-cells along with SDH activity was increased of NK-cells, Treg and TH17-lymphocytes (Fig 1).

High correlation between base excess, hepatomegaly and lymphocytes enzymes activitywas found RBE = 0.99 and R hepatomegaly = 0.87 respectively in GSD patients.

Conclusion: Our investigation revealed features of mitochondrial dysfunction in children with GSD. We found changes of the lymphocytes subsets number and their functional activity, this findings correspond to increased infectious diseases rate in children with GSD. Dehydrogenases activity of lymphocytes correlates with the main clinical - laboratory parameters, and can be used as additional diagnostic criteria of energy metabolism disorders and for the assessment of the severity of children with GSD.

DNA helicases involved in the maintenance of the plant organellar genomes

J. M. Gualberto, C. Wallet, A. Dietrich
Institut de Biologie Moléculaire des Plantes du CNRS, Strasbourg, France

The dynamic state of the plant mtDNA is due to recombination processes involving repeated sequences that modulate its structure. Large repeats are interconvertible by homologous recombination (HR) and contribute to the multipartite structure of mtDNA, while rare ectopic recombination occurs among small repeats and generate alternative mtDNA configurations at substoechiometric levels, which contribute to the rapid evolution of the mtDNA structure in plants. HR is thus important in mtDNA maintenance and evolution but is also involved in repair and replication mechanisms.

Several organellar proteins have been identified as implicated in the control of ectopic HR or in mechanisms of HR-dependent repair. But many additional factors remain to be identified, including the DNA helicases involved in recombination surveillance which are postulated to be required for rejection of ectopic HR intermediates .

We identified an Arabidopsis DNA helicase homologous to the bacterial DNA helicase RecG, that we called RECG1. Bacterial RecG acts as a translocase in DNA recombination, repair and replication. It promotes holliday junctions translocation, the regression of replication forks and avoiding replication re-initiation when replication forks collide. GFP fusion showed that Arabidopsis RECG1 is dually targeted to mitochondria and plastids. Promoter-GUS fusion showed that the gene is expressed in most plant tissues, in particular in leafs and root vascular systems. The Arabidopsis RECG1 is able to complement its bacterial orthologue for the repair of UV-induced DNA repair, but not the additional bacterial DNA translocase RuvAB. Using T-DNA insertion mutants we tested the role of RECG1 in the surveillance of ectopic HR and the repair of DNA damage induced by ciprofloxacine. We found that RecG1 affects the efficiency of mtDNA repair by recombination. In addition, loss of RECG1 results in increased ectopic HR of the mtDNA having as consequence specific changes in the segregation of mtDNA sequence.

Keywords: mitochondrial DNA, Plants, recombination.

Mitochondria are organelles responsible for both ATP production and maintenance of cellular life. Transformed cells present genetic, molecular and biochemical alterations in mitochondria, which may be either causal or contributing factor for cancer development. Mitochondrial dysfunction has been associated with defects in the apoptosis pathway in solid tumors, including head and neck squamous cell carcinoma (HNSCC). Therefore, it is believed that anticancer agents targeted to mitochondria of cancer cells present reduced effects in normal cells. In the present study, we assessed a new dihydropyridine derivative YV-241 with respect to cell viability and mitochondrial membrane potential ($\Delta\Psi_m$), and also the type of cell death promoted by the compound. Cell viability assay was employed in a human HNSCC cell line (HN13) and a normal cell line (primary culture of human fibroblast). The reduction of resazurin (blue and nonfluorescent) to resorufin (pink and highly fluorescent) indicates cell proliferation and viability. The HN13 cancer cell line was more sensitive ($IC_{50} = 7.55$ μM) than the normal human fibroblast, which presented an IC_{50} of 23.76 μM. The JC-1, a cationic carbocyanine dye that accumulates in mitochondria, is a $\Delta\Psi_m$ marker. The HN13 cell line showed a concentration-dependent decrease of $\Delta\Psi_m$ in the presence of the compound, while fibroblast was not significantly affected. The cellular alterations in the presence of the compound were assessed by transmission electron microscopy and cell death signaling by analysis of apoptosis markers such as PARP, caspase-3, caspase-8, as well as cytochrome *c* release from mitochondria. YV-241 presented a cytotoxic effect apparently via apoptosis, with mitochondrial impairment involvement. In this context, YV-241 presents a potential action against cancer cells and mitochondria are the probable target.

Exercise training decreased the sensitivity of calcium-induced mitochondrial permeability transition pore opening via NO-dependent mechanism in rat heart

S. Chorna[1], N. Strutynska[1], O. Semenykhina[1], A. Kotsuruba[1], V. Dosenko[2], V. Sagach[1]
[1]*Department of Blood Circulation,* [2]*Departament of General and Molecular Pathophysiology, Bogomoletz Institute of Physiology, Kyiv, Ukraine*

Aging is characterized by a decline of cardiac function and an increase of oxidative stress, which are major contributors to cell death through mitochondrial dysfunction. Mitochondrial permeability transition pore (MPTP) opening plays a significant role in the transition of mitochondria from a physiological condition to induction of cell death. In contrast, exercise training not only improves cardiac function, but also reduces the risk of heart disease. However, the mechanisms by which exercise training improves heart function and cardiovascular disease risk profile are not understood. The purpose of the present investigation was to study the effect of long-term exercise training on the sensitivity of calcium-induced MPTP opening in adult and old rats including the activity and gene expressions of isoforms of nitric oxide synthases (NOS) such as constitutive NOS (cNOS), which including neuronal NOS (nNOS) and endothelial NOS (eNOS), and also inducible NOS (iNOS)) in this process. Exercise training animals were subjected to dosed physical load carried by the forced swimming five days a week for six weeks for adult rats (5 month) and four weeks for old rats (24 month). We found that mitochondria isolated from hearts of the adult and old trained rats demonstrated the similar decrease in sensitivity to Ca^{2+} of the MPTP-opening in range concentration 10^{-7} to 10^{-4} mol/l compare to untrained. We hypothetized that such decrease in sensitivity of the MPTP-opening occurred due to increased production of NO by cNOS during exercise. Our results demonstrated that administration of NO syhnthase inhibitor N(omega)-nitro-L-argi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

nine methyl ester (L-NAME) in dose of 10 mg/kg to trained rats increased the sensitivity of MPTP-opening to Ca^{2+} in range concentration 10^{-7} to 10^{-4} mol/l. Analysis of NOS isoforms responsible for NO production during exercise revealed significant age differences. In adult trained rats we observed significant stimulation of the cNOS activity and noticable elevation in the iNOS activity. Moreover, the gene expressions of nNOS and iNOS were increased by 5-fold and 24-fold respectively while eNOS was decreased by 3-fold. Alternatively, in old trained rats, the activity of cNOS was modestly increased while the activity of iNOS was decreased. Correspondently, the gene expressions nNOS and iNOS were decreased by 4-fold and 2-fold respectively while eNOS was increased by 3-fold. Taken together, our data suggest that of long-term exercise training reduces the sensitivity of the MPTP opening to the action of calcium ions by increasing the synthesis of nitric oxide - an endogenous inhibitor of MPTP opening.

Functional roles of nitric oxide in roots and mitochondria

J. G. Kpauganti[1], A. U. Igamberdiev[2], N. Kruger[1], R. G. Ratcliffe[1]
[1]Department of Plant Sciences, University of Oxford, Oxford, UK, [2]Department of Plant Sciences, Memorial University, New Foundland, Canada

Nitric oxide (NO) has emerged as an important signal molecule in plants. Reductive and oxidative pathways are involved in NO production. Nitrite is produced by cytosolic nitrate reductase (NR) and then converted to NO by the same enzyme with nitrite reductase activity. Mitochondrial complex III and IV are the sites for nitrite to NO reduction. Nitrite reduction to NO increases as oxygen availability decreases. The reaction leads to ATP synthesis. NO generated in mitochondria converted to nitrate by the hypoxically-induced haemoglobin in cytosol. Under hypoxia plant mitochondrion serves as a nitrite: NO reductase and becomes a major component in anoxic nitrogen cycling where it directly contributes to a decrease of cell reduction level and to limited ATP synthesis. We found that NO inhibits aconitase in mitochondria and increases citrate which then acts as a potent inducer of AOX expression. NO production, inhibition of aconitase, and induction of AOX also leads to a shift of plant metabolism towards amino acid biosynthesis, since citrate is a precursor for the 2-oxoglutarate required for glutamate synthesis.

Keywords: alternative oxidase, mitochondria, nitric oxide.

Functional study of mitochondrial UQCRB, a terpestacin-binding protein, in angiogenesis

J. Chang[1], H. J. Jung[2], J. E. Kim[3], H. J. Kwon[3]
[1]Department of Biotechnology, Yonsei University, Seoul, [2]University of Sun Moon, Chungnam, [3]Yonsei University, Seoul, Korea

Ubiquinol-cytochrome c reductase binding protein (UQCRB), one of the subunits of mitochondrial Complex III, is a target protein of anti-angiogenic natural small molecule, terpestacin. Previously, the biological role of UQCRB was limited to the maintenance of Complex III, however, identification and validation of the protein target of terpestacin have enabled to uncover the role of UQCRB in oxygen-sensing and angiogenesis. To explore the biological role of UQCRB, UQCRB mutant cell lines was generated on the basis of human case report. In this case, the UQCRB mutant implies gain-of-function phenotype of UQCRB. UQCRB mutant stable cell lines exhibit pro-angiogenic activity via mitochondrial ROS-mediated HIF1 signal transduction. Also, morphological abnormality of mitochondria is detected in UQCRB mutant stable cell lines. In addition, proliferative effect of UQCRB mutant is significantly regulated by terpestacin. Further studies including analysis of mitochondrial function of UQCRB mutant stable cells will be presented. Collectively, this study can provide molecular basis underlying UQCRB-related biological process and reveal potential key roles of UQCRB in various cancers and metabolic diseases.

Hydrogen peroxide-induced gain of peroxidase activity of cytochrome c upon phosphate-mediated binding to zwitterionic lipids: implications for apoptosis

D. A. Capdevila[1], W. Marmisollé[1], F. Tomasina[2], V. Demicheli[3], R. Radi[3], D. Murgida[1]
[1]DQIAQF-INQUIMAE, Universidad de Buenos Aires, Buenos AIres, Argentina, [2]Facultad de Medicina, [3]Departamento de Bioquímica and Center for Free Radical and Biomedical Research, Facultad de Medicina, Universidad de la Republica, Montevideo, Uruguay

Cytochrome c (Cyt-c) has been shown to participate in cardiolipin (CL) oxidation and, therefore, in mitochondrial membrane permeabilization during the early events of apoptosis. The gain of peroxidatic activity has been ascribed to CL/Cyt-c interactions which, nevertheless, are also ubiquitous in healthy cells, thereby posing the question of which is the triggering event.

We observed that the cationic protein Cyt-c is able to interact electrostatically with the main lipid components of the mitochondrial membranes, the zwitterionic lipids phosphatidylcholine and phosphatidylethanolamine, through mediating phosphate anions that interact specifically with amino groups in the surfaces of the protein and the membrane models[1]. We have investigated the chemical reactivity of Cyt-*c* associated to model systems and in complexes with PE- and PC-liposomes using a combination of electrochemistry, Raman, fluorescence and mass spectroscopy. In these complexes Cyt-c reacts efficiently with H_2O_2 at submillimolar levels, which specifically sulphoxides the axial ligand Met80

© 2014 The Authors. FEBS Journal © 2014 FEBS

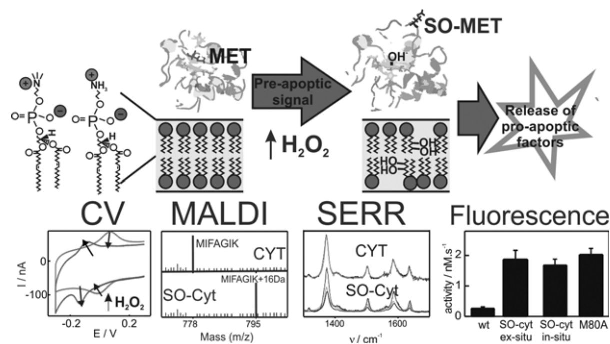

Fig. 1.

(SO-Cyt). The modified protein is stable and presents significantly enhanced peroxidatic activity.

Based on these results, we postulate that the rise of H_2O_2 levels from submicromolar to millimolar registered during the initiation of the apoptotic program may represent one signaling event that triggers the gain of peroxidatic function of Cyt-c.

Hyperpolarization of isolated mitochondria triggers mitophagy in OPA1-mutated fibroblasts

M. S. Kane[1], N. Gueguen[1], M. Ferre[1], V. Desquiret-Dumas[1], D. Bonneau[2], V. Procaccio[2], P. Reynier[2], A. Chevrollier[1]

Mitochondria integrity is regulated by mitophagy, a process which subjects damaged mitochondria to degradation. Mitophagy was shown to be monitored by dynamic events involving fission and fusion of mitochondrial network subsequently engaging mitochondrial membranes remodeling. Mutations on actors of this dynamism among which Optic Atrophy 1 (OPA1) lead to a heterogeneous group of human neurodegenerative disorders. Human studies on OPA1-mutated fibroblasts from patients have shown bioenergetics deficiency and a more or less fragmented mitochondrial network associated with a drop in mitochondrial mass. These data suggest a regulatory role of these dynamic events and their actors in mitochondrial biogenesis, elimination and turnover. Our objective was, combining biomolecular strategies and standardized-imaging approaches using micropatterned coverslips, to highlight an impaired mitophagy in a pathological context affecting mitochondrial dynamics. Our studies have shown that OPA1 mutations associated with high mitochondrial network fragmentation are characterized by a drop in mitochondrial volume per cell, whereas mtDNA content remain rather constant if not increased. Single-cell imaging coupled with 3D-image analysis showed an increased mitochondria-autophagolysosmes contact and immunoblotting analysis comfort these findings with increased autophagy biomarkers activation; thus reflecting an active basal degradation rate of cellular components. Unexpectedly, as opposed to studies correlating drop of mitochondria potential membrane to mitophagy level, imaging approaches showed that isolated mitochondria displayed a higher membrane potential despite a high degradation level in our model. This is concomitant to OXPHOS subunits' expressions which remain rather constant despite an enhanced degradation. These findings led us to the following hypothesis in which OPA1

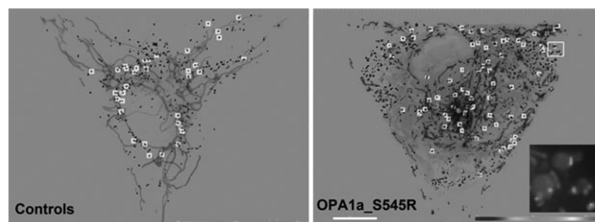

Fig. 1.

mutations associated with fragmentation and cristae disorganization lead to unsuitable OXPHOS repartition. The enhanced energetic activity relative to OXPHOS density seems to correlate with mitochondria elimination; thus highlighting a new stimulus to mitophagy activation. Moreover, studies show that this boosted mitophagy is associated with an impaired biogenesis, resulting in mitochondria turnover imbalance; thus placing mitochondrial degradation machinery as a potential target for future therapeutic strategies.

