We assumed that the process of membrane fusion may underlie the previously described HDA/Ca^{2+}-induced nonspecific permeability of the inner membrane of liver mitochondria. It is possible that HDA and Ca^{2+} induce fusion of inner and outer mitochondrial membranes in the field of contact sites where the membranes are close together, with subsequent formation of fusion pore resulting in swelling of the mitochondria. This study was supported by the Ministry of Education and Science of Russia (No. 1365).

Keywords: Fusion pore, Mtochondrial permeability transition, α,ω-Dicarboxylic Acids.

A new class of aggregation inhibitor of amyloid-β peptide based on green tea catechins

S. Nieto-Ceron[1], A. C. Castillo-González[1], M. Saez-Ayala[2], C. J. Vidal[2], J. A. Noguera[1], M. F. Lopez-Moreno[1], J. N. Rodriguez-Lopez[2], J. Cabezas-Herrera[1]
[1]Clinical Analisis Service, University Hospital Virgen Arrixaca-IMIB, [2]Department of Biochemistry and Molecular Biology A, Universidad de Murcia, Murcia, Spain

Alzheimer's disease (AD), the major dementing disorder of the elderly which accounts for 55% of all dementia patients worldwide, is related to amyloid-beta peptide, the main component of senile plaques in Alzheimer's disease brain. Observations suggest a broad ability for green tea catechins (GTC) to disrupt early-stage and late-stage aggregation processes but the molecular mechanism has not been fully elucidated. To advance the understanding of the potential use of GTC in the prevention or treatment of AD patients, we investigated the effect of natural and synthetic compounds on APP processing. We checked the ability of gallate containing phenolic compounds, including (-)-catechin, (-)- catechin gallate, (-)-epicatechin gallate, (-)-epigallocatechin, (-)- epigallocatechin gallate, gallic acid, and trimethoxy derivatives of epicatechin-3-gallate to inhibit acetylcholinesterase (AChE) activity and AChE-promoted Aβ aggregation. Compounds were analyzed for their ability to inhibit AChE by colorimetric and radiometric assays and for determining their type of enzyme inhibition. Fluorimetric studies with thioflavin T were performed to evaluate their effect on beta amyloid aggregation. We have found that TMCG, a 3,4,5-trimethoxy derivative of catechin gallate, exhibits a non competitive inhibition of AChE, has a disaggregating effect on amyloid fibrils and decreases the secretion of both 1–40 and 1–42 amyloid peptides to the extracellular medium of SH-SY5Y APP695 cell cultures. According to stability and bioavailability, methoxy derivates of catechins are promising drug to ameliorate the Alzheimer′s pathogenesis.

Association of Alzheimer disease with DNA topoisomerase IIβ in primary neuronal cells

S. Terzioglu Usak[1,2], Y. Negiş[3], S. Isik[4]
[1]Department of Medical Biology, Bezmialem University, Faculty of Medicine, [2]Department of Biology, Fatih University, [3]Department of Medical Biochemistry, Bahçeşehir University, Faculty of Medicine, [4]Department of Medical Biology, Fatih University, Faculty of Medicine, Istanbul, Turkey

In mammalian cells, DNA topoisomerase IIβ (topo IIβ) plays an important role in the initiation of selective gene transcription, neuronal differentiation and axonogenesis. Inhibition of topo IIβ activity both in vivo and in vitro results in shorter axon length and increase of DNA damage by suppressing the transcriptional induction of differentiation- related genes. However, in which pathways of axonogenesis controlled by topo IIβ has not been clarified yet. Additionally, the observed symptoms of Alzheimer‘s disease such as axon shortening and increase in DNA damage give rise to thoughts about the abnormalities in the expression of topo IIβ or aberration of the enzyme in different levels. However, there is no outcome related to the effect of topo IIβ in the course of Alzheimer‘s Disease (AD).In our study, it was studied that whether or not the symptoms of Alzheimer‘s disease associates with the function of topo IIβ in rat primary neuronal cell culture. For this purpose, rat cerebellar granule neurons from post-natal 9 days (P9) old rats were firstly isolated and cultured. Then, amyloid beta (Aβ) 1–42 peptide fibrils were synthesized by the incubation of Aβ 1–42 peptide monomers at 370C during 24 and 48 hours, separately while shaking. These fibrils were given to primary neuronal culture on the 4th day in vitro (DIV). To confirm the success of the establishment of in vitro, immunofluorescence and Congo red staining were performed. Moreover, toxicity of Aβ fibrils given to primary neuronal culture on 4th DIV was observed through Real Time Cell Analysis (RTCA) system during a week. As a final step, in order to associate the function of topo IIβ with AD, samples collected from primary neuronal culture were applied to western blot technique upon Aβ fibrils exposure to the cells during a day. To evidence establishment of in vitro AD, amyloid beta plaques around neurons were detected both by Aβ 1–42 antibody and Congo red stain. Besides these, the choice for the concentration of Aβ 1–42 fibril as 7 μM might have been not enough to be neurotoxic to cerebellar granule cells. It would be better to prefer 14 or 28 μM and 48 hours exposure of Aβ 1–42 peptides to primary neuronal culture rather than one day exposure.To gain insight to the association of topo IIβ with Alzheimer's disease we established in vitro Alzheimer's disease model on cerebellar granule neurons isolated from post natal 9 day Wistar rats. We investigated the possible neurotoxicity of amyloid beta 1–42 aggregates on primary neuron culture affect the expression of both Alzheimer related genes (Presinilin1 and cofilin) and topo IIβ assuming its role in neuron developmnent and axonogenesis, simultenously

C2 domain of CPNE1 plays a pivotal role in neuronal differentiation

N. Park, J. C. Yoo, D.-G. Kim, S.-G. Hong, J.-Y. Park
Physiology, Gyeongsang National University School of Medicine, Jinju, Korea

CPNE1 is known as a calcium-dependent membrane-binding proteins that regulate signal transduction and membrane trafficking. Previous study showed that CPNE1 directly induced the neuronal differentiation of hippocampal progenitor cell line, HiB5 (Mol. Cells 34, 549–554). To understand how CPNE1 induces neurite outgrowth of HiB5 cells, we investigated the effect of neuronal differentiation of its several truncated mutants depend on its known domain. Here, we showed that over-expression of CPNE1-C2-domains increased neurite outgrowth and expression of TUJ1, a neuronal marker protein. Here, calcium binding defected mutant of CPNE1 did increased interestingly neurite outgrowth and expression of TUJ1 of HiB5 cells. This may mean that C2 domain of CPNE1 related with differentiation does not depend on calcium. Furthermore, phosphorylation of AKT was increased by over-expression of CPNE1-C2-domain and(or) calcium binding defected mutant of CPNE1. These results suggest that C2 domains of CPNE1 play an important role for neuronal differentiation in HiB5 cells.

MON-351
Determination of cresyl phosphate adduct in F-16 pilots by mass spectrometer

O. Tacal[1], L. M. Schopfer[2]
[1]*Department of Biochemistry, Hacettepe University School of Pharmacy, Ankara, Turkey,* [2]*Eppley Institute, University of Nebraska Medical Center, Omaha, NE, USA*

The oxygen for F-16 fighter pilots is supplied by an on-board oxygen generating system (OBOGS) that uses bleed air from the engine to generate oxygen. The air passes through the jet engine before it is enriched for oxygen and breathed through an oxygen mask. While in the jet engine, the air can become contaminated with jet engine lubricating oil. An important constituent of lubricating oil is tricresyl phosphate, an anti-wear additive. The ortho isomer of tricresyl phosphate (TOCP) is a minor component of tricresyl phosphate. It is suspected that exposure to TOCP and other oil ingredients is responsible for the illness called aerotoxic syndrome. The symptoms associated with aerotoxic syndrome include nausea, blurred vision, dizziness, headache, tremor, confusion, memory loss and breathing difficulties. TOCP is metabolically converted by cytochrome P450 enzymes to cresyl saligenin phosphate (CBDP). CBDP reacts with butyrylcholinesterase (BChE) to make a covalent adduct on serine 198. The presence of phosphorylated BChE in a person's blood is an indication of exposure to TOCP. The purpose of this work was to determine whether the blood of healthy, active-duty F-16 pilots has measurable levels of the cresyl phosphate adduct.

BChE was immunopurified from 0.5 ml plasma by binding to immobilized monoclonal mAb2. BChE protein was released with acetic acid, digested with pepsin and analyzed by LC-MS/MS on the 5600 Triple TOF mass spectrometer. Positive controls for quantifying the limit of detection were plasma samples containing known amounts of cresyl saligenin phosphate treated plasma. The cresyl phosphate adduct eluted at 31.3 minutes with an observed parent ion mass of 966.4 m/z and characteristic daughter ions 778.3, 673.3, and 602.3 m/z. Control experiments demonstrated that as little as 0.1% of the 1 to 2 μg. BChE recovered from 0.5 ml plasma could be detected as the cresyl phosphate adduct on peptide $FGES_{198}AGAAS$. Mass spectrometry analysis of plasma from fifteen healthy F-16 pilots showed that none had evidence of exposure to TOCP. It was concluded that the on-board oxygen generating system, when operating properly, did not deliver tri-ortho-cresyl phosphate in the oxygen supply.

Disassembly of microtubular cytoskeleton underlays neurotoxicity of cytosolic prion protein

T. Zajkowski, H. Nieznańska, K. Nieznański
Biochemistry, Nencki Institute of Experimental Biology, Warsaw, Poland

Prion protein (PrP) plays a key role in the pathogenesis of transmissible spongiform encephalopathies (TSE). TSE are fatal, infectious neurodegenerative diseases that affect humans and animals. PrP is mostly extracellular glycoprotein anchored in the plasma membrane. In pathology, however, fraction of PrP mislocalized

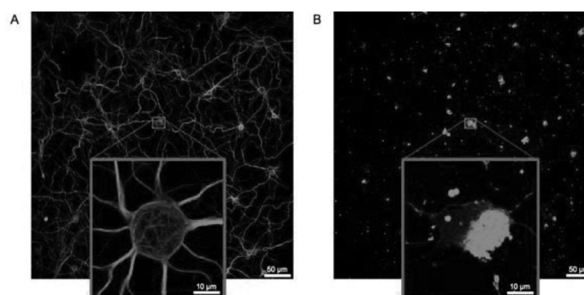

Fig. 1. PrP1-30 disintegrates microtublar cytoskeleton and causes loss of neurites. Untreated primary neuronal cells (A) and treated with PrP1-30 (B) were stained with antibodies to β-tubulin to visualize microtubules.

in the cytosol (cytoPrP) significantly raises. Our previous studies have shown that PrP interacts with tubulin. This interaction induces tubulin oligomerization/aggregation and inhibits microtubule formation. We have also demonstrated that two microtubule-associated proteins (MAPs) which regulate microtubule stability: Tau and MAP2, can prevent above-mentioned effects of PrP. Importantly, we have shown that phosphorylated Tau losses its ability to protect microtubules from deleterious effect of PrP. Noteworthy, hyperphosphorylated Tau has been frequently detected in TSE. To investigate influence of PrP on the microtubular cytoskeleton of primary neurons we have used synthetic peptide encompassing first 30 amino acid residues of PrP (PrP1-30). The peptide consists of the N-terminal signal sequence (1–22) responsible for penetration of the molecule through cell membrane and the major tubulin-binding site (23–30). By means of confocal microscopy we have demonstrated disassembly of microtubular cytoskeleton and loss of neurites of primary neurons exposed to PrP1-30. To examine the role of phosphorylation of MAPs we have modulated activity of GSK3 - main kinase responsible for the modification of Tau and MAP2. As an inhibitor of GSK3 we chose LiCl. We have examined morphology of the neurons incubated simultaneously with PrP1-30 and LiCl and have noticed that they do not differ from the control cells. We have confirmed the involvement of GSK3 in neurotoxicity of cytoPrP by using specific inhibitor of the kinase – CT98014. Cells treated with LiCl or CT98014 sustained proper morphology in contrast to the cells treated with PrP1-30 alone, which had much shorter neurites and tubulin aggregates concentrated in the cell body. To confirm the role of PrP-tubulin interaction in the toxicity of cytoPrP we conducted experiments in which neurons ware treated with taxol in order to stabilize microtubular cytoskeleton and subsequently exposed to PrP1-30. Expectedly, taxol-treated cells retained proper morphology even after incubation with PrP1-30. In cytotoxicity tests (LDH) we have confirmed protection of neurons from toxic effect of PrP1-30 by both inhibitors of GSK-3 as well as taxol. Our observations may help in understanding the molecular mechanism of neurotoxicity of cytoPrP. Since LiCl is well-known pharmaceutical used in the treatment of several mental disorders we believe that our study may be useful in design of TSE therapy.

Keywords: microtubular cytoskeleton, neurotoxicity, Prion protein.

Does GABA shunt contribute to schizophrenia-related GABA deficits? An in vitro study on ketamine-induced rat model of schizophrenia

T. Boczek, M. Lisek, B. Ferenc, L. Żylińska

Department of Molecular Neurochemistry, Medical University of Lodz, Lodz, Poland

A converging body of evidence implicates GABA (γ-aminobutyric acid) in the pathogenesis of schizophrenia. In particular, GABA deficits have been linked to the symptoms of cognitive dysfunctions found in clinical studies and in animal models. *In vivo* GABA is formed by a pathway referred to as the GABA shunt. The first reaction involves the transamination of α-ketoglutarate into L-glutamic acid by GABA α-oxoglutarate transaminase (GABA-T). Then, glutamic acid decarboxylase (GAD) catalyzes the decarboxylation of glutamic acid to form GABA. GAD exists in two isoforms: GAD65 and GAD67 which differ by regulation and specific properties. It is believed that GAD65 in neurons is mainly responsible for synthesis of GABA pool for neurosecretion whereas GAD67 would produce GABA for energy metabolism. GABA is metabolized by GABA-T to form succinic semialdehyde which, in turn, can be oxidized by succinic semialdehyde dehydrogenase (SSADH) into succinate and can then reenter the Krebs cycle. To evaluate whether alterations in synthesis and/or activity of GABA shunt enzymes may affect the total available pool of GABA in schizophrenic brain, we used ketamine-induced rat model of schizophrenia. Following open-field behavioral tests, brains were dissected and cortex, striatum, hippocampus and cerebellum were isolated. Interestingly, GAD and GABA-T activity was decreased in schizophrenic cortex and striatum, an increase was detected in hippocampus but no changes occurred in cerebellum. In case of SSADH, reduced activity was noted in cerebellum and cortex, in contrast to the striatum and hippocampus in which increase or unchanged activity was demonstrated, respectively. Assessing molecular background of this phenomenon, we observed that altered activity of examined enzymes was associated with changes in their mRNAs and protein level, what we evaluated using real-time PCR and Western blot. Also, different enzymatic activities could directly affect GABA level. By using ELISA we detected lower GABA content in schizophrenic cortex and striatum and reduced GABA secretion from synaptosomes obtained from these structures. Finally, we found that changes in GABA level were accompanied by disturbed calcium homeostasis, as increased resting Ca^{2+} level was detected in all examined brain structure isolated from ketamine-treated rats. Our overall data suggest that GABA metabolism may be regulated in unique fashion in different parts of schizophrenic brain. One could assume that altered expression/activity of GABA-metabolizing enzymes may underlie disease-associated deficits in this neurotransmitter.

Effect of cannabinoids on locomotor behavior and sleep/wake regulation in Lipocalin-type prostaglandin D synthase and Adenosine A2A receptors KO mice

N. O. Uchiyama[1], K. Aritake[2], Y. Urade[2]

[1]Division of Pharmacognosy, Phytochemistry and Narcotics, National Institute of Health Sciences, Tokyo, [2]International Institute for Integrative Sleep Medicine (IIIS), University of Tsukuba, Tsukuba, Japan

Cannabinoids are known to have a number of pharmacological effects such as hypolocomotion, hypothermia, catalepsy and memory impairment in rodents. In this study, we focused on the effects of cannabinoids on sleep/wake regulation in mice. As the initial study, we examined the effects of four synthetic cannabinoids, cannabicyclohexanol (CCH), JWH-018, (-)-CP-55940, (+)-WIN-55212-2, and an endocannabinoid anandamide on locomotor activities in WT (C57BL/6) mice. Among them, CCH, JWH-018 and (-)-CP-55940 (5 mg/kg, i.p., respectively) remarkably decreased the locomotor activity. Subsequently, we compared the effects of the three synthetic cannabinoids on locomotor activities in Lipocalin-type prostaglandin D synthase (L-PGDS) KO mice and adenosine A_{2A} receptors ($A_{2A}R$) KO mice as animal models of sleep/wake disorders. The suppressive effects of CCH and JWH-018 on locomotor activities were more potent in L-PGDS KO and also $A_{2A}R$ KO mice than those of WT mice. Additionally, we tested the effects of the three synthetic cannabinoids on sleep/wake regulation evaluated by electroencephalogram (EEG) in WT mice. CCH, JWH-018 and (-)-CP-55940 significantly increased the EEG power in a frequency range of 2 – 3 Hz, which appears during non-rapid eye movement (non-REM) sleep in WT mice, for 12 h, 10 h and 10 h, respectively, as compared with the vehicle-treated control. These data suggested that the hypolocomotion caused by synthetic cannabinoids is partially regulated by prostaglandin D_2/adenosine system, and the changes in EEG by synthetic cannabinoids may relate to sleep/wake system.

Keywords: cannabinoid, locomotor activity, sleep/wake.

Effect of YC-1 on the expression of matrix metalloproteinase 9 in single-dose pentylenetetrazol-induced epileptic seizures

G. Gurol[1], S. Arkan[2], **K. Demircan**[3], T. Utkan[4], N. Ates[2]

[1]Department of Physiology, University of Sakarya, Sakarya, [2]Department of Physiology, University of Kocaeli, Kocaeli, [3]Department of Medical Biology Genetics, University of Turgut Ozal, Ankara, [4]Department of Pharmacology, University of Kocaeli, Kocaeli, Turkey

YC-1, a synthetic bezylindazol derivate (3-(50-hydroxymethyl-20-furyl)-1-benzylindazol), that has been demonstrated to have antiplatelet activity. YC-1 may be reached to central nervous system due to its lipid solubility, at the same time, it could be improved as neuroprotective agents for demonstrating protective effects directly on neurons and the blood brain barrier (BBB). Dysfunction of BBB supported epileptiform activity and showed positive correlation with seizure frequency. The BBB permeability increased in pentylenetetrazol (PTZ)-induced models of epilepsy and it leads to many functional changes. In several studies determinated that matrix metalloproteinases (MMPs) induce the formation of seizures by providing the opening of the BBB and caused epilepsy development. The aim of this study was evaluated the effect of YC-1 on the expression of MMP-9 in a single dose PTZ-induced epilepsy model. 28 male rats were divided into four experi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

mental groups (n = 7) including: 1- received PTZ (55 mg/kg i.p.) and YC- (1 mg/kg i.p), 2-single dose PTZ –recevied rats, 3- YC-1 (1 mg/kg i.p.) as a control group and 4- % 0.1 DMSO (vehicle) treated group. YC-1 was injected 10 minutes prior to PTZ injection for animals. Electrical activity of the cortex and seizure duration and latency recorded with a PowerLab 8S System v.5 (ADI Instruments, U.K.). The expression of MMP-9 in the rat cortex was tested by Western blot. p values <0.05 accepted as statistically significant. Our preliminary findings revealed that YC-1 had no effect on PTZ seizure latencies and minor seizures, but it increased the death rate and major seizure. Additionally, the expression of MMP-9 in cortical tissue did not showed statistically significant differences between groups. As a result, we proposed that the contrabution of YC-1 in the PTZ-induced epilepsy model might be related with very different mechanisms. YC-1's effect on seizures expression should be further studied using new functional and molecular techniques.

Keywords: Matrix metalloproteinase, seizure, YC-1.

Effects of native inorganic particles on membrane potential, proton gradient, Na+ -dependent uptake, and binding of glutamate in rat brain nerve terminals

A. Nazarova, A. Nazarova
Neorochemistry, Palladin Institute of Biochemistry, Kiev, Ukraine

Recent epidemiological, observational, clinical, and experimental studies suggest that certain neurological diseases, such as Alzheimer's disease, Parkinson's disease, and stroke, may be strongly associated with ambient air pollution, one of the components of which is fine and ultrafine inorganic particles. During inhalation, nano/micro-sized particles are efficiently deposited in nasal, tracheobronchial, and alveolar regions and transported to the CNS. Glutamate is the major excitatory neurotransmitter in the CNS, which is involved in many aspects of normal brain functioning and the pathogenesis of neurological disorders. Research was focused on the analysis of the effects of fine and ultrafine inorganic particles originated from volcanic ash (JSC-1a, ORBITEC Orbital Technologies Corporation, Madison, Wisconsin) on the key characteristics of glutamatergic neurotransmission. The average size of particles (even minor fractions) before and after sonication was determined by dynamic light scattering. With the use of radiolabeled L-[^{14}C]glutamate, it was shown that there is an increase in L-[^{14}C]glutamate binding to isolated rat brain nerve terminals in low [Na^+] media and at low temperature in the presence of the particles. The initial velocity of L-[^{14}C]glutamate uptake was not changed as a result of application of the particles. Fluorimetric experiments with potential-sensitive dye rhodamine 6G and pH-sensitive dye acridine orange showed that the potential of the plasma membrane of nerve terminals and acidification of synaptic vesicles were not altered by the particles. Therefore, fine and ultrafine inorganic particles of volcanic ash JSC-1a increase glutamate binding to the nerve terminals. The effect revealed can have deleterious influence on extracellular glutamate homeostasis in the CNS which is extremely important for proper synaptic transmission.

Keywords: fine and ultrafine inorganic particles; volcanic ash; glutamate binding; glutamate uptake; the membrane potential; synaptic vesicle acidification; rat brain nerve terminals.
Keywords: glutamate uptake;, rat brain nerve terminals, synaptic vesicle acidification.

Enhanced store-operated calcium entry in neuronal models of Huntington's disease

V. Vigont, O. Zimina, J. Kolobkova, L. Glushankova, E. Kaznacheyeva
Laboratory of Ion channels of cellular membranes, Institute of Cytology RAS, St. Petersburg, Russian Federation

Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by polyglutamine expansion within Huntingtin protein. The striatal neurons are most affected in HD. It has been suggested that impaired calcium signaling plays an essential role in HD pathogenesis.

Calcium influx via the store-operated calcium (SOC) channels is well established as an important and ubiquitous mechanism for calcium entry in mammalian cells. To model HD in different cell cultures we used a transfection of the full-length mutated Huntingtin (Htt138Q) or lentiviral infection of N-terminal fragment of the mutated Huntingtin (Htt138Q-1exon).

Using patch-clamp technique we demonstrated the strong enhancing of the SOC entry in models of HD in the human neuroblastoma cells (SK-N-SH), mice neuroblastoma cells (Neuro2A) and in the primary culture of striatal neurons isolated from mice (MSN). By using RNAi-mediated knockdown approach we proved a crucial role of calcium sensor STIM1 in activation of the SOC pathway in HD models. Further we demonstrated that for the SOC entry in these cells the channel-forming proteins TRPC1 and Orai1 are required.

Human induced pluripotent stem (iPS) cells hold great promise for therapy of a number of degenerative diseases such as HD, Alzheimer's disease, diabetes mellitus, etc. They also have the therapeutic potential for disease treatment not only by iPS cell-based cell replacement therapy but providing a number of cellular models of neurodegenerative disease for scientific research and drug screening.

The next step of our research was devoted to studying of the SOC entry in Huntington-specific human neurons (MSN-human) differentiated from iPS cell lines generated through somatic reprogramming of fibroblasts obtained from the HD patients. In contrast to our previous studies the expression of the mutated Huntingtin in MSN-human HD model was absolutely endogenous. It is worth mentioning that mutated Huntingtin, expressed in HD patient's brains has only 40–45 glutamine residues in its polyglutamine tract what is close to be norm. Despite this we showed a strong enhancing in the level of the SOC entry in pathological human neurons.

Further we showed that application of EVP4593 compound leads to the reduction of the increased SOC entry to the normal values in SK-N-SH, MSN and MSN-human models of HD.

Our results suggest that SOC entry constitutes a novel target for HD treatment and EVP4593 compound represents a novel potential therapeutic agent for treatment of HD.

The study was supported by the RScF, the RFBR, the Program of the RAS 'MCB', and the fellowship of the President of the RF.
Keywords: Huntington's disease, Patch-clamp, Store-operated calcium entry.

Enhancement of alcohol drinking in mice depends on alterations in RNA editing of serotonin 2C receptors

Y. Watanabe[1], K. Yoshimoto[2], M. Tanaka[1]
[1]Basic Geriatrics, Kyoto Prefectural University of Medicine, Kyoto, [2]Food Science and Biotechnology, Hiroshima Institute of Technology, Hiroshima, Japan

Serotonin 2C receptors (5-HT_{2C}R) are G-protein-coupled receptors with various actions, including involvementin drug addiction. 5-HT_{2C}R undergoes mRNA editing, converting genomically encoded adenosine residues toinosines via adenosine deaminases acting on RNA (ADARs). Here we show that enhanced alcohol drinkingbehaviour in mice is associated with the degree of 5-HT_{2C}R mRNA editing in the nucleus accumbens and dorsalraphe nuceus, brain regions important for reward and addiction. Following chronic alcohol vapour exposure,voluntary alcohol intake increased in C57BL/6J mice, but remained unchanged in C3H/HeJ and DBA/2J mice.5-HT_{2C}R mRNA editing frequency in both regions increased significantly in C57BL/6J mice, as did expressionsof 5-HT_{2C}R, ADAR1 and ADAR2, but not in other strains. Moreover, mice that exclusively express the uneditedisoform (INI) of 5-HT_{2C}R mRNA on a C57BL/6J background did not exhibit increased alcohol intake comparedwith wild-type mice. Our results indicate that alterations in 5-HT_{2C}R mRNA editing underlie alcohol preferencein mice.

Keywords: 5-HT2C receptor, Alcohol addiction, RNA editing.

External magnetic field-mediated movement of brain nerve terminals labeled by D-mannose-coated gamma-Fe2O3 nano-sized particles

T. Borisova[1], N. Krisanova[1], R. Sivko[1], A. Borysov[1], M. Babic[2], D. Horak[2]
[1]Neurochemistry, Palladin Institute of Biochemistry NAS of Ukraine, Kiev, Ukraine, [2]Department of Polymer Particles, Institute of Macromolecular Chemistry AS CR, Prague, Czech Republic

Movement of brain nerve terminals by application of an external magnetic field promises breakthrough in nanoneurotechnology. D-mannose-coated superparamagnetic nanoparticles were synthesized by coprecipitation of Fe(II) and Fe(III) salts followed by oxidation with sodium hypochlorite and addition of D-mannose. Effects of D-mannose-coated superparamagnetic maghemite (γ-Fe_2O_3) nanoparticles on key characteristics of glutamatergic neurotransmission were analysed. Using radiolabeled L-[^{14}C]glutamate, it was shown that D-mannose-coated γ-Fe_2O_3 nanoparticles did not affect high-affinity Na^+-dependent uptake, tonic release and the extracellular level of L-[^{14}C]glutamate in isolated rat brain nerve terminals. Fluorimetric experiments with potential-sensitive dye rhodamine 6G and pH-sensitive dye acridine orange showed that the potential of the plasma membrane of the nerve terminals and acidification of synaptic vesicles were not altered in the presence of D-mannose-coated γ-Fe_2O_3 nanoparticles. The study was focused on analysis of possibility of usage of these nanoparticles for manipulation of nerve terminals by an external magnetic field. It was shown that more than 84.3 $\pm$ 5.0% of L-[^{14}C]glutamate-loaded nerve terminals (1 mg of protein/ml) incubated for 5 min with D-mannose-coated γ-Fe_2O_3 nanoparticles (250 μg/ml) moved to area, where the magnet (250 mT, gradient 5.5 T/m) was applied versus 33.5 $\pm$ 3.0% of label in control and 48.6 $\pm$ 3.0% of label after the application of uncoated nanoparticles. Therefore, it was demonstrated the possibility to manipulate brain nerve terminals by an external magnetic field using D-mannose-coated γ-Fe_2O_3 nanoparticles, which did not affect key characteristics of glutamatergic neurotransmission, that is, D-mannose-coated γ-Fe_2O_3-labeled nerve terminals with normal functioning were obtained.

From IDP to Alzheimer's disease - structural features of beta-amyloid prefibrillar aggregates by sedimented solute NMR

M. Korsak[1,2], I. Bertini[1,2,3], C. Luchinat[2,3,4], E. Ravera[2,4], J. Mao[2,3,5], G. Gallo[2,4]
[1]Giotto Biotech, [2]Magnetic Resonance Center (CERM), [3]Fondazione Farmacogenomica FiorGen onlus, [4]Department of Chemistry 'Ugo Schiff', Sesto Fiorentino (FI), Italy, [5]Goethe Universitat, Frankfurt am Main, Germany

Beta amyloid protein (Aβ) is one of the intrinsically disordered proteins associated with neurodegenerative diseases like Parkinson's, prion disease and Alzheimer's disease (AD) in particular. Although the direct involvement of Aβ peptides in AD is well documented and their aggregative ability is closely related to their neurotoxicity, the precise mechanism of the neurotoxic effects of Aβ peptides remains unclear. Moreover, there is still a significant gap between the site-specific structural information and the complex structural diversity of Aβ amyloids. Most of the published data also reported that the neurotoxicity of Aβ peptides might be ascribed to the oligomeric species, not to the fibrils. Detailed structural and dynamical properties of the various prefibrillar intermediates are crucial for the understanding the role of amyloid formation in AD pathogenesis. NMR spectroscopy is a useful tool to obtain atomic resolution information on IDPs. In this work we report new atomic-level structural features of Aβ assemblies over 60 kDa by a new technique referred to as sedimented solute NMR (SedNMR). We have obtained a qualitative picture of the structure of prefibrillar Aβ40 aggregates prepared from standard ultracentrifugation and some clues toward structural evolution from prefibrillar aggregates to the final fibrillar materials. We prove that *in situ* SedNMR directly inside SSNMR rotors by magic angle spinning (MAS) can be used to address the kinetics of formation of soluble Aβ assemblies by monitoring the disappearance of monomer and the appearance of the oligomers at the same time. *Ex situ* SedNMR via an ultracentrifuge device provides a way to select certain species and reveals atomic – level structural features of soluble Aβ assemblies. These high resolution studies contribute to understand structural polymorphisms of Aβ amyloids and provide valuable information of the molecular basis of AD onset-progress.

the neurite outgrowth of nerve growth factor (NGF)-treated PC12 h cells, the precise cellular and molecular mechanisms underlying neurite outgrowth by fullerene addition are unclear. We have already found that low concentrations of amino group-modified carbon nanotubes promoted the neurite outgrowth of NGF-treated neurons by stimulating extracellular signal-regulated kinase (ERK) through the activation of the phospholipase C (PLC) signaling pathway. Therefore, we investigated whether PLC may play a role in the mechanisms underlying the fullerene-induced potentiation of NGF-treated PC12 h cells.

We investigated whether fullerenes or pyrrolidine-modified fullerenes may stimulate the neurite outgrowth of NGF-treated PC12 h cells by the activation of ERK through the PLC signaling pathway independent of the Ras/Raf/MEK cascade. Fullerenes and pyrrolidine-modified fullerenes stimulated the neurite outgrowth of NGF-treated PC12 h cells at a range of concentrations of 0.11–0.85 μg/ml. On the other hand, they did not influence the proliferation of PC12 h cells at a range of concentrations of 0.11–0.85 μg/ml. When the concentrations of fullerenes were increased to a range of 1.7–17 μg/ml, the numbers of both NGF-treated PC12 h cells with neurite outgrowth and proliferated PC12 h cells decreased. Fullerenes and pyrrolidine-modified fullerenes enhanced the phosphorylation of PLC-γ1 and ERK in NGF-treated PC12 h cells. The activation of PLC-γ1 is known to induce the release of Ca^{++} from intracellular Ca^{++} stores. These fullerenes induced an increase in intracellular Ca^{++} levels of NGF-treated PC12 h cells.

Fullerenes and pyrrolidine-modified fullerenes promote the neurite outgrowth of NGF-treated PC12 h cells by the activation of ERK independent of the Ras/Raf/MEK cascade through the PLC signaling pathway.

Keywords: Fullerene, PC12 h cells, PLC signaling pathway.

Gaining insight into the molecular basis of brain damage in the PKU mouse model

E. Imperlini[1,2], S. Orrù[2,3], C. Corbo[1], A. Daniele[1,4], S. Francesco[1,2]
[1]CEINGE, Biotecnologie Avanzate Scarl, [2]SDN-Foundation, IRCCS, [3]Department of Exercise and Wellness, University of Naples 'Parthenope', [4]Department of Environmental Sciences, Second University of Naples, Biological and Pharmaceutical Technologies, Naples, Italy

Phenylketonuria (PKU) is the most common inherited disorder of amino acid metabolism. The primary cause of PKU is lack of phenylalanine hydroxylase (PAH), the enzyme that in liver metabolizes L-phenylalanine (L-Phe) to L-tyrosine (L-Tyr) using 6R-L-erythro-5,6,7,8-tetrahydrobiopterin (BH4) as essential co-factor. In untreated PKU patients, Phe concentrations in blood and tissues are high. Hyperphenylalaninemia (HPA) leads to a variety of symptoms, but the most prominent symptom occurs in the brain. If not detected and treated in newborns, HPA causes severe neurologic dysfunction with severe and irreversible mental retardation, microcephaly, and cognitive and behavioral deficiencies. At present, prevention of the major symptoms of the disease, including mental retardation, consists of a low Phe diet throughout life. Despite the biochemical characterization of PKU, the molecular mechanisms underlying PKU-associated brain dysfunction remain poorly understood.

In this study, we analyzed the protein expression profiles in brain tissue of homozygous PKU mice versus the normal heterozygous counterpart using two-dimensional differential gel electrophoresis (2D DIGE) technology. Our differential proteomic approach, combined to mass spectrometry, revealed 21 proteins whose expression is affected by HPA: four were overexpressed and 17 underexpressed. The bioinformatic analysis of the identified protein data set showed that about 60% of species are related to nervous system development and functions (neuron differentiation and dendritic growth/branching) and to neurological disorders (progressive motor neuropathy and movement disorders). Moreover, functional annotation analyses showed that some identified proteins were involved in oxidative metabolism. To investigate further the proteins involved in the neurological damage, we validated by western blot two of the proteins that were most strikingly underexpressed, namely, Syn2 and Dpys12, which are involved in synaptic function and neurotransmission. Furthermore, we found that Glu2/3 and NR1 receptor subunits were overexpressed in PKU mouse brain. In conclusion, these findings confirm that alteration in synaptic function, in transmission and in energy metabolism underlie brain damage provoked by PKU.

Global analysis of S-nitrosylation sites of the post synaptic density proteins in mouse models of Alzheimer's disease

M. Zareba-Koziol, K. Bucholc, A. Wyslouch Cieszynska, M. Dadlez
MS Lab Mass Spectrometry Laboratory, Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland

Alzheimer's disease (AD) is the most frequent neurodegenerative disorder, characterized by the progressive deterioration of cognitive functions, learning and memory. AD is characterized by synaptic loss, nerve cell loss, extracellular deposition of beta amyloid protein (forming senile plaques) and tau protein (neurofibrillary tangles). The pathogenesis of this disorder is linked to a condition of oxidative and nitrosative stress occurs due to an imbalance in the production of reactive oxygen species (ROS) and reactive nitrogen species (RNS). One of the consequences of interaction reactive nitrogen species with proteins is S–nitrosylation. S–nitrosylation is the selective covalent modification of cysteine thiols in proteins by nitric oxide to form nitrosocysteine. This modification is emerging as an important redox signaling mechanism which can regulate board range of biologic physiologic and cellular function.

Our research focused on systemic analysis of endogenous S-nitrosylation of proteins from postsynaptic densities (PSDs)–multiprotein structures responsible for the proper functioning of excitatory synapses. PSDs were isolated from transgenic mice with neuronal expression of human mutant APP gene (which are an accepted model of Alzheimer's disease) and control FVB mice. In the project we used methods enabling us to selectively enrich the PSD fraction in S–nitrosylated proteins and mass spectrometry for their identification.

We have worked out a protocol for mapping of the S-nitrosylated peptides coupling liquid chromatography (LC) and mass spectrometry (MS) with SNOSID and biotin switch method. As a result we obtained two dimensional maps (molecular mass versus HPLC retention time) of peptides present in the sample and peptide sequences. We used new bioinformatics tools for datasets analysis which were developed in our laboratory.

This type of S–nitrosome analysis help to defining the quantitative and qualitative differences in S-nitrosylation of proteins among different biological states. The progress in the understand-

Glycogen synthase kinase-3 regulates synaptic Matrix Metaloproteinase-9

I. Kondratiuk[1], T. Jaworski[1], F. Van Leuven[2], L. Kaczmarek[1]
[1]Nencki Institute of Experimental Biology, Warsaw, Poland, [2]KULeuven, Leuven, Belgium

Glycogen synthase kinase-3 (GSK3) activity is crucial for hippocampal function where it plays an important role in the regulation of synaptic functional and structural plasticity. Control of functional synaptic plasticity by GSK3 may be through the regulation of Long Term Depression (LTD). Structurally, GSK3 regulates hippocampal size, dendritic tree morphology and spine density. However, molecular pathways, by which GSK-3 exerts its synaptic functions are not fully known. Matrix Metaloproteinase-9 (MMP-9) has been implicated in regulation of the synaptic plasticity and dendritic spine moprhology. Hence, we decided to investigate whether there is a link between MMP-9 and GSK3. To understand how these two molecules are linked, we used isolated synaptoneurosomes. LTD was induced by the application of DHPG that we found to induce a rapid cleavage of MMP-9 substrate β-dystroglycan. Furthermore, this effect was inhibited by application of Chiron, selective GSK3 inhibitor. Interestingly, application of broad spectrum MMP-9 inhibitor I potentiated DHPG-induced decrease of GSK3 phosphorylation suggesting a possible reciprocal effect.

Next, we analyzed MMP-9 activity, by gel zymography, in mice overexpressing GSK3β (GSK3β[S9A]) and lacking GSK3β (GSK3β(n-/-)), in response to PTZ-induced seizures. Overexpression of GSK3β[S9A] potentiated MMP-9 activity in mice that were treated to PTZ. In contrast, in GSK3β(n-/-) MMP-9 activity was diminished upon PTZ injection as compared to WT mice.

Finally, we confirmed the effect of GSK3β on spine morphology by analyzing spine's shape in brain sections derived from mice overexpressing or lacking GSK3β. The effect of GSK3-MMP-9 relationship on spine morphology is being investigated.

Taken together, these data indicate that GSK3β regulates MMP-9 at the excitatory synapse, and the relationship may be crucial for the structural plasticity regulation.

Keywords: dendritic spines, GSK3, MMP-9.

MON-367
Identification of PP2A as a novel interacting partner of LRRK2

P. Athanasopoulos, on behalf of Prof. Dr. Heumann, R. Heumann, on behalf of Prof. Dr. Heumann
Transpol Molecular Neurobiochemistry, Ruhr Universitat Bochum, Bochum, Germany

Mutations in the leucine-rich repeat kinase 2 (LRRK2) are the most common cause of genetically inherited Parkinson s disease (PD). Two of the common found mutations namely R1441C and G2019S, mediate their toxic effects through their increased kinase activity. Furthermore, the kinase activity of LRRK2 is regulated through some essential serine and threonine autophosphorylation residues, that are located in the LRR, ROC and kinase domain. In this study we identified Protein Phosphatase 2A (PP2A), as an interacting partner of LRRK2. We were able to show that the alpha subunit of PP2A (PP2Aa) is interacting with LRRK2 in the perinuclear region of Hela cells. Finally we investigated the physiological role of PP2A in SH-SY5Y cells transiently expressing R1441C-LRRK2, by silencing the catalytic subunit of PP2A (PP2Ac). As a result, cell death which was induced by R1441C-LRRK2 was significantly aggravated. All these data suggest that PP2A is a new interacting partner of LRRK2 and reveal the importance of PP2A as a potential therapeutic target in PD.

Keywords: LRRK2, Parkinson's disease, PP2A.

Limiting in vivo conditions of reversed glutamate transport in platelets

L. Kasatkina, T. Borisova
Department of Neurochemistry, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kyiv, Ukraine

Platelets express high-affinity glutamate transporters EAAT1-3 in plasma membrane and vesicular glutamate transporters VGLUT1-2 in secretory granules. The mechanisms of glutamate release from platelets are uncertain though glutamate is considered to be an important signalling molecule for the platelets, the other blood cells and endothelium. In current research we assess the availability of non-stimulated, transporter-mediated and exocytotic release of glutamate in platelets and compare glutamate transport in presynapse and in peripheral (non-neuronal) type of the cells. We use the radiolabelled assay (L-[^{14}C]glutamate) and glutamatedehydrogenase assay to monitor the endogenous glutamate release from platelets and isolated brain nerve terminals (synaptosomes).

The absence of non-stimulated and depolarization-induced (high K^+) release of endogenous glutamate from platelets was shown even after the inhibition of glutamine synthetase and glutamate uptake by methionine sulfoximine or DL-threo-*b*-benzyloxyaspartate, respectively. Transportable inhibitor of glutamate transporters DL-threo-*b*-hydroxyaspartate (DL-THA) failed to induce glutamate efflux from the cytosol of platelets by means of heteroexchange.

The protonophore cyanide-p-trifluoromethoxyphenyl-hydrazon (FCCP) and inhibitor of H^+-ATPase V-type bafilomycin A1 caused dissipation of the proton gradient on both platelets and synaptosomes but did not stimulate glutamate release from platelets. It was shown that platelet degranulation (stimulated by ADP or thrombin) was accompanied by massive endogenous glutamate release. High K^+, DL-THA, FCCP and bafilomycin A1 did not prevent this exocytotic release of glutamate.

The depolarization of the plasma membrane of synaptosomes at Ca^{2+}-free conditions caused transporter-mediated release of endogenous glutamate from the cytosol into the extracellular space (glutamate transporter reversal). In contrast to nerve terminals, the heteroexchange, transporter-mediated and non-stimulated release of glutamate are not inherent to platelets. We suggested that the absence of the transporter-mediated release of glutamate was associated with the minority of the cytosolic pool of glutamate and a lack of depolarization-induced Na^+ influx in platelets, i.e., the factors, which determined glutamate transporter reversal. Thus, the glutamate is released from platelets by means of exocytosis only.

Keywords: exocytosis, glutamate transporters, platelets.

MMP-3, MMP-9 and TIMP-1 in serum during thrombolytic treatment of acute ischaemic stroke

J. Kocot[1], A. Boguszewska-Czubara[1], M. Kielbus[2], P. Golab[3], J. Kurzepa[1]
[1]Department of Medical Chemistry, [2]Medical University of Lublin, Lublin, [3]The Holy Family Specialist Hospital in Rudna Mala, Rzeszow, Poland

Introduction: The recommended treatment of acute phase of ischaemic stroke (IS) in humans is limited to recombinant tissue plasminogen activator (rtPA). Previous studies have indicated that intracranial bleeding during rtPA administration can be caused by high activity of matrix metalloproteinase (MMP)-9. MMP-9 is capable to digest type IV collagen, the component of basal membranes. During thrombolysis the enzymatic cascade that follows through plasmin and MMP-3 is triggered by rtPA. Finally, MMP-3 activates MMP-9, theoretically leading to the destruction of basal membranes of brain vessels and intracranial bleeding thereafter. Our objective was to find the relationship between rtPA treatment versus MMP-9 activity, MMP-3, and TIMP-1 (tissue inhibitor of MMP) serum levels related to patients' neurological status during acute ischaemic stroke.
Material and Methods: Thirty five ischaemic stroke patients were enrolled. Fourteen of them underwent thrombolytic therapy with rtPA (rtPA group). The serum samples were obtained at 3 time-points in rtPA group (time-point 0: 1st – 4th hour of stroke; time-point 1: immediately after rtPA administration; time-point 3: on day 5–7 from stroke onset). In remaining patients venous blood was obtained at two time-points: time-point 1: 5th – 10th hour of stroke and time-point 2: on day 5–7 of stroke. MMP-9 was analyzed with gelatin zymography, MMP-3 and TIMP-1 serum levels were analyzed using an ELISA method. Neurological status was assessed by National Institutes of Health Stroke Scale (NIHSS) performed on the admission and discharge of patients. NIHSS improvement ratio (IR) was calculated as a difference between NIHSS score at the admission and discharge of patient.
Results: The active form of MMP-9 (86 kDa) was not observed in any analyzed samples. MMP-9 activity was estimated as the sum of activities of each detected form 92 kDa, 130 kDa and 200 kDa (corresponding to pro-MMP-9, heterodimer MMP-9/lipokalin and homodimer MMP-9/MMP-9, respectively). MMP-9 was significantly elevated and MMP-3 was decreased in serum at time-point 1 in rtPA group in comparison to non-rtPA group. MMP-3 was negatively correlated with IR values for all stroke patients but the results did not reach full statistical significance ($p = 0.06$).
Conclusion: Thrombolysis applied for the treatment of ischaemic stroke increases MMP-9 activity in serum, however rtPA seems not to facilitate the conversion of pro-MMP-9 into the active form. In addition, our results can suggest the involvement of MMP-3 to the biochemical processes occurring during acute phase of IS.

MON-371
Modulation of AMPA receptors by Type II-TARPs

S. Lemos, M. Hollmann
TRANSPOL – Department of Biochemistry I - Receptor Biochemistry, Ruhr University, Bochum, Germany

AMPA receptors (AMPARs) are involved in fast synaptic transmission in the CNS. They are transmembrane proteins that assemble as homo- or heterotretameric combinations of four distinct subunits: GluA1 to GluA4. Phenomena such as alternative splicing and RNA editing contribute to the high diversity of receptor subunit combinations, which ultimately result in an increased multiplicity of channel architectures and properties.

A group of accessory proteins has been found to further increase this broad diversity of channel characteristics. Transmembrane AMPA receptor regulatory proteins (TARPs), are classified into two groups. Besides γ3, γ4, and γ8, type I-TARPs include γ2, also called stargazin, the first TARP discovered. All of these proteins are known to efficiently regulate all AMPA receptor combinations, modulating channel gating and assuring proper receptor expression and trafficking to the membrane. Type II-TARPs comprise γ5 and γ7. Together with γ6, type II-TARPs were initially regarded as 'non-TARPs', because they did not seem to modulate any of the biophysical channel properties. A view that has been recently changed.

Therefore, the role of type II-TARPs in the regulation of AMPARs needs to be further clarified. It is necessary to investigate whether type II-TARPs interact with other glutamate receptor subfamilies, such as kainate and NMDA receptors. It is still not clear which molecular mechanisms and which TARP-interacting domains are involved in type II-TARP modulation of AMPARs. In addition, very little is known about the trafficking pathways and stoichiometry of AMPAR-type II-TARP complexes.

Here, using two-electrode voltage-clamp (TEVC), we investigate the roles that type II-TARPs play in modulating channel properties. Our results show that, in *Xenopus laevis* oocytes, type II-TARPs play a clear role in differentially modulating steady state currents of AMPA receptors, depending on the subunit, splice variant, and the editing form involved. Furthermore, in accordance with the literature, γ6 does not seem to have any significant effect on channel functionality, confirming the 'non-TARP' status that has been attributed to this subunit. Our results also show that kainate receptors are not modulated by type II-TARPs, suggesting an AMPAR-selective modulation.

Modulation of intracellular proteolytic pathways in rational neuroprotection

L. A. Lysenko, N. Kantserova, N. Rendakov, N. Nemova
Institute of Biology, Karelian Research Centre of RAS, Petrozavodsk, Russian Federation

Neurodegeneration both pathology- or age-related is accompanied to the disturbance in protein turnover in nervous tissue and imbalance in intracellular proteolytic pathways. Thus (i) proteasome-dependent protein quality control machinery is inefficient against protein aggregates, (ii) the autophagic elimination of abnormal proteins, organelles or cells is suppressed so that lysosomal compartment is overloaded, and (iii) on the contrary the proteases promoting cell death by apoptotic or necrotic pathways (e.g. caspases and calpains) are excessively activated. Calpain/calpastatine system overactivation in damaged brain depends on multiple factors such as calcium excess in cytosol, calpain expression upregulation, and calpastatine (calpain inhibitor) degradation and spatial separation with controlled protease. Hitherto the resultant calpain hyperactivation effect is considered as the critical event (or 'point-of-no-return') in neurodegeneration. In order to solve the pending issue on rational neuroprotection and neurodegeneration manifestation delay the effectiveness of some selective calpain regulators and exogenous agents of pleiotropic activity aiming to stimulate endogenous neuroprotective mechanisms was estimated. The work was supported by RFBR grant 12-04-01597 and the program 'Leader scientific schools' project 1410.2014.4.
Keywords: Neurodegeneration, neuroprotection, protease.

Molecular mechanism of the interaction between gating modifier toxin VSTx1 and voltage-sensing domain of potassium KvAP channel revealed by NMR spectroscopy

Z. O. Shenkarev[1], E. N. Lyukmanova[1], A. S. Paramonov[1], L. N. Shingarova[1], M. A. Shulepko[1,2], M. P. Kirpichnikov[1,2], A. Arseniev[1]
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, [2]Lomonosov Moscow State University, Moscow, Russian Federation

Voltage-gated K+ channels (Kv) play essential role in the cellular excitability and propagation of nerve signals. The spatial organization of Kv channels is modular and involves a pore domain surrounded by a 'ring' of four loosely associated voltage-sensing domains (VSDs). The VSD is composed of four consecutive transmembrane helices (S1-S4). The S4 helix, sometimes called 'voltage sensor', accommodates several positively charged residues (usually four Arg), which are directly involved in the channel gating. Kv channels are targeted by plethora of toxins produced by venomous animals. The spider toxin VSTx1 (tarantula *Grammostola spatulata*) inhibits activation of the prototypical K+ channel KvAP (archea *Aeropirum pernix*) by blocking the VSD in the depolarized conformation and delaying the domain return to the hyperpolarized conformation (Schmidt et al, JMB, 2009).

In the present work the interaction of VSTx1 with isolated VSD of KvAP channel having depolarized conformation was studied by NMR spectroscopy. The membrane mimicking environment of zwitterionic DPC/LDAO (2:1) micelles and nanodiscs containing partially anionic POPC/DOPG (3:1) membranes were used. VSTx1 demonstrates moderate membrane activity and binds to the micelle surface by large hydrophobic patch surrounded by the ring of the positively charged residues (Lys4, Lys8, Arg24 и Lys26). Changes in the line-width and chemical shift of NMR signals observed upon mutual VSTx1 and VSD titrations permit to map binding interfaces in the toxin/domain complex. The usage of spin-labeled VSD variants permits to determine relative orientation of VSTx1 and VSD molecules. The Phe5-Lys8 loop of the toxin is contacted with the S1-S2 loop of the VSD, and C-terminal VSTx1 fragment (Ser22-Phe34) is directed toward S3b-S4 helical hairpin. NMR data obtained in micellar and nanodisc environment also revealed the presence of additional low-affinity nonspecific interactions between VSTx1 and VSD molecules.

Summarizing the obtained results, we could propose that VSTx1 binds to the interface region of the lipid bilayer and from this state forms the complex with the VSD S1-S2 loop. The bound toxin molecule blocks the S3b helix, thus hinder the movement of the covalently linked voltage-sensor (S4 helix). The presented study for the first time provides direct structural information about interaction of spider gating modifier toxins with the VSD of voltage-gated channels.

This work was supported by the Russian Foundation for Basic Research (14-04-01270).

Molecular pharmacology of synthetic neurosteroidal agonists of Nerve Growth Factor (NGF) receptors: differential neurotrophin receptors signaling

I. Charalampopoulos[1], I. Pediaditakis[1], P. Efstathopoulos[1], M. Zervou[2], J. C. Arevalo[3], V. Nikoletopoulou[4], A. Kourgiantaki[1], T. Calogeropoulou[2], A. Gravanis[1]
[1]Department of Pharmacology, Medical School, University of Crete & Institute of Molecular Biology and Biotechnology, FORTH, Heraklion, [2]Institute of Biology, Medicinal Chemistry, Biotechnology-NHRF, Athens, Greece, [3]Department of Cell Biology and Pathology, Instituto de Neurociencias de Castilla y León, Salamanca, Spain, [4]Institute of Molecular Biology and Biotechnology, FORTH, Heraklion, Greece

Neurotrophins control neuronal cell fate and function during development and adulthood. They act through Trk and $p75^{NTR}$ receptors, exerting potent neuroprotective effects. However, neurotrophins' therapeutic usefulness is compromised by their polypeptidic nature and limited penetrance to the blood-brain barrier (BBB). We have synthesized analogs of neurosteroid dehydroepiandrosterone with anti-apoptotic properties, deprived of androgenic/estrogenic actions. In the present study we provide evidence that derivative BNN27, binds to NGF receptors, TrkA and $p75^{NTR}$, at nanomolar concentrations (Kd: 1.86 ± 0.4 nM and 3.9 ± 1.2 nM respectively). Mutagenesis assays have shown that binding of BNN27 to TrkA receptors does not require its extracellular, NGF binding domain, in contrast to mutated $p75^{NTR}\Delta$ECD receptor where no binding is observed. BNN27 induced TrkA tyrosine phosphorylation in all three tyrosine residues (490, 675 and 785), affecting downstream signaling of Akt and MAPKs in primary sympathetic neurons. However, BNN27 differentially regulated TrkA internalization: it induced internalization and fast return of the receptor into the membrane through activation of rab5 protein and docking of the receptor in the early endosomes. Using cholesterol depletion agents and separating lipid raft microdomains, we showed that BNN –in contrast to NGF- caused TrkA to effectively segregate into lipid raft fractions, presenting differential membrane localization of the receptor. BNN27 significantly reversed apoptosis of NGF-dependent embryonic sensory neurons of NGF null mice and of sympathetic neurons in primary culture. Moreover, BNN27 was effective in promoting the interaction of $p75^{NTR}$ receptors with its interactors RhoGDI, RIP2 and TRAF6. Interestingly, BNN27 was ineffective by itself in inducing differentiation and neurite outgrowth of PC12 cells. However, it enhanced the effects of NGF at low concentrations in both phenomena. NMR studies with BNN27 and recombinant NGF receptors suggest that it facilitates binding of NGF to its receptors. In conclusion, BNN27 exerts strong anti-apoptotic, neuroprotective actions via NGF receptors, differentially activating prosurvival signaling, and thus it may serve as a lead molecule to develop BBB permeable, neurotrophin-like small molecules (microneurotrophins) with potential applications in the treatment of neurodegenerative diseases.

NeuroD2 transcription factor regulates expression of Id2 gene during neuronal differentiation

G. Guzelsoy, E. Bayam, G. Ince Dunn
Molecular Biology and Genetics Department, Koc University, İstanbul, Turkey

NeuroD2 is a neuron-specific basic helix-loop-helix (bHLH) transcription factor with important roles in neuronal differentiation and development. NeuroD2 forms heterodimers with ubiquitous E-proteins to form a transcriptionally active complex which induces transcription of neurogenic genes by binding to E-box elements in their promoters. In order to identify target genes of NeuroD2 during development of the cortex we have compared gene expression profiles between wild-type and *neuroD2* knockout cortex tissue by microarray analysis. We have identified *id2* gene as a top candidate gene and have demonstrated that expression of *id2* is significantly reduced in *neuroD2* knockout mice by using northern blot and *in situ* hybridization. Id2 protein is a member of Id proteins that inhibit E-box mediated gene expression by interfering with binding of neurogenic bHLH proteins to their target promoters. NeuroD2 heterodimerizes with Id (inhibitor of differentiation) proteins which results in being sequestered away from DNA and hence repression of transcriptional activity. Additionally, our results suggest that NeuroD2 and Id2 protein localization are dynamically co-regulated during neuronal differentiation. In young cortical neurons both NeuroD2 and Id2 are predominantly localized to the nucleus, however as neurons mature localization of both proteins shift to the cytoplasm. We continue to investigate the mechanisms of by which NeuroD2 regulates *id2* expression and how these two proteins interact during neuronal differentiation.

Keywords: NeuroD2, Id2, differentiation.

Oxidative stress and antioxidants in diabetic neuropathy

E. M. Guler[1], D. Borucu[2], A. D. Yalcin[2], A. S. Yalcin[1]
[1]*Biochemistry, Marmara University School of Medicine,* [2]*Neurology, Umraniye Training and Research Hospital, Istanbul, Turkey*

Oxidative stres occurs in a cellular system when the production of free radical moieties exceeds the antioxidant capacity of that system. If cellular antioxidants do not remove free radicals, radicals attack and Damage biomolecules such as carbohydrates, proteins, lipids, and nucleic acids. The oxidized and nitrosylated products of free radical attack have decreased biological activity, leading to loss of energy metabolism, cell signaling, transport, and other major functions. On the other hand, diabetes is characterized by chronic hyperglycemia that results dysregulation of cellular metabolism. Oxidative stres and free radicals play important key roles and significant mediators in the development of diabetic neuropathy. In our study, we have examined the contribution and roles of oxidative stres parameters and antioxidants in the pathogenesis of diabetic neuropathy. Blood samples were obtained from both Patients with diabetic neuropathy and healthy subjects. Superoxide dismutase and catalase activities as well as glutathione and glutathione-related antioxidant enzymes were examined in erythrocytes while lipid peroxidation and protein oxidation parameters were measured in plasma. Our results suggest a role for oxidant/antioxidant balance in diabetic neuropathy pathogenesis which may be applied to treatment protocols in the future.

Keywords: Antioxidants, Diabetic Neuropathy, Oxidative Stress.

PDGFRB mutations associated with idiopathic basal ganglia calcification impair the receptor activity and signaling

F. A. Arts, A. Velghe, J.-B. Demoulin
De Duve Institute, University of Louvain, Brussels, Belgium

Platelet-derived growth factor receptors (PDGFRα and PDGFRβ) are tyrosine kinase receptors that stimulate cell proliferation and motility and that are encoded by two different genes, *PDGFRA* and *PDGFRB* respectively. Recently, heterozygous *PDGFRB* mutations have been described in patients diagnosed with idiopathic basal ganglia calcification (IBGC) but were not characterized. Moreover, it was shown that these mutations were segregating with the disease. IBGC, also called Fahr disease, is a rare inherited neurological disease characterized by symmetric and bilateral calcifications which are mostly located in the basal ganglia, the dentate nucleus of the cerebellum and the cerebral cortex. The goal of the present study was to determine whether these mutations had a positive or negative impact on the PDGFRβ activity. Therefore, we stably expressed two different PDGFRβ mutants associated with IBGC, L658P and R987W, in HT-1080 cells. Their expression was confirmed by flow cytometry. Then, we analyzed the signaling pathways that are known to be activated by PDGFRβ. We observed that the L658P mutant did not activate any of these pathways in response to PDGF whereas the R987W mutant activated phospholipase Cγ (PLCγ) and Akt but not signal transducer and activator of transcription 3 (STAT3) after PDGF stimulation. These results were confirmed by luciferase assays in MCF7 and HT-1080 cells. *In vitro* kinase assays demonstrated that the L658P mutant had no kinase activity whereas the R987W mutant had a weaker activity than the wild-type receptor. To conclude, our results indicate that PDGFRβ mutations associated with IBGC impair the receptor activity and signaling. This is consistent with the recent description of loss-of-function mutations in the gene encoding the PDGF-B ligand. Our data suggest that a defect in STAT3 activation by PDGF may play a critical role in this disease.

Keywords: Fahr disease, PDGF receptor, STAT3.

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease affecting motoneurons in the brain and spinal cord leading to paralysis and death. Disruption of protein homeostasis at the endoplasmic reticulum (ER) and abnormal protein aggregation is a salient feature of ALS. Here we report several novel missense variants in two genes encoding key ER foldases (PDIA1 and PDIA3/ERp57) of the protein disulfide

© 2014 The Authors. FEBS Journal © 2014 FEBS

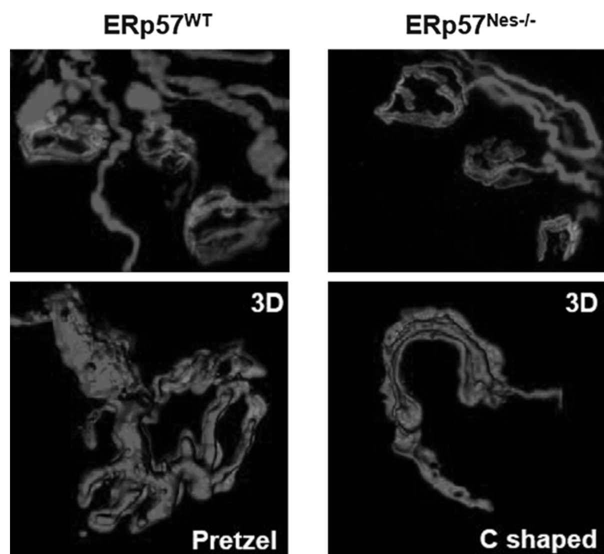

Fig. 1.

isomerase family in ALS patients. Initial phenotypic screening in zebrafish revealed that mutations in these genes can induce motor defects associated with a disruption of motoneuron connectivity and functionality. Consistent with this, expression of mutant PDIs impaired dendritic outgrowth in three different motoneuron cell culture models, including in human motoneurons derived from a human embryonic stem cell line. Cellular and biochemical studies identified distinct molecular defects that underlie the pathogenicity of these ALS-linked PDI mutants. Finally, specific deletion of ERp57 in the nervous system of mice led to a severe motor dysfunction associated with a loss of neuromuscular synapses. We speculate that persistent changes in cellular proteostasis, may result in perpetual decline of neuromuscular connectivity caused by decreased efficiency in the folding of synaptic proteins. Our findings argue strongly that the ER proteostasis is affected in ALS and that ER-protein misfolding mediated by the PDIA1 and ERp57 variants leads to ALS pathogenesis. This study identifies ER proteostasis imbalance as a risk factor to develop ALS.

Quercetin increases bioavailability of nitric oxide in jejunum in normoglycemic and diabetic rats and induces neuronal plasticity in the myenteric plexus

J. N. Zanoni[1], J. V. Colombo Martins Perles[2], S. R. Garcia de Souza[2], F. C. Vieira Frez[3], C. Melo[4], F. Guarnier[5]
[1]Morphological Science, State University of Maringa, Maringa, [2]Morphological Science, [3]Pharmaceutical Science, State University of Maringá, Maringá, [4]Biological Sciences, University of São Paulo, Bauru, [5]Pathological Science, State University of Londrina, Londrina, Brazil

The aim of the present study was to investigate the effect of quercetin on nitric oxide (NO) levels, lipid peroxidation, and total radical-trapping antioxidant potential (TRAP) using chemiluminescence techniques and assess different subpopulations of myenteric neurons: double-staining for neuronal nitric oxide synthase (nNOS) and the pan-neuronal marker anti-HuC/D and determining vasoactive intestinal peptide (VIP) immunoreactivity in the muscular layer of the jejunum from diabetic rat. Thirty-two male Wistar rats were divided into four groups: normoglycemic (C), normoglycemic supplemented with quercetin (Q), diabetic (D), and diabetic supplemented with quercetin (DQ). Supplementation with quercetin in normoglycemic and diabetic rats significantly increased NO tissue detection compared with the control group (Q group, $p < 0.05$; DQ group, $p < 0.001$). Lipid peroxidation was unaltered in the D group, but the DQ group exhibited a significant reduction ($p < 0.05$) of lipid peroxidation compared with the C group, which was followed by a significant decrease ($p < 0.01$) in the TRAP of the intestinal tissue. The assessment of the different subpopulations of myenteric neurons showed that supplementation with quercetin in diabetic animals prevented the diabetes-induced increase in the cell body area (6.44%) of nNOS-immunoreactive neurons and diabetes-induced increase in the area of VIP-immunoreactive varicosities (31.6%) and promoted an increase in the cell body area (16.11%) of HuC/D-immunoreactive neurons but did not prevent the diabetes-induced loss of HuC/D- and nNOS-immunoreactive myenteric neurons. Supplementation with quercetin increased the bioavailability of NO in the jejunum in normoglycemic and diabetic rats and induced neuronal neuroplasticity in the myenteric plexus in these animals.

Real time molecular dynamics of extracellular matrix components

K. Pilobello[1], K. Gerrow[2], A. Triller[1]
[1]Biologie, Ecole Normale Superieure, Paris, France, [2]Biology, University of Victoria, Victoria, BC, Canada

It has been established that extracellular matrix (ECM) components are actors in neuronal signaling. There is evidence of highly localized niches of extracellular matrix which suggests specific and fine functional control. During development, the ECM protein and carbohydrate composition changes with time. However, it is commonly believed that it is a relatively fixed structure topologically. Using confocal time-lapse microscopy (0.5–1 Hz) and single particle tracking (SPT) with quantum dots (QD), we demonstrate, in primary neuronal cell cultures, that extracellular matrix components are dynamic and that the diffusion rates of chondroitin sulfate and hyaluronan and associated molecular components change with maturation. At the synapse, ECM components display confined movements and the diffusion rate increases with maturation between DIV 10 (1×10^{-3} μm^2/sec) and DIV 15 (1×10^{-2} μm^2/sec). In extra-synaptic locations, the ECM components exhibit Brownian motion with relatively fast diffusion rates. The rates of diffusion of chondroitin sulfate components are influenced by pharmacological agents. On average, they slow down when neuronal activity is blocked (treatment with TTX) and accelerate when neuronal activity is increased (treatment with bicuculline or 4AP). These data show that the neuronal extracellular matrix is not a static structure and that its molecular movement is regulated by activity. Moreover, single particle tracking has revealed subpopulation of ECM. In DIV 30 cultured cells, chondroitin 6-sulfate is more frequently confined to synapses with a monomodal distribution of diffusion coefficients. Whereas, chondroitin sulfate monitored by the frequently used WFA lectin is extrasynaptic with a multimodal distribution. Thus, the heterogeneity of ECM and ECM binding protein microdomains is accessible using single particle tracking. This may in turn play a key role in activity dependent signaling and tuning the balance of excitation and inhibition.