Aspergillus fumigatus is an opportunistic pathogen that causes invasive infections in immunocompromised hosts. Previous studies suggested the presence of alternative compounds on its electron transport chain (ETC), such as uncoupling protein (UCP). UCPs are mitochondrial carriers, activated by fatty acids and sensitive to purine nucleotides, which dissipate electrochemical proton gradient generated by ETC during respiration. Here, coding sequences of three mitochondrial carriers [*Af*DC: dicarboxylate carrier (XP_755633), *Af*OAC: oxaloacetate transporter (XP_753416) and *Af*UCP (XP_755831)] were functional reconstituted for assessment of their linoleic acid-induced uncoupling activity. Full-length cDNAs were cloned into pET28a vector. Heterologous expression in *Escherichia coli* was carried out for 4 hours at 37°C after 1 mM IPTG induction. Recombinant proteins were purified from inclusion bodies and solubilized in medium containing 1.67% sodium lauroylsarcosinate and 4% decylpolyoxyethylene at 4°C for 2.5 h. Lipid films were prepared from ethyl ether solution of lecithin, cardiolipin and phosphatidic acid by a stream of nitrogen. Proteoliposomes were prepared with a lipid/protein ratio of 410:1. H^+ fluxes were monitored by a fluorimetric assay based on the quenching of SPQ probe by TES^-. Vesicles containing *Af*UCP and *Af*OAC were able to transport H^+ induced by linoleic acid. However, only proteoliposomes containing *Af*UCP had that H^+ efflux inhibited by ATP, which characterize a UCP-like activity. Furthermore, we performed the heterologous expression of *Af*UCP in *Saccharomyces cerevisiae* and its uncoupling activity was demonstrated by poten-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tial membrane measurements using the safranine O method. The differences in yeasts mitochondrial coupling were analyzed by monitoring $\Delta\psi$ changes during ADP phosphorylation supported by NADH oxidation. Our results showed that, compared with control cells, mitochondrial electrical transmembrane potential of transformant spheroplasts was slightly smaller and the transient $\Delta\psi$ decrease associated with ADP phosphorylation was longer, indicating an uncoupling activity of respiration. The results presented in this work provide evidence that *Af*UCP (XP_755831) protein, expressed in prokaryote and eukaryote system, exhibited functional features of an uncoupling protein, transporting H^+ in a process stimulated by fatty acids and inhibited by purine nucleotide.

Impact of miR-378* and its target desmin intermediate filament on mitochondria distribution and respiration in cardiomyocytes

Y. Mallat[1], J. Lehacaut[1], F. Bouillaud[2], O. Agbulut[1], **M. Mericskay**[1]
[1]*Biology of Adaptation and Aging - CNRS UMR 8256, UPMC Univ Paris 6, Paris Cedex 5,* [2]*Département Endocrinologie, Métabolisme et Cancer, CNRS UMR 8104, Institut Cochin, INSERM U1016, Paris, France*

Background: MiR-378 and miR-378* microRNAs are derived from an intron of the PGC-1β gene, a regulator of mitochondrial biogenesis. Their expression is either repressed or increased during heart failure depending on the model. Through proteomics approaches, we identified new targets of these miRs in H9c2 fetal cardiomyoblasts, among which mRNAs coding proteins involved energy metabolism, endoreticulum stress response and cytoskeletal proteins for miR-378* (1).

Aims: To better assess its role in energy metabolism and differentiation; we overexpressed miR-378* in primary neonate rat cardiomyocytes (NRC) that are more differentiated than H9c2 cardiomyoblasts.

Results: We identified desmin as a new target of miR-378* in NRC. Desmin is a muscle-specific type III intermediate filament that forms a cytoskeletal lattice, which has been proposed to play a key role as a structural integrator of myofibrils and mitochondria positioning. Confocal microscopy analysis showed that miR-378* overexpression altered desmin filaments organization in NRC. It also decreased the basal-to-maximal respiration ratio and ATP synthase coupled respiration as assessed by Seahorse mitochondria stress test assay. Confocal microscopy analysis of NRC stained with the mitochondrial dye MitoTracker revealed that miR-378* overexpression alters mitochondria distribution in the cell and western blot analysis revealed a down-regulation of COX1 and COX4 components of the respiratory chain. AAV-mediated rescue of desmin expression in presence of miR-378* preserved mitochondria distribution.

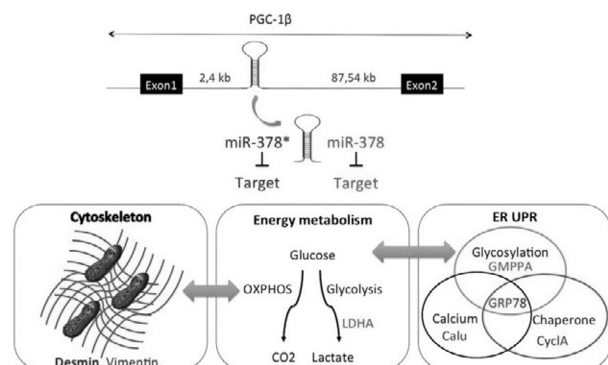

Fig. 1.

Conclusion and perspectives: These results show that miR-378* overexpression in cardiomyocytes alters their oxidative capacities suggesting that miR-378* has an antagonistic action to its host gene PGC-1β. Originally this repressive action could be mediated in part by the alteration of the coupling between desmin filaments cytoskeletal network and mitochondria, two cellular components whose organization is severely perturbated in the context of heart failure.

Influence of p53 on ISR gene expression under mitochondrial dysfunction

A. Garaeva[1], G. Novakovskiy[1], A. Evstafieva[2]
[1]*Faculty of Bioengineering and Bioinformatics, Lomonosov Moscow State University,* [2]*Belozersky Institute of PhysicoChemical Biology, Moscow, Russian Federation*

Tumor suppressor p53 is activated in response to different cellular stresses, particularly as a result of mitochondrial dysfunction induced by the inhibition of mitochondrial respiratory chain complex III. ISR (Integrated Stress Response) is a program of gene expression regulated by transcription factor ATF4 and aimed to increase cell survival. The interrelation of p53 activation and ISR gene expression under mitochondrial dysfunction has been studied in this work.

Gene expression in human colon cancer cells exposed to mitochondrial respiratory chain complex III inhibitor myxothiazol has been analyzed by RT qPCR. Expression of ATF4 and several its target genes has been found to be induced at early time points (5 h), but drop at later time points (13 h) after activation of p53 tumor suppressor. Prevention of myxothiazol-induced p53 activation by uridin supplementation resulted in recovery of increased expression of ISR-related genes.

In contrast, preliminary p53 activation by nutlin-3 before addition of complex III inhibitor has led to the abolishment of ATF4 gene induction in response to short incubation with myxothiazol. The findings indicate that p53 activation negatively regulates expression of ISR genes induced at early stage of III complex inhibition, probably due to suppression of transcriptional factor ATF4.

This conclusion is consistent with the fact that in contrast to complex III inhibition mitochondrial respiratory chain complex I inhibition by piericidine did not result in p53 activation and led to the long-term enhanced expression of ATF4 and its target genes.

Work was supported by Russian Foundation for Basic Research grant 12-04-01444.

Interaction between VDAC1 and ALS-linked SOD1 mutants: implications for mitochondria health

A. Magrì[1], S. Reina[1], M. C. Di Rosa[1], F. Tomasello[2], D. Ben-Hail[3], V. Shoshan-Barmatz[3], A. Messina[1]
[1]Biological, Geological and Enviromental Sciences, Section of Biochemistry and Molecular Biology, University of Catania, [2]CNR Institute of Biostructure and Bioimaging, Catania, Italy, [3]Life Science Department and National Institute for Biotechnology in the Negev, Ben Gurion Univesity of the Negev, Beer Sheva, Israel

Mutations in superoxide dismutase 1 gene (hSOD1) represent the first cause of familial form of Amyotrophic Lateral Sclerosis. Most of ALS-linked SOD1 mutants still show enzymatic activity, suggesting that the SOD1-mediated disease is caused by the gain of some unknown toxic properties, such as impairment of mitochondrial function. As observed in affected cells, mitochondria appear enlarged, vacuolated and disorganized [1]; in addition, the most diffused mutants SOD1, G93A and G85R, have been found associated with the outer mitochondrial membranes (OMM) [2], suggesting that SOD1 aggregates may be responsible of the mitochondrial degeneration. As recently demonstrated, this SOD1 accumulation on OMM is made possible by the presence of the Voltage-Dependent Anion Channel isoform 1 (VDAC1) [3]. VDAC1 is the main pore-forming protein of OMM, directly involved in metabolic cross-talk between mitochondria and cytoplasm [4]. VDAC1 sequence is highly conserved in eukaryotes: e.g., a high level of similarity was found between VDAC1 and por1, its homologous in yeast *S. cerevisiae*. It has been shown that expression of corresponding ALS-linked yeast SOD1 mutant G93A, in ΔSod1 strain, promotes accumulation of this protein on OMM [5], underlining the suitability of yeast to study the distribution of mutants SOD1 between cytosol and mitochondria. To better understand the role of VDAC in mitochondrial impairment SOD1-mediated, the yeast strain lacking of endogenous porin (Δpor1) was used in this work. As reported, Δpor1 is not able to grow in a not fermentable carbon source (glycerol) at 37°C, while VDAC1 and 2 complement the growth defect. Exploiting this feature, we analyzed the effect of co-presence of human forms of VDAC and SOD1 proteins on yeast phenotype. Our preliminary data show that no effect on yeast growth was observed with fermentable glucose source; on the contrary, with glycerol, the overexpression of human wild-type SOD1 or misfolded G85R in presence of VDAC1 strongly inhibits yeast growth. Surprisingly, the human SOD1 mutants G93A and G37R, are able to restore and ameliorate yeast growth. These data highlight how the activity of SOD1 proteins are linked to the mitochondrial metabolism and are mediated by VDAC. Use of VDAC1 mutants or chimeras as in [6] has allowed us to propose the VDAC regions involved in the process.

Interaction of the mitochondrial ISC proteins Yah1 and Isu1 studied by NMR spectroscopy

A. Gallo[1], S. A. Freibert[2], H. Webert[2], U. Mühlenhoff[2], L. Banci[1], R. Lill[2]

[1]CERM-Department of Chemistry, University of Florence, Sesto Fiorentino (FI), Italy, [2]Institut für Zytobiologie und Zytopathologie, Philipps-Universität Marburg, Marburg, Germany

Mitochondria contain the complex Iron-Sulfur-Cluster Assembly (ISC) machinery which is crucial for the maturation of both mitochondrial and cytosolic iron-sulfur (Fe/S) proteins in eukaryotes. Here, we determined the 3D structure of the mitochondrial [2Fe-2S] ferredoxin Yah1 in both redox states through NMR spectroscopy performing classical and non-conventional NMR experiments. In the latter approach, paramagnetic tailored NMR experiments were used to overcome fast relaxation of nuclei close to the Fe/S cluster which makes their detection impossible with standard approaches. Thereby, backbone resonance assignments for 92 and 88 out of 115 amino acid residues were obtained for oxidized and reduced Yah1, respectively. The undetected residues (stretches 96–108 and 143–145 in oxidized Yah1; 95–109 and 142–146 in reduced Yah1) were all located close to the [2Fe-2S] cluster. The NH signals in the C-terminal region (160–169), i.e. far from the cluster, were also extensively broadened suggesting an unstructured polypeptide chain. For better insight into the biochemical nature of the protein interaction, we used NMR spectroscopy combined with several biophysical and biochemical methods to structurally determine the contact interface between Yah1 and Isu1. To explore the regions of interaction between Yah1 and Isu1 we performed NMR titrations through ^{1}H-^{15}N HSQC spectra under anaerobic conditions. In the presence of Isu1, spectral changes were observed only for reduced but not for oxidized Yah1, consistent with the affinity measurements by the equilibrium interaction method thermophoresis. Residues of Yah1 with largest variation were Ala133, Tyr134, Gly135, Gln88, Glu95, and Ile110. These residues are located in a region surrounding the [2Fe-2S] cluster on the α3 helix side, and likely represent the Yah1-Isu1 interaction region. Conspicuously, a group of acidic residues (Gln88, Glu95, Asp128, and Asp131) in helix α3 is present in the interaction region, suggesting a key role of these electrostatic residues in electron transfer to Isu1. The final goal of this study is the understanding of the role of Yah1 as an electron donor in Fe-S protein biosynthesis.