Role of spinal melanocortins/melanocortin receptor MC3 system in the development of diabetes-induced neuropathy

I. Shymanskyy, M. Veliky
Medical Biochemistry, O.V. Palladin Institute of Biochemistry of NAS of Ukraine, Kyiv, Ukraine

Aims: One of the recent breakthroughs in pain research has been recognition that non-neuronal cells might play an important role in initiating and modulating activity in primary afferent nociceptors. This study was aimed at defining diabetes-related changes in the activity of glial cells in dorsal horns of the lumbar spinal cords. As the possible role of melanocortins (MC) in nociception has recently attracted attention in the field, we focused on an attempt to better define whether spinal MC/melanocortin receptor MC3 (MC3R) system contributes to neuropathic pain by evaluating the therapeutic efficacy of a specific MC3R agonist Dtrp-g-MSH.

Methods: After 4 weeks of streptozotocin-induced diabetes male C57Bl6/J mice were maintained with or without acute treatment with Dtrp-g-MSH (1 μM in 3 μl, intrathecal infusions). Neuropathy variables included motor and sensory nerve conduction velocities and tactile response (by flexible von Frey filament test). Glial cells markers (Iba-1 and GFAP), phosphorylated p38 MAP kinase and MC3R expressions were measured by spinal cord tissue immunostaining.

Results: Diabetic mice developed nerve conduction velocity deficits and tactile allodynia. Quantification of glial cell revealed prominent elevation of microglia in the dorsal horns, whereas a slight reduction in the number of astrocytes was established in diabetes. These alterations were accompanied by p38 MAP kinase activation in the spinal cord in diseased animals as it is evident from a substantial increase in the spinal levels of phosphorylated p38. It is noteworthy that p38 was activated in cells labelled with microglial marker Iba-1 antibodies but not in GFAP-expressing astrocytes. Acute intrathecal infusion of Dtrp-g-MSH to diabetic mice reversed neuropathic pain behaviour as early as the first hour after each of two administrations and its effect was maintained for 4 h. Dtrp-g-MSH administration was shown to decrease the number and activity of microglial cells. Agonist action was unlikely to be mediated via alterations in the expression of the MC3 receptors as no detectable changes in MC3R immunoreactivity in the dorsal horn were observed compared with vehicle-treated groups.

Conclusion: Taken together, current data suggest that diabetic neuropathy is associated with microglia activation in the dorsal horns and melanocortins/MC3R system might be involved in enhanced nociception. Our findings support the potential use of MC3R agonists to treat diabetes-induced neuropathy.

S-acylation in neurodegeneration

C. Diez, J. Greaves, L. Chamberlain
[1]Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK

Neuronal Ceroid Lipofuscinoses (NCLs) are a group of hereditary, progressive neurodegenerative disorders characterized by the accumulation of intracellular autofluorescent lipopigment (ceroid lipofuscin) in neurons and other cells of the body. This aggregation causes the loss of nerve cells in the brain, leading to neurodegeneration. Mutations in the DNAJC5 gene encoding cysteine-string protein (CSP) have been recently identified as the cause of autosomal-dominant adult-onset NCL (ANCL) (Hachiya et al. 2006; Nosková et al. 2011; Anderson et al. 2013). These mutations (L115R and ΔL116) are situated within the cysteine-string domain, a region of CSP that is extensively S-acylated. S-acylation is a post-translational modification consisting of the attachment of fatty acids to cysteine residues through a thioester bond.

We found that ANCL mutations cause CSP to form SDS-resistant aggregates, which are induced and maintained by S-acylation (Greaves et al. 2012). This observation is interesting as protein aggregation is a hallmark feature of different neurodegenerative conditions. The present study aims to extend upon these observations by assessing: (i) how ANCL mutations affect the intracellular localisation of CSP; (ii) the turnover and degradation of wild-type CSP and mutant CSP aggregates; (iii) how different fatty acids affect the aggregation of CSP mutants; and (iv) the potential of specific S-acyltransferase enzymes to serve as drug targets to prevent CSP aggregation in ANCL. Collectively, these analyses will

© 2014 The Authors. FEBS Journal © 2014 FEBS

shed light on potential mechanisms whereby CSP aggregates lead to ANCL and potential therapeutic mechanisms to treat this disorder.

Sensory dysfunction in oral mucosa of patients with fibromyalgia

D. Hellin Meseguer[1], P. Melgarejo Moreno[2]
[1]*Otorhinolaryngology, Reina Sofia Hospital, Murcia,*
[2]*Otorhinolaryngology, Santa Maria Hospital, Lleida, Spain*

Studies have described oral problems associated with fibromyalgia syndrome (FM), including sicca, oral ulcerations, and orofacial pain. Our preliminary observations on a small group of FM patients indicated a change in the non-nociceptive, tactile sensory function in oral mucosa and provided evidence for the hypothesis of a neuropathic etiology in orofacial pain.

In the present clinical study on a group of 5 FM patients were studied. The sensory nerve endings of the oral mucosa, were studied using electron microscopy analysis. The specimens were fixed and embedded for study. The nerve fibers in the oral mucosa were examined by electronic microscopical analysis for localization. These fibers run very close to the basal lamina of the epithelium and extend into the filliform and fungiform papillae. Electron microscopic observations showed clearly nerve fibers, which are located very close to the basal lamina of epithelial cells. Some electron-dense granules may be observed in the axoplasms.. The terminal axons revealed numerous mitochondria, neurofilaments, microtubules and clear vesicles in the base of axoplasmic protrusions. All the structures observed are involved in the transmission of pain and mechanoreceptors stimulus of these oral mucosae.

The present findings with strong evidence for neuropathic background in FM will hopefully provide insights for new therapeutic strategies.

Single molecule analysis reveals coexistence of stable serotonin transporter monomers and oligomers in the live cell plasma membrane

A. Anderluh[1], E. Klotzsch[1], A. H. Newman[2], H. H. Sitte[3], G. J. Schütz[1]
[1]*Applied Physics, Vienna University of Technology, Vienna, Austria,* [2]*National Institute on Drug Abuse, Baltimore, MD, USA,* [3]*Medical University of Vienna, Vienna, Austria*

The human serotonin transporter (hSERT) is responsible for the termination of synaptic serotonergic signaling. The formation of dimers of SERT in the plasma membrane has already been indicated by various approaches, including optical methods such as Förster resonance energy transfer (FRET) and classical biochemical ensemble analysis. However, neither application is suitable to yield quantitative interpretation and decipher the exact configuration of the oligomerization states; additionally, biochemical methods do not take the influence of the membrane environment into account. Here we used single molecule fluorescence microscopy to obtain the oligomerization state of SERT via brightness analysis of single diffraction limited fluorescent spots. The techniques applied in this study allow for identification and quantitative evaluation of subpopulations of SERT complexes exhibiting different degrees of oligomerization in a living cell. Heterologously expressed SERT was labeled either with the fluorescent cocaine derivate JHC 1-64, or via fusion to mGFP. We found a variety of oligomerization states of membrane-associated transporters, revealing molecular associations at least up to pentamers and demonstrating the coexistence of different degrees of oligomerization in a single cell; the data is in agreement with a linear aggregation model. The oligomerization was found to be independent of SERT surface density, indicating a stable interaction of the subunits. Therefore, we developed a special bleaching protocol to decipher the interaction kinetics of SERT oligomers; the complexes remained stable over several minutes in the live cell plasma membrane. Together, the results indicate kinetic trapping of preformed SERT oligomers at the plasma membrane. Indeed, by evaluating the oligomerization of SERT in the endoplasmic reticulum we show that the oligomerization process is chemically equilibrated at ER membranes; after trafficking to the plasma membrane, the SERT stoichiometry remains fixed.

STIM sensors as a molecular targets for memory loss treatment connected with calcium homeostasis impairments in Familial Alzheimer's Disease

M. Ryazantseva[1], K. Skobeleva[1], A. Panova[2], L. Glushankova[1], N. Kamyshev[2], E. Kaznacheyeva[1]
[1]*Institute of Cytology RAS,* [2]*Pavlov Institute of Physiology RAS, St. Petersburg, Russian Federation*

Familial Alzheimer's disease (FAD) which leads to memory impairments is caused by mutations in presenilin-1 (PS1) gene in approximately 50% of cases. PS1 is well known as a component of the gamma-secretase enzyme which cleaves APP to A-beta. To become a catalytic part of enzyme PS1 holoprotein undergoes an endoproteolysis. It was shown that FAD connected mutations in PS1 gene disrupt endoproteolysis increasing holoprotein level. In our study we found effects of FAD PS1 mutants (PS1DE9, PS1 D247A) on ER calcium storage and activity of store-operated and voltage-gated calcium channels in neurons and Neuro2a cell line. The PS1 endoproteolysis levels were estimated with SDS PAGE and western-blot of total cell lysates which demonstrated increased PS1 holoproteins levels. Disrupted channels activities were detected with direct single-cell electrophysiological measurements. Intracellular calcium concentrations were measured in calcium imaging experiments with fura2-AM. The effects were connected with calcium sensors STIM impaired signal transduction from ER to calcium channels in plasmatic membrane (PM) under control of ER calcium levels, which was demonstrated by experiments with sensors knock-downs. The impaired intracellular signal transduction by STIM sensors was revealed in live confocal imaging experiments. Moreover a feeding of Drosophila

Structural NMR study of the isolated voltage-sensing domain from the second pseudosubunit of human sodium channel Nav1.4

A. S. Paramonov[1], E. N. Lyukmanova[1], Z. O. Shenkarev[1], M. Myshkin[1], D. S. Kulbatskii[1,2], M. A. Shulepko[1,2], M. P. Kirpichnikov[1,2], A. Arseniev[1]
[1]M.M. Shemyakin & Yu.A. Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, [2]Lomonosov Moscow State University, Moscow, Russian Federation

Voltage-gated Na+ channels (Nav) are essential for signal transduction in nervous, cardiac, and muscle systems of multicellular organisms. These membrane proteins represent promising targets for treatment of epilepsy, psychotic syndromes, ataxia, migraine and chronic pain. In spite of the large significance for basic science and pharmacology applications little is known about Nav structure at atomic level. Polypeptide chain of eukaryotic Nav channel (α-subunit) encloses 24 transmembrane helices. This makes expression, purification and structural studies of full-sized Nav channels extremely difficult. Each α-subunit includes four pseudosubunits which form four voltage-sensing and one pore domain. This multidomain organization make possible to use 'divide and conquer' approach for studies of Nav channels.

Here we present the first structural study of isolated voltage-sensing domain from the second pseudosubunit of human Nav1.4 channel (VSD). VSD samples were produced by cell-free expression. To find optimal conditions for NMR structural study, the different types of membrane mimicking media (micelles of zwitterionic and anionic detergent, lipid/detergent bicelles) and sample conditions (pH, temperature, ionic strength) as well as several variants of VSD amino acid sequence were tested. It was found that the lyso-palmitoylphosphatidylglycerol (LPPG) micelles at pH 6.0 provided sufficient NMR spectra quality and sample stability. At this conditions, using ^{13}C,^{15}N-labelled VSD sample the nearly complete backbone and partial side-chain resonance assignments were obtained. The VSD secondary structure determined from the chemical shift values was in general agreement with the expected VSD topology and involved four conservative helical regions (S1-S4). However, two additional short helices were observed at the N-terminus of VSD. Moreover, unlike the situation observed in the VSDs of K+ channels, the S3 segment of VSD-Nav1.4 represents one continuous helix without pronounced hinges and kinks, and S4 helix contains the break at the level of R2 residue. The Mn^{2+} titration revealed that S1, S2 and S4 helices adopt transmembrane orientation within the micelle, but S3 is water accessible. These data revealed the formation of water-filled cavities in the spatial structure of micelle embedded VSD. Obtained ^{15}N relaxation data pointed to the enhanced mobility of the VSD loops in the ps-ns timescale. The overall reorientation of VSD/micelle complex in solution takes place with characteristic time ~15 ns (45 °C).

Structure and function of a sodium channel gating modifier from the crab spider *Heriaeus melloteei*

A. Berkut[1,2], M. Myshkin[1,2], S. Peigneur[3], A. S. Paramonov[1], E. N. Lyukmanova[1], Z. Shenkarev[1], J. Tytgat[3], A. Arseniev[1], E. Grishin[1], A. Vassilevski[1]
[1]M.M. Shemyakin & Yu.A. Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, [2]Moscow Institute of Physics and Technology (State University), Moscow, Russian Federation, [3]Laboratory of Toxicology and Pharmacology, University of Leuven, Leuven, Belgium

Voltage-gated sodium channels are critical for propagating action potentials in the nervous system. Their malfunction may lead to severe diseases, such as epilepsy, myotonia, long QT syndrome etc. Sodium channels are therefore considered as prospective drug targets. The known variety of sodium channel ligands is classified based on the interaction site and the produced effect. For instance, tetrodotoxin from the puffer fish is a classic pore blocker affecting site 1. Scorpion α-toxins bind to so-called site 3 and inhibit inactivation, whereas β-toxins bind to site 4 and promote activation of the channels. Here we present structural and functional studies of a sodium channel activation inhibitor from crab spider venom.

Hm-3 is a peptide toxin isolated from the spider *Heriaeus melloteei*, which consists of 35 residues. It was produced recombinantly in *Escherichia coli* with a yield of ~0.4 mg per 1 L of bacterial culture. Hm-3 solution structure was determined by NMR spectroscopy. It was found to adopt the so-called 'inhibitory cystine knot' fold stabilized by three disulfide bonds. Electrophysiological studies showed that at concentration of ~100 nM the toxin effectively inhibited both mammalian and insect sodium channels. What was more interesting, the toxin shifted the dependence of channel activation to more positive voltages. This effect is shared by a few other spider toxins, such as JZTX-III from *Chilobrachys jingzhao*, HWTX-IV from *Haplopelma schmidti*, and ProTx-I and II from *Thrixopelma pruriens*. This type of toxin is likely to bind to receptor site 4. To distinguish between site 1 and site 4 activity, competitive binding with tetrodotoxin was performed demonstrating a lack of pore blocking activity for Hm-3. Moreover, the toxin was shown to bind to both neutral and negatively charged lipid vesicles testifying in favor of a 'membrane-access' mode of Hm-3 action.

This work was supported by the Russian Foundation for Basic Research (grant number 12-04-01712), the Program of Molecular and Cell Biology of the Russian Academy of Sciences, and by the stipend of the President of the Russian Federation.

Studies of a glial-specific G-protein-coupled receptor GPR37L1

S. Jolly, N. Pringle, H. Zhuang, H. Li, W. D. Richardson
Wolfson Institute for Biomedical Research, University College London, London, UK

Glial cells are the most abundant cells in the brain. There is growing interest in the normal functions of glia and their potential roles in neurological diseases. It has long been known that oligodendrocytes (OLs, the myelin-forming cells) and their precursors (OPs, also known as NG2 glia) are critically involved in demyelinating diseases such as multiple sclerosis. More recently, astrocytes have been recognized as having essential physiological functions in the normal central nervous system

© 2014 The Authors. FEBS Journal © 2014 FEBS

(CNS) and have also been implicated in stroke, brain trauma, Alzheimer's disease, Parkinson's disease, motor neuron disease and Rett syndrome. Our understanding of glial heterogeneity is limited. For example, astrocytes have been classified according to their morphology (e.g. fibrous versus protoplasmic astrocytes in the white and grey matter respectively) but little is known regarding their molecular and regional diversities. The molecular characterization of different subsets of astrocytes could shed light on their functions in various regions of the brain.

The superfamily of G-protein-coupled receptors (GPCR) is a large family of seven-pass transmembrane proteins. The majority of these bind specific extracellular ligands, which trigger an intracellular response. GPCRs are major drug targets; it has been estimated that more than half of clinically useful drugs interact with these receptors. We conducted a visual screen of expression patterns in the Allen Brain Atlas for gene products that seemed likely to mark glial cells and analysed these further by *in situ* hybridization and immunocytochemistry. Among several genes picked in this way, we found one GPCR (GPR37L1) that is expressed exclusively in glia. GPR37L1 is first expressed at early postnatal stages (P7-P14), at the onset of synaptogenesis, and maintains its expression into adulthood. It is expressed throughout the adult brain and spinal cord in subsets of astrocytes and OPs. To explore the functional properties of GPR37L1 and its potential role in neuromodulation or myelination, we generated several transgenic lines: GPR37L1-null and over-expressing mice, mice that express the Diptheria toxin A chain (DTA) in GPR37L1-positive cells and lines that conditionally express green fluorescent protein (GFP) and/or tandem-duplicated Tomato (tdTom) in GPR37L1 cells. Preliminary examination of GPR37L1 knockout mice suggests that this receptor might be involved in synaptic function in the hippocampus.

Study the specificity of mutants forms of extracellular domain of α7 neuronal nicotinic acetylcholine receptor

L. Ojomoko[1], E. Spirova[2]
[1]Institute of Bioorganic Chemistry RAS, [2]Moscow State University, Moscow, Russian Federation

Neuronal nicotinic acetylcholine receptors (nAChR) are widely represented in the central nervous system (CNS). Cholinergic innervation in the CNS, acting through nAChR, regulates the processes of mediator release, neuronal excitability, which affects a number of physiological and cognitive functions. α7 nAChR – one of the most widely presented neuronal nAChR subtype in in CNS, which dysfunction associated with diseases such as schizophrenia, Alzheimer's, Parkinson's, nicotine addiction. α7 nAChR is a target for many drugs, therefore, binding of ligands mechanisms and spatial structure of the receptor of interest for investigation.

Chimeric receptor α7/GlyR is an appropriate model for the study of the extracellular domain of α7 receptor [1, 2]. Using α7/GlyR facilitates some stages of the experiment. Based on bioinformatics and computer modeling data it had been hypothesized that the replacement of Tyr168 and Glu189 in extracellular domain to alanine will affect the specificity of the interaction α7/GlyR with agonists. The methods of site-directed mutagenesis in the coding sequence of α7/GlyR chimera were introduced appropriate replacements. Expression of of α7/GlyR and Tyr168Ala, Glu189Ala mutant forms was carried out in oocytes *Xenopus laevis*.

The results of two-electrode voltage clamp measurements revealed that the value of EC_{50} mutants Tyr168Ala and Glu189Ala for acetylcholine decreased by 38% and 49%, respectively, and for — nicotine decreased by 49% and 43%, respectively, compared with α7/GlyR.

The results obtained that introduction of an alanine residue at position 168 or 189 of the extracellular domain increases the α7/GlyR affinity for acetylcholine and nicotine. Thus, it is experimentally confirmed that Tyr168 and Glu189 do not contact to agonist but in the same time contribute to low affinity of α7/GlyR.

[1]Analysis and Control Laboratories of General Directorate of Pharmaceuticals and Pharmacy, Ministry of Health of Turkey, 06100 Sıhhiye, [2]Department of Biochemistry, Faculty of Pharmacy, [3]Department of Biochemistry, Faculty of Pharmacy, Hacettepe University, 06100 Sıhhiye, Ankara, [4]Department of Bioinformatics and Genetics, Faculty of Engineering and Natural Sciences, Cibali Campus, Kadir Has University, 34083 Fatih, Istanbul, [5]Department of Pharmaceutical Chemistry, Faculty of Pharmacy, Ankara University, 06100 Tandogan, Ankara, Turkey

The monoamine oxidase (MAO), a mitochondrial outer membrane enzyme, catalyzes the oxidative deamination of biogenic amines. MAO exists in two isoforms as MAO-A and -B (1). Selective MAO-A inhibitors are widely used in the treatment of depression and anxiety while selective MAO-B inhibitors are used in the treatment of Alzheimer's and Parkinson's diseases (2,3). Most of the prodrug-based MAO inhibitors having hydrazine, hydrazide and amine moiety such as isocarboxazid, phenelzine and moclobemide show prominent antidepressant activity (4). Earlier studies demonstrated MAO inhibitory activities of 2-pyrazolines (4-6). Hydrazone compounds also have antidepressant activities (4). Based on the above literature and in pursuing our previous research concerning to the synthesis of novel selective MAO inhibitors, we report here the synthesis, docking studies and hMAO inhibitory activity of some new 2-pyrazoline and hydrazone derivatives. Chemical structure of the compounds have been elucidated by their IR, ^{1}H NMR, Mass, and elementary analysis data. All compounds inhibited hMAO isoforms competitively and reversible. Compound **VIr,** which carries 2-hydroxy-4-methoxyphenyl group at the 3rd position and 2-methoxyphenyl group at the 5th position of the 2-pyrazoline ring, showed the highest hMAO-A inhibitory activity with a Ki value at nM concentration. Newly synthesized compounds were docked computationally to the active site of the hMAO-A and -B forms, and the data indicated a significant correlation between the docking results and experimental ones. Further derivatives should be prepared to explore the possibility of getting a potent and selective hMAO-A inhibitor of this kind.

Systematic study on alpha-Synuclein internalization and accumulation

J. Gerez, P. Picotti

D-Biology, Swiss Federal Institute of Technology Zurich (ETHZ), Zurich, Switzerland

Background: Parkinson's disease (PD), a progressive neurological disorder of unknown etiology, is characterized by two processes, massive death of neurons of the subtantia nigra pars compacta and accumulation of insoluble inclusions enriched in unfolded alpha-Synuclein (aSyn) called Lewy Bodies (LB). Recent works have shown that uptake of extracellular aSyn can enormously contribute to LB formation, however, the molecular species responsible for aSyn internalization and accumulation have not been systematically characterized. In this study, we studied the ability of structurally different aSyn species to be internalized and accumulate in neuronal cells.

Observations: In order to study internalized aSyn accumulation, SH-SY5Y neuronal cells were treated with 13 structurally different aSyn species, including monomers, oligomers and fibrils. Internalized aSyn was quantified by Selected Reaction Monitoring mass spectrometry (SRM) and confocal microscopy. We found that insoluble aSyn fibrils are efficiently internalized and accumulate in neuronal cells. aSyn uptake was strongly dependent on the insolubility of the fibrils, which are internalized in a dose and time-dependent manner. In contrast to insoluble higher-order structures, we did not observe accumulation of aSyn monomers, oligomers, or dissociable fibrils. Importantly, accumulation of insoluble fibrils leads to a significant reduction of cell viability. We then assayed the ability of cell-produced aSyn to be internalized, and established a cellular model system to produce fibrillar aSyn in neuronal cells. These cells were used to set up a cell-to-cell propagation assay. We observed transmissibility of high-molecular weight aSyn, indicating that donor cells secrete aSyn fibrils, which are internalized by acceptor cells. Finally, and in order to characterize the cellular responses to aSyn accumulation, we quantified the proteomes of cells treated with monomeric, oligomeric and fibrillar aSyn using a mass spectrometry-based approach. We found pronounced proteomic changes in cells treated with insoluble aSyn fibrils, indicating that aSyn accumulation leads to a substantial cellular response.

Conclusions: By establishing a novel cellular model system that recapitulate some aspects of the cell-to-cell propagation of pathological aSyn and Parkinson's Disease pathology, we found that insoluble aSyn fibrils are efficiently internalized and accumulate in neuronal cells, leading to impaired cell viability and substatial proteomic changes.

Systemic approaches to identifying mobile homeodomain transcription factors

E. J. Lee, J. W. Kim

Biological Sciences, Korea Advanced Institute of Science and Technology, Deajeon, Korea

Owing to the inherent function as transcription regulators, the homeodomain transcription factors (HM-TFs) have been believed to function in the nuclei of cells that expressing them. However, several HM-TFs have been identified as having unexpected non-cell autonomous functions in developing nervous system. The HM-TFs, including Engrailed-2, Pax6, Otx2, and Vax1, can be secreted out from the cells express their transcripts and move into neighboring cells that don't express the transcripts. The secretion and internalization of HM-TFs were shown to be mediated by secretion (Sec) and penetration (Pen) motifs in homeodomains. Although the Sec and Pen sequences are highly conserved in most HM-TFs, which are over 200 in human genome, it is still unclear all HM-TFs possess these unconventional biophysical properties. Here, we evaluated secretion of 168 human HM-TFs in culture cell-lines by semi-quantitative dot blot method. Our screening results indicate that differential secretion properties of each sub-homeodomain class; importance of extra-homeodomain motifs for HM-TF secretion.

Keywords: homeodomain transcription factor.

MON-394
Systemic oxidative stress might be in the path from normal cognitive function to dementia: data from cross-sectional and longitudinal study

A. Romani[1], E. Cremonini[1], C. Cervellati[1], C. Bosi[2], S. Magon[2], M. Squerzanti[1], C. M. Bergamini[1], G. Zuliani[2]

[1]*Biomedical and Specialist Surgical Sciences,* [2]*Department of Medical Science, University of Ferrara, Ferrara, Italy*

Growing evidence from *in vitro* and animal model experiments suggest a role of oxidative stress (OxS) in the pathogenesis of late Alzheimer's disease (LOAD) and vascular dementia (VAD). However, the definitive appreciation of the involvement of OxS in these two most common forms of dementia-related diseases need a confirmation in a population-based study on a large sample. The aim of our study was to investigate the possible relationship between OxS and the onset and clinical progression of LOAD and VAD. To achieve this purpose a sample of 431 older individuals: 101 LOAD, 43 VAD, 188 mild cognitive impairment (MCI, pre-dementia condition) and 99 healthy controls were enrolled and assessed for serum levels of hydroperoxides (HY; i.e., by products of lipid peroxidation), total amount of non-enzymatic antioxidants (RAP), uric acid (UA), thiols (TH) and advanced oxidation protein products (AOPP). In addition, a subgroup ($n = 126$) of MCI patients were followed-up for averagely 2 years to evaluate if baseline levels of OxS markers were either related or not to the conversion to LOAD or VAD. Multivariate analysis (covariates: age, gender, smoking and comorbidities) of our cross-sectional data showed a significant ($p < 0.01$ for all) decrease of RAP levels compared to controls in MCI (−24.5%), LOAD (−24.2%) and VAD (−29%) patients. On the other hand, HY emerged as significantly higher ($p < 0.05$) in LOAD patients

© 2014 The Authors. FEBS Journal © 2014 FEBS

(+30.6%), (but not in MCI and VAD) with respect to healthy. Multivariate logistic regression highlighted the presence of a similar unfavourable oxidative balance (high HY and low RAP) in MCI (O.R.: 4.87; 95%CI: 1.02–23.55) and LOAD (O.R.: 6.99; 95%CI, 1.87–25.21). Noteworthy, no differences were found in OxS markers between MCI patients who converted to LOAD (n = 29) or to VAD (n = 15) and those that remained stable (n = 82) after follow-up time. Overall, our results suggest that systemic redox imbalance might be a significant feature of early stage of dementia. Moreover, the similar (deranged) oxidative profile in MCI and LOAD, could account for the observed inability of OxS markers to predict the conversion from prodromal phase to dementia.

Tetrahydropalmatine to rats ameliorates development of anxiety and depression related symptoms induced by singles prolonged stress

B. Lee, B. Sur, I. Shim, H. Lee, D.-H. Hahm
AMSRC, Kyung Hee University, Seoul, Korea

Abnormal adaptation of the stress-response system following traumatic stress can lead to an altered hypothalamic-pituitary-adrenal (HPA) axis that may contribute to post-traumatic stress disorder (PTSD) development. The present study was designed to investigate the anxiolytic-like and antidepressant activity of tetrahydropalmatine (THP) in an experimental rat model of anxiety and depression induced by single prolonged stress (SPS) animal model of PTSD by several behavioral tests. For 8 consecutive days, male rats were treated intraperitoneally (i.p.) with vehicle or varied doses of THP, 30 min prior to SPS. Daily THP (50 mg/kg) administration significantly increased open arms visits in the elevated plus maze (EPM) test, spent longer time in open arms, had lower anxiety index, higher risk assessment, and more head dips over borders in open arms performed after SPS. They also exhibited spent longer time in the center of the open filed, reduced grooming behavior in the elevated plus maze (EPM) test, and reduction of immobility time in the forced swimming test (FST). It also blocked the increase in neuropeptide Y (NPY) and decrease in corticotrophin-releasing factor (CRF) expression in the hypothalamus. This is the first study revealing pronounced anxiolytic-like and antidepressant effects of THP on development of behavioral and biochemical symptoms co-morbid with PTSD, indicating its prophylactic potential. Thus, THP reversed several behavioral impairments triggered by the traumatic stress of SPS and has potential for non-invasive PTSD therapeutic intervention.

The M146V mutation in presenilin-1 gene cause disruption of calcium homeostasis

K. Skobeleva, M. A. Ryazantseva, E. V. Kaznacheeva
Ion Channels of Cell Membranes, Institute of Cytology RAS, St. Petersburg, Russian Federation

Mutations in presenilin-1 (PS1) gene are found in approximately 40% cases of Familial Alzheimer's disease (FAD). The M146V mutation in PS1 gene causes disruption of calcium homeostasis. We aimed to detect channels types involved in the calcium homeostasis impairments. Calcium imaging experiments were performed with Fura2-AM with human neuroblastoma SK-N-SH cell line, transfected with PS1-M146V mutant or PS1-WT as a control. To measure calcium concentration in endoplasmic reticulum (ER) we used ionophore ionomycin. The PS1-M146V expression elevated the calcium concentration in ER comparing to control value. There are two calcium sensors in ER which activate store-operated calcium channels in case of decrease in free calcium concentration in ER. Sensor STIM1 has higher affinity to calcium than sensor STIM2 and works in 'all-or-nothing' way as it needs strong signal for activation. On the other hand spontaneous activity of STIM2 is known to be important for refilling ER calcium stores. Knockdown of STIM2 as well as SOC channel subunit TRPC1 with shRNA recovered the calcium concentration in cells with PS1-M146V mutant to control values. We measured SOC entry induced by thapsigargin (inhibitor of calcium ATPase of ER). In 9 hours after transfection SOC entry was higher in cells expressing mutant than in control cells, but after 24 hours of mutant expression SOC entry was suppressed comparing to control. Therefore cells expressing PS1 M146V might had spontaneous SOC entry through TRPC1-formed channels driven by STIM2 that preceded detected total SOC entry reduction due to inactivity of STIM1 sensor. Experiments on primary cultures of mouse hippocampal neurons revealed the increase in ionomycin sensitive pool and reduction of SOC entry in neurons expressing PS1 M146V mutant comparing to control as well. Active STIM1 is known to be an inhibitor of L-type voltage-gated calcium channels. Depletion of internal calcium stores in free-calcium solution following by depolarization with 140 mM KCl in 2 mM calcium solution revealed that voltage operated calcium entry in neurons expressing PS1 mutant was higher than in control. Thereby we concluded FAD PS1-M146V mutant ceases a misbalance in STIM sensors activity that leads to overload of internal calcium stores and interfere with store-operated channels activation and voltage-gated calcium channels inhibition.

The molecular aspects of peptide regulation of Glutamate and GABA- ergic receptor systems functional activity

T. V. Vyunova, L. A. Andreeva, K. V. Shevchenko, N. F. Myasoedov
Sector of Regulatory Peptides of Department of Physiologically Active Substances Chemistry, Institute of Molecular Genetics of Russian Academy of Sciences, Moscow, Russian Federation

The processes of normal functioning of nerve cells, ensuring intercellular signaling, synchronization of neural activity, etc. will largely depend on the chemical environment of cells, the presence of neurotransmitters and readiness of receptor cell systems to interact with signaling molecules. The main endogenous neurotransmitters of cellular excitation and inhibition processes are glutamate and GABA. Medical action of many drugs is based on the modulation of receptors binding functional activity. In the work presented, we have studied the molecular base of action of short synthetic neuropeptides with double psychotropic effects (nootropic and anti-anxiety) - Selank (used in clinical practice) and its C-terminal fragment (RPGP). Were also researched molecular effects of potential neuroleptics - biologically active analogues of neurotensin: WPYF and APYF. By using the radioligand-receptor method of analysis of specific intermolecular interactions we found that neuropeptides above able to modulate [^{3}H]GABA and [^{3}H]Glu specific binding to rat brain cells plasmatic membranes. The quantitative assessment of regulatory peptides impact on specific binding of [^{3}H]GABA

© 2014 The Authors. FEBS Journal © 2014 FEBS

shown the existence of two areas of peptides concentration, which is a sharp (almost two-fold) increase in the specific binding. So, for Selank it makes from 5 nM to 20 nM and from 5 mkM up to 50 mkM. In addition, it was shown that in the presence of ultralow concentrations of peptides (from 1 pM to 10 pM), exist the increase (in 1.5 times) in the number of binding places of tritium labeled GABA. At the next stage of research we tested the joint introduction of synthetic peptides and different GABA(A) receptors allosteric modulators (some of them use in clinical practice, like Diazepam). It is shown that in the presence of one of the neuropeptides (Selank and other) and one of known allosteric modulators of the GABA(A) receptor there is a formation of cooperative effects of specific [^{3}H]GABA binding. Neuropeptides above shown a good influence on [^{3}H]Glu specific binding as allosteric modulators in wide range of peptide concentrations. Also we study the 'ex vivo' effects of delayed in time after intranasal delivery of the neuropeptides influence on specific [^{3}H]GABA binding. In two hours after administration of neuropeptides some changes in the number of binding sites and in the affinity of specific [^{3}H]GABA binding were observed. Thus, we can conclude that neuropeptides with anxiolytic effects (Selank and other) able to make modulatory changing in specific GABA and Glu binding, and also can cause changes in functional activity of receptors by starting cell biochemical mechanisms (when peptide molecules presence is need no more).