Interplay between mitochondrial membrane potential loss, microglia, and neuron causes massive neuronal loss

M.-K. Nam[1], J.-H. Han[1], J.-Y. Jang[1], J. Yi[1], J. E. Yun[1], H. Rhim[1]
[1]*Department of Biomedical Sciences, The Catholic University of Korea, Seoul, Korea*

Depolarization in mitochondrial membrane potential (ΔΨm loss) have been closely associated with many neurodegenerative disorders. However this relationship has not been clearly demonstrated. By co-culture with neuron and microglia and CCCP treatmentm, we established simple and biological relevant in vitro neurophathological mimic system for neurodegeneration caused by ΔΨm loss. Using this system, we have demonstrated that neuronal loss is triggered by phagocytosis-enhancing effect of microglia to neighboring neuron with ΔΨm loss. Notably, at cell morphological and molecular levels, we show that microglia more vlunerable to ΔΨm loss than neuron, which is correlate with microglial activation. Our results provide important evidence that it is necessary to microglia activated- as well as neuron damaged by ΔΨm loss for ΔΨm loss-associated with neurodegenerative progression. Furthermore, these findings will contribute to new strategy for targeted therapeutics regulated microglial ΔΨm in progressive neurodegenerative disorder. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIP) (NRF-2010-0027963).

Intrarenal angiotensin-II crosstalk with mitochondrial dysfunction in nephrotoxicity-induced by adriamycin in rats

E. Taskin[1], K. Ozdogan[2], E. Kunduz Kindap[2], N. Dursun[2]
[1]*Department of Physiotherapy and Rehabilitation, School of Health Sciences, Istanbul Bilim, Istanbul,* [2]*Department of Physiology, Faculty of Medicine, University of Erciyes, Kayseri, Turkey*

Adriamycin (ADR) is commonly used for many of solid tumors treatment. Its clinical utility is, however, largely limited by the adverse reactions, are known to be nephrotoxic. But the mechanism by which it induce kidney damage is still not completly understood. But its nephrotoxicity might relate to increase reactive oxidant status (ROS), mitochondrial dysfunction. Until now, neurohormonal activation of its is unclear. ADR might activate the renin angiotensin system. Angiotensin-II also induced ROS and mitochondrial dysfunction. The aim of this study was to investigate whether angiotensin-II production inhibition has the protective effect on attenuation of mitochondrial function in rats with acute ADR-nephrotocixity or not. Rats were divided into five groups as a control, ADR, co-treated ADR with captopril, co-treated ADR with Aliskren, co-treated ADR with both captopril and Aliskren groups. Creatinin kinase (CK) levels were measuremented at the end of treatment period. The kidneys were homogenized and biochemical measurements were made in mitochondria, cytosol. Mitochondria membrane potential (MMP) and ATP levels were determined. ADR incresead CK levels and oxidative stress in mitochondria too ($p < 0.05$). ADR significantly decreased MMP and ATP level in kidney mitochondria ($p < 0.05$). Co-administration with ADR and Aliskren and captopril improved the dissipation of MMP ($p < 0.05$). The decreased in ATP level was restored by treatment with inhibitors of ACE and renin. We concluded that inhibitors of angiotensin-II are effective against acute ADR induced nephrotoxicity via the restoration of MMP and ATP production and prevention of mitochondrial damage in vivo.

Investigating quality control in human mitochondrial translation using ribosome profiling

M. Wesolowska[1], K. Rooijers[2], F. Loayza-Puch[2], R. Agami[2], Z. Chrzanowska- Lightowlers[1], R. Lightowlers[1]
[1]*Wellcome Trust Centre for Mitochondrial Research, Newcastle University, Newcastle upon Tyne, UK,* [2]*Division of Gene Regulation, The Netherlands Cancer Institute, Amsterdam, Netherlands*

The ability of mammalian mitochondria to conduct intra-organellar protein synthesis is a well-known phenomenon. Disruptions to this process are very often linked to serious disorders, making it an extremely important area of study. Unfortunately many aspects of mitochondrial (mt-) translation remain undefined, especially quality control mechanisms that recycle stalled ribosomes. We lack this detailed knowledge due to a lack of tools to study mt-protein synthesis in vivo. We believe that ribosome profiling is an approach to overcome these limitations.

Ribosome profiling reveals mRNA fragments protected by ribosomes. Deep sequencing then provides a ribosome profile that represents their distribution throughout the whole transcriptome. This project aims to apply a modified ribosome profiling protocol to human mitochondria. This will help elucidate previously undescribed mechanisms that rescue stalled mitoribosomes during organellar translation. I will focus specifically on investigating potential candidates for quality control and rescue factors, such as protein C12orf65. The importance of C12orf65 in mt-translation was confirmed in a patient who harbours a mutation in *C12orf65* gene. Disruption in assembly of OXPHOS complexes I, IV and V was shown by BN-PAGE, in agreement with published data of patients with similar genetic defects. However the exact role of this protein remains unknown and can only be determined by more advanced techniques like ribosome profiling.

To validate the adapted ribosome profiling protocol in detecting stalled mitoribosomes I applied it to analyse a cell line containing a homoplasmic mutation in mitochondrial tRNA valine. This mutation causes lower levels of mt-tRNA^{Val} that I expected would cause mitoribosome stalling at valine codons compared to control cell lines. Preliminary results show differences in distribution of mitoribosomes compared to a control cell line. However more detailed statistical analysis is being conducted to determine whether this is exclusively due to stalling at mitochondrial valine codons.

In conclusion the modified ribosome profiling protocol optimised for mitoribosomes will be applied to analyse cell lines with mutated or depleted of C12orf65. Increase and position of mitoribosome stalling in the absence of C12orf65 will reveal if this protein plays a role of mitoribosome rescue factor.

Involvement of mitochondria-mediated apoptosis in α and β-Zearalenol cytotoxicity, prevention by Crocin

I. Salem[1], M. Boussabbeh[1], A. Prola[2], C. Lemaire[2], H. Bacha[1], S. Abid-Essefi[1]
[1]*Laboratory Research on Biologically Compatible Compounds, University of Monastir, Monastir, Tunisia,* [2]*INSERM UMR S-769, Paris-Sud 11 University, Châtenay-Malabry, France*

Zearalenone (ZEN) and its metabolites are commonly found in many food commodities and harmfully affect the gastrointestinal tract. The major ZEN metabolites are α-zearalenol (α-ZOL) and β-zearalenol (β-ZOL). Since it is well known that mitochondria play a central role in apoptosis triggered by many stimuli, an effort was made to examine whether α /β-Zearalenol -induced cytotoxicity occurs through mitochondria-mediated apoptotic pathway. The intestinal system being one of the primary targets of mycotoxins, the human colon carcinoma cell line HCT116 was used in this study. Using flow cytometric analyses we showed that α-ZOL and β-ZOL induced a loss of cell viability by inducing apoptosis. α and β -ZOL-induced apoptosis was mediated through a mitochondria-dependent pathway, characterized by the loss of mitochondrial transmembrane potential (DYm), a downstream generation of O_2 and caspase 3 activation. Besides, deficiency of the pro-apoptotic proteins Bax and Bak partially protected cells against α and β –ZOL-induced mitochondrial alterations.

Therefore, we showed that treatment by α and β –ZOL combined to the Crocin (CRO), a common dietary carotenoid with well-known antioxidant activity, showed a significant reduction of α and β –ZOL induced mitochondrial damages for all tested markers. It could be concluded that *CRO* is effective in the protection against α and β –ZOL hazards. This could be relevant, particularly with the emergent demand for natural products which may prevent multiple human diseases.

Keywords: crocin, Mitochondrial dysfunction, zearalenone.

Kinetic characterization of recombinant alternative oxidase from *Aspergillus fumigatus*

S. Suzuki[1], F. G. Cardoso[1], L. D. L. D. L. Bálico[2], E. S. Santos[2], A. F. Garcia[3], A. J. Costa Filho[3], S. A. Uyemura[2]
[1]*Biochemistry and Immunology, Ribeirão Preto Medical School,* [2]*Clinical Analysis, Toxicological and Bromatological, Faculty of Pharmaceutical Sciences of Ribeirão Preto,* [3]*Physics, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, Ribeirão Preto, Brazil*

Aspergillus fumigatus is a saprophytic fungus, thermotolerant and able to grow up to 55°C. This characteristic is important to stress resistance during the development of aspergillosis in immunosuppressed patients which is associated the alternative mitochondrial pathway. Previous studies in our laboratory showed the presence of this pathway in *A. fumigatus* and identified the protein alternative oxidase (AOX). AOX is an ubiquinol oxidase cyanide resistant, inhibited by salicylhydroxamic acid (SHAM) and molecular mass of 40.80 kDa. Furthermore, the alternative pathway maintains the ubiquinone pool to avoid auto-oxidation of the reduced ubiquinone when the flow of electrons from the cytochrome pathway is limited. Consequently prevents the formation of reactive oxygen species. The objective of this study was to purify active recombinant AOX (rAOX) for enzymatic characterization. The AOX cDNA was cloned into pTZ57R vector, subcloned into pET28a vector and the sequences were confirmed by DNA sequencing. Heterologous expression was optimized in *Escherichia coli* BL21(DE3) at 37°C with 0.5 μM isopropylthio-β-galactoside following 4 hours of induction and it was validated by mass spectrometry (MS-MS) and western blot using anti-AOX. The rAOX of inclusion bodies (IB) were purified from bacterial cell of expression after lysis by sonication and successive washes with buffer A [50 mM Tris-HCl, 50 mM NaCl, 1 mM Tris2-carboxyethylphosphine hydrochloride (TCEP), 5% glycerol, 1% Triton X-100]. The rAOX of IB were denatured with buffer B [5 mM TCEP, 5,25% N-Lauroylsarcosine] and refolded at 4°C for 48 hours by dilution of rAOX into buffer C [12.5 mM methyl-beta-D-cyclodextrin, 1 mM EDTA]. The circular dichroism of rAOX refolded showed α-helix secondary structure predominantly and when it was incubated with SHAM showed loss of

© 2014 The Authors. FEBS Journal © 2014 FEBS

structure. The AOX activity was performed by ubiquinol oxidase assay which measures the absorbance change of ubiquinol-1 or decyl-ubiquinol at 278 nm. The AOX refolded showed activity in the presence of substrate ubiquinol-1 (V_{max} = 1421.28 µmol/min/mg) and decyl-ubiquinol (V_{max} = 1261 µmol/min/mg). The inhibitor SHAM decreased the activity of AOX refolded in the presence of both substrates respectively (V_{max} = 355 µmol/min/mg and V_{max} = 710 µmol/min/mg). The purification of active rAOX of IB was effective because it showed ubiquinol oxidation in both conditions of the assay. Further studies of AOX structure and interaction with inhibitors will enable the development of drugs for treatment of aspergillosis.

Mapping the critical residues for hVDAC3 activity: electrophysiological study and phenotypic assays in yeast cells of hVDAC3 cysteine mutants

S. Reina[1], F. Tomasello[2], A. Magrì[1], L. Leggio[1], V. De Pinto[1]
[1]*Biological, Geological and Enviromental Science Section of Biochemistry and Molecular Biology, University of Catania,* [2]*CNR-Institute of Biostructures and Bioimmaging, Catania, Italy*

VDAC3 is the most ancient member of the family of mitochondrial porins [1]. It shares 60–70% sequence identity with VDAC1 and VDAC2, but the mitochondrial function of VDAC3 is not clear. In literature, it is reported that VDAC3 is involved in apoptotic pathways in synovial fibroblast, respiratory electron transport, ATP synthesis by chemiosmotic coupling and heat production by uncoupling proteins (Parkinson's disease and Huntinghton's disease), toll-like receptor signaling pathway (Hepatitis B), viral carcinogenesis, calcium signaling and HTLV-I infection [2] but any rationale is still lacking. Differently from VDAC1 and VDAC2, recombinant VDAC3 is not able to form channels in an artificial membrane and its heterologous expression in Δpor1 yeast cells can only partially complement the growth defect in glycerol at 37°C. In a previous work, we demonstrated that the replacement of the first 20 amino acids of hVDAC3 N-terminal region with the corresponding residues of hVDAC1 (hN1-VDAC3) allows VDAC3 to fully restore the wild type phenotype [3]. In a more recent work [4], we characterized the chimera hN1-VDAC3 also electrophysiologically. Unlike hVDAC3, hN1-VDAC3 forms channels with a conductance comparable to that of hVDAC1. The sequence analysis of the VDAC isoforms reveals that a significant difference is the number of cysteines, 7 in hVDAC3 and only 2 in VDAC1. Bioinformatic studies made us to hypothesize that the hVDAC3 N-terminus Cys oxidation may cause formation of disulfide bridges or other adducts. It is tempting to speculate that such Cys oxidation may cause problems for the channel formation. By site-directed mutagenesis we replaced the VDAC3 Cys with Ala, (as in hVDAC1). hVDAC3 mutants were cloned into pET21a, expressed in *E. coli* together with proper controls. The mutated proteins were refolded by dialysis and their electrophysiological activity studied upon reconstitution in planar lipid bilayer (PLB). The mutant proteins were also cloned in a yeast shuttle vector and expressed in *Δpor1* yeast cells to study their effects on phenotype, apoptosis and ROS production. The main result from this study is that, both in vitro and in cellulo, the mutagenesis of cysteine provokes a drastic change in the pore-forming activity of VDAC3 and in the ability to restore a normal oxidative function of mitochondria. This result highlights the role of Cys in VDAC3 and explains the presence of different isoforms in the cell. From the structural and mechanistical point of view a model is presented of the activity of this pore-forming protien, completely neglected till now.

Mitochondria of rat myometrium possess ATP-sensitive channels, which can be activated by Ca ions

O. Vadzyuk, S. O. Kosterin
Muscle biochemistry, Palladin Institute of Biochemistry, Kyiv, Ukraine

Isolated mitochondria were loaded with K^+-sensitive probe PBFI for 10 min. under room temperature in K^+-free medium. After dilution with isolation medium and final centrifugation at 12000 g pellets were resuspended in isolation medium without EDTA and stored on ice. PBFI fluorescence was measured using an excitation ratio technique (λ_{exc} 340/380, λ_{em} 480) after addition of mitochondrial aliquots into K^+ medium. For the measurements of mitochondrial side scattering pellets after second centrifugation were resuspended in isolation buffer without EDTA and stored on ice.

Results: Accumulation of K^+ in mitochondrial matrix resulted in fast increase of PBFI fluorescence, which was effectively suppressed by addition of ATP (200 µM). Nevertheless, no suppression was observed when the activator of K^+_{ATP}-channel diazoxide (50 µM) was added along with ATP These results provide reason to assume the existence of the functional of K^+_{ATP}-channel in mitochondria of the rat myometrium. Measurements of the side scattering of mitochondrial suspension at 520 nm confirmed our assumption. Fast swelling of mitochondrial matrix as a result of K^+ accumulation was slowed down significantly under presence of ATP (200 µM). In contrast to this, diazoxide addition (50 µM) along with ATP caused restoration of the rate and the steady-state volume of mitochondrial swelling to the levels of ATP- and diazoxide-free control.

Addition of $CaCl_2$ (100 µM) into the incubation medium resulted in acceleration of the swelling rate of mitochondria as well as in lowering of steady-state volume in comparison to the level of Ca^{2+}-free control. These effects of high Ca^{2+} concentration were suppressed either by 1 µM CsA or 10 µM RuR. Thus Ca^{2+}-induced mitochondrial swelling that we observed was mediated by Ca^{2+} accumulation through the mitochondrial Ca^{2+} uniporter and the permeability transition pore (PTP) opening. Further, blockers of K^+_{ATP}-channel glybenclamide (2 µM) and 5-HD (200 µM) partially blocked mitochondrial swelling rate. Effect of K^+_{ATP}-channel blockers was observed only in K^+ medium and did not observed when K ions were substituted equimolarly for Na^+.

Conclusions: These results allow to assume the existence of functional K^+_{ATP}-channels on the mitochondria isolated from rat uterus. High concentrations of Ca^{2+}, which evoke the PTP opening, can induce the opening of K^+_{ATP}-channel either.

Mitochondrial DNA import and the TIM22 channel

F. Weber-Lotfi[1], J. Bermejo[2], M. Koulintchenko[3], Y. Konstantinov[3], A. Gallardo[2], S. Martínez-Caballero[2], A. Dietrich[1], M. L. Campo[2]
[1]Institut de Biologie Moléculaire des Plantes, CNRS/UdS, Strasbourg, France, [2]Department of Biochemistry and Molecular Biology, University of Extremadura, Cáceres, Spain, [3]Siberian Institute of Plant Physiology and Biochemistry, RAS, Irkutsk, Russian Federation

We previously demonstrated that isolated plant, mammalian and *Saccharomyces cerevisiae* mitochondria are able to import double-stranded DNA through an active mechanism [1–3]. This imported DNA can be transcribed or repaired *in organello* [4–5]. For plant and yeast organelles, the voltage-dependent anion channel (VDAC) seems to be involved in DNA translocation through the outer membrane. We took *S. cerevisiae* as a model to identify the still elusive inner membrane proteins participating in mitochondrial DNA import. Using native yeast mitochondrial membranes for patch-clamp experiments, we showed that the TIM22 complex can form a channel [6]. By BN-PAGE and co-immunoprecipitation, we also found that VDAC, which is involved in DNA transport through the mitochondrial outer membrane, interacts with the TIM22 complex. DNA import assays were thus performed with mitochondria from yeast strains with different expression levels of Tim22p and Tim18p. It turned out that the absence of TIM22 complex significantly impairs DNA import into the organelles. Taken together, our data raise the possibility that the channel formed by the TIM22 complex could be a way for the DNA to cross the inner membrane of yeast mitochondria.

Mitochondrial network and respiration in primary fibroblasts derived from ALS patients

J. Walczak[1], S. Vielhaber[2], G. Dębska-Vielhaber[2], J. Duszyński[1], J. Szczepanowska[3]
[1]Department of Biochemistry, Nencki Institute for Experimental Biology, Warsaw, Poland, [2]Department of Neurology, University of Magdeburg, Magdeburg, [3]Department of Biochemistry, Nencki Institute for Experimental Biology, Warsaw, Germany

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder characterized by progressive, gradual degeneration of motor neurons responsible for controlling voluntary muscles. Most of the cases of ALS are sporadic with only 10% of recognized inherited (familial) forms. Among the familial forms the most common are diseases caused by mutations in *SOD1* gene. A growing body of evidence suggests that impaired mitochondrial functions are involved in the pathophysiology of many neurodegenerative diseases. Early cellular symptoms in ALS development are defects in mitochondrial energy production and mitochondrial dynamics. Understanding the relationship between mitochondrial malfunctions and progress of ALS may provide a useful tool for early diagnosis and potential pharmacological targets for treatment of this disease.

In order to verify presence of mitochondrial stress in fibroblasts derived from patients diagnosed with ALS (familial and sporadic forms) we studied mitochondrial membrane potential, cytosolic [Ca^{2+}], ROS production as well as respiration rates and activity of complex I and IV of electron transport chain. The mitochondrial structure and organization were visualized by confocal microscopy.

We found decreased mitochondrial membrane potential and increased cytosolic [Ca^{2+}] in cells with both forms of ALS. Control flux coefficient calculated on the basis of titration with specific respiratory inhibitor (sodium amytal) was higher in fibroblasts with sporadic form of ALS while maximal respiration rate on complex I substrates was slightly lowered which may suggest abnormalities in functioning of the complex. Organization of mitochondrial network in ALS cells was different than in control cells.

Keywords: ALS, mitochondrial dynamics, Neurodegeneration.

MON-315
MtDNA genetic comparison between Chinese and domestic diving beetles, *Cybister (Cybister) japonicus* (Coleoptera: Dytiscidae)

M. A. Kim, H. Park, E. Yun, J. Hwang
Department of Agricultural Biology, NIAST, RDA, Suwon-si, Korea

Diving beetles (Coleoptera: Dytiscidae) have been known to about 3800 species in the world (Nilsson, 2001) that the hind legs are flattened and setose, and set way back, separating the anterior abdominal sternites spiracles open up under the elytra and many taxa use ‘physical gills’ (air bubbles brought down from the surface), the larvae are also predacious, sometimes called ‘water tigers’; can crawl, paddle, or use serpentine movement in swimming, grooved mandibles for inserting enzymes and removing liquids from prey.

The population of *Cybister* (*Cybister*) *japonicus* are more and more decreasing, so are extinct species in Korea. *Cybister* (*Cybister*) *japonicus* imported from China are being reared and selling by merchant in these days. Therefore, geophylogenetic relationships among 14 districts of domestic species and the genetic comparison between the Chinese and domestic diving beetles was accomplished by mitochondrial gene Cytochrome Oxidase I(COI) and 16S rRNA partial sequencing. The phylogenetic tree based on the nucleotide sequence of COI(567 bp) and 16S rRNA (547 bp) was divided into 3 groups, and the similarity rate of intra-group was more than 98% and inter-group was 75% from COI and 64% from 16S rRNA gene. Also, Chinese diving beetles belonged to one of the 3 groups.

Keywords: MtDNA, genetic comparison, diving beetles, *Cybister* (*Cybister*) *japonicus*, Coleoptera, Dytiscidae.

Multiparametric redox imaging in different cellular compartments

Y. G. Ermakova[1], D. S. Bilan[1,2], M. E. Matlashov[1,2], N. M. Mishina[1], K. N. Markvicheva[1], O. M. Subach[2], F. V. Subach[2], I. Bogeski[3], M. Hoth[3], G. Enikolopov[2,4], V. V. Belousov[1,2]
[1]*reactive oxygen species biology group, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry,* [2]*Moscow Institute of Physics and Technology, Moscow, Russian Federation,* [3]*Department of Biophysics, School of Medicine, Saarland University, Germany,* [4]*Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA*

Mitochondrial reactive oxygen species (ROS) production is often linked to cellular Ca^{2+} signaling. There is a general notion that Ca^{2+} load stimulates mitochondrial ROS increase. There is a large body of evidence showing either increase, or decrease in mitochondrial ROS production upon Ca^{2+} load. However, these data were obtained using isolated mitochondria and it remains unknown to what extent these observations can be extrapolated to mitochondrial ROS production *in situ*. Can this ROS production be detected using genetically encoded redox probes targeted to mitochondrial matrix? Would H_2O_2 production in the matrix be associated with concomitant changes in reduced-oxidized glutathione (GSH/GSSG) ratio? Will the changes in the mitochondrial ROS production, if any, spread to the cytoplasm? To address these issues, we took an advantage of simultaneous imaging of red H_2O_2 sensor and green fluorescent sensors for H_2O_2, pH and GSH/GSSG.

We designed HyPerRed, red genetically encoded fluorescent probe for hydrogen peroxide detection, targeted it to mitochondrial matrix and co-expressed HyPerRed-mito in HEK-293 cells with a variety of green redox biosensors targeted to either mitochondria or cytoplasm in order to detect changes in H_2O_2, GSH/GSSG and pH simultaneously. Although both ATP and thapsigargin (TG), an inhibitor of SERCA Ca^{2+} pump, were able to increase cellular Ca^{2+}, only TG induced small but well defined peak of H_2O_2 production in the mitochondrial matrix.

To localize mitochondrial H_2O_2 production we co-transfected cells with H_2O_2 probes targeted to the matrix (HyPerRed-mito) and to the mitochondrial intermembrane space (HyPer2-IMS). Addition of TG induced an increase of HyPerRed-mito fluorescence, but did not affect HyPer2-IMS signal. This is indicative of the absence of IMS-specific ROS generation or the spread of H_2O_2 from the matrix to the IMS. The GSH/GSSG and pH levels remained stable in both mitochondrial matrix and cytoplasm. Mitochondrial H_2O_2 generation coincided with Ca^{2+} increase in the matrix. Ca^{2+} increase started 10–20 seconds before H_2O_2 elevation.

Taken together, our results show that inhibition of Ca^{2+} reuptake into the ER induces small, local and transient increase in matrix H_2O_2 production which is not accompanied with detectable GSH oxidation. Furthermore, they indicate that H_2O_2 does not spread from the matrix to the IMS and cytoplasm.

Neuroprotective effects of Tauroursodeoxycholic acid upon mitochondrial dysfunction

G. Gordino[1], M. J. Gama[1,2], E. Rodrigues[1,2], C. M. P. Rodrigues[1,2], **M. Castro-Caldas**[1,3]
[1]*Instituto de Investigação do Medicamento (iMed.ULisboa),* [2]*Department of Biochemistry and Human Biology, Faculdade de Farmácia, Universidade de Lisboa, Lisbon,* [3]*Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal*

Mitochondrial dysfunction and oxidative stress play a crucial role in Parkinson's disease (PD) progression. Nuclear factor E2-related factor 2 (Nrf2) is the master regulator of redox homeostasis, binding to the antioxidant responsive element in the promoter of several phase II antioxidant enzymes. Another protective mechanism is mitophagy, which is mainly regulated by PTEN-induced putative kinase 1 (PINK1) and Parkin. This involves the voltage-dependent cleavage of full-length PINK1 in polarized healthy mitochondria to a shorter fragment that has no affinity for mitochondrial membrane. Loss of mitochondrial membrane potential inhibits PINK1 cleavage, which accumulates in the outer mitochondrial membrane, leading to recruitment of Parkin. Once in the mitochondria, Parkin polyubiquitinates mitofusin and voltage-dependent anion channel 1, leading to mitochondria clearance and prevention of fusion of dysfunctional mitochondria. Tauroursodeoxycholic acid (TUDCA), is an endogenous bile acid with neuroprotective properties in different models of neuropathologic conditions. Importantly, we have recently showed that TUDCA exerts a neuroprotective activity in a mice model of PD, but the mechanisms involved are still unidentified.

This work aims to characterize the neuroprotective effect of TUDCA upon mitochondrial depolarization triggered by the mitochondrial uncoupler carbonyl cyanide m-chlorophelyhydrazone (CCCP). SH-SY5Y cells were treated with CCCP in the presence or absence of TUDCA. TUDCA increases LC3II/LC3I ratio, mitochondrial full-length PINK1 and the recruitment of Parkin to mitochondria, indicating an up-regulation of mitophagy. Furthermore, CCCP leads to the activation of Nrf2 and the up-regulation of antioxidative enzymes. However, in cells pre-treated with TUDCA, CCCP administration no longer triggers the activation of Nrf2, suggesting that this bile acid is modulating the threshold of oxidative stress, so that the redox environment, even in the presence of CCCP, is not sufficient to elicit its activation.

Overall, our results show that TUDCA protects against CCCP-induced cell death. The characterization of the mechanisms through which TUDCA modulates oxidative stress and neurodegeneration should provide evidences to validate and extend its future clinical application to neurodegenerative diseases like PD.