The protective effects of tideglusib against NMDA receptor activation in neural stem cells

G. Armagan[1], T. Dagci[2,3], A. Keser[2,3]
[1]Biochemistry, Ege University, Faculty of Pharmacy, [2]Physiology, Ege University, Faculty of Medicine, [3]Center for Brain Research, Ege University, Izmir, Turkey

N-methyl-D-aspartate (NMDA) receptor is a subtype of the ionotropic glutamate receptors. It plays important roles in brain function, brain development, learning, memory and neurotoxicity. These receptors are major pharmacological targets to prevent or reduce the progression of neurodegenerative diseases where NMDA receptor overactivation occurs. Successful therapy with NMDA receptor antagonists in humans has been limited by the severe side effects of complete receptor blockade. The aim of the present study was to investigate the possible protective effects of tideglusib, a glycogen synthase kinase-3 inhibitor, against NMDA receptor overactivation induced by NMDA and D-serine in neural stem cells. We measured the alteration in membrane integrity, free radical generation, intracellular Ca^{2+} accumulation and mitochondrial membrane potential following treatments. We found that NMDA treatment, alone or with the combination of D-serine, significantly increased LDH leakage and triggered cell death in neural stem cells. Reactive oxygen species (ROS) formation and intracellular Ca^{2+} levels were increased following NMDA receptor overactivation as well. Furthermore, the significant reduction in mitochondrial membrane potential was found in NMDA/D-serine-treated cells. On the other hand, treatment with tideglusib significantly decreased ROS production, membrane degradation, but did not change intracellular Ca^{2+} levels following NMDA receptor activation. Both in the presence or in the absence of NMDA/D-serine, tideglusib had no effect on mitochondrial membrane potential. As a conclusion, tideglusib may be considered as a neuroprotective agent against NMDA receptor-mediated excitotoxicity in the brain, but data obtained by Ca^{2+} measurements showed that the protection by tideglusib was far from NMDA receptor inactivation. Our preliminary results suggest that the mechanisms involved in ROS generation or mitochondrial dysfunction may be crucial targets for tideglusib against neurodegeneration triggered by NMDA receptor overactivation.

Keywords: excitotoxicity, neuroprotection, tideglusib.

MON-399
The role of peripheral anionic site in binding of Toluidine blue O to human butyrylcholinesterase

K. Biberoglu, S. Turk Ghasemi, **M. Yuksel Tek**, O. Tacal
Department of Biochemistry, School of Pharmacy, Hacettepe University, Ankara, Turkey

Toluidine blue O (TBO) is a cationic phenothiazine dye which is widely employed in the staining applications. Previously, TBO has been reported as an antifungal and antibacterial drug for the inactivation of yeast and some gram-positive/negative bacteria. Our recent kinetic studies have showed that TBO is a potent inhibitor of human plasma butyrylcholinesterase (BChE) (K_i = 7 nM) as well as human erythrocyte acetylcholinesterase (AChE) (K_i = 46 nM). Considering that TBO may be a potential drug candidate for Alzheimer's disease, in the present study, we investigated the role of peripheral anionic site (PAS) in inhibition of human butyrylcholinesterase by TBO. Site-directed mutants of BChE with PAS modifications were generated by PCR-mediated site-directed mutagenesis. Recombinant wild-type and mutant BChEs were expressed in human embryonic kidney cells in serum free medium and then purified by DEAE-Trisacryl anion exchange and procainamide-Sepharose affinity chromatography. The inhibitory effects of TBO on wild type and mutant BChEs were studied spectrophotometrically at 25 °C, in 50 mM MOPS buffer (pH 8), containing 0.025–0.4 mM butyrylthiocholine as substrate, and
0–8 μM TBO. TBO acted as linear mixed type inhibitor of A277W, Y332A and Y332A/A277W. Based on the rapid equilibrium inhibitory model, K_i values for A277W, Y332A and Y332A/A277W were 0.11 ± 0.01 μM, 0.42 ± 0.06 μM and 0.30 ± 0.014 μM, respectively. On the other hand, TBO caused complex nonlineer inhibition of wild type BChE and T120F. K_i values determined by nonlinear regression analysis were 0.007 μM (for wild type) and 0.297 μM (for T120F). Inhibition studies showed that the mutations in peripheral anionic site of human BChE cause a 15–60-fold increase in K_i value, compared to recombinant wild-type. These results suggest that peripheral anionic site of human BChE may contribute in binding of TBO to enzyme.

Thrombolysis affects leucine serum level during ischaemic stroke

A. Horecka[1], M. Szpetnar[2], A. Hordyjewska[1], P. Golab[3], J. Kurzepa[1]
[1]Chair and Department of Medical Chemistry, [2]Medical University of Lublin, Lublin, [3]The Holy Family Specialist Hospital, Rzeszów, Poland

Introduction: Several compounds specific to neurons or glial cells are releasing through damaged blood-brain barrier into the circulation during ischaemic stroke (IS). Branch chain amino acids (BCAAs) were considered as a potential biomarker of numerous diseases including cerebrovascular diseases. The

© 2014 The Authors. FEBS Journal © 2014 FEBS

decrease of BCAAs during acute phase of IS has been noticed previously. However, there is no information about the influence of intravenous thrombolytic treatment with recombinant tissue plasminogen activator (rtPA) on BCAAs serum level. In addition, the relationship between patients' neurological status and BCAAs level during acute phase of IS is also unknown.

Material and Methods: Seventeen ischaemic stroke patients and ten healthy controls were enrolled into the study. Seven of them underwent intravenous thrombolytic therapy with rtPA (rtPA group). The serum samples were obtained at 3 time-points in rtPA group (time-point 0: 1st – 4th hour of stroke; time-point 1: immediately after rtPA administration; time-point 3: on day 5–7 from stroke onset). Remaining stroke patients (without thrombolysis, n = 10) had venous blood collection at two time-points: time-point 1: 5th – 10th hour of stroke and time-point 2: on day 5–7 of stroke. Control serums were obtained once. Before the analysis samples were deproteinised with 6% sulphosalicylic acid in lithium–citrates buffer (pH 2.8) and centrifuged. BCAAs were determined by the automated ion-exchange chromatography with five lithium-citrate buffers using Amino Acids Analyser (AAA 400) by INGOS Corp., Praha, Czech Republic. Amino acids were separated using analytic column OSTION LG FA. The amino acids were identified in comparison to the standards provided by INGOS Corp. The original software MIKRO version 1.8.0 (INGOS) was used for BCAAs evaluation. The amino acids serum level was expressed in microM/ml.

Results: The leucine and valine serum level was gradually increased at time-point 1 and 2 in comparison to the time-point 0 in rtPA group. In addition the leucine level was significantly higher at time-point 1 of rtPA group compared to corresponding time-point at group non treated with rtPA or control patients (median value: 0.134 versus 0.089 or 0.099 microM/ml in rtPA versus non-rtPA or control groups respectively, $p < 0.05$). Neither the significant fluctuation of isoleucine serum level nor the relationship between BCAAs serum level and the degree of neurological deficits was observed.

Conclusion: We suggest that the increase of leucine serum level in patients treated with rtPA could be the indicator of quickened recanalization resulting in the washing out of leucine from the ischaemic focus.

Keywords: ischaemic stroke, thrombolysis, branched chain amino acids.

MON-401
Toluidine Blue O is a potent inhibitor of human cholinesterases

K. Biberoglu, S. Turk Ghasemi, O. Tacal
Department of Biochemistry, School of Pharmacy, Hacettepe University, Ankara, Turkey

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by synaptic loss, impairment of cholinergic function and abnormal protein depositions in brain. The symptomatic treatment of AD is based on the enhancement of cholinergic function by cholinesterase inhibition. Human brain contains two major forms of cholinesterases: acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). In healthy human brain, AChE activity is higher than BChE activity. In AD, AChE activity decreases while BChE activity increases with disease progression.

In this study, we tested inhibitory effects of three cationic phenothiazine dyes [(toluidine blue O (TBO), thionine (TH) and methylene violet (MV)] and a structurally related phenazine dye, neutral red (NR) on human plasma BChE. Human plasma BChE was purified from outdated human plasma by DEAE-Trisacryl anion exchange chromatography and procainamide- Sepharose affinity chromatography. Inhibition studies were performed at 25 °C in the assay mixture containing 50 mM MOPS buffer pH 8, 0.125 mM 5,5′-dithiobis (2-nitrobenzoic acid), 0.025–0.4 mM butyrylthiocholine and 0–80 μM dye. Kinetic analyses yielded following information: MV acted as a linear mixed inhibitor of human BChE with K_i value of 1.42 μM. TBO, TH and NR caused nonlinear inhibition of human BChE pointing to cooperative binding at two sites. K_i values for TBO, NR and TH estimated by nonlinear regression analysis were 0.007 μM, 0.93 μM and 2.0 μM, respectively. The inhibitory effect of TBO was also tested on human erytrocyte AChE using acetylthiocholine as substrate. TBO acted as linear mixed type inhibitor of human erytrocyte AChE with K_i value of 0.046 μM. Our kinetic results indicate that TBO is a potent inhibitor of human cholinesterases with K_i in nM range. We suggest that it may be a potential drug candidate for treatment of Alzheimer's disease.

Variability of potassium channel blockers in *Mesobuthus eupeus* scorpion

A. Kuzmenkov, A. Vassilevski, K. Kudryashova, O. Nekrasova, A. Feofanov, M. P. Kirpichnikov, E. Grishin
IBCh, Moscow, Russian Federation

The lesser Asian scorpion *Mesobuthus eupeus* (Buthidae) is one of the most widely spread species of the genus *Mesobuthus*, and its venom is thoroughly investigated. Currently, two main strategies are used in animal toxin research. One is direct isolation of toxins by chromatographic methods and the other is based on cDNA cloning and analysis. Nevertheless, considerable amount of active compounds remain elusive due to the high complexity of *M. eupeus* venom.

Here we present a comprehensive study on the variability of potassium channel blockers in *M. eupeus*. We combine methods from both strategies, including multi-dimensional chromatography, mass spectrometry, venom gland transcriptome sequencing and computational analysis. As a result, we report in total 59 candidate potassium channel toxins assigned to two types of fold. Nine toxins were found to effectively interact with some potassium channel isoforms, and six of them represent novel Kv1.1 and Kv1.3 ligands that may find future application in drug development. We rationalize that our integrated approach is a powerful method to characterize potassium channel toxins from scorpions.

This work was supported by the program for fundamental research of the Presidium of Russian Academy of Sciences no. 24 and by the stipend of the President of the Russian Federation.

Recent works suggest that α-synuclein assemblies propagate in a prion-like manner, thus contributing to Parkinson's disease pathology. The interaction of exogenous α-synuclein assemblies

© 2014 The Authors. FEBS Journal © 2014 FEBS

with neuronal plasma membrane and proteins is poorly documented. Using single particle tracking and immunofluorescence studies, we observed that α-synuclein assemblies form aggregates on the neuronal plasma membrane. A fraction of these aggregates are localized at synapses both *in vitro* and *in vivo*. The presence of α-synuclein aggregates impaired stimulus-evoked Ca^{2+} and Na^{+}-flux in neurons as measured by Ca^{2+}- and Na^{+}-imaging respectively. Lastly, using proteomics approach, we have identified several α-synuclein interacting membrane proteins. Our results demonstrate that the interaction of extracellular α-synuclein initiates a signaling cascade leading to an impaired ion-gradient in neurons.

Artificial analogues of small nucleolar RNAs modulate the gene expression in human cells

G. Stepanov, D. Semenov, J. Filippova, E. Kuligina, O. Koval, V. Richter
Laboratory of Biotechnology, Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

In order to analyze the regulatory potential of artificial small nucleolar RNAs (snoRNAs), the series of box C/D snoRNA analogues were designed and synthesized. Synthetic RNAs hold canonical elements of human snoRNAs, such as U24 and U25, and novel guide sequences, so these RNAs were targeted at modifying nucleotides of different types of cellular RNAs. We have found that such RNA-constructions directed to pre-mRNA nucleotides affected splicing of target RNA and suppressed the mature mRNA level [1, 2]. Our results have shown possibility to use artificial box C/D snoRNAs as specific gene regulators.

Moreover the transfection with box C/D RNAs analogues was found to decrease human adenocarcinoma cell viability. To reveal the characteristic features of the influence of snoRNAs on gene expression we analyzed whole transcriptome of human adenocarcinoma cells MCF-7 with Illumina HT microarrays. It was found that genes relating to innate immune response and apoptotic cascades were activated in cells transfected by artificial snoRNAs compared with control cells. The data suggest that box C/D RNAs are able to act as mediators of cellular stress and modulate cell viability and proliferation via stress signal cascades. Interestingly, the list of RNAs with increased level included several miRNAs. Further bioinformatic analysis allowed us to establish that the box-C/D-RNA-dependent activation of these miRNAs induced downregulation an extensive mRNA group. The last fact sheds light on the relationship regulatory pathways controlled by different types of small non-coding RNAs.

Biochemical characterization of two Cas5d ribonucleases in CRISPR-mediated microbial immunity

E. Bae[1], D. Ka, N. Suh[2,3]
[1]*Department of Agricultural Biotechnology, Seoul National University,* [2]*Department of Medicine, University of Ulsan College of Medicine,* [3]*Asan Institute for Life Sciences, Asan Medical Center, Seoul, Korea*

Clustered regularly interspaced short palindromic repeats (CRISPRs) and CRISPR-associated (Cas) proteins constitute an RNA-guided microbial immune system against invading foreign genetic materials. Cas5 proteins belong to one of the most prevalent Cas protein families in CRISPR-Cas systems and are predicted to have RNA recognition motif (RRM) domains. Cas5d is a subtype I-C-specific Cas5 protein that can be divided into two distinct subgroups, one of which has a long C-terminal tail while the other contains an insertion in the middle of its N-terminal RRM domain. Here, we report crystal structures of two Cas5d proteins from *Streptococcus pyogenes* and *Xanthomonas oryzae*, which respectively represent the two Cas5d subgroups. Despite a common domain architecture consisting of an N-terminal RRM domain and a C-terminal β-sheet domain, the structural differences between the two Cas5d proteins are highlighted by the presence of an extended helical region protruding from the N-terminal RRM domain of *X. oryzae* Cas5d. Cas5d proteins contain not only specific endoribonuclease activity for CRISPR RNAs but also non-specific double-stranded DNA binding affinity. These findings suggest that Cas5d may play multiple roles in CRISPR-mediated immunity. Furthermore, the specific RNA processing was also observed between *S. pyogenes* Cas5d protein and *X. oryzae* CRISPR RNA and vice versa. This cross-species activity of Cas5d provides a special opportunity for elucidating conserved features of the CRISPR RNA processing event.

Characterization of stress-inducible ncRNAs in *L. monocytogenes*

M. Mollerup, A. Lund, E. M. S. Lillebæk, B. H. Kallipolitis
Department of Bichemistry and Molecular Biology, University of Southern Denmark, Odense M, Denmark

Listeria monocytogenes is a Gram-positive, intracellular foodborne pathogen. It is the causative agent of listeriosis, a severe infectious disease affecting elderly, immune-compromised and pregnant individuals. Regulation exerted by small non-coding RNAs (ncRNAs) is a key event in all organisms. In *L. monocytogenes* studies have shown that many ncRNAs are specifically expressed in response to various stress conditions or in environments encountered by the bacteria during infection such as blood and the intestinal lumen. This suggests that ncRNA-mediated regulation is important for the stress tolerance and pathogenesis of *L. monocytogenes*. At present, more than 150 ncRNAs have been identified in *L. monocytogenes*. However, only a subset of these has been studied in detail.

This project aims to characterize seven stress-inducible ncRNAs recently identified in *L. monocytogenes*. The ncRNAs will be investigated in regards to 1) expression profile, 2) target genes, and 3) regulatory mode of action. Studies from our laboratory indicate that these ncRNAs are expressed in response to various stress conditions, including osmotic stress and exposure to antibiotics affecting the integrity of the bacterial cell envelope. Furthermore, our results suggest that the expression of the seven ncRNAs is regulated by the two-component system LisRK or the alternative sigma factor σ^B, which are known to be key regulators of the cell envelope- and general stress response of *L. monocytogenes*. Future studies aim to further characterize these ncRNAs. Through transcriptomic analyses it will be possible to identify genes affected by one or several of the seven ncRNAs. Putative target genes will be verified by quantitative PCR, and the effect of the ncRNAs on target gene expression on both the transcriptional and translational level will be investigated through implementation of reporter gene assays. Moreover, direct targets

© 2014 The Authors. FEBS Journal © 2014 FEBS

and the molecular mechanism by which the ncRNAs exert their regulation will be studied by means of *in vitro* binding assays. Lastly, *ex vivo* as well as *in vivo* infection assays may help to determine the role of these ncRNAs in bacterial virulence.

The results of this project may ultimately lead to a better understanding of the function of ncRNAs in *L. monocytogenes* and how they contribute to bacterial stress tolerance and pathogenesis.

MON-408
Characterization of the heart miRNome of the Nile tilapia (*Oreochromis niloticus*)

P. G. Nachtigall[1], A. C. Oliveira[1], S. Moxon[2], L. A. Bovolenta[3], D. Pinhal[1]
[1]Genetics, UNESP, Botucatu, Brazil, [2]The Genome Analysis Centre, Norwich, UK, [3]Biofísica, UNESP, Botucatu, Brazil

Heart is the first organ to form in the embryo and all subsequent events in the life of an organism depend on its function. In this sense, miRNAs had been described to operate as key regulators on diverse biological processes, including the cardiac biology. In fact, several miRNAs highly or specifically expressed in cardiac muscle have been identified through experiments carried out in a restrict number of model organisms. The Nile tilapia *O. niloticus* can be considered an excellent biological model for investigating miRNAs due to its economic importance and genome fully sequenced. Hence, the main aim of the present study was to characterize the heart miRNome and evaluate evolutionary relationships throughout vertebrates by comparative analysis. For this purpose, Illumina next-generation sequencing was used to identify and quantify the heart miRNAs of tilapia. As result, a total of 891 594 mapplable reads were generated, of which 891 476 referred to 113 known conserved Chordata miRNAs expressed, which potentially represents novel orthologs. A suit of 118 reads referred to three novel putative miRNAs expressed in cardiac tissue. Preliminary comparative analysis revealed that miR-26, -30, -126 and let-7 present a highly conserved expression in vertebrate's heart (from fish to mammals), indicating they might be involved in conserved pathways despite of large divergence times isolating these organisms. Intriguingly, there is a feasible exchange of function between miR-499 and miR-208 once we detected a higher expression of miR-499 and no expression of miR-208 in fish and birds with an inverse expression pattern in mammals. Indeed, miRNA target analysis revealed miR-208 and -499 shared >95% of the total number of predicted targets. Furthermore, the Nile tilapia heart miRNome represents a valuable resource for future teleost functional and comparative genomic studies, as well as for relationships between human and fish cardiac evo-devo. Further functional experiments are under development to determine interactions between selected miRNAs and their targets in cardiac development and homeostasis.

Conservative subtelomeric tandem PO41 repeat is transcribed both in chicken and Japanese quail somatic cells

I. Trofimova, D. Popova, **D. Chervyakova**, A. Krasikova
Saint-Petersburg State University, St.Petersburg, Russian Federation

Transcriptional silencing was for a long time considered to be a fundamental property of satellite DNA arrays located in (peri) centromeric, subtelomeric and telomeric regions of chromosomes. Occasional reports about satellite DNA transcription remained unnoticed until recently. Nowadays, active transcription of satellite DNA both in somatic and germ cells is an evident fact. Here we aimed to analyze transcriptional activity of subtelomeric tandem repeat in two representatives of Galliform species: domestic chicken (*Gallus gallus domesticus*) and Japanese quail (*Coturnix coturnix japonica*). Subtelomeric tandem PO41 ('pattern of 41 bp') repeat was chosen due to its high primary DNA sequence conservation and similar chromosomal distribution in Galliform species, which indicate that its transcripts could have important functions.

Using RNA FISH we demonstrated transcription of both strands of PO41 repeat in chicken and Japanese quail tissues: cerebellum, neoncephalon, muscles, oviduct, small and large intestine. To confirm the results of RNA FISH we adapted a method of RT-PCR on RNA samples from indicated tissues. Comparative analysis of the pattern of transcription in normal somatic and malignized cells demonstrated the similar distribution of transcripts in interphase nuclei. One, two or dispersed foci of PO41 transcripts were detected in euchromatin, close to clusters of heterochromatin. RNases treatments indicate that transcripts are predominantly single-stranded and partly able to form double-stranded structures such as hairpin or supercoiled RNA. Using immuno-FISH we revealed that RNA Pol II participates in transcription of PO41 repeat. Our results also indicate that PO41 RNA does not co-localize with known nuclear bodies like Cajal bodies, splicing speckles and nuclear stress bodies. A scheme representing possible structure of PO41 repeat transcripts is suggested. Presumably, nuclear foci with high concentration of PO41 RNA correspond to transcription factories and consist of nascent PO41 repeat transcripts associated with RNA polymerases.

In prophase PO41 transcripts were detected as bright foci in nuclei, while in metaphase they were located between condensed chromosomes. As can be seen on 3D-reconstrunctions, in early anaphase transcripts of tandem PO41 repeat are oriented on spindle equator. In early telophase PO41 RNA divide equally between daughter cells. It late telophase PO41 RNA is associated with chromosomes indicating its potential regulatory role in heterochromatin maintenance.

The work was partially performed using experimental equipment of the Research Resource Centers 'Chromas' and 'Molecular and cell technologies' of St Petersburg State University.

sized as single and multi-unite structures, which can be used for drug or gene delivery, targeting, and releasing. Doxorubicin, a common therapeutic agent for several cancer types, was intercalated and covalently bound to origami. The effects of the system were determined on the MDA-MB-231 and A549 cell lines via toxicity trials. DNA origami structures were modified with different targeting agents such as lactose, folic acid, and RGD peptide for targeting cancer cells.

The synthesis of single and multi-unit origami structures were carried out. Therapeutic agent, doxorubicin, was incorporated into the origami structure with intercalation or covalent binding. The intra-cellular uptake of the doxorubicin-DNA origami adduct was determined using cancer cells with comparing free doxorubicin. The cellular uptake of doxorubicin loaded origami structures was shown using confocal microscopy and fluorescence spectroscopy. The fluorescence spectroscopy results confirmed that our carrier system deliver the drug more efficiently than free doxorubicin.

Using programmable DNA hybridization and its structural features, many of functionalized materials and structures with desired shape and size can be prepared. These structures will contribute to the development of delivery systems, which is based on biomacromolecules. *In vivo* studies of these delivery systems will contribute to the development of effective biomolecular carrier systems.

Discovery of natural antisense transcripts in *Plasmodium vivax* clinical isolates

B. P. Arunachalam[1], A. K. Subudhi[1], S. Garg[1], S. Middha[2], J. Acharya[2], D. Pakalapati[1], V. Saxena[1], M. Aiyaz[3], B. Chand[3], R. C. Mugasimangalam[3], S. K. Kochar[2], P. Sirohi[2], D. K. Kochar[4], A. K. Das[1]
[1]Department of Biological Sciences, Birla Institute of Technology And Science, Pilani, Pilani, [2]Department of Medicine, Sardar Patel Medical College, Bikaner, [3]Genotypic Technology Pvt. Ltd., Bangalore, [4]Rajasthan University of Health Sciences, Jaipur, India

Plasmodium vivax is the most geographically widespread human malaria parasite causing approximately 130–435 million infections annually. It is an economic burden in many parts of the world and poses a public health challenge along with the other *Plasmodium sp*. Despite this the biology of this parasite is less studied and poorly understood. Emerging evidence of severe complications due to infections by this parasite provides an impetus to focus research on the same. Gene expression studies of this parasite directly obtained from the patients has provided evidence of gene regulation resulting in varying amount of transcript levels in the different blood stages. However, the mechanisms regulating gene expression in malaria parasites are not well understood. Discovery of natural antisense transcripts (NATs) in *P. falciparum* has suggested that these might play an important role in regulating gene expression.

Studies have not been initiated to document genome-wide distribution of NATs in *P. vivax* isolates until a study published by our lab. To identify *in vivo* prevalence of antisense transcripts in *P. vivax* clinical isolates, we performed whole-genome expression profiling using custom designed microarray having strand-specific probes. We identified a total of 1348 NATs against annotated gene loci. Our data shows condition specific expression patterns of varying sense (S) and antisense (AS) transcript levels. Few genes with AS transcripts have been validated using strand-specific reverse transcriptase polymerase chain reaction (RT-PCR) and ratios of AS to S transcripts were confirmed using strand-specific quantitative real-time PCR (qPCR). We have also linked experimental and *in silico* studies to understand possible mechanisms of AS transcript production in this parasite.

The results of this study was recently published and is the first study to reveal the presence of NATs in *P. vivax* clinical isolates (Boopathi et al., 2013). In conclusion, our data suggests differential regulation of gene expression in diverse clinical conditions, as shown by differing sense/antisense ratios and thus would lead to detailed investigation of gene regulaion in future.

Keywords: Natural antisense transcripts, *Plasmodium vivax*, Strand specific microarray.

Genome wide identification of uridylated RNAs in humans

D. Ustianenko[1], **L. Bednarik**[1], B. Bilen[2], M. Zavolan[2], S. Vanacova[1]
[1]*CEITEC, Masaryk University, Brno, Czech Republic,* [2]*Biozentrum, University of Basel, Basel, Switzerland*

The 3′-end RNA modification by uridylation has been generally linked to RNA degradation. The uridylated pre-miRNAs in mammals and uridylated mRNAs in fission yeast are targeted by the DIS3L2 3′ to 5′ exoribonuclease. DIS3L2 has been associated with Perlman syndrome development and Wilms tumor progression. However, no functional link has been made between uridylation and the involvement of DIS3L2 in these diseases.

Here we report on the RNA binding studies of human DIS3L2 that were performed by Crosslinking in vivo and immunoprecipitation (CLIP) method. Our study uncovers a broad spectrum of DIS3L2 RNA substrates in vivo. A specific bioinformatics approach identifies that many of these targets contain untemplated oligo(U) tail in average length of 8–10 nucleotides. The spectrum of such modified RNAs includes snRNAs, snoRNAs, tRNAs, pre-miRNAs, rRNAs and mRNAs. This points to the essentiality of oligo(U) modification in the cell metabolism.

Keywords: dis3 l2, uridylation.

Heat-shock can strongly increase the lifetime of a small RNA with rapid decay

K. Tatosyan, A. Koval, I. Gogolevskaya, D. Kramerov
Evolution of eukaryotic genomes, Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

4.5SH RNA is a 94 nt small nuclear RNA with an unknown function. Hundreds of its genes are present in the genomes of four rodent families including Muridae [1]. 4.5SH RNA genes contain an internal RNA-polymerase III promoter consisting of A and B boxes. It was reported that 4.5SH RNA turns over rapidly, but its lifetime remained unknown [2]. We estimated 4.5SH RNA half-life in Krebs ascites carcinoma (KAC) cells, in different rodent cell lines (L929, 3T3NIH, and Rat1), and in HeLa cells after their transfection with 4.5SH RNA gene. It was found that 4.5SH RNA was indeed short-lived with $t_{1/2}$ about 20 min in various cell types. Then we studied how cell stress could influence 4.5SH RNA in cell. 4.5SH RNA level strongly increased under heat-shock in KAC (10 times), L929 (5 times), 3T3NIH (3 times), Rat1 (5 times), and in transfected HeLa cells (3 times). Additionally, 4.5SH RNA level increased in KAC cells during infection with encephalomyocarditis virus (5 times). We determined the RNA half-life on the peak of heat-shock reaction or viral infection. It turned out to be much longer than in control cells: 90 min in KAC cells, 90 min in L929, 80 min in Rat1, 40 min in transfected HeLa cells after heat-shock, and 30 min in KAC cells after viral infection. Thus, 4.5SH RNA accumulation under heat-shock or viral infection was due to its lifetime increase. It may be a specific stress reaction of this RNA. Alternatively, it can be suggested that heat-shock and viral infection affect the RNA degradation machinery.

Identification of flax microRNAs involved in nutrient stress response.

N. V. Melnikova[1], M. S. Belenikin[1], N. L. Bolsheva[1], A. A. Dmitriev[1], A. S. Speranskaya[1,2], V. A. Lakunina[1], N. V. Koroban[1], A. A. Krinitsina[2], A. F. Sadritdinova[1], A. V. Zelenin[1], O. V. Muravenko[1], A. V. Kudryavtseva[1]
[1]*Engelhardt Institute of Molecular Biology, Russian Academy of Sciences,* [2]*Department of Higher Plants, Lomonosov Moscow State University, Moscow, Russian Federation*

Nutrients are needed for plant growth and development. Expression level alterations of microRNAs (miRNAs) in plants were shown under different nutrient concentrations in soil or nutrient solutions. We sequenced three flax (*Linum usitatissimum* L.) small RNA libraries and obtained 7.2M (inorganic phosphate – Pi - deficiency), 11.6M (normal nutrition), and 7.6M (excessive fertilizer) raw reads. We identified 76 conserved miRNA homologues which belong to 20 distinct miRNA families. Pi deficiency and excess fertilizer responsive miRNAs were identified in flax for the first time. The most significant down-regulation was shown for miR395 (fold change = –2.3, p-value = $4.4*10^{-6}$) and miR169 (fold change = –1.9, p-value = $3.4*10^{-4}$) in flax grown in redundancy of macro- and micronutrients. Under Pi deficiency up-regulation of miR398 (2.0-fold change; p-value $1.5*10^{-11}$), miR399 (2.2-fold change; p-value 0.02) and miR408 (2.3-fold change; p-value $6.6*10^{-7}$) was observed.

We identified 156 potential novel flax miRNAs with predicted hairpins secondary structures. Predicted target genes for new miRNAs are involved in a wide range of processes occurring in the plant, including cell differentiation, immune responses, phosphate homeostasis regulation, plant growth and development. We identified potential novel flax miRNA lus-miR-N1 which was down-regulated under Pi deficiency.

Quantitative real-time PCR (qPCR) on the extended sampling was performed to validate the results obtained from the high-throughput sequencing for miR169, miR395 and lus-miR-N1. However, qPCR confirmed differential expression only for miR395 and lus-miR-N1, but not for miR169. Target genes of miR395 are involved in sulfate uptake and assimilation. We speculate that alterations of the expression level of miR395 could be associated not only with excess sulfur application but also with redundancy of other macro- and micronutrients especially phosphorus and nitrogen which are necessary for protein synthesis. Target gene of lus-miR-N1 encodes ubiquitin-activating enzyme E1. This enzyme catalyzes the first step in the ubiquitination reaction, and in this way this miRNA could regulate phosphate starvation response in flax.

Revealed alterations of flax miRNA expression under excess fertilizer and Pi deficiency clarify molecular mechanisms of nutrition regulation in plants and provide a wide area for further investigations.

MON-416
Identification of transcribed Alu elements in the human genome

A. Conti[1], D. Carnevali[2], G. Dieci[2]
[1]*Dipartimento di Medicina Clinica e Sperimentale,* [2]*Dipartimento di Bioscienze, University of Parma, Parma, Italy*

Non-long terminal repeat retrotransposons, including Long and Short Interspersed Elements (LINEs and SINEs), are the most successful and abundant mobile elements in the human genome. The primate-specific *Alu* elements (*Alus*), belonging to the SINEs class, are over one million copies in the human genome and continuously retrotranspose contributing to disease through insertional mutagenesis. Although most human *Alu* loci are inactive or silenced, *Alu* RNA overexpression may occur under various cell perturbation conditions and it also takes place under pathological conditions including cancer. *Alus* derepression might also impact on human transcriptome to increase genomic instability through both transcriptional and post-transcriptional roles played by *Alu* RNAs. The body of modern *Alus* is about 300 bases in length and it is composed of two divergent dimers separated by a short A-rich region. The left arm contains the internal *cis*-regulatory promoter elements, A box and B box, recognized by the RNA polymerase III (Pol III) transcription machinery, while the right arm is followed by a poly A stretch. The *Alu* transcription unit further includes the genomic sequence extending to the transcription termination site, mainly consisting of four thymines (T4) in the flanking genomic region. Most *Alu*s in the human genome are unique in sequence, due to accumulated mutations in the *Alu* body and to the presence of the 3′ trailer (the sequence between the poly A stretch and the T4) of variable length and sequence. Thus, most *Alu* RNAs, originating from transcription of specific *Alu* loci, can be unambiguously identified, and they can be distinguished between *Alu* RNAs derived from individual *Alu*s directly transcribed by Pol III, and *Alu* RNAs embedded within protein-coding or other RNA polymerase II-transcribed genes whose expression can occur from host gene promoters. A computational screening of RNA-seq and ChIP-seq datasets let us identify dozens of *Alu* RNAs expressed from individual, transcription-prone *Alu* loci in different human cell types. Some of these loci are intergenic, others are within introns of protein-coding genes in antisense orientation, suggesting the possibility of regulatory effects based on sense-antisense RNA pairing. The parallel exploration of ChIP-seq datasets revealed the association of the Pol III machinery to some of the transcript-producing *Alu*s. We identified the internal Pol III promoter elements in a number of active *Alus,* and we demonstrated they are actively transcribed *in vitro* with a key role played by the B box as demonstrated by mutational analysis. Our data also show evidence of Pol III terminator *read through* and recognition of non-canonical termination sites, as well as of post-transcriptional processing of primary *Alu* transcripts.