New insights on the molecular mechanisms underlying the medium-chain fatty acid acyl-CoA deficiency (MCADD)

C. A. Bonito[1,2,3], P. Leandro[1,2], F. V. Ventura[1,2], R. C. Guedes[3,4]
[1]Department of Biochemistry and Human Biology, [2]Metabolism and Genetics Group, Research Institute for Medicines, iMed.ULisboa, [3]Medicinal Chemistry, Research Institute for Medicines, iMed.ULisboa, [4]Department of Pharmaceutical Chemistry and Therapeutics, Faculty of Pharmacy, University of Lisbon, Lisboa, Portugal

The MCADD is the most common genetic disorder of the mitochondrial fatty acid ß-oxidation (mFAO) pathway. The MCAD enzyme catalyzes the first step of mFAO, a dehydrogenation reaction of the fatty acyl substrates in the C2-C3 carbon atoms, yielding an enoyl-CoA derivative. The MCAD is a homotetramer being each monomer composed by 396 amino acids (mature form). The most common mutation found in MCADD patients is translated in the substitution of lysine 304 residue by a glutamic acid (p.K304E) being associated with protein conformational changes. To better understand the molecular mechanisms underlying MCADD an *in silico* assessment of structural features of the wild-type MCAD and the p.K304E mutant form were performed through Molecular Dynamics simulations. The enzyme's coordinates were obtained from the crystal structure of *Sus scrofa* (pig) MCAD complexed with the FAD cofactor and 3-thiaoctanoyl-CoA as substrate. Our results show that the protein surface is the most flexible region while the interface between the two dimers (protein core) is the most stable. Interestingly, the p.K304E mutation is located at the protein core, being involved in helix-helix interactions, essential for the tetramer assembly. The catalytic pockets formed by the two monomers of the same dimer, are highly dynamic and flexible. Upon substrate binding the number of water molecules inside the pocket is considerably reduced and the conformation of the E99 and Y375 residues' side-chains show a significant change to better accommodate the substrate. Unlike the crystallographic structure, the side-chain of the catalytic residue E376, switches towards the opposite side of the lipid's C2-C3 bound which may suggest an indirect interaction between them. Our simulations also reveal that the R256 residue may play an important role on MCAD catalysis through the stabilization of the intermediate enolate form. To our best knowledge, this is the first *in silico* study of MCAD dynamics behavior. The MCAD structural data gathered are currently being applied in the study of other MCAD mutants aiming the discovery of potential therapeutic drugs for the treatment of MCADD patients.

New role of cytochrome c in programmed cell death

K. González-Arzola, J. Martínez-Fábregas, A. Díaz-Quintana, I. Díaz-Moreno, M. A. De la Rosa
Institute of Plant Biochemistry and Photosynthesis (IBVF), cicCartuja, University of Seville-CSIC, Seville, Spain

Programmed Cell Death (PCD) is a fundamental event for the development of living organisms. In mammalian cells, early events in PCD involve the release of cytochrome *c* (C*c*) from mitochondria to the cytoplasm to act at the first stages of the apoptotic process, playing a key role in assembling the apoptosome. In plants, PCD is part of a general process – the so-called hypersensitive response - that also involves the release of C*c* to the cytoplasm but its role in cell death remains veiled. Such a highly conserved cytoplasmic location of C*c* upon apoptotic stimuli made us to think of a common link for PCD in evolutionarily distant species.

To better understand the role of C*c* in the onset of PCD in humans and plants, a proteomic approach based on affinity chromatography with C*c* as bait was used. Upon combining this approach and Bimolecular Fluorescence Complementation (BIFC), a total of 8 human and 9 plant novel proteins interacting with C*c* under PCD were found [1,2,3]. These C*c*-partners are involved in protein folding, translational regulation, oxidative stress and DNA damage, as well as in energetic and mRNA metabolism. Strikingly, some of the novel human C*c*-targets are closely related to those of plant C*c*, indicating that the evolutionarily well-conserved cytosolic C*c* – from plants to mammals - interact with a wide range of targets under PCD conditions.

Computational modeling of the complexes formed by human and plant C*c* with their counterparts shows how the heme crevice of C*c* is located at the complex interface, as is it at the vast majority of known redox adducts of C*c*. However, in contrast to the high turnover of the redox complexes formed by C*c* with its mitochondrial partners, those occurring under PCD conditions lead to the formation of rather stable nucleo-cytoplasmic ensembles, as inferred from Surface Plasmon Resonance (SPR) and Nuclear Magnetic Resonance (NMR) measurements. On the basis of these findings, we suggest that human and plant C*c* interacts with pro-survival, anti-apoptotic proteins after its release into the cytoplasm. Then, C*c* may interfere with cell survival pathways and unlock PCD in order to prevent the spatial and temporal co-existence of antagonist signals.

NO-dependent prevention of mitochondrial permeability transition pore opening by hydrogen sulfide in old rat heart

O. Semenykhina[1], N. Strutynska[1], S. Chorna[1], A. Budko[1], V. Dosenko[2], V. Sagach[1]
[1]Blood Circulation, [2]General and Molecular Pathophysiology, Bogomoletz Institute of Physiology, Kyiv, Ukraine

Hydrogen sulfide (H_2S) is known as the gaseous signaling molecule like nitric oxide (NO) and carbon monoxide (CO) that participates in variety of cellular functions in cardiovascular system. H_2S is produced enzymatically by three enzymes: cystathionine
γ-lyase (CSE), cystathionine ß-synthase (CBS), and 3-mercatopyruvate sulfurtransferase (3-MST). But there is limited evidence of cross-talk between H_2S and NO. In aging heart mitochondria permeability transition pore (mPTP) opening causes membrane potential collapse leading to mitochondrial dysfunction and apoptosis. The aim of our research was to investigate the impact of H_2S on the sensitivity of the mPTP to Ca^{2+} and mRNA expression of CSE, eNOS, nNOS and iNOS in heart tissue. It was shown that in physiological concentrations, NaHS inhibits calcium-induced mPTP opening, which testifies H_2S protective effect on pore formation in the heart of adult and old rats. It has been shown in experiments *in vivo* that a single administration of either NaHS or L-cysteine leads to decreasing the mPTP sensitivity to Ca^{2+} in adult and old rat hearts, but a single administration of PG leads to its significant increasing only in old rat hearts. At the same time in combination with L-cysteine, this increased sensitivity was restored to the control level in old animals mitochondria. In the heart of adult rats under condition of both PG and L-cysteine introduction it was shown that mRNA expression of CSE as well as nNOS and iNOS increased in comparing to control, but eNOS mRNA expression was in 2,7-fold decreased. In the heart of old rats mRNA expression levels of CSE and eNOS were reduced in 12,7- and 2,4-fold compared with adult animals. Thus, the results obtained suggest that both exogenous and endogenous H_2S participate in the modulation of mitochondrial membrane permeability changes, in particular through inhibition of calcium-induced mPTP opening in the heart of adult and old rats. Therefore, H_2S can be an important regulatory factor in the cardiovascular system under physiological and pathological conditions. The findings of this study revealed that cytoprotection elicited by CSE-derived H_2S is eNOS-dependent. Hereby, it could be suggested that mitochondrial eNOS activity is normally affected by H_2S, so that the protective effect of H_2S on Ca^{2+}-dependent mPTP opening can be mediated by constitutive NO *de novo* synthesis. Future studies will aim to more fully understand the mechanisms related to crosstalk between H_2S and eNOS-derived NO in the context of cardiovascular diseases protection.

NRH:quinoneoxidoreductase 2 and its role in p53 tumor suppressor stabilization in response to mitochondrial electron transport chain dysfunction

A. Alexanderova[1], A. Khutornenko[2], A. Evstafieva[2]
[1]Faculty of Bioengineering and Bioinformatics, Lomonosov Moscow State University, [2]Belozersky Institute of Physico-Chemical Biology, Moscow, Russian Federation

NRH:quinoneoxidoreductase 2 (NQO2) is a cytosolic protein that catalyzes metabolism of quinones. NQO2 is ubiquitously present in all tissues and induced along with a battery of defensive genes in response to different stresses. It is concerned that NQO2 plays an important role in development of neurodegenerative disorders and cancer, but the mechanism of its action in disease initiation and progression is unknown. The same is definitely true for p53 and mitochondria being the most important regulatory protein and organelle in human cells and playing crucial roles in cancer, neurodegenaration, inflammation and ageing. Perhaps, NQO2, p53, and mitochondria could act in cooperation.

We previously found that NQO2 contributes to the p53 stabilization and activation after mitochondrial electron transport chain complex III inhibition. But the mechanism of its action is unknown.

To study the possible interaction of NQO2 and p53 in different cancer cell lines under normal conditions and after mitochondrial electron transport chain inhibition we used Bimolecular Fluorescence Complementation (BiFC) method. N-terminal (N-YFP) and C-terminal (C-YFP) fragments of YFP were fused to p53 and NQO2 proteins and the fusion proteins were expressed in HeLa or RKO cells. Expression of fusion proteins was verified by Western-blot analysis with NQO2 and p53 antibody. Recovery of the whole YFP fluorescence was detected in the cells expressing C-YFP-NQO2 and N-YFP-p53 by fluorescent microscopy (picture below).

Thus, using BiFC we received rather strong experimental evidence that p53 forms a complex with NQO2 in cells under normal conditions and after mitochondrial complex III inhibition. According to immunofluorescent images under normal conditions NQO2-p53 complexes are localized predominantly in the cytoplasm, and after complex III inhibition they can be seen mainly in cell nuclei, where p53 performs its function. This result is a good start for investigation of the role and detailed mechanism of p53-NQO2 interaction in cancer cells under normal conditions and mitochondrial dysfunction.

Funding support was from RFBR Grant 14-04-32210 mol_a.

p53 interacts with VDAC1 to regulate apoptosis

E. Gigi, V. Shoshan-Barmatz
Department of Life Sciences and the National Institute for Biotechnology, Ben-Gurion University of the Negev, Beer-Sheva, Israel

p53, a tumor suppressor and transcription factor, functions as a stress sensor, responding to a myriad of signals, including DNA damage, oxidative stress and ischemia, by arresting the cell cycle, initiating DNA repair, or initiating cell death. Inactivation of p53 function is an almost universal feature of human cancer cells. While the mechanism by which p53 mediates apoptosis remains unclear, evidence indicates that p53 encodes a sequence-specific transcription factor that controls the expression of genes whose products mediate apoptosis. However, sub-organellar localization by various methods shows that p53 also localizes to the surface of the mitochondria and induces apoptosis without requiring further DNA damage. p53 protein can directly promote mitochondrial outer membrane (OMM) permeabilization (MOMP) to trigger apoptosis. Upon stress, a cytoplasmic pool of p53 rapidly translocate to the mitochondrial surface, where it physically interacts with both anti- and pro-apoptotic Bcl-2 family members to inhibit or activate their respective functions, leading to MOMP and apoptosis. Recently, p53 was demonstrated to drive the mitochondrial protein voltage-dependent anion channel (VDAC1) into high molecular weight complexes. VDAC1, at the OMM, regulates cellular energy production and cell metabolism by controlling the traffic of metabolites including ATP, ADP and other ions, between mitochondria and the rest of cell, thereby regulating cell survival. VDAC1 has been proposed to be a critical player in apoptosis. Studies in our lab have demonstrated that VDAC1 oligomerization, as induced by various apoptosis stimuli, mediates the formation of a large, flexible pore between individual subunits of VDAC1, serving as a channel for Cytochrome c (Cyto c) crossing the OMM leading to apoptotic cell death. In this study, we demonstrate the direct interaction of p53 with VDAC1 and the regulation of VDAC1 oligomerization-mediated apoptosis by p53. We found that purified p53 interacts with purified VDAC1, as revealed by microscale thermophoresis and as reflected in the decrease in channel conductance of bilayer-reconstituted VDAC1. Moreover, overexpressing p53 in p53-null cells enhanced the level of VDAC1 oligomeric state as revealed by chemical cross-linking and immunobloting and apoptosis in the absence of apoptotic stimuli. Furthermore p53 also promotes VDAC1 over-expression by an as yet unknown signaling pathway. Our proposed model suggests that p53 increases VDAC1 monomeric levels which shift the equilibrium towards VDAC1 oligomerization allowing Cyto c release, and subsequently apoptosis. These findings point to VDAC1 as a new target of p53 and further support VDAC1 oligomerization as being a key step in the induction of apoptosis.

Proteomic studies of plasma membrane-mitochondrial proteins involved in recognition memory of visual imprinting in chicks

R. Solomonia[1], M. Meparishvili[1], G. Margvelani[1], M. Nozadze[1], E. Mikautadze[2], T. Kiguradze[2], B. J. McCabe[3]
[1]*Institute of Chemical Biology, Ilia State University,* [2]*I.Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia,* [3]*Sub-Department of Animal Behaviour, Department of Zoology, Cambridge University, Cambridge, UK*

Visual imprinting is a learning process through which young, visually naïve animals come to recognize a visual object by being exposed to it (training) and subsequently approach the object in preference to other objects. A large body of evidence implicates a restricted part of the forebrain, the intermediate medial mesopallium (IMM), as a memory storage site for visual imprinting in the domestic chick [1]. A number of learning-related, time-dependent molecular changes have been identified in the IMM. Most of these changes were found in plasma membrane and mitochondrial proteins [2]. Therefore we have undertaken a proteomic investigation of the plasma membrane – mitochondrial P2 fraction to identify proteins involved in visual imprinting. Two-dimensional gel electrophoresis with subsequent mass spectrometry was employed to identify differentially expressed proteins across chicks with different estimated levels of imprinting 24 h after training. We further inquired whether the amounts of those proteins in the IMM were correlated with memory strength. The amounts of the following proteins in the left IMM increased significantly with memory strength: membrane cognin, voltage dependent anionic channel, dynamin, a protein similar to the p32 subunit of splicing factor SF2, heterogeneous nuclear ribonucleoproteins A2/B1. The learning-related increase of mitochondrial proteins observed in the present study and previously [2] could be mediated by an increase in the number of mitochondria. However, levels of transcription factors involved in mitochondrial biogenesis and copy number of mitochondrial DNA did not change significantly in the left IMM. We suggest that the mitochondrial proteome rather than the number of organelles is changed in a learning-related manner 24 h after training and is involved in long-term memory associated with imprinting.

Recovery of adriamycin induced mitochondrial dysfunction in liver by selenium

E. Taskin[1], N. Dursun[2]
[1]*Istanbul Bilim University, Department of Physiotherapy and Rehabilitation, School of Health Sciences, Istanbul,* [2]*Erciyes University, Kayseri, Turkey*

Background: Adriamycin (ADR) is a chemotherapeutic drug. Its toxicities may associate with mitochondriopathy. Selenium (Se) is a trace element for essential intracellular antioxidant enzymes. However, there is lack of data related to the effect of selenium on the liver tissue of ADR-induced mitochondrial dysfunction.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Objective: The study was to investigate whether Se could restore mitochondrial dysfunction of liver-exposed ADR.

Methods: Rats were divided into four groups as a control, ADR, Se, co-treated ADR with Se groups. The livers biochemical measurements were made in mitochondria, cytosol. ATP level and mitochondria membrane potential (MMP) were measured. Total oxidant (TOS), total antioxidant (TAS) status were determined and oxidative stress index (OSI) was calculated by using TOS and TAS.

Results: ADR incresead TOS in mitochondria and also oxidative stress in mitochondria. ADR sligtly decreased MMP, and ATP level. Even if co-administration with ADR and Se partially restorated the dissipation of MMP, but this partial restoration resulted in a significant elevation of ATP level. TOS in mitochondria and cytosol was diminished, as well as OSI.

Conclusion: We concluded that selenium can prevent against to ADR induced oxidative stress in liver by the restoration of MMP and ATP production and prevention of mitochondrial damage in vivo.

Reduced tryptophan and NAD synthesis pathway is associated with valproate treatment: a novel mechanism underlying mitochondrial dysfunction and potential drug-induced liver injury

M. Moedas[1,2], A. van Cruchten[2], L. IJlst[2], W. Kulik[2], I. Tavares de Almeida[1], R. Houtkooper[2], R. Wanders[2], M. Silva[1]
[1]*iMed.UL – FFUL, Lisboa, Portugal,* [2]*Lab-GMZ, AMC, Amsterdam, Netherlands*

Valproic acid (VPA) is an important anticonvulsive drug with potential adverse hepatotoxic effects and lysine deacetylase inhibitor (KDACi) with established anti-cancer properties. The effects of VPA on Zinc-dependent lysine deacetylases and histone acetylation have been reported. The links between VPA, non-histone acetylation and NAD metabolism have yet to be elucidated. This work aims to characterize the *in vivo* effects of VPA on amino-acid metabolism and to quantify the crucial cofactor NAD^+ and its biosynthetic precursors in biological samples.

Plasma and liver samples were obtained from Wistar rats subjected to administration of VPA under different regimens (acute and sub-chronic) as two dosages (n = 10/group). Controls were treated similarly with vehicle. Human plasma samples were collected from individuals under chronic treatment with valproate (n = 33) and controls (n = 39). Analyses of individual amino acids in plasma samples and rat liver tissues were performed using GC-FID and MS/MS, respectively. Novel sensitive UHPLC-MS/MS-based methodologies were optimized and validated for the analyses of $NAD(P)^+$, NAD(P)H and nicotinic acid.

Plasma profiling of amino acids in rats, revealed a significant depletion of tryptophan (Trp) associated with VPA treatment, with a reduction of up to 30% during acute and subchronic treatment with 100 mg/Kg regimen ($p < 0.05$). Trp levels in rat liver tissues were not significantly different from controls. Human plasma samples also revealed a significant reduction of Trp levels (up to 30%; $p < 0.005$). Quantification of NAD-related compounds in rat liver revealed a significant decrease of up to 30% of NAD^+ and $NADP^+$ levels after a single drug administration (100 mg/Kg) ($p < 0.001$). No significant reduction was observed after sub-chronic treatment (100 mg/Kg/day for two weeks).

The present work reveals a significant effect of VPA treatment on the levels *in vivo* of the amino acid tryptophan, with downstream effects on the hepatic availability of the essential cofactor NAD^+ at onset of therapy (animal study). NAD levels reduction *in vivo* may affect mitochondrial energy metabolism as well as disturb post-translational modification of proteins involved in these pathways. The rescuing of NAD levels during sub-chronic treatment hints a probable compensatory mechanism, resulting in reduced tryptophan levels during this regimen.

These novel findings, correlating tryptophan depletion and NAD reduction during VPA treatment *in vivo*, will contribute to gain new insights on the molecular mechanisms underlying the adverse or therapeutic properties of VPA.

Role of the mitochondrial import complex TOM and the PINK1/Parkin pathway in mitochondrial quality control in neurons

M. Jacoupy[1,2,3,4], G. Bertolin[1,2,3,4], C. Gautier[1,5], A. Brice[1,2,3,4], O. Corti[1,2,3,4]
[1]*ICM, 75013,* [2]*CNRS, UMR 7225, F-75013,* [3]*Inserm, U 1127, F-75013,* [4]*Sorbonne Université, UPMC Univ Paris 06, UMR S 1127, F-75013,* [5]*Servier-Diverchim, Laboratoire de chémogénétique, ICM, Paris, France*

Mutations in genes encoding Parkin and PINK1 cause autosomal recessive forms of Parkinson's disease. These proteins regulate jointly several processes relevant to maintenance of mitochondrial quality. Using FRET microscopy to explore local physical proximities between proteins, we showed that Parkin interacts with PINK1 at the TOM machinery, a protein complex responsible for the mitochondrial import of the vast majority of the mitochondrial proteins. The data accumulated suggest that after massive mitochondrial depolarization, the degradation of key subunits of TOM initiates Parkin-dependent mitophagy. These results were obtained in cell lines, such as COS7 and HEK293.

Here, we explored the relevance of these findings in primary cortical neurons from wild type and Parkin-deficient mice. By confocal and FRET microscopy, we show that following mitochondrial depolarization triggered by the protonophore CCCP, PINK1 accumulates on the outer mitochondrial membrane (OMM) and recruits Parkin in proximity of TOM. These events are impaired in Parkin-deficient cells, suggesting that Parkin plays a role in stabilizing PINK1 on the OMM. Using an image-based quantitative analysis of different mitochondrial subcompartment markers at different time points after CCCP treatment, we confirm significant mitochondrial loss in wild type but not Parkin-deficient cells. Components of the TOM machinery are lost earlier than other mitochondrial markers, confirming that this machinery is an early target for Parkin-depedent degradation. In parallel, we investigated the relationship between PINK1/Parkin-mediated mitochondrial degradation and mitochondrial biogenesis by exploring the expression of master genes of this process, as well as nuclear and mitochondrial genes encoding key mitochondrial components. Our results indicate that mitochondrial biogenesis is slowly activated following CCCP treatment in neurons, and that this process is compromised in the absence of Parkin.

Altogether our results confirm that the TOM machinery acts as a molecular switch in the PINK1/Parkin pathway, coupling loss of mitochondrial protein import efficiency with different quality control mechanisms, including mitochondrial degradation and biogenesis.

Post-translational modifications of proteins are relevant regulatory mechanisms to control an ample number of cell metabolic processes. One of the most usual modifications is phosphorylation, which can alter the electrostatic and structural features of proteins thereby affecting their interactions with other proteins.

Cytochrome *c* (C*c*) stands out as a target for post-translational modification. Indeed, C*c* phosphorylation appears in some pathological situations, such as ischemia or cancer [1]. C*c* has a double role, transferring electrons from the cytochrome bc_1 complex to cytochrome *c* oxidase and triggering Programmed Cell Death (PCD) under oxidative stress conditions. Both functions are regulated by phosphorylation of the residues Thr, Ser and Tyr at positions 28, 47 and 48, respectively [2–4].

Since the specific C*c*-phosphorylating kinases are still unknown, we have constructed three phosphomimetic mutants. Two of them correspond to substitutions of Thr28 and Ser47 by the canonical amino acid Asp. To mimic Tyr48 phosphorylation, we resorted to the evolved tRNA technique. Thus, the Tyr48-encoding triplet was replaced by an AMBER codon. Then, we incorporated a non-canonical amino acid (*p*-carboxymethyl-L-phenylalanine, *p*CMF) that emulates phosphotyrosine, with the help of an evolved tRNA targeting the AMBER stop codon. Such a mutation has drastic consequences not only on the structure and dynamics of C*c* (3D conformation, thermal stability, redox potential), but also on its biological function.

Sumoylation of human mitochondrial NADH dehydrogenase (ubiquinone) Fe-S protein 7 (NDUFS7) by SUMO-1

M.-C. Kao, J.-S. Wu
Institute of Molecular Medicine, National Tsing Hua University, Hsinchu, Taiwan

Human NADH dehydrogenase (ubiquinone) Fe-S protein 7 (NDUFS7) is one of the most conserved core subunits of mitochondrial complex I. It has a bound iron-sulfur cluster N2 (tetranuclear) which is the terminal redox center in the electron transport chain (ETC) of complex I. NDUFS7 protein is encoded by the nuclear genome and is incorporated in the peripheral segment of complex I. Most mitochondrial matrix proteins are synthesized in the cytosol and imported into mitochondria by mitochondrial targeting sequences (MTSs). We previously defined the N terminus of the first 60 amino acids of NDUFS7 is an effective MTS. We also identified that there is a nuclear localization signal (NLS) and a nuclear export signal (NES) located in the C-terminus of NDUFS7.

Sumoylation has been recognized to play an important role in protein localization, function and turnover. Small ubiquitin-related modifiers (SUMOs) can be conjugated to target proteins by E1 (SAE1/SAE2), E2 (UBC9) and E3 enzymes after translation. Using *in silico* analysis, NDUFS7 protein was found to have several potential sites for sumoylation. In this study, we co-transfected plasmids expressed NDUFS7, SUMO-1 and UBC9 into HEK293 cells, and detected the conjugation of NDUFS7 with SUMO-1 by immunoblotting analysis with various antibodies. The results indicated that NDUFS7 could indeed be sumoylated *in vivo*. To confirm this finding, SUMO-specific protease SENP was co-expressed with NDUFS7, SUMO-1 and UBC9 proteins in some experiments. The results showed that overexpression of SENP could reduce the level of interaction between NDUFS7 and SUMO-1. These results suggested that NDUFS7 can be sumoylated by SUMO-1 in cells. In addition, by using site-directed mutagenesis, we also identified that lysine 202 in NDUFS7 is the major site for sumoylation, which is consistent with the consensus sumoylation motif. Moreover, sumoylation of NDUFS7 was found to be associated with protein stability and thus its turnover. Further studies are on the way to explore the functional details of NDUFS7 sumoylation.

Keywords: mitochondrial complex I, NDUFS7, sumoylation.

The 18 kDa protein TSPO interacts with VDAC1 and limits mitochondrial quality control

J. Gatliff[1], D. East[1], M. Campanella[1,2,3]
[1]Comparative Biomedical Sciences, Royal Veterinary College, [2]Consortium for Mitochondrial Research, University College London, London, UK, [3]European Brain Research Institute, Rita Levi-Montalcini Foundation, Rome, Italy

Selective autophagic removal of mitochondria (mitophagy) is critical for maintaining normal cell homeostasis but our knowledge of its regulatory pathways is limited. The mitochondrial Translocator Protein (TSPO) is an 18 kDa multi-drug binding protein with a canonical role in mitochondrial cholesterol transport. Dysregulation of mitophagy and differential expression of TSPO, are both associated with pathological conditions characterized by cumulative damage to mitochondria. We therefore explored the role of TSPO mitophagy. Here, we report that TSPO inhibits mitochondrial autophagy downstream of the PINK1/Parkin pathway, preventing essential ubiquitination of proteins. TSPO abolishes mitochondrial relocation of P62/SQTSM1, and consequently that of the autophagic marker LC3, thus leading to an accumulation of dysfunctional mitochondria. Independent of cholesterol regulation, the modulation of mitophagy by TSPO is instead dependent on the Voltage Dependent Anion Channel 1 (VDAC1), to which TSPO binds, reducing mitochondrial coupling and promoting an overproduction of the Reactive Oxygen Species (ROS) that counteracts Parkin mediated ubiquitination of proteins. This set of data identifies TSPO as a novel element in the regulation of mitochondrial quality control by autophagy, and demonstrates the importance of its expression ratio with VDAC1 in mitochondrial and cell homeostasis making TSPO an

The action of citrus flavonoid – nobiletin on some aspects of mitochondrial bioenergetics

N. Sharikadze[1], N. Jojua[1], E. Zhuravliova[2], N. Narmania[1], T. Barbakadze[3], D. Mikeladze[3]
[1]Institute of Chemical Biology, Ilia State University, [2]Department of Biochemistry, I.Beritashvili Centre of Experimental Biomedicine, [3]Department of Biochemistry, I. Beritashvili Centre of Experimental Biomedicine, Tbilisi, Georgia

The changes in mitochondrial biochemistry are one the most important processes accompanying pathophysiology of many types of disorders, including neurodegenerative diseases and cancer. It was revealed that some citrus flavonoids could change the activities of mitochondrial bioenergetics. Among these compounds nobiletin attracts a lot of attention for its neuroprotective and anti-inflammatory action. Nobiletin affects brain cognitive function, facilitates learning and memory formation. This polymethoxylated flavone has anti-amnesic effect and neurotrophic activity, prevents bulbectomy- and amyloid-beta protein-induced memory impairment, improves cerebral ischemia-induced memory deficits suppresses microglial activation, and produces an antidepressant-like effect. However, mechanism of action of nobiletin on the brain mitochondrial metabolism, as well as the target of nobiletin in mitochondria is not revealed. The aim of our study was to investigate the influence of nobiletin on the some aspects of the bioenergetics of isolated brain mitochondria; and determine the target molecules, involving in nobiletin-induced alterations. For this purpose the action of nobiletin on the main mitochondrial enzyme systems was investigated. We have found that action of nobiletin leads to enhancement of SDH activity and improvement of α-KGDH activity and matrix substrate-level phosphorylation in Citric Acid Cycle. Besides, the addition of nobiletin to isolated mitochondria increases NADH dehydrogenase and rotenone-insensitive NADH/CoQ reductase. Furthermore, nobiletin reduces the peroxide production, inducing by Ca^{2+} elevated concentration only in the presence of glutamate/malate; and slightly elevates mitochondrial membrane potential. Our results suggest that the possible molecular target of nobiletin is I complex of respiratory chain and the neuroprotective effects of nobiletin involve activation of α-KGDH activity coupling with acceleration of matrix substrate-level phosphorylation.

Keywords: bioenergetics, mitochondria, nobiletin.