Identification, functional analysis of non-coding Y RNAs from Chinese hamster cells and binding analysis with kin17 protein

Q. A. D. L. Neto, F. D. S. Rando, D. V. B. de Freitas, **M. A. Fernandez**
Biotecnologia, Genetica e Biologia Celular, Universidade Estadual de Maringá, Maringa, Brazil

Non-coding Y RNAs are essential for chromosomal DNA replication in vertebrate cells. They are functionally required for the reconstitution of the initiation of chromosomal DNA replication in late G1 phase template nuclei in a human cell-free system. In vertebrates, genes coding for Y RNAs are evolutionarily conserved. These genes form a small family of up to four short RNA polymerase III transcripts that are located in close proximity to each other in vertebrate genomes, including human, mouse and *Xenopus*. So far, no information is available about Y RNAs in Chinese hamster cells. Here, we report the identification and functional characterization of Y RNAs from Chinese hamster (chY RNAs) as factors for chromosomal DNA replication, and we perform an analysis of interaction among chY RNAs and kin17 protein. We have found DNA sequences in the Chinese hamster genome of four Y RNAs (chY1, chY3, chY4 and chY5), with upstream promoter sequences, which are homologous to the four main types of vertebrate Y RNAs. The chY1, chY3 and chY5 genes were most conserved, whilst the chY4 gene showed the highest degree of diversification from the other vertebrate Y4 genes. We analysed the expression of all chY RNAs in the Chinese hamster cells line GMA32 using quantitative RT-PCR. Despite the presence of genes for all four Y RNAs in hamster genome, we only found that the chY1 and chY3 RNA are expressed. This pattern of expression is consistent with that of other rodents like mouse and rat. After that, we tested if chY RNAs support DNA replication in a cell-free system. We synthesised all four chY RNAs by in vitro transcription from synthetic templates and purified them by ion exchange chromatography. All four chY RNAs were able to initiate chromosomal DNA replication in human late G1 phase nuclei in the additional presence of human initiation proteins. Finally, we carried out the interaction analysis of chY1 RNA with kin17 protein. We chemically coupled purified chY1 RNA covalently to agarose beads and pull-down proteins from GMA32 cell extracts that interact with chY1 RNA. Western blot made with pulled-down proteins revealed the presence of kin17 protein, that confirming its binding to chY1 RNA. These data therefore establish that non-coding chY RNAs can substitute for human Y RNAs in a reconstituted cell free DNA replication initiation system. These experiments suggest that Y RNAs are evolutionarily and functionally conserved in Chinese hamster cells.

Knockdown of antisense noncoding mitochondrial RNAs targets survivin and Bcl-2 for selective death of tumor cells

V. A. Burzio[1,2], C. Fitzpatrick[1,2], M. Briones[1,2], S. Vidaurre[1,3], L. Oliveira-Cruz[1,4], L. O. Burzio[1,2]
[1]*Andes Biotechnologies, Fundacion Ciencia & Vida,* [2]*Facultad de Ciencias Biologicas, Universidad Andres Bello,* [3]*Facultad de Salud, Deporte y Recreacion, Universidad Bernardo O'Higgins,* [4]*Instituto de Ciencias Naturales, Universidad de Las Americas, Santiago, Chile*

The Noncoding Mitochondrial RNAs (ncmtRNAs) are a family of long noncoding transcripts derived from the mitochondrial 16S ribosomal RNA gene. These RNAs contain inverted repeats (IR) at their 5′ ends, forming stem-loop structures. The family comprises Sense transcripts (SncmtRNAs), composed mainly of the sense 16S transcript, and Antisense counterparts (ASncmtRNAs), containing mainly the antisense 16S transcript. Knockdown of the

© 2014 The Authors. FEBS Journal © 2014 FEBS

ASncmtRNAs by transfection of antisense oligonucleotides (ASO) causes selective death of several tumor cell lines without affecting viability of normal cells. Cell death induced in this manner displays hallmark features of apoptosis such as nuclear and chromatin fragmentation, loss of mitochondrial membrane potential and plasma membrane asymmetry, activation of caspases and release of cytochrome c from the mitochondria. In this work we show that apoptosis is brought on by relocation of the anti-apoptotic protein Bcl-2 to the nucleus, where it has been reported to exert a pro-apoptotic function. The change in subcellular localization of Bcl-2 is caused by a reduction in FKBP38, a chaperone that carries Bcl-2 to the cytoplasm. Notably, knockdown of ASncmtRNAs also induces a strong downregulation of survivin, a member of the inhibitor of apoptosis protein (IAP) family, which is over-expressed in virtually every known cancer type. This reduction in protein is not reflected in mRNA levels of survivin, which remain unaffected by the treatment, suggesting a post-transcriptional mechanism which affects only translation of survivin mRNA. To explore this possibility, we conducted a luciferase reporter assay, in which the 3′UTR sequence of survivin mRNA was cloned downstream of the firefly luciferase ORF. Luminiscence was reduced in cells transfected with the ASO directed to the ASncmtRNAs, suggesting the induction of microRNAs (miRNAs; miRs) that bind to the 3′UTR of survivin thus inhibiting its translation. We hypothesized that these putative miRs could be derived from the double-stranded region of the ASncmtRNAs. In agreement with this notion, we found that these transcripts co-immunoprecipitate with a specific antibody against Dicer, suggesting that the ASncmtRNAs are substrates of this enzyme involved in miRNA generation. Taken together, our results suggest a role for the ncmtRNAs in gene expression control through the miRNA pathway. [FONDECYT #1110835 and #1140345; INNOVA-Corfo 12IEAT-16317]

Small non-coding RNAs (microRNAs or miRNAs) have been shown essential for the regulation of specific cell pathways, including the skeletal muscle development, maintenance and homeostasis in vertebrates. However, the relative contribution of miRNAs for determining red and white cells phenotype is far to be fully comprehended. Aiming to better characterize miRNA roles into skeletal muscle cells biology, we investigated muscle-specific miRNAs (myomiRs) signatures in Nile tilapia fish. Quantitative (RT-qPCR) and spatial (FISH) expression analyses revealed a highly differential expression (forty-four fold base on qPCR) of miR-499 in red skeletal muscle in comparison to white cells, whereas remaining myomiRs were equitably low expressed in both muscle cell types. Deep examination on miR-499 targets through bioinformatics led us to sox6 and rod1 genes, which were found to be down-regulated at red muscle cells according to RT-qPCR, FISH, and immunofluorescence profiling experiments. Interestingly we verified that miR-499 overexpression distinctively affects target genes expression by predominantly promoting sox6 mRNA destabilization and ROD1 protein translational decay. We also demonstrate, through a genome-wide comparative analysis of SOX6 and ROD1 protein domains and through an *in silico* gene regulatory network, that both proteins are essentially similar in vertebrate genomes, suggesting their gene regulatory network may be also widely conserved. Overall, our data shed light on the mechanisms governing miR-499 target regulation associated to slow-twitch muscle fiber type phenotype, as well as brings up novel valuable insights into the evolutionary dynamics of miRNA and target genes enrolled in a molecular pathway potentially constrained in the skeletal muscle cells of vertebrates.

Mitochondrial non-coding RNAs as therapeutic target in cervical cancer

R. Avila[1], N. Farfan[1], L. Lobos[1], V. Silva[1], C. Villota[2], L. O. Burzio[3], **J. Villegas**[1,2,4]
[1]Cancer Lab, Fundacion Ciencia & Vida, [2]Faculty of Ciencias Biológicas, Universidad Andrés Bello, [3]Cancer Lab, [4]Andes Biotechnologies S.A., Santiago, Chile

Human cells express a family of noncoding mitochondrial RNAs (ncmtRNAs). Normal proliferating cells express both sense and antisense transcripts (SncmtRNA and ASncmtRNAs). However, tumor cells in culture or human biopsies express only the SncmtRNA and down regulate the ASncmtRNAs. This expression pattern is independent of tumor origin and distinguish tumor cell from normal cell. The goal of this work was to establish primary cultures of human biopsies of advance cervical cancer. We obtained five successful cultures that were characterized by western blot and HPV genotyping. In vitro 'therapy' using antisense oligonucleotides (ASO) against the AS-ncmtRNA show a massive cell death mediated by apoptosis and strong reduction in tumorigenic properties as showed by sphere formation assay.

The established primary cultures were used to evaluate the efficacy of the ASO treatment in xenografts models. We established the temporal tumor growth curve for each culture and 2 out of five were successful. Once the tumor reach 100 mm^3 we initiated the ASO treatment and found that after ten ASO injections a strong reduction in growth tumor was observed. We evaluated the effect over growth tumor comparing the ASO administration pathway (I.P v/s E.V). We will discuss the effect of ASO treatment *in vivo* over surviving and dose regimen.

Molecular mechanisms of piRNA amplification

J. Xiol, Pillai lab
Cell Biology, Harvard Medical School, Boston, MA, USA

Germline-specific Piwi-interacting RNAs (piRNAs) protect the genome against selfish genetic elements and are essential for fertility in animals. piRNAs targeting active transposons are amplified by a feed-forward loop known as the Ping-pong cycle, which links endonucleolytic slicing of target RNAs by Piwi proteins to biogenesis of new piRNAs. However, the biochemical framework for this pathway remains elusive. Here, we describe the identification of a transient Amplifier complex mediating the biogenesis of secondary piRNAs in insect cells. This complex is nucleated by the DEAD box RNA helicase Vasa and contains the two Piwi proteins participating in the Ping-pong loop, the Tudor protein Qin/Kumo and antisense piRNA guides. These components assemble on the surface of Vasa's helicase domain, which functions as an RNA clamp to anchor Amplifier onto transposon transcripts. We show that ATP-dependent RNP remodelling by

Ms1, a novel sRNA interacting with the RNA polymerase core in mycobacteria

M. Šiková[1], J. Hnilicová[1], J. Jirát Matějčková[1], P. Halada[2], J. Pánek[3], L. Krásný[1]

[1]Molecular Genetics of Bacteria, Institute of Microbiology, [2]Molecular Structure Characterization, Institute of Microbiology, [3]Bioinformatics, Institute of Microbiology, The academy of sciences of the Czech Republic, Prague, Czech Republic

Gene expression and its regulation are vital for all organisms. An important class of molecules that regulate gene expression are non-coding small RNAs (sRNA). In mycobacteria we found a new sRNA, called Ms1 in *Mycobacterium smegmatis*. Ms1 is a ~300 nt long sRNA that is highly abundant in stationary phase of growth. By several approaches, we demonstrate that Ms1 binds to the RNA polymerase (RNAP) core. This is in contrast with most other species where the RNAP-binding sRNA (6S RNA) binds the holoenzyme containing the primary sigma factor (σ^A). This difference can be explained by the composition of the transcription machinery in mycobacteria that in stationary phase of growth contain a relatively low level of σ^A and the RNAP-σ^A holoenzyme. Thus, Ms1 represents a new class of sRNAs interacting with RNAP.

This work is supported by grant No.P305/12/G034, from the Czech Science Foundation.

Noncoding 7SK human snRNA and HIV1 Tat interaction

S. N. Khan, on behalf of VMD, S. N. Khan

Department of Pharmacy, East West University, Dhaka, Bangladesh

Human immunodeficiency virus (HIV) exploits host's cellular proteins during its replicative cycle and latent infection. The positive transcription elongation factor b (P-TEFb) is a key cellular transcription factor critical for these viral processes.

7SK is an abundant, 331-nucleotide small nuclear RNA (snRNA) that functions as a transcriptional regulator during the elongation phase. 7SK sequesters P-TEFb as 7SK/HEXIM1/P-TEFb ribonucleoprotein complex. 7SK RNA binds to HEXIM1 regulatory domain and promotes the binding of the HEXIM C-terminal domain to cyclin T1/T2 of P-TEFb. P-TEFb shows little CTD kinase activity which indicates that 7SK snRNA in collaboration with HEXIM1 function as an inhibitory factor of P-TEFb.

During viral replication, P-TEFb is recruited via interactions of its cyclin T1 subunit with the HIV Tat (transactivator of transcription) protein and TAR (transactivation response) element.

Currently 7SK snRNA structure is understood and Tat contains an arginine-rich motif (ARM) in which a single arginine residue has been shown to confer specific binding to the TAR bulge region.

In the presentation we will be presenting the strong interaction of 7SK snRNA and Tat through 2D NMR spectroscopic studies and ITC (isothermal calorimetric analysis). In our study we have evidence for preformed arginine binding motifs in 7SK snRNA with pseudo triple platform which is responsible for its strong interaction with Tat peptide. ITC data and NMR data also supports this strong binding interaction with preliminary data indicates a high binding affinity of TAT peptide to 7SK-SL1 (Kd = ~50 nM, n = ~1.36).

On-enzyme refolding permits small RNA and tRNA surveillance by the CCA-adding enzyme

C. D. Kuhn[1], J. E. Wilusz[2], Y. Zheng[3], P. A. Beal[3], P. A. Sharp[4], L. Joshua-Tor[1]

Eukaryotic transcription yields a wide variety of long non-coding RNAs (lncRNAs) with important, yet largely mysterious functions. Two of these lncRNAs, MALAT1 and Menβ, give rise to a tRNA-like small RNA in addition to the mature lncRNA. The stability of these tRNA-like small RNAs, as well as of *bona fide* tRNAs, is assessed by the CCA-adding enzyme which initiates degradation of unstable RNAs through tandem addition of CCA. Here, we are able to characterize this second CCA-addition cycle by combining nine co-crystal structures and biochemical experiments. We find that a unique RNA bulge enables the second catalytic cycle. Nucleotide binding to the active site triggers a clockwise screw motion, which initiates RNA refolding with the RNA's 3′-end refolding 'on-enzyme' while its 5′-end stays put. Intriguingly, unstable RNAs are not specifically detected by the CCA-adding enzyme. Instead, the versatility of RNA folding allows the enzyme to proofread unstable RNAs without altering its mode of substrate recognition.

Polyadenylation of transcripts synthesized by RNA polymerase III: requirements for RNA structure

K. Tatosyan, O. Borodulina, J. Golubchikova, D. Kramerov

Evolution of eukaryotic genomes, Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

Until recently it was believed that only transcripts synthesized by RNA polymerase II (e.g., mRNA) were subject to AAUAAA-

© 2014 The Authors. FEBS Journal © 2014 FEBS

dependent polyadenylation. We previously showed that RNA transcribed by RNA polymerase III (RNAPIII) from B2 elements of the mouse genome III could be polyadenylated in AAUAAA-dependent manner [1]. B2 is referred to mobile genetic elements called SINEs (Short Interspersed Elements). SINEs are capable of RNAPIII transcription due to the presence of the internal promoter which consists of two boxes (A and B) spaced by 30–35 bp. Many species of SINEs end with the RNAPIII transcriptional terminator (TTTTT) and contain AATAAA hexamers in their A-rich tail. Such SINEs were united into Class T+, whereas SINEs lacking TTTTT and AATAAA sequences were classified as T- [2]. Here we studied requirements for polyadenylation of RNAPIII transcripts of SINEs. Seven and six SINEs families from Class T+ and T-, respectively, were analyzed. Derivatives of these SINEs with nucleotide substitutions and insertions were constructed. The resulting constructs were transiently transfected in HeLa cells and isolated RNA was analyzed by Northern blot hybridization. It was found that replacement of AATAAA with AACAAA in T+ SINEs abolished the RNA polyadenylation. In this work, we determined the areas of T+ class SINEs that are important for polyadenylation of their RNAPIII- transcripts. Three species of SINEs were studied: B2 (mouse), DIP (jerboa) and VES (bat) [3]. Derivatives of these SINEs with nucleotide deletions, insertions, and substitutions, were constructed. The resulting constructs were transiently transfected in HeLa cells and isolated RNA was analyzed by Northern blot hybridization. It has been shown that the presence of the polyadenylation signal (AATAAA) as well as two other regions was important for polyadenylation of transcripts of these three SINEs. The first (beta) resides immediately downstream the promoter box B and the second (tau) is located upstream the A-rich tail. In the case of SINEs DIP and VES (but not B2), the tau region is a polypyrimidine motif. Such a motif is also located immediately upstream the A-rich tail in most other SINEs of class T+ [2]. Apparently polyadenylation mechanisms for RNAPIII-transcripts and mRNA greatly differ.

Prediction of RNA-RNA interactions in *H. salinarum* by using self-orgazning map (SOM)

A. Khan
Department of Compting and Mathemtics, University of Sao Paulo, Ribeirao preto, Brazil

Ribonucleoprotein (RNP) interactions engage in critical roles within a broad range of cellular processes, ranging from transcriptional and post-transactional regulation of gene expression to host protection in opposition to pathogens. High throughput experiments to recognize RNA–protein interactions produce details about the complexity of interaction networks, but require time and considerable efforts. Therefore, there is need to have for trustworthy computational approaches for predicting ribonucleoprotein interactions. In this paper, we predict the RNA-RNA interactions as ncRNA by Self Organizing Map (SOM). SOM is an unsupervised learning algorithm proposed by Kohonen. The principal goal of the SOM algorithm is to map an incoming pattern in a higher dimensional space into a lower usually one or two dimensional space, and perform this transformation adaptively in a topological ordered fashion.

Quantitative measurement of iron in bacterial cells using a new fluorescent probe

S. Caulet[1,2], L. Alfonsi[1], N. Linder[1,3], N. Lensen[3], V. Arluison[1,2]
[1]Laboratoire Léon Brillouin UMR 12, CEA CNRS, Gif-sur-Yvette, [2]Université Paris Diderot, Sorbone Paris Cité, Paris, [3]Laboratoire Synthèse Organique Sélective et Chimie bio-Organique, Université de Cergy-Pontoise, Cergy-Pontoise, France

During a bacterial infection, iron becomes rapidly limiting. Thus, bacteria must cope with this deficiency. Stress response mechanisms involve a series of regulatory RNAs called small non-coding RNAs (sRNAs). Among them, RyhB sRNA regulates the expression of about fifty proteins involved in iron homeostasis. When the intracellular concentration becomes too low, RyhB transcription activation occurs, resulting in an inhibition of the expression of non-essential protein using iron to redirect resources to essential proteins. The sRNA exerts its action by pairing with target mRNAs in order to modulate their translation efficiency and stability. Nevertheless, cellular factors that could influence the action of RyhB are ill-understood. Furthermore, methods to correlate iron concentration to cellular stresses are still lacking. In this context, we initiated the development of a new molecular tool to probe iron and measure its concentration *in vivo*. Our progress toward studying the effect of RyhB-based regulation on iron concentration will be presented during this meeting.

Regulation of the colon cancer methylome by long intergenic non-coding RNAs

S. McMahon[1], C. Merry[1], L. Beard[1], M. W. Jackson[2], Z. Wang[1], S. Markowitz[1], **A. M. Khalil**[1]
[1]Genetics and Genome Sciences, [2]Pathology, Case Western Reserve University School of Medicine, Cleveland, OH, USA

We have previously identified a novel class of non-coding RNAs in humans termed long intergenic non-coding RNAs (lincRNAs). The human genome encodes over 8000 lincRNAs, and numerous lincRNAs are associated with epigenetic-modifying complexes and affect gene expression *in trans*. In a preliminary study, we identified ~148 lincRNAs that associate with the DNA methyltransferase DNMT1 in a colon cancer cell line HCT116. Since DNMT1 is a key enzyme that regulates DNA methylation patterns, we hypothesized that the deregulation of DNMT1-associated lincRNAs may disrupt DNMT1 normal function; and thus, contribute to cancer-associated abnormal DNA methylation. First, we examined the expression of DNMT1-associated lincRNAs in normal colon and patient-derived colon cancer cell lines, and found DNMT1-associated lincRNAs to be highly deregulated in colon cancer. For example, the expression levels of a lincRNA, designated lincSMAD, are significantly down-regulated in colon cancer cell lines in comparison to normal colon samples. Transfecting lincSMAD back into colon cancer cell lines significantly surprised their ability to form colonies *in vitro*. Moreover, cells into which we transfected lincSMAD showed significantly altered DNA methylation patterns at multiple loci distributed

© 2014 The Authors. FEBS Journal © 2014 FEBS

throughout the genome, as assayed by Illumina 450K methylation arrays. These results suggest that loss of lincSMAD in colon cancer may be a novel mechanism involved in cancer associated aberrant DNA methylation, and that deregulation of lincRNAs may contribute to colon cancer etiology.

Resveratrol promotes apoptosis, autophagy and suppressed cell division via upregulated miR-181 family and target genes in human K562 cells

Z. Mutlu[1], C. Caliskan[1], B. Goker[1], C. Kayabasi[1], F. Sahin[2], G. Saydam[2], C. Gündüz[1], C. B. Avci[1]
[1]Medical Biology, [2]Hematology, Ege University,Medical School, Izmir, Turkey

Chronic myeloid leukemia (CML) is a malignant disorder of the haematopoietic stem cell characterized by philadelphia chromosome. Resveratrol is a natural phytoalexin that induces apoptosis and autophagy. MicroRNAs (miRNAs) are noncoding, single stranded RNAs which hold regulation of gene expressions in different cancers.

In this study we aimed to evaluate the cytotoxic, apoptotic and autophagic effects of resveratrol in CML cells by questioning miRNA expression levels and gene expression of miRNA targets which are associated with CML progression.

K562 cells were treated with RES time and dose dependent manner and cytotoxicity was evaluated by using WST-1 assay. The RT-qPCR is used for miRNA and gene expression analysis. miRNAs and genes expression levels were evaluated by using miScript miRNA PCR Array and RT2 Profiler PCR Array, respectively.

Significant increase in miR-181 family was observed in K562 treated with resveratrol. Resveratrol upregulated miR-181a, miR-181b, miR-181c and miR-181d expressions 8.96, 6.42, 10.15, 17.19 fold according to the control cells, respectively. Target gene expression levels of miR-181 family such as ATG5, CASP3 and p27KIP1 were increased respectively 10.41, 8.63 and 36 fold via up-regulated miR-181 family.

Our findings showed that Resveratrol induced apoptosis and autophagy in K562. Resveratrol upregulated tumor suppressor miR-181 family and the target genes, leaded CASP3 activation and modulation of Atgs in autophagic pathway in K562. Resveratrol regulates autophagosome formation via upregulated-ATG5 expression. p27KIP1 upregulation induced prevented progression from G1 to S-phase and suppressed cell division. These results provide that Resveratrol may be a therapeutic candidate for CML treatment.

Ribonucleic acids of circulating complexes from human blood plasma

A. V. Savelyeva[1,2], D. Semenov[2], D. Baryakin[2], E. Chikova[3], V. Kozlov[4], E. Kuligina[2], V. Richter[2]
[1]Novosibirsk State University, [2]Institute of Chemical Biology and Fundamental Medicine, Siberian Branch of the Russian Academy of Sciences (ICBFM SB RAS), [3]Center of New Medical Technologies, [4]Novosibirsk Regional Cancer Center, Novosibirsk, Russian Federation

Circulating RNAs were shown to play an important role in normal physiological processes, such as immune response, cell differentiation as well as in pathological processes, including tumorigenesis and neurodegeneration. It is well-known that ribonucleic acids are present within extra-cellular membrane covered vesicles, and as part of circulating ribonucleoprotein complexes not associated with cells or vesicles. Circulating RNAs were found within exosomes, microvesicles, apoptotic bodies, ribonucleoprotein complexes and high-density lipoproteins. The object of the present work was RNA of exosomes, microvesicles, apoptotic bodies, ribonucleoprotein complexes from blood of healthy donors and of non-small cell lung cancer patients.

To analyze circulating RNA structures we used an approach which allowed to consider all types of RNA fragments from biological samples. Pooled non-hemolyzed blood samples were separated into 5 fractions: blood cells, plasma, microvesicles, exosomes and membrane-free ribonucleoprotein complexes. For each blood fraction RNA the cDNA-libraries were obtained and analyzed by SOLiD high-throughput massively parallel sequencing technology. To analyze SOLiD sequencing data we applied the unique bioinformatic approach utilizing Bowtie and Cufflinks software. It was found that circulating membrane vesicles as well as membrane-free ribonucleoprotein complexes contain: fragments of rRNAs, tRNAs, mtRNAs, mRNAs, lncRNAs, snRNAs, snoRNAs and mature microRNAs. Distribution of particular RNA species in different blood plasma fractions was documented. We also detected diagnostically significant differences between RNA distributions in particular blood fractions of healthy donors and lung cancer patients.

Sensing viral RNA in *Drosophila melanogaster*

S. Paro[1], E. Aguiar[2], B. Claydon[1], J. T. Marques[2], J.-L. Imler[1,3], **C. Meignin**[1,3]
[1]IBMC, CNRS UPR9022, Strasbourg, France, [2]Laboratory of RNA Interference, Biochemistry and Immunology, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Université de Strasbourg, Strasbourg, France

RNA interference plays a central role in antiviral innate immunity in flies. Indeed, flies mutant for the three key components of the small interfering (si)RNA pathway, namely Dicer-2, R2D2 and Argonaute2 (AGO2) are highly sensitive to a wide range of viruses (1). Drosophila Dicer-2 is a RNaseIII able to cleave long dsRNA (dsRNA) into 21 nt long small interfering RNAs (siRNAs). Dicer-2 contains a DExD/H-box helicase domain at its N-terminus sharing important phylogenetic similarity with DExD/H-box helicase of known mammalian viral sensors, namely the RIG-I-Like-Receptors (RLRs). The RLRs (e.g. RIG-I, MDA-5) sense conserved viral molecular patterns, like 5′ triphosphates or dsRNA duplexes, and activate, through their caspase recruitment domains (CARD), a signaling cascade leading to interferon production. The structural similarity between the DExD/H-box helicase domains of mammalian RLRs and Dicer-2, added to their common functional role in sensing viral RNAs, point to some similarities between antiviral immunity in mammals and flies.

Although *in vitro* and *in vivo* experiments clearly indicate that Dicer-2 can process long double stranded RNA, the exact nature of the viral RNAs sensed *in vivo* in infected cells remains mysterious. We are interested in understanding how Dicer-2 senses viral RNAs, with a particular focus on the contribution of the N-terminal DExD/H helicase domain, which is conserved in mammalian RIG-I like receptors. Indeed, *in vitro* experiments have revealed a critical role of this domain in both processivity of the enzyme and discrimination of the extremities of the template

Specific labeling of miRNAs and siRNAs by HEN1 methyltransferase

A. Osipenko, A. Plotnikova, V. Masevičius, S. Klimašauskas, G. Vilkaitis
Institute of Biotechnology, Vilnius University, Vilnius, Lithuania

Small non-coding RNAs such as microRNAs (miRNAs) and small-interfering RNAs (siRNAs) are among the most studied biological objects of the last decade. Present in the widest range of eukaryotes, including humans, these small molecules with its numerous functions have high importance in almost all main biological processes. It is not surprising that differences in small RNA levels were determined as potential biomarkers in cancer, neurological and many other diseases. However detection and extraction of these molecules are still challenging to scientists. Here we present novel fast and easy one-step labeling of small RNAs that allows extraction of these molecules and more labile two-step labeling that provides wide selection of different available reporter groups, such as biotin and fluorophores. Both methods use synthetic analogues of S-adenosyl-L-methionine and exploit high specificity of methyltransferase HEN1 to double-stranded 21 to 24 nt long RNA molecules, namely miRNA/miRNA* and siRNA/siRNA*, minimizing non-specific detection and/or extraction of DNA or irrelevant types of RNA molecules, such as tRNAs or fragments of long RNAs.

Keywords: labeling, miRNAs, siRNAs.

Structural analogs of tRNA form a complex with Cytochrome C

R. Pawlowska[1], D. Jedrzejczyk[1], M. Janicka[1], **A. Chworos**[1]
[1]*Department of Bioorganic Chemistry, Centre of Molecular and Macromolecular Studies Polish Academy of Sciences, Lodz, Poland*

One of the most fundamental RNA molecules in every living cell is transfer RNA (tRNA). It plays an essential role in the protein biosynthesis process, where it is responsible for amino acids delivery to the ribosome machinery and their arrangement based on the codon-anticodon complementarity with mRNA sequence. Recently, it has been shown that specific tRNAs interact with cytochrome C stronger then other RNA types [1]. Cytochrome C is a relatively small protein involved in electron transfer process in the cellular respiratory system [3]. Additionally, cytochrome C plays a critical role in the internal pathway of programmed cell death process (apoptosis). Triggered by the internal signals such as DNA damage or excessive reactive oxygen species (ROS) formation, cytochrome C is released from mitochondrial membrane, forms an apoptosome complex and activates the caspase cycle, finally leading to cell death [4].

Recently it has been postulated that the specific tRNA molecules interact with cytochrome C and this complex may influence the apoptosis process [1,2]. To test this hypothesis, we synthetized the series of specific tRNA analogs (RNA transcripts) and used them to study the complex formation with cytochrome C *in-vitro*. Our results suggest, that synthetic tRNA molecules (without nucleobase modifications) interact with cytochrome C in the similar fashion as natural tRNAs. Gel mobility assay and spectroscopic analysis indicate the ratio of RNA to protein is in the range 2–5. However, slight differences can be found in the circular dichroic and fluorescents spectra, suggesting, the structure of RNA component is important for the nature of the complex. For instance analogs of $tRNA^{Ala}$ and $tRNA^{Phe}$ apparently undergo larger structural change upon binding to cytochrome C, compared to $tRNA^{His}$. In summary, this study shed new light on the meaning of the tRNA/cytochrome C interactions.

Signal transducers and activators of transcription (STAT) proteins function in the JAK/STAT signaling pathway and are activated by phosphorylation. As a result of this signaling event, they affect many cellular processes including cell growth, proliferation, differentiation, and survival. Increases in the expressions of STAT5A and STAT5B play a remarkable role in the development of leukemia in which leukemic cells gain uncontrolled proliferation and angiogenesis ability. At the same time, these cells acquire ability to escape from apoptosis and host immune system. In this study, we aimed to suppress STAT-5A and -5B genes in K562 CML cells by siRNA transfection and antisense oligonucleotides (ODN) targeting and then to evaluate apoptosis rate. Finally, we compared the transfection efficiencies of these approaches. Quantitative RT-PCR and Western blot results indicated that STAT expressions were downregulated at both mRNA and protein levels following siRNA transfection. However, electroporation mediated ODN transfection could only provide limited suppression rates at mRNA and protein levels. Moreover, it was displayed that apoptosis were significantly induced in siRNA treated leukemic cells as compared to ODN treated cells. As a conclusion, siRNA applications were found to be more effective in terms of gene silencing when compared to ODN treatment

© 2014 The Authors. FEBS Journal © 2014 FEBS

based on the higher apoptosis and mRNA suppression rates. siRNA application could be a new and alternative curative method as a supporting therapy in CML patients.

The molecular function of the long noncoding RNA SPRY4-IT1 in human melanocytes

W. Zhao, J. Mazar, B. Lee, J. Shelley, S. S. Govindarajan, M. E. Dinger, **R. J. Perera**
Sanford-Burnham Medical Research Institute, Orlando, FL, USA

Expression of the long noncoding RNA (lncRNA) *SPRY4-IT1* is low in normal human melanocytes but high in melanoma cells. siRNA knockdown of *SPRY4-IT1* blocks melanoma cell invasion and proliferation, and increases apoptosis. To investigate its function further, we affinity purified *SPRY4-IT1* from melanoma cells and used mass spectrometry to identify the protein lipin 2, an enzyme that converts phosphatidate to diacylglycerol (DAG), as a major binding partner. *SPRY4-IT1* knockdown increases the accumulation of lipin2 protein and upregulate the expression of diacylglycerol O-acyltransferase 2 (DGAT2) an enzyme involved in the conversion of DAG to triacylglycerol (TAG). When *SPRY4-IT1* knockdown and control melanoma cells were subjected to shotgun lipidomics, an MS-based assay that permits the quantification of changes in the cellular lipid profile, we found that *SPRY4-IT1* knockdown induced significant changes in a number of lipid species, including increased acyl carnitine, fatty acyl chains, and triacylglycerol (TAG). Together, these results suggest the possibility that *SPRY4-IT1* knockdown may induce apoptosis via lipin 2-mediated alterations in lipid metabolism leading to cellular lipotoxicity.

The non-coding tandem repeat LL2R on chicken chromosome 2 is transcribed in growing oocytes at the lampbrush stage

D. Chervyakova, A. Zlotina, T. Kulikova, A. Fedorov, A. Krasikova
Saint-Petersburg State University, St.Petersburg, Russian Federation

The role of non-coding RNA in a cell remains largely unknown. Massive transcription of tandemly repetitive DNA is typical for certain period of diplotene in avian and amphibian oocytes. Here we characterize the transcriptional activity of the novel non-coding tandem 'lumpy loop 2 repeat' (LL2R) that was revealed on the q arm of the chicken chromosome 2 by means of bioinformatic analysis. Using different approaches, such as DNA/RNA FISH, confocal imaging, atomic force microscopy and scanning electron microscopy, we have previously shown that synthesized during oogenesis non-coding transcripts of LL2R repeat highly enrich RNP-matrix of special transcription units (so-called 'lumpy loops') on lampbrush chromosome 2. Here we demonstrate data on transcriptional activity of the non-coding LL2R cluster by the reverse transcription (RT)-PCR on RNA isolated from chicken ovary. The RT-PCR products generated from transcripts of one of the LL2R repeat strands differed slightly in size and band intensity from the products from another DNA strand transcripts. These data indicate transcription of both strands of LL2R repeat and elucidate the tandem organization of the non-coding LL2R transcript, demonstrating that it may contain not only direct, but also inverted repeats. RT-PCR products of about 380 base pairs were cloned in AT-vector and sequenced. The alignment of cDNA sequences isolated from several clones with the *Gallus gallus* genome confirmed that the RT-PCR products consist of LL2R repeat unit. RNA FISH on chicken lampbrush chromosome 2 with strand-specific LNA probes to LL2R repeat demonstrated transcriptional activity of only one strand of this genomic locus in chicken growing oocytes. The observed difference between FISH with LNA probes data and RT-PCR results may indicate differential transcriptional activity of LL2R strands in growing oocytes and somatic cells of the ovary. Immunostaining technique has demonstrated that elongating form of RNA polymerase II associates with LL2R repeat transcription unit on chicken lampbrush chromosome 2. Loops formed by LL2R-repeat transcription unit do not contain markers of repressed chromatin but demonstrate low rate of transcription as shown by BrUTP injection experiments. We also confirmed that non-coding LL2R RNA co-transcriptionally associates with splicing factors including U6 snRNA and SR-protein SC35. An emerging model of the LL2R repeat transcription and co-transcriptional association of LL2R transcripts with splicing factors will be presented.

The work was partially performed using experimental equipment of the Research Resource Centers 'Chromas' and 'Molecular and cell technologies' of St Petersburg State University.

The peculiarities of complex formation of porphyrins with transfer RNA

I. Vardanyan
Molecular Physics, Yerevan State University, Yerevan, Armenia

The interaction of meso-tetra-(4N-oxyethylpyridyl)porphyrin (TOEPyP4) and its Zn(II), Cu(II), -metallocomplexes with tRNA at low ionic strength we have investigated earlier [1]. In this work we have studied the binding of the same porphyrins with tRNA which has 2 forms: hairpin structure and spatial reversed 'L' structure. The interaction of tRNA from E.Coli with porphyrins is studied by UV/Vis Spectrophotometry and Circular Dichroism methods.

The measurements were performed in 0.1 BPSE and 1BPSE buffers (1 BPSE = 6 mM Na_2HPO_4+ 2 mM NaH_2PO_4 +185 mM NaCl + 1 mM Na_2EDTA), correspondingly $\mu = 0.02M$ and $\mu = 0.2M$, pH 6.57. (tRNA has hairpin form at $\mu = 0.02M$ and reversed 'L' structure, when $\mu = 0.2M$.)

From the spectrophotometric titration datas the Scatchard binding isotherms for porphyrin-tRNA complexes are built and binding parameters are calculated (N – the number of binding sites per molecule of tRNA, and K – the binding constant).

For all complexes of tRNA-porphyrin there are also found induced CD spectra, which are crucially different from ICD spectra of DNA-porphyrin complexes. In case of tRNA's hairpin structure for the values of induced CD spectra (at 400–470 nm) for complexes tRNA with TOEPyP4 and CuTOEPyP4 there is an optimum concentration of porphyrins at which the anisotropy of system is maximal. For complexes of ZnTOEPyP4 with tRNA the induced CD spectra are essentially different. The induced CD spectra of complex change a sign and continue to grow (remain-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ing negative) starting from a certain relative concentration. This unusual ICD spectra profile is found for all three porphyrin-tRNA complexes in case of tRNA's reversed 'L' structure. It is possible that at high relative concentration of porphyrins the liquid crystal form may exist in the solution.

The binding constants with tRNA in case of hairpin form are an order of magnitude greater than in case of reversed 'L' structure. It means that this porphyrin interacts stronger with tRNA when it has hairpin form.

The spatiotemporal expression patterns of microRNA in response to high temperature stress in rice

S. Goel, N. S. Mishra
Plant Molecular Biology, International Centre for Genetic Engineering and Biotechnology, New Delhi, India

Global warming coupled with climate change is one of the important limiting factors that affect crop yields throughout the world. MicroRNAs (miRNAs) are a novel class of endogenous, non-coding small RNAs that have been established as ubiquitous regulators of post-transcriptional gene regulation via degradation or translational repression of the cognate mRNA targets. Thus, understanding the miRNAs mediated regulatory schemas for heat stress tolerance is necessary to raise novel crop varieties that can withstand or avoid stresses imposed by changing environment. In the present study, Analysis of NGS datasets (IIlumina, GA) of control and heat stressed c-DNA libraries generated from Flag leaf and Spikelet's of heat tolerant and sensitive indica rice cultivars identified several known and novel miRNAs that displayed a spectrum of response ranging from stable to very variable in nature between tissues and across cultivars. In depth profiling of miRNA expression patterns across tissues under various heat stress treatments also identified specific miRNAs that are highly de-regulated by high-temperatures. To understand the functional implications of miRNAs,their targets were identified. The predicted targets include transcription factors, protein kinases, ATP-binding proteins, HSPs, HSFs, Growth-regulating Factors, oxidoreductases, antioxidants etc. that are linked with various metabolic & cellular processes thereby regulating the stress responses. Future studies of these miRNAs may provide better understanding of the molecular links behind these regulatory networks and may deliver fresh application routes for rice improvement during heat stress.

Twister ribozymes: from synthetic biology to in vivo function investigations

M. Felletti, B. Klauser, J. Hartig
Chemistry, University of Konstanz, Konstanz, Germany

The recent description by Breaker and coworkers (2014) of a new class of small endonucleolytic ribozymes termed Twister opened new avenues into the field of the alternative regulatory functions of RNA and in particular into the field of catalytic RNAs.

One of the most exciting applications of ribozymes is their use in synthetic biology and in particular in the construction of artificial genetic circuits. In particular ribozymes can be used in association with aptamers and riboswitches (generating the so-called aptazymes) to create ligand-controlled genetic circuits.

Here we present a method to design and select new Twister based ligand-dependent riboswitches, to control gene expression *in vivo*, not only in bacteria, but also in eukaryotic model systems. In bacteria, our approach is based on the use of artificial constructs in which the ribozyme moiety acts as a molecular scaffold for the sequestration of the ribosome-binding site (RBS). Aptamer domains are attached to the ribozyme as exchangeable ligand-sensing domains. Addition of ligands to the bacterial growth medium changes the activity of the ligand-dependent self-cleaving ribozyme which in turn switches gene expression on or off. Alternative designs and apatameric moieties binding different ligands were successfully used paving the way to the development of Boolean logic operators at the post-transcriptional level. Besides the important implications for synthetic biology, our data represent the first evidence for Twister ribozyme activity in bacteria *in vivo*.

Moreover, we investigate the possibility of employing our Twister-based aptazymes as ligand-dependent gene expression switches in eukaryotic model systems such as *Saccharomyces cerevisiae*, *Caenorhabditis elagans* and mammalian cell cultures. In these organisms the cleavage of mRNA in either the 5′-end or 3′-end regions is sufficient to cause the degradation of mRNA.

These new findings provide new tools for the study of the *in vivo* function of Twister ribozymes.

Keywords: Bacteria, Riboswitch, Twister ribozyme.

MON-442
A new type of peptide nucleic acids derived from L-Glu

G. Pozmogova[1], M. Tankevich[2], A. Dezhenkov[2], A. Varizhuk[1], I. Smirnov[1], Y. Kirillova[1,2]
[1]*Institute of Physical-Chemical Medicine,* [2]*Lomonosov Moscow University of Fine Chemical Technology, Moscow, Russian Federation*

Methods for obtaining a new modification of nucleic acids - negatively charged peptide nucleic acids (PNA) – are described. Introduction of charged groups into PNA backbone ensures good solubility of PNA oligomers in aqueous solutions and enables their complexation with cationic transfectants, such as gene-carrying peptides or lipid-like amphiphilic compounds. The synthetic part of our work was aimed at consecutive development of methodology for obtaining all structural components of PNA – pseudopeptides, monomers and some oligomers of alpha- and gamma-series. Hybridization properties of the newly synthesized negatively charged PNA oligomers were studied using UV-spectroscopy (thermal dissociations profiles) and circular dichroism (CD) spectroscopy (Figure 1). Homothymidine g-PNA decamers were shown to form duplexes of increased stability with complementary DNA, while alpha-PNA oligomers of various sequences demonstrated significantly weaker (if any) binding affinity towards DNA. The results of our work suggest that gamma-derivatives are appear generally more promising for constructing DNA mimics with a predetermined structure than alpha-isomers.

Allele-specific genome editing and correction of disease-associated phenotypes in rats using the CRISPR/Cas platform

T. Mashimo, K. Yoshimi, B. Voigt, T. Kaneko
Institute of Laboratory Animals, Graduate School of Medicine, Kyoto University, Kyoto, Japan

The bacterial CRISPR/Cas system has proven to be an efficient gene-targeting tool in various organisms. Here, we employed CRISPR/Cas for accurate and efficient genome editing in rats. The synthetic chimeric guide RNAs (gRNAs) discriminated a single nucleotide polymorphism (SNP) difference in rat embryonic fibroblasts, allowing allele-specific genome editing of the dominant phenotype in (F344 × DA)F1 hybrid embryos. Interestingly, the targeted allele, initially assessed by the allele-specific gRNA, was repaired by an interallelic gene conversion between homologous chromosomes. Using single-stranded oligodeoxynucleotides, we recovered three recessive phenotypes: the *albino* phenotype by a SNP exchange; the *non-agouti* phenotype by integration of a 19-bp DNA fragment; and the *hooded* phenotype by eliminating a 7098-bp insertional DNA fragment, evolutionary-derived from an endogenous retrovirus. Successful *in vivo* application of the CRISPR/Cas system confirms its importance as a genetic engineering tool for creating animal models of human diseases and its potential use in gene therapy.

Antigenic properties of VP1 protein of human polyomaviruses

I. Kucinskaite-Kodze, A. Zvirbliene, R. Lasickiene, A. Gedvilaite
Institute of Biotechnology, Vilnius University, Vilnius, Lithuania

The aim of this study was to identify immunodominant epitopes of yeast-expressed major capsid proteins VP1 of different polyomaviruses. Sequence alignment of VP1 proteins of human JC and BK (JCPyV, BKPyV), primate (SV40), hamster (HaPyV) and mouse (MPyV) polyomaviruses revealed homologous sequences within these proteins. Recombinant yeast-expressed VP1 proteins of polyomaviruses have a capacity to self-assemble to virus-like particles (VLPs). Therefore, it is expected that recombinant VLPs may share antigenic properties with native polyomavirus VP1 proteins.

VP1 proteins of JCPyV, BKPyV, SV40, HaPyV and MPyV were expressed in yeast *S.cerevisiae* and purified by density gradient centrifucgation. The antigenic structure of recombinant VP1 proteins was investigated according to their reactivity with 4 monoclonal antibodies (MAbs) raised against recombinant JCPyV VP1 protein. Yeast-expressed JCPyV-VP1 protein was reactive with serum antibodies induced by JCPyV infection. These results demonstrate that the immunodominant epitopes recognized by serum antibodies are exposed in recombinant VLPs thus confirming the antigenic similarity between yeast-expressed and virus-derived JCVPyV-VP1 protein. The reactivities of MAbs raised against yeast-expressed JCPyV-VP1 with recombinant VLPs of JCPyV, BKPyV, SV40, HaPyV and MPyV were investigated by ELISA and Western blot assay. It was determined that two MAbs (clones #8E8, #11C8) are cross-reactive with all tested VP1 proteins except MPyV-VP1 protein. One MAb (clone #8G8) was cross-reactive with all tested VP1 proteins except SV40-VP1 protein. The MAb #2E4 demonstrated a broad cross-reactivity with all tested VP1 proteins. For epitope mapping, deletion mutants of VP1 protein were employed. The MAb epitopes were localized at the C–terminus (aa 295–354) of VP1 protein. In conclusion, the current study enhances knowledge on the antigenic structure of polyomavirus VP1 protein and its immunodominant epitopes.

This work was founded by the European Social Fund under national Integrated Programme Biotechnology and Biopharmacy, grant VP1-3.1-SMM-08-K01-005.

Application of novel non-viral gene delivery carrier to mammalian cells

N. Finiuk[1], M. Kitsera[1], N. Mitina[2], A. Zaichenko[2], R. Stoika[1]
[1]Department of Regulation of Cell Proliferation and Apoptosis, Institute of Cell Biology of National Academy of Science of Ukraine, [2]Lviv National Polytechnic University, Lviv, Ukraine

Gene delivery is a promising method to cure various diseases, such as cancer, diabetes, and genetic and autoimmune diseases. The progress of gene delivery is limiting by its inefficiency due to the presence of biological barriers for gene transfer, as well as high toxicity and immunogenicity. Non-viral gene delivery vectors, especially cationic polymers, have attracted much attention in gene therapy.

Novel comb-like carriers, named BG-2, based on dimethyl aminoethyl methacrylate were synthesized at Lviv National Polytechnic University, Ukraine via controlled radical copolymerization using oligoperoxide Cu^{+2} coordinating complexes.

Good plasmid DNA-binding ability of the polymers was determined using agarose gel electrophoresis and zeta potential analysis. The plasmid DNA condensation of the polymers was attributed to their cationic properties, of which zeta potentials were all in the range of 18.3–40.8 mV. The average particle size of the polymer/plasmid DNA complexes was determined at the level of 65.9–95.6 nm. We observed the protection effect of the complexes against DNA degradation by DNase I. It is considered that cytotoxicity of cationic polymers is another important factor of biocompatibility. Low cytotoxicity of carriers was showed using the MTT assay towards 293T, MCF-7 and HeLa cells. Besides, polymers exhibited lower cytotoxicity than that of PEI. We did not found high toxity of the polymers *in vivo*. The carriers demonstrated no mutagenic potencial towards treated cells. It was indicated the low hemolytic activity of studied polymers. The erythrocytes incubated with carriers and PEI were deformed and aggregated only at the effect of high polymers concentration. BG-2 was efficient in crossing cellular barriers due to high lipophilic activity and forming stable and small sized complexes with DNA. Transfection conditions were optimized for plasmid DNA delivery into seven cells lines. BG-2 polymers possessed higher gene delivery efficiency than that of PEI (classical transfection agent). We indicated the increase of p53 and p21 expression in MCF-7 cells using BG-2 carriers.

Novel DMAEM-based polymers are perspective for the use as non-viral gene delivery vectors. They are non-toxic and non-mutagenic. Their application is handy and time saving.

Applications of nanoparticles are among the most active research areas, mainly in the field of the pharmaceutical and biomedical domains. In this work, biological activity of 3-Hydroxyflavone (3-HF) in a silver nanoparticles complex (SNPs) as well as the contribution of the carrier protein, Bovine Serum Albumin (BSA), to the biological activity of 3-HF, have been investigated. Transmission Electron Microscopy (TEM) analysis showed that the average size of the silver particles is ~ 9 nm, and the core-shell structure of the 3-HF-SNPs has been supported by UV-Vis spectra. The structure, stability, dynamics and conformation of the BSA protein have been investigated by fluorescence, circular dichroism and Atomic Force Spectroscopy (AFM) spectroscopies. Insights on the antioxidant activity of the 3-HF into the BSA – SNPs systems have been investigated using the chemiluminescent system luminol-hydrogen peroxide, in phosphate buffer, pH 7.4. To evaluate the effect of 3-HF, in the BSA-SNPs systems, on the cell viability and on the cell morphology, a mouse fibroblasts cell line, has been used. The results are discussed with relevance to the oxidative stress process.

Biosynthesis of stable iron nanoparticles in aqueus extracts of *Nicotiana benthamiana* and *Hordeum vulgare*

V. Makarov[1], S. Makarova[2], N. Kalinina[1], A. Love[3], M. Taliansky[3]
[1]A.N. Belozersky Institute Of Physico-Chemical Biology MSU, [2]Biology Department, Moscow State University, Moscow, Russian Federation, [3]The James Hutton Institute, Dundee, UK

Plant extracts contain a potent array of various metabolites, including terpenoids, polyphenols, sugars, alkaloids, phenolic acids, and proteins, which can bioreduce metal ions into nanoparticles. We report the synthesis of amorphous iron nanoparticles from iron salts in aqueous extracts of dicotyledonous (*Nicotiana benthamiana*) and monocotyledonous (*Hordeum vulgare*) plants, and also discuss their characterization using TEM, SAED, DLS, XRD and EELS. *H. vulgare* extracts produced smaller nanoparticles (average diameter of 10 nm) than was observed in *N. benthamiana* (average diameter of 20 nm). Subsequent XPS analysis of the nanoparticles revealed that the binding energies for 2p iron electrons were typical for Fe_3O_4 iron oxide, where iron atoms were contained in combined (II and III) oxidation states. These iron nanoparticles were found to be intrinsically unstable and prone to aggregation: one hour after synthesis the hydrodynamic diameter of the nanoparticles increased by more than 10 times. It was subsequently found that addition of 40 mM citrate buffer pH 3.0 into plant extracts leads to long-term nanoparticle stability. The differences in the sizes of nanoparticles measured using TEM and DLS methods, likely indicates the presence of organic components in their composition. Using AFM analysis, textural differences between the extracts were identified: *H. vulgare* contained smaller nanosized organic aggregates to a higher level than *N. benthamiana*. We suggest that these aggregates might act as nucleation sites, with their different morphologies and numbers likely accounting for the differential modulation of iron nanoparticle formation.

Changes in levels of hydrogen peroxide and phenolic compounds in grapevine latent buds during the annual cycle

S. Qsaib, F. E.-Z. Ikbal, M. Faize, T. Koussa
Laboratory of Plant Biotechnology, Ecology and Ecosystems Valorization, Faculty of sciences, University of Chouaib Doukkali, El Jadida, Morocco

The quantitative analysis of phenolic compounds and of hydrogen peroxide (H_2O_2) amounts in the latent buds of the vine (*Vitis vinifiera.* L) showed seasonal variations. These compounds change also as function of the vine development cycle. The total amounts of phenolic compounds are strongly accumulated in the buds in beginning of dormancy phase in mid-August. Never the less, the ending of dormancy phase in mid-November in the buds is associated with increasing of the hydrogen peroxide yield and a considerable drop in the content of the total amount of phenolic compounds. These variations appear to be strictly related to the climatic conditions. This is particularly visible in ending of dormancy phase. This is coinciding with the cold period where the temperature is below 10 ° C for at least 7 consecutive days.

Keywords: dormancy, buds Vitis vinifera, phenolic compounds.

Characterization and biocompatibility of synthesized PCL/nHAp bio nanocomposites

M. E. Diken[1], S. Doğan[1], M. Doğan[2], Y. Turhan[2]
[1]*Biology,* [2]*Chemistry, Balikesir Universty, Balıkesir, Turkey*

PCL (poly (capro lactone) is a biodegradable polymers that used to both biomedical and industrial applications, Nano hydroxy apatite (nHAp) is an inorganic component that constitutive human skeleton percent 60–70, and based on Ca (calsium) and P (phosphat) components. nHAp is taken advantage of biomedical applications, due to its bioactivity and biyocompatibilty properties. Composite materials consist of two or more different components. Composites, due to they have high strength and low elastic modulus, especially they are preferred for ortopedic applications.

İn our study, we synthesized PCL/nHAp films which used to for biomedical applications or as food packing. PCL was selected to use as a matrix, and nHAp was selected as a filler that used different concentration (1, 2.5 and 5% wt.). PCL/nHAp composites were synthesized as the films by solvent blending method. The films were characterized wit some parameters that are XRD, TG/DTA, FTIR-ATR, TEM, contact angle and uv-visible Spectrofotometer. The films was passed some biological tests like hemocompatibility, antioxidant stress enzyme activities and antimicrobial test. We have detected that physico-chemical properties of PCL were healed to used to as a filler by nHAp. When XRD and FTIR-ATR results have been looked into, all of the synthesized nanocomposites using the different concentration nHAp (%1, %2.5 and %5 wt) were shown an homogen distribution in the matrix (PCL). The optical transmittance spectra of PAA and its bio nanocomposites in the wavelength range from 200 to 700 nm were analysed that blocked uv rays increasing the filler amount. PCL and its bionanocomposites have been detected hemocompatibilty that showing between 0,35 and 1,76% hemolysis. Antioxydant enzyme activities havent been effected treatment with PCL and its bionanocomposites, apart from glutation reductase activity increased a little range.

Keywords: Bio nanocomposite, Biocompatibilty, PCL/nHAp.

Codon optimization is a key step for thermostable serine protease expression

N. Poklar Ulrih[1], M. Snajder[2], M. Mihelic[3], D. Turk[3]
[1]*Biotechnical Faculty,* [2]*University of Ljubljana,* [3]*Institute Jozef Stefan, Ljubljana, Slovenia*

Background: Pernisine is an extracellular thermostable serine protease from hyperthermophilic archeon *Aeropyrum pernix* K1. A lower yield from natural host and expression problems in heterologous host inhibits its characterization and potential application in industry.

Principal findings: Challenges of pernisine overexpression in *Escherichia coli* were overcome by codon preference optimization and DNA synthesis *de novo*. Wild type (pernisine^{wt}) and codon-optimized (pernisine^{co}) were cloned into pMCSGx series of vectors and expressed in *E. coli* cells. Fusion tagged pernisine were purified using fast protein liquid chromatography system equipped with Ni^{2+} chelate and gel filtration chromatography columns. The identity was confirmed with N-terminal sequencing, tandem mass spectrometry analysis and immunodetection. Pernisine^{wt} was not expressed and could not be detected even with immunodetection; meanwhile pernisine^{co} was purified as a proform with a yield of around 10 mg per liter of culture. Recombinant pernisine was heat activated at temperature 90°C for 1 h in buffer 10 mM HEPES pH 8,0 containing 1 mM $CaCl_2$. Proteolytic activity of mature pernisine^{co} was confirmed with zymogramphy at molecular weight 36 kDa. The temperature and the pH optima of the enzymatic activity of the recombinant pernisine, evaluated by azocasein assay, were around 105°C and pH 7, respectively.

Significance: Our findings reveal that codon optimization is crucial for pernisine overexpression in *E. coli*. Recombinant pernisine is activated by autoproteolytical cleavage of its N-terminal proregion consisting of the first 91 aminoacids. Further on, we confirmed that recombinant pernisine retains characteristics of a native one being calcium modulated thermostable serine protease.

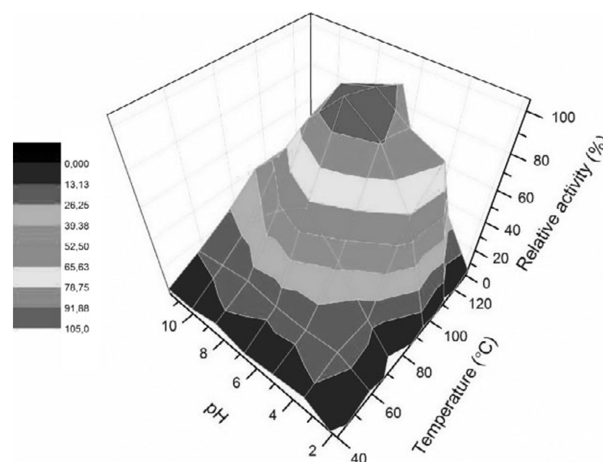

Fig. 1. Recombinant pernisine activity dependence of temperature and pH. Relative activity of recombinant pernisine was incubated at different temperatures from 40–120°C along with six different pH at range from pH 2–12. Average values of pernisine relative activity dependence as a function of temperature and pH are presented in a 3D graph.

Combinatorial approach for expression level modulation of a multigene pathway: what effects can we really expect?

M. Carquet, G. Truan, D. Pompon
Laboratoire d'Ingénierie des Systèmes Biologiques et des Procédés, INSA, Toulouse, France

Microorganisms are widely used in biotechnologies as microbial factories for the sustainable production of value-added molecules. Most of the chemicals that are actually targeted exist in natural producers, but, unfortunately, in low yield natural producers or even non cultivable organisms. To overcome these limitations, synthetic biology approaches in metabolic engineering aim to design and implement the transposition of full natural or artificial synthetic pathways in heterologous hosts.

It is known that unregulated expression of foreign enzymes can be toxic to the host, in relation with metabolic burden, overconsumption of resources, or accumulation of toxic intermediates. One way to control such imbalances is to regulate separately the expression level of each metabolic step within the biosynthetic pathway. This goal can be achieved at the transcriptional level by varying promoter's strength in front of each gene.

Among the panel of available microorganisms for metabolic engineering, *Saccharomyces cerevisiae* is widely used (Xu et al., 2012). In this host, a list of constitutive promoters is available, associated with their assumed strength in their natural configuration. A previously published study investigated the differences between some of these promoters by associating them with the Green Fluorescent Protein encoding gene and then measuring the produced fluorescence (Lee et al., 2012).

In a context of metabolic engineering, we are wondering if we can expect an expression level that would reflect the strength of the considered promoter, regardless of the open reading frame put immediately below.

To answer that question, we performed a thorough analysis at the transcriptional, translational and metabolic levels, of the real strength of three promoters supposedly different. We worked in the context of heterologous expression of three consecutive steps of the zeaxanthin biosynthesis pathway. The three genes involved were put under the control of a set of three constitutive promoters of *Saccharomyces cerevisiae,* assembled in a combinatorial manner. The resulting 14 strains are currently examined by RT-qPCR and by quantifying the generated products.

Comparative physicochemical studies of human albumin monomer and the cross-linked dimer

M. Kujda[1], Z. Adamczyk[1], M. Morga[1], E. Kowalska[2]
[1]Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences, [2]Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Cracow, Poland

Human serum albumin (HSA) is one of the most important blood protein playing various essential roles. It regulates the osmotic pressure and effectively transports a variety of ligands such as drugs, vitamins, fatty acids, ions due to its specific binding properties. HSA is also used clinically as a drug especially as plasma expander in patients with hypoalbuminemia and can also function as a drug carrier. In order to avoid the risk of transmitting possible allergenic contaminants, recombinant albumin monomeric form (rHSA) is more often used. However, rHSA is readily eliminated from the blood circulation. It is postulated in the literature that cross-linked with 1,6-bis(maleimido)hexane (BMH) HSA dimer shows a longer blood circulation than rHSA monomer and is suited as a drug carrier. Therefore, the main goal of this work is a thorough physicochemical characteristics and binding properties of rHSA albumin monomer in comparison to the synthetic BMH dimeric form. In the first step synthesis of BMH dimer is carried out according to the method described in literature. The purity and stability of dimer is determined by the SDS-PAGE electrophoresis. Subsequently, the electrophoretic mobility and the hydrodynamic diameter of both albumins were determined as a function of pH and ionic strength using the micro-electrophoresis and DLS methods. The obtained results indicate that the hydrodynamic diameter for rHSA monomer and HSA dimer (in 0.15 M NaCl pH 7.4) are 8.0 nm and 11.00 nm, respectively. Next, monolayers of rHSA and BMH dimer are prepared on negatively charged mica surface and characterized using the *in situ* streaming potential method. Protein adsorption is carried out for the range of ionic strength 10^{-2} to 0.15 M NaCl at pH 3.5. It is determined that maximum coverage of albumins increases as a function of ionic strength and reaches 1.3 mg m^{-2} in 0.15M NaCl solution. The study of desorption process confirmed the stability of monolayers in various conditions of pH and ionic strength. The obtained stable albumin monolayers can be used to perform extensive studies of ligand bindings using the precise electrokinetic methods.

Comparative study between mammal and plant GPI modification mechanism

H. Sugita[1], N. Takachio[1], N. Kato[2], H. Kaku[3], Y. Ikeda[2]
[1]Dept.Electr., Grad.Sch.Sci. & Tech, [2]Dept.Electr. & Bioinfo, [3]Dept.Life science, School of Agriclture, Meiji University, Kawasaki, Japan

GPI (glycosylphosphatidylinositol) is a kind of glycolipid which can anchor proteins to the cell membrane. GPI-anchored proteins (GPI-AP) are known to localize themselves to the microdomain on the cell membrane, called raft, via the endoplasmic reticulum (ER). Human GPI-APs are closely related to incurable human disorders including cancer, Parkinson's disease and BSE (bovine spongiform encephalopathy). Plant proteins which have similar GPI modification systems as mammal GPI-APs, can translocate to the cell wall or the raft on the cell membrane. However, because few plant proteins have been isolated as GPI-APs, the GPI modification mechanism is not clear. CEBiP (Chitin Elicitor Binging Protein), one example of a plant GPI-AP, is known to exist in monocotyledons and dicotyledons as well as other types of plants. In order to protect themselves, plants produce a significant amount of CEBiP which spurs a chitin-oligosaccharides interaction.

Based on this information, plant GPI modification was compared to that of human modification to clarify the plant GPI modification mechanism in this study. The CEBiP sequence was first inserted into a human cell expression vector, pCMV-script. HeLa cells then underwent transfection when the vector entered the cell, this causing the CEBiP gene to be expressed in the HeLa cells. The CEBiP protein could then be observed by confocal laser microscope after undergoing the immunostaining method to make the protein fluorescent. By doing this, the subcellular localization of CEBiP could be evaluated.

Keywords: CEBiP, GPI-AP.

Computational identification of cis-elements in 5′ regulatory regions of genes associated with carbohydrate metabolism-related events

I. G. Matsoukas, **A. Spanos**, T. Venables
The University of Bolton, Bolton, UK

Cis-acting regulatory elements are important molecular switches involved in the temporal and spatial expression of a dynamic network of gene activities. This network controls hormone responses, abiotic stress responses and multiple developmental events. In this analysis, a particular emphasis was placed on *cis*-acting regulatory elements present within the 5′ regulatory region of sucrose synthase (SuSy), cell wall invertase (CWI) and sucrose transporter (SUT) gene families in *Arabidopsis thaliana* and *Oryza sativa*. The potential *cis*-acting regulatory elements were predicted by scanning 1.5 kbp of 5′ regulatory regions of the SUT, CWI and SuSy genes translational start sites, using various resources for *cis*-element bioinformatics. *Cis*-elements associated with phytohormone responsiveness, light responsiveness, elicitor responsiveness and abiotic stress were predicted in varying frequencies within the 1.5 kbp of 5′ regulatory region. In addition, *cis*-elements involved in sugar repression, mineral responses, and cold- and light-inducible gene expression were also identified. Some of the predicted *cis*-elements have experimental precedent, but many are novel and encourage further exploration. This analysis provides a basis for elucidating transcription regulatory interactions of SUT, CWI and SuSy gene families in regulation of developmental phase transitions under abiotic stress conditions.

Construction of a prophage-free, hybrid-genome *E. coli* BL21 host strain by directed genome shuffling

K. Umenhoffer, B. Bogos, G. Pósfai
Institute of Biochemistry, Biological Research Centre of Hungarian Academy of Science, Szeged, Hungary

E. coli BL21(DE3) is a widely used host strain for recombinant protein production. While being a superior protein producer, the strain is poorly accessible to genetic engineering (poor transformability by plasmids, unpredictable recombination events, propensity for lysis). On the other hand, K-12 strains are easy to manipulate genetically. Moreover, genome streamlining and elimination of mobile genetic elements, as well as genes involved in generation of mutations were shown to yield further improvements in the applicability of the K-12 host cell. We set out to combine the favorable traits of BL21 and K-12. Taking advantage of the 'clean'-genome (mobile genetic element free, reduced-genome) K-12 derivative MDS42, a BL21 strain-based hybrid-genome E. coli was constructed.

K-12 and BL21 have similar core genomes (99% core sequence identity with notable variations), but possess significantly diverged, laterally transferred genomic islands, including prophages and other mobile genetic elements. Marked segments of 'clean'-genome K-12 MDS42 were sequentially transferred to BL21 by P1 transduction to replace regions occupied by prophages. To further improve engineering, the genomic region responsible for host restriction and modification was removed. To ensure that the resulting cell lines possess the desired characteristics, after each genome re-arranging step a recombinant strain pool was screened for efficient protein-expression and for preserving good growth profiles. The T7 polymerase-expressing construct (important for recombinant protein production) of the original BL21(DE3) strain was replaced by a modified, tightly controlled lac-T7 polymerase system. Altogether, 9 regions of the BL genome were replaced by the corresponding K-12 MDS42 sequence, and all prophages were eliminated from the genome. The resulting, BL21-based strain harbors an estimated 270 kb K-12 sequence, retains the excellent protein producing features, displaying unaltered stress tolerance and increased genomic stability.

CS2 hydrolase, a rare example of a biological catenane

B. Pieters[1], M. Eldijk[2], J. Mecinovic[2]
[1]*Synthetic Organic Chemistry/ BioMolecular Chemistry,* [2]*Synthetic Organic Chemistry, Radboud University, Nijmegen, Netherlands*

Catenanes, structures in which two rings are mechanically interlocked, have been studied widely by the chemical community. Contrary to synthetic catenanes, however, biological catenanes have rarely been observed. Recently the CS_2 hydrolase protein from the thermophilic archaeon *Acidianus*, has been proven to be such a biological catenane.

Because CS2 hydrolase is perhaps one of the few biological catenanes, we are interested in understanding the effect of the quaternary catenane structure of this protein. By employing FFF-MALLS and native mass spectrometry, we have shown that the catenane form can disassemble into its ring structure, whereas the ring does not assemble into the catenane structure under the same conditions. Also, using enzyme kinetics studies, we found that the quaternary protein structure affects its enzymatic activity.