The differences in sensitivity to hypothyroidism in synaptic and non-synaptic mitochondria of hippocampus

N. Jojua[1], E. Zhuravliova[1,2], N. Sharikadze[1], T. Barbakadze[1,2], E. Zaalishvili[2], N. Narmania[1], D. Mikeladze[1,2]
[1]Institute of Chemical Biology, Ilia State University, [2]Department of Biochemistry, I. Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia

Thyroid hormones, as important regulators of growth, development, and metabolism, also exert nongenomic effects on the mitochondrial energy metabolism and several clinical complications of hypotiroidism, like fatigue, cold intolerance, weight gain, bradychardia, etc. are associated with the decrease in basic metabolic rate and oxygen consumption. It was revealed that synaptic (SM) and non-synaptic mitochondria (CM) could differently response to some pathological factors. Therefore, our purpose was study the changes of some parameters of mitochondrial bioenergetics in SM and CM fractions of hippocampus of adult rats in following groups: euthyroid (control), hypothyroid (methimazol-treated), and T4-treated hypothyroid states.

nNOS translocation to CM was observed with concomitant increase of mtNOS activity in hypothyroid rats. Furthermore, oxidation of cytochrome c oxidase and production of peroxides with substrates of complex I (glutamate + malate) were enhanced, whereas the activity of aconitase and mitochondrial membrane potential ($\Delta\phi_m$) were decreased. Additionally, the elevation of hexokinase activity in CM was also found. No differences in these parameters were observed in SM between control and hypothyroid animals. The total ATP production was significantly decreased in both synaptic and nonsynaptic mitochondria in hypothyroid conditions, but the part of ATP, produced by substrate level phosphorylation is significantly increased. The total ATP production was restored to control level in nonsynaptic mitochondria of T4-treated animals.

Our results suggest that hypothyroidism induces mild oxidative/nitrosative stress in neuronal and glial cell bodies of hippocampus that leads to acceleration of aerobic glycolysis. Such compensatory elevation in glycolytic metabolism and substrate level phosphorylation does not occur in synaptic endings and therefore, synaptic mitochondria could be more susceptible to apoptosis during hypothyroidism.

This study was supported by Shota Rustaveli Georgian National Scientific Foundation Grant for Doctorate Program DO/123/7-220/13 and Ilia State University.

The effect of long term humic acid administration is on redistribution and usability of metals as cofactors rather than chelating

J. Vašková[1], **L. Vaško**[1], P. Patlevič[2], D. Žatko[1]
[1]*Pavol Jozef Šafárik University, Košice,* [2]*Prešov University, Prešov, Slovakia*

The humic acids (HAs) are well documented for their antioxidant effects, but also for their chelating properties towards metals in soil. Antioxidant enzymes commonly use the oxido-reduction properties of metal cofactors for catalytic activity. The question arises of how the proposed chelating properties of HAs can affect the antioxidant status and current levels of these metals. We investigated mitochondria from major synthetic and xenobiotic-metabolizing organs and plasma from chickens, having received HAs in food (0.6%) for 42 days.

There was no demonstrated change in the activity of superoxide dismutase (SOD), but the activity of glutathione peroxidase (GPx) was significantly lower. The activity of glutathione reductase (GR) was significantly higher in the liver and kidneys. Levels of metals detected by atomic absorption spectrometry pointed to particularly significant changes in the amounts of metal present. Cu was higher in liver and plasma, but lower in the kidney. The amounts of Zn decreased in the liver and kidneys, as did Mn. The levels of Fe were uniformly significantly high. Se-containing enzymes are responsible for GPx activity but, as a non-metal, Se was not pursued here. Regarding the activity of GPx and GR enzymes and concurrent lower levels of reduced glutathione (GSH), we can only consider the oxidative stress conditions in mitochondria. Mitochondria provide cellular Fe-S clusters and GR is required to maintain oxidant-labile Fe-S enzymes such as aconitase. It is therefore logical to assume that the total Fe concentration will rise. The increased amount of Fe may contribute to oxidative stress alone, but also to increased activity of iron-dependent enzymes for synthesis of antioxidant enzymes thus directly relating to the use of Cu, Zn and Mn in the mitochondria. Conditions for the oxidation of SOD to form disulfides are essential for the activity of SOD and Cu transfer into the active site. The binding of Cu is the limiting step for the use of Zn. Mitochondrial Mn, however, is normally 1–2 orders less than Fe. Presently we cannot say whether there is metal competition for SOD binding due to an increase in Fe and thereby reduced MnSOD synthesis; however, high Mn levels in the plasma may prevent the impairment of arginase activity and nitrosative stress. Finally, GSH levels in plasma were offset. Despite this, there is an expectation that the administration of HAs does not affect the binding abilities to metals but rather competition, leading to a decline in Se use and compensatory responses. Further studies will be focused on clarifying this, as it may be an important factor for the length of safe and beneficial usage of HAs.

The effects of repeated curcumin administration on nociception in mice

A. Luca[1], T. Alexa[1], A. Dondas[2], G. D. Luca[1],
C. R. Bohotin[1]
[1]*Pathophysiology,* [2]*Cardiovascular Surgery Clinic, University of Medicine and Pharmacy 'Gr.T.Popa' Iasi and Centre for the Study and Therapy of Pain, Iasi, Romania*

Introduction: Curcumin is a mitochondrial modulator that protects mitochondria and modulates certain antioxidant enzymes. Latest years studies suggested that the balance between anti-oxidants and oxidants is directly involved in different types of pain so that mitochondrion as a redox modulator might by implicated in pain perception.

Aim of the Study: To evaluate the effect of repeated curcumin administration on nociception in mice.

Materials and methods: 17 BALB/c male mice were divided into two groups that received repeated gavage with either curcumin (120 mg/kg b.w., n = 5), either an equivalent dose of olive oil (n = 12). The hot-plate (HPT), tail-flick (TFT), mechanical sensitivity (MST) (*Von Frey method*) and plantar (PT) (*Hargreaves method*) tests were performed to measure nociception, mechanical allodynia and thermal hyperalgesia, before (baseline) and after two weeks of curcumin or olive oil daily administration. Percentage change from baseline was calculated and the data expressed as mean ± S.E.M. and analyzed using paired and unpaired Student's t-test.

Results: Oral administration of curcumin has a significantly effect on tail flick test ($p = 0.032$), mechanical sensitivity test ($p = 0.049$) and Hargreaves test ($p = 0.0047$) latencies expressed as changes from baseline when compared with control group. When compared with the baseline values, curcumin significantly increases latencies of TFT (3.5 ± 0.2 s versus 4.8 ± 0.1 s) and PT (6.4 ± 0.8 versus 11.8 ± 0.8 s). Even if an increase in plantar test latencies were also observed after 2 weeks of olive oil treatment, the effect of curcumin was significant ($p = 0.0047$) regarding the percentage change from baseline ($130.5 \pm 46.6\%$ in curcumin treated group versus $32.7 \pm 8.3\%$ in olive oil treated group).

Discussions: Our findings demonstrate that 14 days of curcumin administration has an antinociceptive effect on the tail flick test and no effect on the hot plate test. These results suggest that curcumin might exert its effects on the spinal level as long as tail flick is mainly spinally and HP supraspinally mediated. Curcumin in in a similar way as olive oil, increases plantar test latencies but has no effect on mechanical allodynia. However a more important percentage change from baseline ($p = 0.0047$) was observed after curcumin administration.

In *conclusion,* we demonstrate that repeated curcumin administration modulates thermal nociception and allodynia but the exact mechanisms by which this occurs need further studies.

The effects of single-dose intrathecal administration of methylene blue on acute and inflammatory pain in mice

T. Alexa, A. Luca, A. Dondas, C.-R. Bohotin
Center for the Study and the Therapy of Pain, University of Medicine and Pharmacy 'Gr. T. Popa', Iasi, Romania

Introduction: Methylene blue (MB) acts as an electron transfer mediator, significantly increasing mitochondrial complex I–IV activity in isolated mitochondria and resistance to oxidative stress [1]. Recent studies indicate that mitochondrial modulation might influence pain perception and transmission.

Purpose: To investigate the effects of acute MB i.t. administration on the formalin orofacial pain test.

Methods: BALB/c male mice received by means of intrathecal administration single-dose of either MB (0.05 mg/kg b.w.) or saline (equivalent volume). Two hours after administration, the mice were injected with 20 μl of 5% formalin into the upper lip in order to assess the orofacial pain (FOF). The nociceptive score was determined by recording the number of seconds animals

© 2014 The Authors. FEBS Journal © 2014 FEBS

spent grooming the injected area and expressed as mean ± SEM, separately for the 2 phases of the formalin test: the first phase (neurogenic) respectively the second phase (inflammatory). The results were compared by means of unpaired Student t test.

Results: Intrathecal MB administration induced a statistically significant decrease in inflammatory pain behavior as assessed by the second phase. Thus, MB injected mice spent an average of 56.4 ± 14.4 s grooming the affected area, whereas control group had an average of 138.8 ± 28.1 ($p = 0.02$). MB administration had no effect on the first phase of the test (acute pain), with an average nociceptive score of 37.1 ± 9.9 s in the MB group and 49.1 ± 5.9 s in the control group.

Conclusions: Our study results indicate that i.t. MB administration exerts a significant anti-nociceptive effect. Its mechanism is linked probably to MB action on the central nervous system structures implied in the inflammatory phase of the formalin pain. Further studies are needed in order to elucidate the mechanism by which MB exerts its effects.

Introduction: Mammary carcinogenesis was induced in female Sprague-Dawley rats by exposure to N-methyl-N-nitrosourea (NMU). Resveratrol (3,5,4′-trihydroxy-trans-stilbene) is a widely known polyphenolic agent from red wine, which has been shown to exert antioxidant, anti-inflammatory and anticarcinogenic effects. Resveratrol is a bioactive compound which can be used against cancer cells in human body but a molecular mechanism is currently not known. Resveratrol and its derivatives are resistant against metabolizing enzymes therefore were suggested for the treatment of cancer and as a pharmacologically significant modifiers of other antineoplastic drugs in use. Mitochondria is highly organized multifluorescent system of endogenous fluorescent molecules, which can be detected by fluorescence spectroscopy.

Materials and Methods: Mammary carcinogenesis was induced by N-methyl-N-nitrosourea (NMU), which was administered in two intraperitoneal doses (50 mg/kg of body weight). Chemoprevention with resveratrol (100 mg/kg of body weight) started 12 days before the first dose of NMU and the administration lasted until the end of the experiment. The tumour incidence and latency period were evaluated. Mitochondria of mammary gland tumor were isolated according to Johnson and Lardy. Protein content of isolated mitochondria was determined by the method of Bradford. The suspension of isolated mitochondria was diluted to a final concentration of 2 mg/ml using a respiration medium (pH 7.4) containing the substrate succinate. Autofluorescence of the blood serum/plasma samples was analysed by synchronous fluorescence fingerprint on Luminescence Spectrophotometer Perkin-Elmer LS 55.

Results: Resveratrol administration resulted in reduced tumour incidence (22%) and prolonged latency period ($p < 0.01$) in compare to NMU group. The significant increase of the fluorescence intensity at 280 nm (proteins) was observed in the experimental groups which received NMU ($p < 0.001$) and NMU after chemoprevention with resveratrol ($p < 0.05$) in comparison with the control group. The significant increase of the fluorescence intensity at 350 nm (reduced coenzyme NADH+H^+) was observed in the experimental groups which received NMU ($p < 0.01$) and NMU after chemoprevention with resveratrol ($p < 0.001$) in comparison with the control group.

Conclusions: Resveratrol administered at a dose 100 mg/kg showed both prooxidative and antioxidative effect with the prevalence of cytotoxic effect.

The mitochondria in testing drug-induced toxicity

D. Aliverdieva[1], M. Efendieva[2], D. Mamaev[3]
[1]Caspian Institute of Biological Resources, Russian Academy of Sciences, Makhachkala, [2]State Research Institute of Eye Deseases of Russian Academy of Medical Sciences, [3]A.N. Bach Institute of Biochemistry, Russian Academy of Sciences, Moscow, Russian Federation

Mitochondria are now of an increasing interest in medical research due to the facts that mitochondria play a central role in various metabolic processes of the cell and that mitochondrial dysfunction is related to several important pathologies. Mitochondrial membrane potential ($\Delta\psi$) is the driving force for ATP synthesis in the cell. Maintenance of membrane potential is known to be the critical factor determining mitochondrial viability, as well as the system of mitochondrial quality control, essential for normal mitochondrial functioning. We have shown that mitochondria may be used as a biosensor for evaluation of toxic effects of potential drugs on mitochondria *in situ*. We studied effects of toxic agents – mastoparan, alamethicin and melittin (that are able to permeabilize biological membranes) in rat liver mitochondria preparations generating transmembrane potential ($\Delta\psi$). Mitochondrial $\Delta\psi$ was determined by changes in fluorescence in the same media as control oximetric measurements. Rates of succinate oxidation were determined with a Clark-type electrode. The effect of studied toxic agents was accompanied by decrease of mitochondrial $\Delta\psi$. But the magnitude of activation of State 4 respiration rate (v_4) by different peptides does not correlate with the effect on $\Delta\psi$. Melittin and mastoparan have not dissipated mitochondrial $\Delta\psi$ radically. In the presence of these peptides mitochondria retain stable $\Delta\psi$, so these peptides may be less harmful (compared with alamethicin). The comparison of $\Delta\psi$ dissipation value and value of the ratio of peptide concentration causing lysis of mitochondria/peptide concentration activating v_4 by 200%, of potential drugs may be used for comparative testing on their toxicity. The prospects of appearance of novel medicals, the problem of increasing the activity or reducing the toxicity of new drugs, the limitations of their medicinal use, problems that may enhance existing anticancer and anti-infectious therapies are in the focus of drug research now. The use of isolated mitochondria as a test system for screening potential drugs for their safety may be useful in preclinical studies of new drugs.