Keywords: catenane, CS2 Hydrolase, enzyme kinetics.

Cytotoxic enhancement of a bispecific diabody with specificity for EGFR and CD3 by rearranging a domain order

R. Asano, T. Kumagai, K. Nagai, S. Taki, M. Umetsu, I. Kumagai
Department of Biomolecular Engineering, Graduate School of Engineering, Tohoku University, Sendai, Japan

Bispecific antibodies can be applied to cancer immunotherapy by cross-linking of tumor cells with various immune cells such as T lymphocytes. Recombinant technologies can be used to generate smaller bispecific antibodies, called bispecific diabodies, consisting of only variable domains from two different antibodies. The compact structure of diabodies contributes to low immunogenicity, high tumor-penetration, and the potential for large scale preparation through bacterial expression systems.

We previously reported the marked antitumor effects of a humanized bispecific diabody that targets EGFR and CD3 (hEx3-HL). The domains of bispecific diabodies can be ordered in four different ways and several previous reports have suggested that the order of the variable domain might affect the function of bispecific diabodies; however, only one study has systematically assessed this feature. Here, we rearranged the domains of hEx3-HL to examine the influence of domain order on the function of bispecific diabodies. We successfully prepared homogenous dimers of hEx3 in all four domain configurations. Interestingly, all three rearranged hEx3s inhibited cancer growth more effectively than did the original hEx3-HL, in which both components were in VH-VL order, and the highest effects were observed with hEx3-LH, in which both components were in VL-VH order. In addition, hEx3-LH had comparable *in vitro* growth inhibitory effects to those of the tandem scFv format of hEx3 (hEx3-taFv), which we previously showed to have greater cytotoxicity than does hEx3-HL. Flow cytometry suggested that the enhanced cytotoxicity of hEx3-LH is attributable to structural superiority for cross-linking, similar to that of hEx3-taFv. Furthermore, hEx3-LH inhibited cancer growth in mice more effectively than did hEx3-taFv; this difference may be due to differences in antibody stability. Our results show that merely rearranging the domain order of bispecific diabodies can enhance their effects beyond those with structural format conversion.

Design of a remodeling acto-myosin network driving membrane dynamics

D. V. Koester[1], K. Husain[1], E. Iljazi[1], D. R. Mullins[2], M. Rao[3], S. Mayor[1]
[1]*National Centre for Biological Sciences, Bangalore, India,* [2]*Department of Cellular and Molecular Pharmacology, University of California, San Francisco, CA, USA,* [3]*Raman Research Institute, Bangalore, India*

The major aim of our work is to understand the mechanisms behind dynamic organization of the cellular plasma membrane, especially local heterogeneities such as nanometer sized lipid domains (Mayor and Rao, 2004). As reported previously, glycosyl-phosphatidylinositol-anchored protein (GPI-AP) organization in nano-clusters in the plasma membrane is driven by the activity of cortical actin (Goswami *et al*., 2008). A recent theoretical framework proposed by Gowrishankar *et al*. (2012) suggests that the engagement of short actin filaments together with myosin-

© 2014 The Authors. FEBS Journal © 2014 FEBS

motor like activity at the cytoplasmic leaflet is sufficient to explain all the unusual features of GPI-AP organization.

Here, we present a strategy to reconstitute cortical actin dynamics *in vitro* on supported lipid bilayers. This allows us to explore the role of proteins thought to be involved in actin cluster formation and to test predictions of the theoretical model. In a first step, we investigate how the diffusion of membrane bound actin binding proteins is affected by actin filaments of varying lengths. Then, we increase the complexity of the system by including myosin motors and capping protein, and identify conditions under which actin remodeling, i.e. transient formation of actin asters, occurs. As suggested by observation in cells and by the theoretical framework, short actin filaments (<1 μm) are the main source of fast remodeling events whereas longer filaments create a more static meshwork, which can confine membrane bound particles. In summary, we introduce a new kind of minimal actin cortex, and show how dynamic short actin can drive the organization of plasma membrane particles.

Development of a new protocol for topology detection using NHS cross-linking approach

H. Chavarria-Drecourt, A. Conzelmann
Institut of Biochemistry, University of Fribourg, Fribourg, Switzerland

Chemical crosslinking in combination with mass spectrometry has been an emerging strategy to study protein-protein interactions. Using microsomes from *Saccharomyces cerevisiae,* we are developping a high throughput method based on crosslinkers to define protein topology. As a first approach, we used the thiol-cleavable, membrane impermeable and lysine-specific crosslinker, 3,3-dithiobis (sulfosuccinimidylpropionate DTSSP) to define the topology of control proteins. In this manner, we have been using the luminal protein Kar2p from BY4742 microsomes. We observed, with this method, a derivatization of Kar2p without any detergent. These results led us to hypothesize that DTSSP could disturb membrane stability due to the derivatization of Phosphaditylserine (PS) and/or Phosphatidylethanolamine (PE). To test this hypothesis, we used the *dpl1Δcho1Δ* double mutant strain affected in the biosynthesis of PE. Using the same method, we observed under optimal growth conditions, a decrease of derivatization of the protein Kar2p from *dpl1Dcho1D* microsomes compare to the WT BY4742. These results suggest a possible interaction between DTSSP and the phospholipids present in the microsomes, which could destabilize and increase membrane permeability.

Development of targeted delivery ways for antitumor peptide lactaptin

A. Vaskova, E. Kuligina, A. Savelyeva, A. Fomin, O. Koval, D. Semenov, V. Richter
Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

Apoptosis is a critical defense mechanism against the formation and progression of cancer. Proteins inducing apoptosis in cancer cells are considered as potential anticancer pharmacological agents. Lactaptin, the proteolytic fragment of human milk kappa-casein, induces apoptosis of various cultured cancer cells. Recombinant analog of lactaptin RL2 was constructed to be expressed in *E. coli*. The anti-tumor potential of RL2 was investigated *in vivo* and *in vitro* [1, 2].

A major problem in systemic therapy is that only a small proportion of administered drug reaches its intended target site. Selective drug delivery to the target tissue or organ could alleviate this problem. Targeted delivery of RL2 will reduce the potential cytotoxic effect on normal cells, diminish the therapeutic dose and enhance antitumor efficacy by increasing the local concentration of the drug within the tumor.

We have chosen peptides as the molecular targeting agents. Targeting peptides display high tissue penetration due to small size, low immunogenicity, high affinity to targets, acceptable stability and ability to be easily conjugated with other agents. To obtain tumor specific peptides we applied a selection method using phage peptide libraries (Ph.D.™- Phage Display Peptide Library Kit, New England Biolabs). Two displayed peptides GLHTSATNLYLH and SGVYKVAYDWQH were selected to mice hepatocarcinoma A-1 (HA-1) *in vivo*. The same phage clones appeared to possess the highest affinity to ascites tumor cells of hepatocarcinoma A-1 and Lung adenocarcinoma *in vitro*. The selected phage clones were studied for the ability to bind other types of tumors *in vivo*. It was also shown the affinity of the selected peptides for Lung adenocarcinoma (A/Sn mice), Melanoma B16 (C57 Black mice), Krebs-2 adenocarcinoma (C57 Black mice) and Lewis lung carcinoma (CBA mice) *in vivo*.

We constructed several plasmid vectors producing fusion proteins united targeted peptides and lactaptin. Here we investigated cytotoxic and anti-tumor effects of targeted protein lactaptin *in vitro* and *in vivo*.

Differential in vitro inhibition studies of some cerium vanadate derivatives on Xanthine oxidase

B. E. Öz, E. Terzi, M. O. Kaya, Y. Kaya, G. Celik, F. Kurtulus, O. Arslan, O. O. Guler
Medical biology, Health sciences, ANKARA, Turkey

In this preliminary study a new series of some cerium vanadate derivatives have been investigated as new type of inhibitors of Xanthine oxidase (E.C 1.17.3.2, XO). Xanthine oxidase is a superoxide-producing enzyme found normally in serum and the lungs and its activity is concerned with several important health problems such as gout, severe liver damage, vascular dysfunction and injury, oxidative eye injury,and renal failure. Here we present a critical overview of the effects of these novel types agents on XO with comparing the efficacy and safety profiles of allopurinol, the efficient classical inhibitor of XO.

Keywords: Cerium vanadate derivatives, Enzyme inhibition, Xanthine oxidase.

Direct tentative identification and characterization of phenolic compounds from crude extracts of buds and internodes in grapevine (*Vitis vinifera* L. Merlot)

S. Qsaib[1], N. Mateus[2], F. E.-Z. Ikbal[1], L. A. Rifai[1], V. de Freitas[2], T. Koussa[1]
[1]*Laboratory of Plant Biotechnology, Ecology and Ecosystems Valorization, Faculty of sciences, University of ChouaibDoukkali, El Jadida, Morocco,* [2]*Portugal Departamento de Quimica, Faculdade de Ciencias, Universidade do Porto, Rua do Campo Alegre 687, 4169-007, Porto, Portugal*

In this study, the crude methanol extracts of latent buds and internodes *Vitis vinifera* L. cv. Merlot were used for the determination of phenolic compounds by a combination of reverse phase HPLC with diode array detection (HPLC-DAD) and mass spectrometry (LC-MS). This method allowed the identification of nine phenolic compounds without purification or fractionation. These nine compounds were divided into three groups: procyanidins, flavonols and stilbenes. Detection by HPLC-DAD at different wavelength of 280 nm to 320 nm allowed the estimation of concentrations of those compounds. This method allowed for the first time both characterization and quantification of polyphenolic compounds in buds of grapevine. The comparison with the results obtained in internodes showed that quercetin, resveratrol tetramer and ε-viniferin are present in similar levels in buds and internodes while six other compounds identified were in higher levels in buds.

Keywords: mass spectrometry LC-MS, Phenolic compounds, Vitis vinifera.

Effect of heterologous pre-pro leader sequence on the expression of the human factor IX in cultured mammalian cells

S. Khorshidi[1], A. Zomorodipour[2]
[1]*Molecular Genetics Department, Tarbiat Modares University,* [2]*Molecular Genetics Department, National Institute of Genetic Engineering and Biotechnology, Tehran, Iran*

Hemophilia B is an X -linked recessive bleeding disorder caused by deficiency or malfunctioning of coagulation factor IX (FIX), a vitamin K dependent (VKD) g-carboxylated glycoprotein. Production of recombinant human FIX (rhFIX) in mammalian cells is usually encountered with low secretion efficiency and incomplete g-carboxylation. To improve the rhFIX expression, we replaced the hFIX leader (prepro-)peptide, with those of the human and porcine *Prothrombins* (pProt and hProt, respectively), which are VKD and γ-carboxylated efficiently, to be examined in a human cell line, in transient state. *In silico* analysis of the examined prepeptides predicted their respective secretion potentials as: pProt >hProt>hFIX. Besides, lower minimum free energies of the resulted transcripts of the chimera transgenes suggested for their higher translation rates in comparison with that of the native *hFIX*. In consistent with our *in silico* predictions, improvement of secretion of FIX by the transgenes equipped with either of the pProt and hProt prepro was shown in the human cell line. Biological activities of the expressed rhFIXs indicated in occurrence of γ-carboxylation for the three examined mini-genes products. However, the propeptides of the pProt and hProt appeared more appropriate substrates for the human γ-carboxylase, probably due to their greater turnover. These results confirmed that the total hydrophobicity, rather than the length of the hydrophobic region of a signal peptide is crucial for its secretion efficiency. This study demonstrated the incorporation of a heterologous leader peptide coding region in both transcription and post-transcriptional efficiencies of the linked gene and displayed the feasibility of a leader-peptide replacement approach for the improvement of the expression of the gene of interest.

Keywords: human and porcine Prothrombin, Human coagulation factor IX, Prepro-leader peptide.

Efficient strategy for the selection of DNA aptamers specific to recombinant proteins

A. V. Kozyr, A. V. Kolesnikov, A. K. Ryabko, N. M. Luneva, A. E. Khlyntseva, I. G. Shemyakin
Laboratory of Molecular Biology, State Research Center for Applied Microbiology and Biotechnology, Obolensk, Russian Federation

We have developed highly efficient technique for selection of aptamers binding recombinant proteins. The recombinant protein of interest is fused to the affinity tag separated from the protein by recognition peptide for a site-specific protease. The fusion protein is produced, purified by affinity chromatography, and immobilized on the solid support (paramagnetic beads, chromatographic media, immunoplates etc.) containing the tag-binding moiety. Beads are further incubated with random DNA aptamer library to afford interaction of aptamers with immobilized target. After extensive washing, the target protein with captured DNA aptamers is cleaved off the support using site-specific protease. Protease-eluted DNAs are further amplified by PCR and proceeded to the next panning round.

Presumably, any affinity tag and any expression system as well as any site-specific protease can be used in this selection strategy. In the present work, the in vivo biotinylated peptide and His tag were used with equal success. SUMO and anthrax lethal factor tested as site-specific protease also showed excellent performance in specific aptamer elution.

Using the described technique, we selected high affinity DNA aptamers to *C. botulinum* neurotoxin light chain and *B. anthracis* lethal factor. The developed strategy helps to reduce the quantity of selection rounds and achieve obtaining of high-affinity aptamers within 2–5 selection cycles while avoiding co-selection of aptamers specific to the solid phase. The work is supported by research grant 14-15-00630 from Russian Science Foundation.

MON-465
Elucidation of the molecular mechanism of GPI transamidase

D. Takahashi[1], K. Etchuya[1], T. Ogawa[1], K. Hamada[1], Y. Mukai[2]
[1]Dept. Electr., Grad. Sch. Sci. & Tech., [2]Dept. Electr. & Bioinfo., Sch. Sci. & Tech., Meiji University, Kawasaki, Japan

Many proteins anchored to the plasma membrane by Glycosylphosphatidyl-inositol (GPI) exist on the eukaryotic cell surface. The protein modified by the GPI transfer enzyme, GPI transamidase, is called the GPI-anchored protein (GPI-AP). In the endoplasmic reticulum (ER), GPI transamidase recognizes the GPI-attachment signal sequence and then modifies GPI to the ω-site of the protein. The GPI-attachment signal sequence is then separated by GPI transamidase. GPI transamidase is known as a protein complex consisting of GPI8, GAA1, PIG-T, PIG-S and PIG-U. In order to predict GPI-APs, ω-site prediction tools have recently been developed. However these methods have not been successful in clarifying these factors. Therefore, the mechanisms related to the recognition and digestion of the GPI-attachment signal by GPI transamidase were focused on in this study.

The sequence dataset of GPI-AP was extracted from the UniProt KB/Swiss-Prot Release 2014_01. The amino acid propensities around the ω-site and the hydrophobic region of the GPI-attachment signal sequence were calculated. As a result, a large number of serine and threonine were confirmed downstream from the ω-site. Glycine, proline, serine and threonine were also confirmed in the hydrophobic region in the GPI-attachment signal sequences. Based on these facts, the phosphorylation of these residues is thought to be a trigger of the tertiary structural change of GPI-AP. The fact that many small residues were found in the hydrophobic region of the GPI-attachment signal sequence suggests that the polypeptides in these regions form disordered secondary structures in order to interact with GPI transamidase.

Keywords: Bioinformatics, GPI-AP, transamidase.

Enzyme linked immuno mass spectrometric assay (ELIMSA)

A. Florentinus-Mefailoski, J. Marshall
Chemistry and Biology, Ryerson University, Toronto, ON, Canada

Enzyme Linked Immuno Mass Spectral Assay (ELIMSA) may detect and quantify the binding of molecular probes such as ligands and receptors to zeptomole amounts using only common reagents and equipment that may be of great significance to basic biology and medical diagnosis. ELIMSA combines Enzyme-linked immunosorbent assay (ELISA) using a substrate that yields ionizable products that may be measured by liquid chromatography-electrospray ionization and mass spectrometry (LC-ESI-MS) with a high signal to noise ratio to create the transformative new technology. We favourably compared the enzyme alkaline phosphatase (AP) and horseradish peroxidase (HRP) for detection by LC-ESI-MS/MS. Here we show the substrates adenosine monophosphate (AMP) or pyridoxamine-5-phosphate (PA5P) are converted by AP-SA conjugate to adenosine (A) and pyridoxamine (PA) respectively that are resolved well in isocratic LC and ionized very efficiently in an electrospray and showing a linear intensity relationship with AP-SA concentration after log transformation. The A and PA reporter products were observed to show a linear relationship between log ion intensity and quantity to as low as femtomole amounts. Here the enzyme AP bonded to Streptavidin (AP-SA) catalyzed the release of A and PA that showed a direct and linear intensity relationship with AP-SA concentration after simple log transformation as measured by MS. Internal ^{13}C adenosine (A) or pyridoxamine (PA) isotope dilution curves, internal ^{13}C isotope one point calibration, external A or PA dilution curves and external ^{13}C A or ^{13}C PA curves showed close agreement on the linear quantification of the LC-ESI-MS/MS assay. Thus, MS can be used to measure an ELISA that produces A or PA against external protein standards with great sensitivity and accuracy. We applied the system to measure PSA to 1 picogram by ELIMSA with linear and normal results, high sensitivity and high signal to noise ratios that provides a universal system for quantification at vanishingly low concentrations. ELIMSA with the products A or PA was flexible for measuring multiple ions, log linear and quantitative from picomole to zeptomole amounts of the biotinylated probe or prostate specific antigen (PSA) analyzed. The PSA ELIMSA efficiently detected and quantified PSA clearly quantifying samples with <10 pg of PSA that was below the detection limit of the colorimetric or ECL methods. In practical terms ELIMSA showed that all normal patient PSA levels are now within the range of common quantification. ELIMSA allows the direct quantification of enzyme labelled probes to 1 femto gram i.e. ~ 1zeptomole amounts by LC-MS. ELIMSA permitted the routine analysis of quantifying receptor-ligand complexes of biological molecules to attomole amounts or less.

Keywords: ELIMSA, ELISA, mass spectrometry.

Evolutionary computation to understand signaling and TFTG network in Leishmania: a mechanistic perspective

S. Singh
Compuational and Systems Biology Lab, National Centre for Cell Science, Pune, India

Mathematical modelling of biological processes helps unravel the dynamics associated with transcriptional-translational machinery and the signaling network reconstructed. Perturbation of any biological process through internal or external agents can lead to disease etiology. Leishmaniasis is a protozoan disease that perturbs the immune signalling response eventually affecting the gene regulatory network (GRN) in macrophages that results in an anti-inflammatory phenotype. Through systems biology approach, we are trying to develop a robust GRN that will maintain stable phenotypes under varying conditions. To this end, it is important to understand the inherent stochasticity associated with the network, which can be lowered by introducing a negative feedback loop acting on the system through allosteric changes. The negative feedback loop can also reduce the response time delay that can assist in tuning the system to a desired behaviour. The mechanistics of allosteric changes in gene regulation can help understand and predict the behaviour of the transcriptional control machinery. A transcription factor – target gene (TFTG) network with a negative feedback loop was built and evolutionary trade-offs of the network was mapped. Further insights were also laid down in terms of evolutionary computation of signaling network of Leishmania through genetic algorithm. The resultant morphospace of the infected macrophage may help to decide the tuning factors responsible for changing an anti-inflammatory phenotype to a pro-inflammatory phenotype and there off leading to homeostasis for a disease resolving effect.

Keywords: Leishmaniasis, Mathematical modeling, morphospace.

MON-469
Evolving highly red shifted congener protein by expanding the genetic code

A. Niraikulam
Biotechnology, Central Leather Research Institute, Chennai, India

Fluorescent proteins are important tools in biotechnology and cellular biology studies. It has been well reported that incorporation of natural and unnatural amino acids into the chromophore residues has shown a variety of spectral variations, but it still failed to offer red fluorescent variant from the wild type Green fluorescent protein. Here, we will introduce the donor-acceptor system into GFP for the generation of new large stock shift red variant. The presence of amino donor in the chromophore and its surrounding region in the stockGFP, it will also acquired the ability to bind selectively and sensitively with metal ions, and resulted in the generation of novel protein-based biosensor. Since, the transition metal ions are plays a crucial role as a metal cofactor in oxidative scavenging mechanisms in human body. Developing novel stockGFP will be an important toolkit to generate novel classes of tailor-made GFP variants, which is not possible through the canonical amino acid modification. This tailor-made stockGFP opened a new door for multiple cell imaging and creation of new protein-based biosensor for metal ion quantification in biological science.

Keywords: green fluorescent protein, expanding the genetic code, non canonical aminoacid.

Expression, purification and characterisation of glycosylated influenza H5N1 hemagglutinin produced in yeast.

E. Kopera[1], **A. Macioa**[1], J. Dębski[1], B. Szewczyk[2], W. Zagórski-Ostoja[1], K. Grzelak[1]
[1]*Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw,* [2]*Department of Recombinant Vaccines, University of Gdansk and Medical University of Gdansk, Gdansk, Poland*

Hemagglutinin (HA) plays crucial role in virus infection. HA glycoprotein is synthesized as an inactive HA0 molecule assembled as noncovalently bound homotrimers on the viral surface. This precursor protein is cleaved by trypsin-like proteases to create two subunits, HA1 and HA2 which are linked by a single disulfide bond [1]. After cleavage, at the specific site, these two disulfide-bonded protein domains produce the mature form of the HA protein. The A/swan/Poland/305-135V08/2006 (H5N1- subtype) hemagglutinin gene was cloned and expressed in yeast *Pichia pastoris* (*P. pastoris*). The HA cDNA lacking the C-terminal transmembrane anchor-coding sequence was fused to α-factor leader peptide and placed under control of the methanol-inducible *P. pastoris alcohol oxidase 1* (*AOX1*) promoter. Two *P. pastoris* strains: SMD 1168 and KM 71 were used for protein expression. Recombinant HA protein was secreted into the culture medium reaching the approximately 15 mg/L. The fusion protein with His6 tag was purified to homogeneity in one step affinity chromatography. SDS-Page and MS/MS analysis indicated that the protein is cleaved into HA1 and HA2 domains but linked with disulphide bond. Analysis of the N-linked glycans revealed that the overexpressed HA is fully glycosylated at the same sites as the native HA in the vaccine strain.

Folate-targeted cationic liposomes for the efficient delivery of nucleic acids into tumor cells

E. Shmendel[1], N. Morozova[1], M. Zenkova[2], M. Maslov[1]
[1]*Department of chemistry and technology of biologically active substances, Lomonosov Moscow State University of Fine Chemical Technology, Moscow,* [2]*Laboratory of nucleic acid biochemistry, Institute of chemical biology and fundamental medicine SB RAS, Novosibirsk, Russian Federation*

Gene therapy is a promising approach for the treatment of cancer *via* the administration of therapeutic nucleic acids (anti-sense oligonucleotides, plasmid DNA, siRNA). Cationic liposomes are widely used as nucleic acid delivery systems due to their ability to protect their cargo against serum nuclease degradation and to efficient transfer nucleic acids through the plasmic membrane. Early we have demonstrated that liposomes composed of spermine-based cationic amphiphiles and DOPE provided the successful delivery of FITC-labeled oligonucleotide, plasmid DNA and siRNA into HEK293 cells with the efficiency significantly higher than that of Lipofectamine 2000. It is known that the introduction of a tumor cell-selective ligand in liposomal formulations can enhance their transfection activity. Folate receptor is overexpressed on the surface of several human cancer cells (ovarian carcinoma, endometrial cancer etc.), therefore, folic acid can be used as a targeting ligand for the improvement of the efficacy of nucleic acid delivery systems.

We have synthesized folate-containing lipoconjugates differed with a length and a nature of the spacer group to study the influence of this structure element on the nucleic acid delivery efficiency. Using folate lipoconjugates targeted cationic liposomes were formulated and their biological activity namely the cytotoxicity and the transfection efficiency was estimated. Targeted cationic liposomes were established to be non-toxic to the different types of eukaryotic cells. To determine the optimal conditions for the targeted delivery folate receptor-bearing cells (KB-3-1 and HEK293 cells) and cells without folate receptors (A549 and HGF cells) were used. Small size slightly positively charged nucleic acid/liposomes complexes were found to penetrate into cells *via* receptor-mediated endocytosis. Besides the presence of lipoconjugate with long polyethylenglycol spacer in these complexes provided the best *in vitro* targeted delivery. Cationic liposomes containing this lipoconjugate were selected as promising candidates for further *in vivo* transfection studies.

Folding kinetics of outer surface protein A

K. Makabe[1], K. Kuwajima[2]
[1]*Science and Engineering, Yamagata university, Yonezawa,* [2]*Institute for molecular science, Okazaki, Japan*

Outer surface protein A (OspA) from *Borrelia burgdorferi* has been an excellent model system for studying b-sheet folding and peptide self-assembly. OspA has an unusual dumbbell shape composed of sequential 21 antiparallel β-strands followed by a single α-helix at the C terminus. In the middle of the molecule is a single-layer β-sheet (SLB) segment. Both faces of this SLB segment are exposed to the solvent, and consequently the segment is not associated with a hydrophobic core. Previous equilibrium unfolding studies showed that OspA unfolding follows the three-state mechanism among fully folded (N), C-terminus unfolded (I), and fully unfolded (U) states. Here, we report the folding kinetics of

© 2014 The Authors. FEBS Journal © 2014 FEBS

OspA studied by a rapid mixing technique. We found that there is a lag phase during the formation of the N state detected by tryptophan fluorescence change. The presence of the lag phase provides strong evidence for the formation of an on-pathway intermediate and we conclude that the kinetic folding of OspA also follows the three-state mechanism with the productive intermediate. The identity of the folding intermediate and the equilibrium intermediate is currently under investigation. We also prepared the N-terminal and the C-terminal domains separately and evaluated their folding properties.

Generation of extremely sensitive and selective scFv antibodies to protein C

K. Palyvoda[1], O. Oliinyk[1], E. Lugovskoy[2], S. Komisarenko[1]
[1]Department of Molecular Immunology, [2]Department of Protein Structure and Function, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kyiv, Ukraine

Introduction: Protein C is the key effector protease of the natural protein C anticoagulation pathway. A lack of protein C lead to excess clotting in veins. Therefore, protein C level measure in plasma is required. For this purpose anti-protein C antibodies are used. However, generation of specific antibodies is complicated since protein C is high homologic with a lot of human plasma proteins. The aim of this study was to select protein C fragment which has low homology to other plasma proteins and obtain antibodies to this fragment.
Methods: Protein C fragment selection was made using bioinformatic databases, tools and algorithms. Peptide that mimic a protein C sequence was synthesized by manual solid-phase method using Fmoc strategy. Monoclonal single chain variable fragment (scFv) antibodies were generated by phage display. Obtained antibodies were tested in ELISA and Western bloting.
Results: Pro^{146}-Leu^{157} protein C fragment was selected because of its capability to form an unique protein C epitope and its high immunogenicity. The scFv library of mouse immunized with Pro^{146}-Leu^{157} peptide was constructed and the protein C specific scFv were selected from the constracted library. The results showed that obtained recombinant scFv antibodies could specific bind both Pro^{146}-Leu^{157} protein C fragment and activated protein C. It was shown that scFv were suitable for protein C detection by ELISA and Western bloting. ScFv bound target antigen in Western bloting under non-reducing conditions. The scFv antibodies dissociation constant was found to be $2x10^{-9}$ M.
Conclusion: Obtained scFv antibodies could be further used as a tool for protein C investigation and for the development of diagnostic system.

Keywords: Protein C, scFv.

MON-474
Genome wide analysis of SF1 and SF2 helicases in archaea

H. Chamieh, H. Ibrahim, J. Kozah
Beirut Arab University, Tripoli, Lebanon

Helicases represent one of the largest classes of enzymes found in all prokaryotic, eukaryotic organisms and many viruses. These enzymes unwind structured nucleic acids (DNA, RNA) in Adenosine Triphosphates (ATP)-dependent manner and are further grouped into six superfamilies based on their structural motifs and consensus sequences. Superfamily helicases 1 and 2 (SF1 and SF2) play an important role in almost every process of DNA and/or RNA metabolism. All these helicases share a central helicase core domain with characteristic motifs responsible for their ATPase and unwinding activity. Using extensive bioinformatics analysis, we have surveyed the presence of SF1 and SF2 helicase superfamilies in the archaeal genomes. We have identified the sets of SF1 and SF2 helicases in archaea. Our study validated two SF1 family and 14 SF2 families among archaeal sequence genomes. Analysis of the distribution of protein families reveals that some families are ubiquitous among archaeal genomes while other families are specific to each archaeal group. We additionally highlight the conserved motifs and uncharacterized domains in the detected families. We also report the presence of a novel SF2 helicase family specific to archaea that we named ASH. Phylogenetic analysis indicated that ASH is a close homolog of the ski2-like family and analysis of its distribution showed that it is specific to euryarchaeota. Our study provides the first comprehensive analysis of SF1 and SF2 helicases from archaea.

Keywords: Archaea, genomics, helicase.

Immunological properties of yeast-derived secreted influenza virus hemagglutinin

M. Pietrzak[1], E. Kopera[1], P. Kosson[2], K. Florys[3], V. Sączyńska[3], V. Cecuda-Adamczewska[3], B. Szewczyk[4], W. Zagórski-Ostoja[1], K. Grzelak[1]
[1]Protein Biosynthesis, Institute of Biochemistry and Biophysics Polish Academy of Sciences, [2]Mossakowski Medical Research Centre Polish Academy of Sciences, [3]Institute of Biotechnology and Antibiotics, Warsaw, [4]University of Gdansk and Medical University of Gdansk, Gdańsk, Poland

Influenza virus is a pathogen inducing respiratory disease with symptoms varying from mild to severe. The realistic barrier against the disease remains still in vaccination against influenza. It is well established that the virus hemagglutinin is the main antigen, inducing the neutralizing antibodies. The HA gene mutates however fast and requires constant creation of novel vaccine versions acting against the seasonal version of the pathogen. This is rather compelling task as the standard vaccines are prepared from the viruses grown on large scale in chicken embryos. The production of recombinant HA in appropriate expression systems is an alternative approach. Looking for the optimum antigen production method we opted for simple and cheap *Pichia pastoris* system. Here the secretion of the overexpressed polypeptide considerably facilitates the purification of the product. The A/swan/Poland/305-135V08/2006 (H5N1- subtype) hemagglutinin gene was cloned and expressed in yeast *Pichia pastoris* (*P. pastoris*). The HA cDNA lacking the C-terminal transmembrane anchor-coding sequence was fused to α-factor leader peptide and placed under control of the methanol-inducible *P. pastoris alcohol oxidase 1* (*AOX1*) promoter. Recombinant HA protein was secreted into the culture medium reaching the approximately 15 mg/L. The immunological activity of hemagglutinin protein was tested in mice, where rHA elicited high immune response. HA is the main IV antigene inducing the host neutralizing antibodies protein overexpressed in Pichia is a promising candidate subunit vaccine.

MON-476
Intermolecular domain swapping induces intein-mediated protein alternative splicing

A. S. Aranko, J. S. Oeemig, T. Kajander, H. Iwai
Institute of Biotechnology, University of Helsinki, Helsinki, Finland

Protein sequences are diversified on the DNA level by recombination and mutation and can be further increased on the RNA level by alternative RNA splicing, involving introns that have important roles in many biological processes. The protein version of introns (inteins), which catalyze protein splicing, were first reported in the 1990s. The biological roles of protein splicing still remain elusive because inteins neither provide any clear benefits nor have an essential role in their host organisms. We now report protein alternative splicing, in which new protein sequences can be produced by protein recombination by intermolecular domain swapping of inteins, as elucidated by NMR spectroscopy and crystal structures. We demonstrate that intein-mediated protein alternative splicing could be a new strategy to increase protein diversity (that is, functions) without any modification in genetic backgrounds. We also exploited it as a post-translational protein conformation–driven switch of protein functions (for example, as highly specific protein interference).

Keywords: 3D domain swapping, intein, protein alternative splicing.

MON-477
Metabolic engineering of *Saccharomyces cerevisiae* for the production of plant derived antioxidants

A. Moglia[1], L. Goitre[2], S. Gianoglio[1], E. Baldini[3], A. Genre[4], L. Trabalzini[3], J. Beekwilder[5], S. F. Retta[2]
[1]Dipartimento di Scienze Agrarie, Forestali e Alimentari, University of Turin, Grugliasco, [2]Dipartimento di Scienze Cliniche e Biologiche, University of Turin, Orbassano, [3]Dipartimento di Biotecnologie, Chimica e Farmacia, University of Siena, Siena, [4]Dipartimento di Scienze della Vita e Biologia dei Sistemi, University of Turin, Torino, Italy, [5]Plant Research International, Wageningen UR, Wageningen, Netherlands

The expression of plant metabolic pathways in heterologous organisms such as *Saccharomyces cerevisiae* is an attractive strategy for the production of valuable secondary metabolites.

By engineering a *S. cerevisiae* strain with two plant genes (4 cl-2 from tobacco and hct from globe artichoke) encoding key proteins involved in the biosynthesis of phenolic esters we previously set up a system for the production of two novel phenolic compounds, N-(E)-*p*-coumaroyl-3-hydroxyanthranilic acid (Yeast avenanthramide, YAv I) and N-(E)-caffeoyl-3-hydroxyanthranilic acid (Yeast avenanthramide II, YAv II). These compounds possess structural similarity with a class of bioactive oat compounds called avenanthramides. The antioxidant, anti-proliferative, anti-inflammatory and anticancer activities of oat avenanthramide have been demonstrated both *in vitro* and in animal models

We set up a large scale fermentation system for yeast avenanthramides production following optimization of yeast strain, plasmid constructs, and culture conditions. The production of yeast avenanthramides reached a final yield of 125 mg/L for YAv I and 22.5 mg/l for YAv II.