The mitochondrial pyruvate carrier. Old and recent findings call for more attention to this main substrate transport system

S. Papa
Institute of Biomembranes and Bioenergetics (IBBE), CNR, Bari, Italy

The first evidence of the existence of a mitochondria pyruvate carrier dates back to 1971 (Papa et al., FEBS Lett. 12, 285) followed by characterization of kinetics, substrate specificity, inhibitor sensitivity (Paradies and Papa, Abstr. Commun. International Congr. Biochem. 1973, p. 288; Papa and Paradies, Eur. J. Biochem. 1974, 49, 265) confirmed by specific inhibition by α-cyano-4-hydroxycinnamate (Halestrap and Denton, Biochem. J. 1974, 138, 313). After nearly forty years, two independent groups (Bricker at al., Science, 2012, 337, 96; Herzig et al., Science, 2012, 337, 93) identified a complex of two mitochondrial proteins, MPC1 and MPC2 and the genes of the pyruvate carrier. The carrier, since of its essential role for mitochondrial degradation to CO_2 of glycolytic pyruvate and the capacity of pyruvate/acetoacetate exchange-diffusion plays a key role in energy metabolism, ketogenesis, fatty acid synthesis, etc. Depression of the pyruvate carrier was, in fact, found in mitochondria from different experimental tumours (Paradies et al., Cancer Research, 1983, 43, 5068) and from liver of experimental diabetic rats (Kielducka et al., J. Bioenergetics and Biomembranes, 1981, 13, 123). Recently mutations in the MPC1 genes have been detected in families with children affected by lactic acidosis (Bricker, see above ref.). All this calls for more attention to the role of the pyruvate carrier in human pathophysiology (see Shell and Rutter, Cancer Metabolism, 2013, 1: 6).

The molecular selectivity of type II NADH: quinone oxidoreductase for quinones – a docking study

A. Duarte, M. M. Pereira
Instituto de Tecnologia Química e Biológica, Universidade Nova de Lisboa, Oeiras, Portugal

Type II NADH: quinone oxidoreductase is a flavoprotein that catalyzes the transfer of electrons from NADH to quinones and it can, in several organisms, replace the respiratory system (complex I-V).

Recent high resolution structures show that NDH-II is a homo dimmer membrane bound protein with an amphiplilic anchor that allows the interaction with the membrane.

Different microorganisms produce different quinones: e.g. in *E. coli* the physiological quinone is ubiquinone, while *S. aureus* and *B. subtilis* synthesis menaquinone, thus NDH-II will have a different molecular interaction and selection mechanism for different organisms.

Despite the high resolution structural information available for NDH-II in complex with quinone, NAD and FAD, the mechanism behind the molecular selection and interaction with is still elusive.

To unravel the interaction mechanism of NDH-II:quinone we setup a modeling and *in silico* docking calculation based on the published high resolution structures of NDH-II. We identified the interaction hotspots of NDH-II from different species to different quinones and discuss the role in the enzymatic mechanism.

The protective role of Sestrin2 induction against glucose deprivation via modulation of mitochondrial function

K. Seo, S. H. Ki, **S. M. Shin**
Chosun University, Gwangju, Korea

Sestrin2, an Nrf2-dependent antioxidant enzyme, regulates diverse cellular functions in response to various stresses including metabolic and oxidative stress. In this study, we demonstrated that the role of Sestrin2 induction in glucose deprivation-induced oxidative stress. First, we observed that glucose deprivation significantly increased Sestrin2 expression in mRNA or protein levels in primary hepatocytes, AML12, Huh7 and HepG2 cells. Glucose deprivation increased intracellular reactive oxygen species (ROS) production, which contributed induction of Sestrin2. To elucidate whether induction of Sestrin2 by glucose deprivation is accompanied by Nrf2 activation, the phosphorylation of Nrf2 was examined. Glucose deprivation increased a phosphorylation of Nrf2. Moreover, Sestrin2 induction by glucose deprivation was decreased in ARE-deleted Sestrin2 reporter gene assay. To study the role of Sestrin2 induction, we used Sestrin2 overexpressed stable cells. Overexpression of Sestrin2 in cells rescued cells from glucose deprivation-induced cytotoxicity. Moreover, glucose deprivation-induced ROS production and mitochondrial impairment was decreased in Sestrin2 overexpressed stable cells. However, mitochondrial membrane potential was significantly lost by siRNA knockdown of Sestrin2. Collectively, we provide evidence for the functional importance of Sestrin2 induction in prevention of glucose deprivation-induced oxidative stress and cell death.

The role of Sestrin2 induction by resveratrol in methylglyoxal-induced toxicity

K. Seo, J. Y. Han, S. H. Ki, **S. M. Shin**
Chosun University, Gwangju, Korea

Resveratrol, a naturally occurring polyphenolic compound, is found in grapes. Previous reports have shown that resveratrol has various beneficial effects in metabolic diseases including diabetes and obesity. This study investigated whether methylglyoxal, a glucose-derived dicarbonyl intermediate, causes ROS-mediated cytotoxicity in HepG2 cells and resveratrol protects cells from the methylglyoxal-induced cell death. Methylglyoxal significantly induced apoptosis in cells and oxidative stress was involved in its cytotoxicity. However, pretreatment of resveratrol protected cells from methylglyoxal-induced apoptosis. In addition, resveratrol recovered the level of GSH and attenuated ROS production. In addition, methylglyoxal-induced mitochondrial impairment, as evidenced by the increase of ADP/ATP ratio increase and observation of mitochondrial permeability transition was restored by resveratol. Resveratrol induced Sestrin2, as a novel antioxidant protein, which contributed to repress methylglyoxal-induced apoptosis. Collectively, our results demonstrated that resveratrol could protect cells from methylglyoxal-induced ROS production, mitochondrial impairment which is mediated with Sestrin2 induction.

The study of calcium capacity and induction of Ca^{2+}-dependent nonspecific permeability of the inner membrane in the liver mitochondria of guinea fowl (*Numida meleagris* L.)

A. Vedernikov, M. Dubinin, V. Zabiakin, S. Adakeeva, V. Samartsev
Department of Biology, Biology and Chemistry Faculty, Mari State University, Yoshkar-Ola, Russian Federation

It is known that the mitochondria of animals not only provide cell ATP and heat, but also involved in cell death by apoptosis and necrosis. Induction of Ca^{2+}-dependent nonspecific permeability of the inner membrane (pore open) is one of the cell death pathways associated with the mitochondria. Mechanisms and regulation of the opening pores mainly studied in liver and heart mitochondria of laboratory rats, which have a relatively short lifespan. However, similar mechanisms of induction of mitochondrial nonspecific permeability in birds' vital organs, which are characterized by greater longevity, are unexplored.

In the study, we used males of 'wild' gray-speckled population of guinea fowl (*Numida meleagris* L.), and white lab male rats as control animals. Mitochondria from the liver of mature male white rats and guinea fowl were isolated by conventional differential centrifugation with subsequent separation of endogenous fatty acids with fatty acid-free BSA. Mitochondrial calcium capacity, or ability of mitochondria in the presence of inorganic phosphate and other penetrating anions capture and hold of calcium ions in matrix, was determined by a calcium-selective electrode. Induction of calcium-dependent pore evaluated by mitochondrial swelling in the sucrose incubation medium by recording the change in optical density of the mitochondria suspension at a 540 nm.

We have found that calcium capacity of the liver mitochondrial of guinea fowl in the presence of 1 mM inorganic phosphate is 1.4 mM in the absence and 2 mM to presence of 1 μM cyclosporin A (CsA). At the same time, calcium capacity of rat liver mitochondria in the absence of CsA does not exceed 100 μM. At these concentrations of calcium liver mitochondria of rats and guinea fowl intensively swell in sucrose incubation medium, that indicating on opening nonspecific pores. In experiments on rat liver mitochondria established that 20 μM hexadecanedioic acid (HDA) in the presence of 200 μM Ca^{2+} is able to induce nonspecific permeability of organelles by insensitive to CsA mechanism. Similar data were obtained on the liver mitochondria of guinea fowl. However, the intensity of the swelling of guinea fowl liver mitochondria is much less marked than in rat liver mitochondria. The mechanisms underlying the phenomena, which described above, is expected to examine in subsequent research.

Understanding the regulation of mitochondrial bioenergetics by the immune adaptor protein SARM1 and its role in age-related neurodegeneration

P. Mukherjee[1], M. Sur[1]
[1]*Biological Sciences, Presidency University, Kolkata, India*

Aging poses a risk factor for the development and progression of neurodegenerative diseases like Alzheimer's (AD) and Parkinson's disease (PD) which share common morphological features

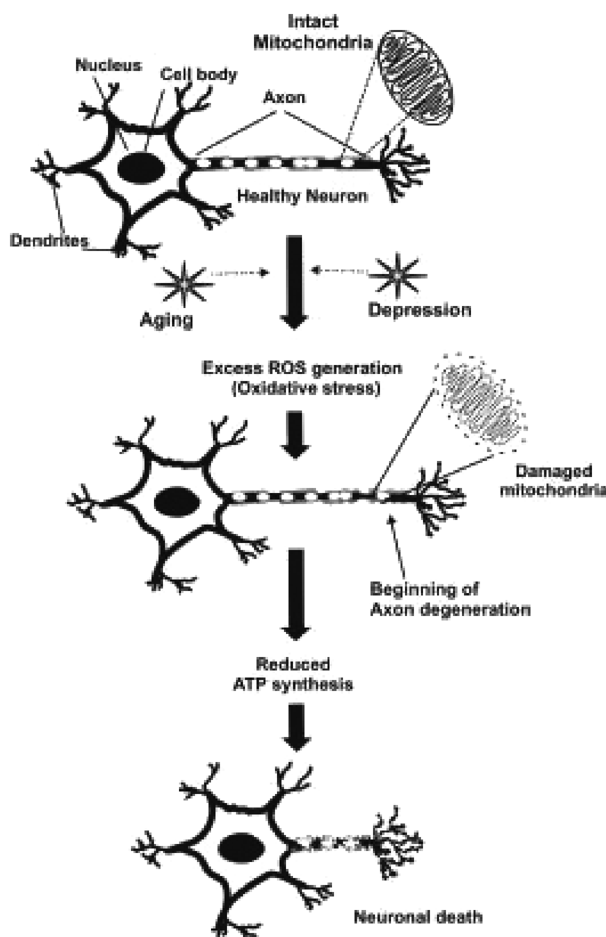

Fig. 1. Neuronal loss in aging and depression.

of mitochondrial dysfunction and axon degeneration as an early pathological mechanism. Although recent evidence suggests that normal aging and the degeneration of specific neuron populations in AD or PD may be linked by the same cellular mechanisms, this remains a topic of intense debate. Mitochondria are required to meet the high energy demands of neuronal cells and any defect in this pathway make the neurons particularly susceptible to bioenergetic failure ultimately resulting in energy crisis and neuronal loss. An exciting area of research involves understanding the various components of mitochondrial energy metabolism that may eventually lead to axon degeneration in normal aging and age-related neurodegeneration. The adaptor molecule, sterile alpha and TIR motif-containing 1 (SARM1) mediates excess reactive oxygen species (ROS) generation in the neuronal mitochondria that may lead to mitochondrial dysfunction and neuronal death. Interestingly, SARM1 plays an important role in the axonal self-destruction program through a mechanism not yet known. This study aims to analyze whether SARM1 is a direct player in the ROS generating machinery of neurons particularly axons during aging resulting in mitochondrial damage, energy crisis and axonal retraction. In summary, the regulation of an intrinsic death pathway by SARM1 may provide the missing link between the process of age-related decline in mitochondrial bioenergetics and subsequent axon loss.

Keywords: Neuron mitochondria neurodegenration SARM1 ROS.

Ca^{2+}-dependent fusion pore induced by α,ω-dioic acids as a possible mechanism of the mitochondrial permeability transition

M. Dubinin[1], V. Samartsev[1], K. Belosludtsev[2]
[1]*Mari State University, Yoshkar-Ola,* [2]*Institute of theoretical and experimental biophysics RAS, Pushchino, Russian Federation*

Recently we found that the α,ω-dioic acids (among them α,ω-hexadecanedioic acid (HDA) was most effective) are able to induce the opening of the 'non-classical' cyclosporin A (CsA)-insensitive pore in the liver mitochondria loaded with Ca^{2+} or Sr^{2+}. It has been suggested that such permeability is based on the formation of a pore in the membrane of organelles which has lipid nature. In this paper, in order to clarify the molecular mechanism of this process, we studied the effect of HDA on the Ca^{2+}-dependent permeability of artificial membranes using the model of large unilamellar liposomes (LUV) loaded with the fluorescent dye sulforhodamine B (SRB). It was shown that HDA, like palmitic acid (PC), is able to induce permeability of LUV for SRB in the presence of Ca^{2+}. However, the kinetics of SRB release upon the induction of Ca^{2+}-dependent permeability of LUV by HDA and PC is different. Furthermore, it was found that HDA is inferior to PC in ability to induce LUV permeability for SRB. Under the same conditions, α,ω -tetradecanedioic acid which acyl chain is 2 carbon atoms shorter than HDA is less effective. Consequently, the effectiveness of these α,ω-dioic acids as inducers of pore opening is sharply reduced with decreasing number of carbon atoms in their acyl chain, which may be associated with a decrease in their ability to dissolve in lipids. It was established that HDA/Ca^{2+}-induced SRB release from LUV is also dependent on the pH of the surrounding solution. The maximum release of SRB from LUV induced by HDA/Ca^{2+} complex formation was observed at alkaline pH (pH 9.0–10.0). Using the method of ultrasonic interferometry it's shown that HDA, unlike PC, doesn't induce a chemotropic phase transition in the lipid bilayer of membrane in the presence of Ca^{2+}, which as was shown earlier underlies the permeability of lipid membranes induced by Ca^{2+} and PC. Thus, it can be assumed that the Ca^{2+}-dependent permeability of the LUV, induced by HDA and PC occurs by different mechanisms. The method of dynamic light scattering showed that the addition of Ca^{2+} to HDA-modified LUV induces their fusion. We believe that the process of LUV fusion may be accompanied by partial SRB release from LUV due to the formation of fusion pores.