In order to evaluate the biological properties of yeast avenanthramides, we tested their anti-oxidant properties in distinct cell models, including Mouse Embryonic Fibroblasts (MEF) and the HeLa cancer cell line. In particular, we analyzed the effects of yeast avenanthramides on FoxO1, a member of the FoxO family of transcription factors that has been demonstrated to play a major, highly conserved role in regulating ROS levels by modulating the expression of antioxidant enzymes such as Superoxide Dismutase 2 (SOD2). Real Time PCR and Western Blot analysis suggested that yeast avenanthramides positively regulate the antioxidant defense mechanism through the up-regulation of FoxO1 and SOD2 expression level. Furthermore, we demonstrated that YAv compounds enter the cells, accumulating into discrete cytosolic regions, and may exert an antiproliferative effect by facilitating the down-regulation of Cyclin D1.

Keywords: avenanthramides, metabolic engineering, antioxidant.

Mixed organic-inorganic nanocomposites as potential virus inhibitors

P. Boltovets[1], S. Kravchenko[1], O. Polischuk[2], O. Kovalenko[2], B. Snopok[1]
[1]Institute of Semiconductor Physics, [2]Institute of Microbiology and Virology, Kyiv, Ukraine

Usually when investigating biospecific interactions by biosensing methods typical approach is the immobilization at the sensor surface of the one reagent (receptor) and detection of its binding to other ones (analytes) one by one, which rest in the solution. However in real situation simultaneous multicomponent interactions are much more typical. Earlier we proposed an approach to the detection of the virus-antibody complex by surface plasmon resonance method based on the refractive index variation within the layer of the virus-antibody complexes depending on the antibody concentration, on the example of tobacco mosaic virus (TMV)[1]. The effectivness of this approach for the multi component mixes was demonstrated on the quantification of the effect of polysaccharide glucuronoxylomannan (GXM) on the interaction between TMV and specific antibodies [2].

Here we consider an approach to the formation of the nanocomposite with potent antivirus ability based on the *Ganoderma adspersum* glycane with embedded gold nanoparticles and its further interaction with TMV and specific antibodies. Au-glycane nanocomposite was obtained by reduction of metal from $HAuCl_4$ saltunder the base condition where glycane play a role of macromolecular reducer and stabilizer. Absorption spectra of product demonstrated the presence of the wide band with the maximum near 560 nm specific for local surface plasmon excitation in gold nanostructures. TEM imaging showed that Au nanoparticles were embedded in glycan matrix with size dispersed in the range from 5 to 30 nm. It was demonstrated, that the incubation of the untreated virus and the virus, firstly preincubated with above mentioned nanocomposite, with antibodies with further observation of the complex immobilization to the sensor surface allows one to state the complexation with the nano-composite changes the binding capabilities of the virus which make it potentially useful as virus inhibitor.

Molecular dynamics simulation of 3D structural models of Baeyer-Villiger Monooxygenases with the help of a structural alphabet

J. Rebehmed[1], P. Craveur[1], T. Fadeev[1], V. de Berardinis[2], V. Alphand[3], **A. G. de Brevern**[1]
[1]*INSERM UMR_S 1134, DSIMB, Univ Paris Diderot, Sorbone Paris Cité, GR-Ex, Paris,* [2]*Genoscope, CEA, DSV, IG, Evry,* [3]*CNRS iSm2 UMR 13397, Aix Marseille Université, Marseille, France*

Baeyer-Villiger monooxygenases (BVMOs) are flavoenzymes and belong to the class of oxidoreductases (Alphand & Wohlgemuth, 2010). They catalyze the oxidation of various ketones to esters and lactones (see Figure A for a visualisation of the protein structure, different domains are underlined in colors). During enzymatic oxidation, one atom of oxygen is incorporated between a carbon-carbon bond, whereas the other oxygen atom ends up in a water molecule with the hydrogen atoms originating from the cofactor NAD(P)H. BVMOs' flavin cofactor is crucial for catalysis and is tightly, but not covalently, bound in the active site. These enzymes require the reduction of the flavin cofactor to activate it for molecular oxygen binding (see Figure B for FAD of PAMO from *Thermofibidafusca* in its neighborhood).

We have carefully searched protein databases for new BVMOs related sequences. We had applied strict selection criteria as the flavopotein monooxygenase superfamily is suffering from many annotation problems in the databases. Hence, the 116 proteins we have analyzed are highly characteristic of BVMOs type I family (Rebhemed et al., 2013). We propose efficient structural models of these BVMOs using up-to-date approaches.

Molecular dynamics were performed for each structural model. Interestingly, simulations are analyzed using a structural alphabet, namely Protein Blocks (de Brevern et al., 2000). The latter consists in a library of 16 fragments of 5 residues length able to approximate efficiently every part of protein structures (Joseph et al., 2010). This database of structural models may be useful from a fundamental viewpoint, but also for modelling purposes and therefore, will be freely accessible to the scientific community via a website.

Monolayers of human albumins on colloidal carrier particles and flat surfaces: thorough physicochemical characteristics in terms of electrokinetic methods

K. Sofińska, Z. Adamczyk, M. Kujda
Jerzy Haber Institute of Catalysis and Surface Chemistry Polish Academy of Sciences, Cracow, Poland

Physicochemical properties of two different types of human albumin were studied, human serum albumin (HSA) and recombinant human albumin (rHSA). HSA is obtained by purification of the blood plasma by Cohn process. The final product received by this method contains up to 10% dimeric forms of albumin. On the other hand, rHSA, which is expressed in Saccharomyces cerevisiae via genetic engineering and molecular biology method, consists of only monomeric species.

In this work, adsorption of HSA and rHSA on colloidal particles surface was studied. Monodisperse, negatively charged polystyrene latex particles, 800 nm in diameter were used as colloidal carriers. The adsorption of proteins was studied via electrokinetic measurements (micro-electrophoresis) and AFM imaging. Adsorption of proteins was carried out at pH 3.5 and 7.4 and ionic strength range of 0.001–0.15 M NaCl. The concentration of polystyrene latex carriers was changed in the range of 40–100 mg L^{-1}.

It was observed that the electrophoretic mobility (zeta potential) of latex monotonically increased with the albumin concentration in the suspension. This was quantitatively interpreted in terms of the three dimensional electrokinetic model. The coverage of adsorbed albumin was quantitatively determined using the depletion method, where the residual protein concentration was determined by the above mentioned methods. These measurements enabled a precise determination of the monolayer coverage of rHSA and HSA on polystyrene latex particles. The maximum coverage of both proteins at pH 3.5 increased with ionic strength and varied between 0.7 mg m^{-2} for 0.001 M NaCl to 1.3 mg m^{-2} for 0.15 M NaCl. These results were interpreted using the random sequential adsorption approach.

In order to evaluate the albumin adsorption mechanism, the experimental results obtained for colloid carrier particles were compared with adsorption on the model mica substrate characterized by uniform charge distribution. These measurements revealed that deep analogies exist between albumin adsorption on colloidal carriers and flat interfaces governed by electrostatic interactions. Therefore, it was concluded that recombinant albumin as a monomeric, free of dimers and less immunogenic protein can be widely used in a wide range of research and practical applications instead of the human serum albumin that can be immunogenic.

Acknowledgments: This presentation was made possible by: POIG 01.01.02-12-028/09-05.

[1]*Institute of Molecular and Cell Biology,* [2]*Institute of Technology, University of Tartu, Tartu, Estonia,* [3]*Department of Neurochemistry and Neurotoxicology, The Arrhenius Laboratories for Natural Sciences, Stockholm University, Stockholm, Sweden*

Nucleic acids hold a great therapeutic potential due to their high specificity and low toxicity. However, the poor permeability of

© 2014 The Authors. FEBS Journal © 2014 FEBS

plasma membrane to nucleic acids complicates the development of these molecules for therapeutic applications. Cell-penetrating peptides as efficient and non-toxic vectors have been widely used to assist the intracellular delivery of nucleic acids. We recently developed two novel transportan-based CPPs – NickFect 1 (NF1) and NickFect 51 (NF51) for the delivery of nucleic acids.

We show that NFs are highly efficient transport vectors for plasmid DNA (pDNA) and splice correction oligonucleotides (SCOs). NF1 and NF51 form spherical or slightly elliptical (mean aspect ratio <1.4) and monodisperse nanoparticles with pDNA in water that have a size around 40–50 nm. Nanoparticles formed with splice correction oligonucleotide (SCO) had a similar shape and mean size, but showed significantly higher size variation compared to NF-pDNA nanoparticles.

For the detection of plasmid molecules in cells by transmission electron microscopy (TEM) we labeled pDNA with neutravidin-colloidal gold (NA gold) conjugate prior complex formation with CPPs. We show that NA-gold labels efficiently pDNA with more than 80% of gold being associated giving us confidence to use this labeling approach for examining intracellular trafficking of NF-pDNA nanoparticles using TEM.

Using different endocytosis inhibitors and TEM analysis we show that NF-nucleic acid nanoparticles internalize cells via endocytosis. Inside cells, the vast majority of nanoparticles were entrapped inside early and late endosomes, however, a small fraction of nanocomplexes had escaped into cytosol already after 1 h of incubation.

In conclusion, we show that NFs condense nucleic acids to nanoparticles of rather homogenous size, which are taken up by cells using endocytosis. Although a large fraction of nanoparticles are entrapped inside endosomes, the NF assisted delivery of nucleic acids leads to high level of gene expression modulation *in vitro*.

NMR Studies of large protein assemblies using specific isotopic labeling of methyl group

G. Mas[1], R. Kerfah[1], I. Ayala[1], R. Sounier[2], E. Crublet[1], **P. Gans**[1], O. Hamelin[3], J. Boisbouvier[1]
[1]Institut de Biologie Structurale, CEA-CNRS-UJF, Grenoble, [2]Institut de Génomique Fonctionnelle, CNRS –INSERM – Univ. Montpellier, Montpellier, [3]IRTSV, CEA-UJF-CNRS, Grenoble, France

Large protein complexes are involved in many of the key processes in the cell but their study by NMR has been a real challenge for a long time. Nowadays, it is unequivocally recognized that the strategy of specific isotope labeling of methyl groups in a perdeuterated protein has significantly extended the frontier of liquid state NMR. Production of perdeuterated protein with selective protonation of the methyl groups can be carried out by adding the specifically labeled metabolic precursors in the fully deuterated culture medium before induction of protein expression. Wewill present here our recent development of new precursors and their applications to large protein complex. In the last years, we have exploited metabolic pathways in E. coli and synthesized new isotope-labeled precursors to extend the library of methyl labeling methods. These new strategies allow the stereospecific labeling of the prochiral methyl groups of Leucine and Valine as well as the regioselective labeling of Isoleucine methyl probes. To further improve quality of spectra for protein system with molecular size of several hundred of kilodalton, we have demonstrated that the specific labeling of methyl of Valine groups without Leucine enhances significantly the resolution of spectra. Additionally, new protocols have been developed to extend and optimize specific labeling approaches to methyl groups of Methionine and Threonine residues, as well as Alanine residues. Using these new tools, we have setup robust and scrambling-free protocols to label in targeted proteins any combination of methyl groups. Combined with rapid and cost effective assignment strategies based on mutagenesis, these advances allow to extend the limitation of liquid state NMR, offering the possibility to study more and more challenging protein systems.

Applications to the functional, dynamic and structural studies of a 500 kDa homododecameric protein will be presented.

Human carbonic anhydrase XII (CA XII) is a single-pass transmembrane protein with an extracellular catalytic domain. This enzyme is being recognized as a potential biomarker for different tumours. It is involved in tumor progression by acidification of the extracellular milieu and regulation of intracellular pH. CA XII is aberrantly overexpressed in breast, cervix, brain cancers, renal carcinomas. The current study was aimed to generate monoclonal antibodies (MAbs) neutralizing the enzymatic activity of CA XII. Bioinformatics analysis of CA XII structure revealed surface-exposed sequences located in a proximity of its catalytic centre. Two MAbs against the selected antigenic peptide spanning 167–180 aa sequence of CA XII were generated. The MAbs were reactive with recombinant catalytic domain of CA XII expressed either in E. coli or mammalian cells. Inhibitory activity of the MAbs was demonstrated by a stopped flow CO_2 hydration assay. The study provides new data on the surface-exposed linear CA XII epitope that may serve as a target for inhibitory antibodies with a potential immunotherapeutic application.

Keywords: human carbonic anhydrase XII, inhibition of enzymatic activity, monoclonal antibodies.

Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences (IBCh RAS), Moscow, [3]Laboratory of synaptic processes biophysics, Sechenov Institute of Evolutionary Physiology and Biochemistry of the Russian Academy of Sciences (IEPHB), Saint Petersburg, Russian Federation

Insect pests act disturbingly to different human activities. Increasing human population would require high amount of food in the future, so large annual reductions in crop yields by insects pose a threat. From other side, spiders are nature-born insect killers. Venom of the most spiders is a complex mixture of differ-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ent compounds delicately tuned for the aim of paralyzing or immediate killing of insect prey.

In this light, we see the area of spider venom components research having potential in application to production of new generation insecticides.

As the object of this particular research was chosen *Tibellus oblongus* - Middle East spider, completely non-harmful to human. Its crude venom was fractionated by combination of SEC and RP-HPLC. At each step of chromatographic separation, insect-toxicity of each fraction was tested on *Musca domestica* larvae via injections. The most active fractions were being separated until one individual polypeptide component has been found. Novel toxin was named TboIT1. EST-database data to MALDI-MS analysis result comparison together with MS analysis of trypsin hydrolysate allowed determining amino acid sequence. Recombinant production of toxin in *E.coli* provided sufficient amount for toxicity and electrophysiological experiments.

It was determined that recombinant TboIT1 has LD_{50} 12 γ/g (on *M. domestica* larvae). Toxin slows down transmitter release in neuro-muscular junction of *Calliphora vicina* bottle fly. TboIT1 reversibly inhibited evoked EPSC (eEPSC), but did not affect frequency of spontaneous EPSC (sEPSC). Interestingly, inhibition of eEPSC was accompanied by significant change of rise time (rt) or delay (τ) of the eEPSC. Such parameters for sEPSC were unaffected.

Moreover, toxin does not affect any parameter of transmission in frog neuro-muscular junction. These data point out for TboIT1 may being novel selective inhibitor of insect pre-synaptic calcium channels.

Keywords: insect-toxins, spider venom.

Optimal number of ribosomal RNA operons in *Escherichia coli* is determined primarily by the stability of environmental conditions

Z. Gyorfy[1], G. Draskovits[1], V. Vernyik[1], F. R. Blattner[2], T. Gaal[3], G. Pósfai[1]
[1]Inst of Biochemistry, Biological Research Center of Hungarian Academy of Sciences, Szeged, Hungary, [2]Scarab Genomics LLC, [3]Department of Bacteriology, University of Wisconsin, Madison, WI, USA

Background: The copy number of the ribosomal RNA operons (rrn) is a characteristic trait of bacterial genomes. It influences rRNA availability, which in turn, regulates the amount of ribosomes, key players of cellular physiology and economy. It is thought that the rrn operon number reflects the organism's ecological strategy. Bioinformatic and some experimental data suggest that lower copy numbers are favored in bacteria living in low-nutrient, relatively stable environments, and higher numbers (7 in *E. coli*) seem to be associated with fluctuating, feast and famine conditions. It is not clear, however, what the primary determinant of rrn operon copy number is: the benefit of fast growth, the capability of quick adjustment to favorable conditions, or the economic utilization of nutrients.

Results: We constructed isogenic variants of *E. coli* K-12 with 5 to 10 copies of rrn operons, analyzed their growth parameters, measured their RNA and protein contents, and subjected them to pairwise competitions under both fluctuating (serial growth in batch cultures) and stable nutrient influx (growth in a chemostat) conditions. While growth parameters showed only minor changes, competitions revealed a clear pattern: 7–8 copies were optimal under fluctuating conditions, and lower numbers were favored in a stable environment. These patterns persisted at two different growth rates. Interestingly, while the RNA: protein ratio remained constant, an increase in protein and RNA content, accompanied by a slight increase in cell size was observed in the 5 to 8 operon range.

Conclusions: By delineating the effects of nutrient quality and availability, we found that the stability of the environmental conditions is the primary factor determining the optimal number of rrn operons in *E. coli*. Our experiments confirm that the wt rrn copy number of *E. coli* reflects adaptation to fluctuating conditions. However, the results also show that lower rrn copy numbers are beneficial for *E. coli* when environmental conditions are stable. Adjustment of the rrn number to the planned environmental conditions should thus be taken into account when constructing designer bacterial genomes.

Overcoming recombinant protein insolubility: case study of C1q domain of otolin-1

R. Houbowicz, M. Wojtas, P. Dobryszycki
Department of Biochemistry, Wroclaw University of Technology, Wrocaw, Poland

Otolith and otoconia are calcium carbonate biominerals which are responsible for perception of linear acceleration in fish and land vertebrates, respectively. Apart from calcium carbonate, these biominerals contain an organic matrix composed of proteins, glycoproteins and proteoglycans. Otolith and otoconia differ in size, organic matrix composition and calcium carbonate polymorph. Both biominerals however contain otolin-1, which is a collagen-like protein strongly conserved in variety of species. It contains an N-terminal domain, collagen-like chain and C1q-like globular domain. C1q-like domain of otolin-1 (OtolC1q) may bind calcium and interact with other proteins from organic matrix of otolith and otoconia, and thus otolin-1 may provide a scaffold for calcium carbonate biomineralization.

Human and zebrafish OtolC1q fused with a hexahistidine tag or a solubility enhancing maltose-binding protein (MBP) tag were expressed in Escherichia coli BL21(DE3)pLysS cells. Protein solubility assay showed that OtolC1q fused with hexahistidine tag (His-OtolC1q) was poorly soluble in Escherichia coli in 29°C. In contrast, OtolC1q fused with MBP (MBP-OtolC1q) was well-soluble in these conditions. However, MBP-OtolC1q was resistant to proteolytic cleavage and in non-denaturing conditions, OtolC1q was inseparable from undigested fusion protein. Decrease of bacterial culture temperature to 15°C increased solubility of His-OtolC1q and allowed to purify protein of interest using Co^{2+} affinity chromatography and gel filtration.

This work was supported by a statutory activity subsidy from the Polish Ministry of Science and High Education for the Faculty of Chemistry of Wroclaw University of Technology.

Polyanions are a powerful tool for the control of protein aggregation

P. Semenyuk[1], V. Izumrudov[2], V. Muronetz[1]
[1]Belozersky Institute of Physico-Chemical Biology, [2]Faculty of Chemistry, Lomonosov Moscow State University, Russia, Moscow, Moscow, Russian Federation

The searching for the means of suppression of protein aggregation is an important problem of biochemistry, bioengineering, biotechnology, and even medicine. Thus, production of the recombinant protein in bacterial cells often causes the inclusion

© 2014 The Authors. FEBS Journal © 2014 FEBS

bodies formation. Inclusion bodies also appear in neural tissues due to neurodegenerative diseases such as Alzheimer's, Parkinson's and Huntington's diseases and prion infections.

In the present work the influence of polyanion structure and the nature of charged groups on the thermal aggregation of glyceraldehyde-3-phosphate dehydrogenase was investigated. Polyphosphate anions have been found to interact with protein less tightly than polysulfoanions and to do not affect protein structure (in contrast to polysulfoanions, especially relatively hydrophobic polystyrenesulfonate anions). However, they are able to almost completely suppress protein aggregation (though less effectively than polysulfoanions).

Beside of aggregation suppression, polyanions have been shown for the first time to solubilize already formed protein aggregates of different nature. Polysulfoanions solubilized effectively both amyloid and amorphous inclusion bodies as well as amorfous thermal aggregates. The treatment by polysulfoanions of prion protein inclusion bodies resulted in significant decrease of the amyloid structures amount. Solubilization of glyceraldehyde-3-phosphate dehydrogenase thermal aggregates was accompanied by partial recovery of the enzymatic activity. The efficiency of aggregation suppression and solubilization of aggregates has been shown to depend on the polyanion degree of polymerization and hydrophilicity. Thus, amyloid aggregates (the most stable of examined) was solubilized only by highly polymerized polystyrenesulfonate anions, whereas amorphous aggregates can be disassembled even by hydrophobic dextran sulfate.

The developed approach for the protein aggregation control seems to be relevant for extraction of the recombinant protein from inclusion bodies as well as (in the long term) for therapy of the amyloid diseases.

The work was supported by Russian Foundation for Basic Research, project No 14-04-00331.

Polysaccharide nanocapsules designed for enhanced daunorubicin delivery; in vitro release and biocompatibility studies

U. Bazylinska[1], J. Pietkiewicz[2], J. Rossowska[3], K. A. wilk[1]
[1]Department of Organic and Pharmaceutical Technology Group, Faculty of Chemistry, Wroclaw University of Technology, [2]Department of Medical Biochemistry, Medical University of Wroclaw, [3]Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland

An ideal drug delivery system apart from its nanoscale size and sustained release, should also have high biocompatibility to enhance cargo bioactivity and to reduce its side-effects. Successful targeting of a cytostatics to the cancer cells using newly designed oil-core polyelectrolyte (PE) nanocapsules can be achieved solely if the nanosystem remains long time in the blood stream enough to accumulate at its site of action. Thus, the fundamental issue for the nanocarrier biocompatibility is evaluating its low cytotoxicity and safe interaction with erythrocytes and macrophages. Hence, the key approach to form optimal delivery nanocapsules consists in using the capacity of some polysaccharide-based PEs to favorable change their macromolecular properties and selective cellular internalization (Bazylińska et al., Soft Matter (2011) 7:6113; Eur. J. Pharm. Sci. (2012) 47:406).

The main purpose of the present study was to investigate which type of polysaccharide-coated nanocapsules may substitute popular PEG-ylated structures and enhance daunorubicin (DN) delivery to the cancer (MC38) cells. Thus we fabricated long-sustained nanocapsules by layer-by-layer adsorption of chitosan-CHIT, λ-carrageenan-CAR or dextran-DEX directly on the nanoemulsion core (created by cationic dicephalic-type N,N-bis [3,3′-(trimethylammonio)-propyl]dodecanamide dimethylsulphate $C_{12}(TAPAMS)_2$ and oleic acid (OA)). The all DN-loaded nanocapsules, with the four or five bilayer of the PEs and with size <150 nm (analyzed by DLS, AFM and SEM), were subjected to *in vitro* release and biocompatibility studies. Drug remaining profiles showed their long-term stability in physiological condition (pH 7.4) and in the presence of HSA. Hemolytic potential determined in whole human blood, does not exceed value of 2% indicating the nanosystem hemocompatibility. The internalization yield by macrophages observed in FACS and interaction with HSA of the nanosystems with the outer DEX layer was about 5-fold and 2-fold lower than those containing CHIT and CAR respectively. Finally, we improved that all DN-loaded systems, are non irritated for MC38 cells, which demonstrate their potential low side effects in comparison to the high cytotoxic free daunorubicin.

Our results provide conclusions that the obtained polysaccharide nanocapsules, primary coated by DEX, might become biocompatible and long-sustained DN delivery systems in potential chemotherapy of colon cancer as a promising alternative to the common PEG-ylated nanocarriers.

This work was supported by statutory activity subsidy from the Polish Ministry of Science and Higher Education for the Faculty of Chemistry of Wrocaw University of Technology.

Production of virus-like particles of porcine circovirus type 2 (PCV2) capsid protein in yeast and their employment for generation of PCV2-specific monoclonal antibodies and PCV2 diagnostics

A. Gedvilaite[1], J. Nainys[1], R. Lasickiene[2], R. Petraityte-Burneikiene[1], R. Lelesius[3], V. Sereika[3], A. Zvirbliene[2], K. Sasnauskas[1]
[1]Department of Eukaryote Genetic Engineering, [2]Department of Immunology and Cell Biology, Institute of Biotechnology Vilnius University, Vilnius, [3]Institute of Microbiology and Virology, Veterinary Faculty of Veterinary Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Porcine circovirus type 2 (PCV2) is very small (about 17 nm), spherical, non-enveloped virus with icosahedral symmetry classified as a member of the family Circoviridae. This virus is considered to be an important emerging pathogen associated with a number of different syndromes and diseases in pigs such as post-weaning multisystemic wasting syndrome, porcine dermatitis, nephropathy syndrome, porcine reproductive disorders and other all known as PCV2-associated diseases. PCV2 can cause a serious problem to the swine industry and can lead to significant negative impacts on profitability of pork production. PCV2 have circular, single-stranded DNA genomes of approximately 1700 nucleotides, encoding 2 major ambisense open reading frames, ORF1 and ORF2. ORF1 is predicted to encode a replicase protein (Rep) essential for replication of viral DNA. ORF2 encodes the capsid protein (Cap), which plays a key role in the process of virus particle assembly. The Cap protein is highly immunogenic and reacts strongly with the serum of PCV2-infected pigs. Therefore, it is a good candidate antigen for the design of new recombinant vaccines against PCV2 infection and for the development of serological assays. In this study we have demonstrated that PCV2 capsid

© 2014 The Authors. FEBS Journal © 2014 FEBS

(Cap) protein was efficiently produced in yeast *S.cerevisiae* and formed virus-like particles (VLPs). Yeast-derived PCV2-Cap VLPs mimicked the structure of authentic virus particles and induced production of monoclonal antibodies reactive with virus-infected cells. Moreover, PCV2 Cap VLPs was tested as a recombinant antigen for the development of an indirect IgG PCV2 Cap VLP-based ELISA for the detection of virus-specific IgG antibodies in swine sera. The high sensitivity and specificity of the indirect IgG PCV2 Cap VLP ELISA clearly suggested that developed assay is potentially useful diagnostic tool for screening PCV2–suspected samples.

This research was funded by the European Social Fund (Grant No. VP1-3.1-SMM-10-V-02-017).

Protein engineering via assembly of catalytic domains: lessons from a natural bidomain electron transfer protein

O. Frances[1], F. Fatemi[1], J. Pérez[2], E. Lescop[1], **G. Truan**[3]
[1]ICSN, CNRS, [2]SWING beamline, Synchrotron SOLEIL, Gif-sur-Yvette, [3]LISBP, INSA TOULOUSE, Toulouse, France

Synthetic Biology aims to reconstruct existing or novel biochemical reactions through the designed and controlled assembly of natural modules bearing defined functions. Among the various exploratory paths targeting new functionalities in biological molecules, the design of multifunctional enzymes is under heavy scrutiny. First, the fixed stoichiometry between catalytic domains guarantees a constant metabolic flux. Second, multidomain enzymes can accelerate subsequent reactions in a metabolic pathway and protect unstable or toxic intermediates due to spatial confinement. Here, I will describe the catalytic and structural mechanisms by which a natural bidomain electron transfer (ET) protein, the NADPH cytochrome P450 reductase (CPR), reaches the optimum catalytic efficiency.

CPR is a bidomain flavoprotein that belongs to the family of diflavin reductases. Structural studies of CPR have evidenced reorganization and rearrangement of the two catalytic domains at the resting state or during catalysis. Through a combined SAXS, NMR, biochemical and theoretical approaches, we have fully described the architectural reorganization of CPR at resting state and evidenced two states (named locked and unlocked) that correspond to the two catalytically active states. Both states are in rapid exchange and the equilibrium is controlled by ionic strength and pH. When the locked and unlocked states are equally populated, CPR presents its maximum catalytic activity. We proposed a kinetic model demonstrating a direct link between the domain movements and ET efficiency during the catalytic cycle of CPR. This model is based on rapid stochastic interdomain interactions, short lifetime of domain interfaces and rapid sampling of the various conformational states present at each catalytic step. The maximal efficiency of the enzyme is obtained when the relative populations of productive conformations match individual catalytic rates. This mechanism is analogous to the cellular metabolic situation where the ratio between enzymes participating in sequential reactions of a metabolic pathway are adjusted to their catalytic rates (slower enzymes will be present at higher concentration than faster enzymes) in order to minimize the accumulation of intermediates.

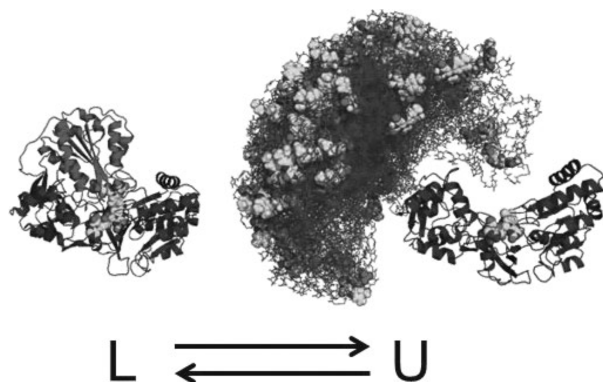

Fig. 1.

Beyond the specific results proposed on our model, I will present possible generalization on how our results could be applied to catalytic domain association in protein engineering: controlling the domain interface stability in multidomain enzymes may represent a direct way to adjust overall enzymatic activity.

Purification and covalent immobilization of benzoylformate decarboxylase with heterofunctional chelate-epoxy modified magnetic nanosupport

B. Tural, M. S. Ece, S. Tural
Chemistry, Dicle University, Diyarbakir, Turkey

Histidine-tagged benzoylformate decarboxylase (BFD) from *pseudomonas putida* was immobilized on the epoxy-chelate magnetic solid support following a two-step mechanism; first, the protein is physically adsorbed and second, the covalent bonding takes place. This mechanism has been exploited to combine the selectivity of metal chelate affinity chromatography with the covalent immobilization capacity of epoxy supports. In this way, it has been possible to accomplish, in a simple manner, the purification, immobilization, and stabilization of a histidine-tagged benzoylformate decarboxylase. To fulfill this objective we prepared and characterized a multifunctional Co^{+2}-IDA-epoxy functionalized magnetic nanoparticles which are modified with glycidyloxypropyltrimethoxysilane (GPTMS) and iminodiacetic acid (IDA).

The covalently bounded BFD was characterized in terms of its activity and stability for the formation of (*S*)-2-hydroxypropiophenone (2-HPP). The results obtained from the formation of (*S*)-2-hydroxypropiophenone that was performed with this simple and convenient heterogeneous biocatalyst were comparable to that of free-enzyme-catalyzed reaction.

Keywords: Immobilized Benzoylformate Decarboxylase; epoxy-chelate magnetic support; metal-affinity magnetic nanoparticles; selective immobilization; multipoint covalent attachment; one step purification.

Rational design of small molecule inhibitors targeting ASK1

G. P. Volynets, S. A. Starosyla, V. G. Bdzhola, S. M. Yarmoluk
Department of Medicinal Chemistry, Institute of Molecular Biology and Genetics, NAS of Ukraine, Kyiv, Ukraine

Apoptosis signal-regulating kinase 1 (ASK1) plays important roles in many cardiovascular and neurodegenerative diseases suggesting that small compounds inhibiting ASK1 could possibly be used for the treatment of these pathologies.

To discover the protein kinase ASK1 inhibitors we have performed screening program, using both in silico and in vitro approaches. AutoDock and DOCK software were used to con-

© 2014 The Authors. FEBS Journal © 2014 FEBS

duct receptor-ligand flexible docking. The best-scored compounds of different chemical classes were taken for the kinase assay analysis.

In vitro observations revealed that derivatives of 2-Thioxo-thiazolidin-4-one exhibited inhibitory activity towards ASK1. The most active compound inhibited ASK1 with IC_{50} = 2 μM. Then, in-depth study of this chemical class was performed using the pre-selected library of 2-thioxo-thiazolidin-4-one derivatives. Ten best-scored compounds were taken for the kinase assay analysis. Compound 2-{5-[5-(3,4-Dichloro-phenyl)-furan-2-ylm-ethylene]-4-oxo-2-thioxo-thiazolidin-3-yl}-propanoic acid (PFTA-1) inhibited ASK1 with an IC_{50} = 650 nM. Our preliminary selectivity studies demonstrated that this ligand seems to be selective inhibitor of ASK1. In silico analysis of the complexes of ASK1 with compounds indicated, that the peculiarity of the PFTA-1 in the comparison to other nine inactive derivatives is its ability to bind simultaneously to the hinge region and the phosphate-binding region of the ATP-binding cleft. Molecular dynamics simulations allowed us to accurately predict binding mode of PFTA-1 inhibitor with ASK1.

The core structure of PFTA-1 was used for developing more potent and selective inhibitors of ASK1. A series of derivatives has been synthesized and evaluated in vitro towards human protein kinase ASK1. It was revealed that the most active compounds inhibit ASK1 with IC_{50} of 200 nM. Structure-activity relationships of 33 compounds have been studied and binding mode of this chemical class has been predicted.

Recombinant chimeric bifunctional proteins with alkaline phosphatase activity of marine bacterium Cobetia marina for the assessment of lectin-binding patterns

L. Balabanova, V. Golotin, S. Kovalchuk, G. Likhatskaya, A. Bulgakov, O. Chernikov, I. Chikalovets, V. Molchanova, V. Rasskazov
PIBOC FEB RAS, Vladivostok, Russian Federation

The strong innate defense system and the absence of the acquired immunity in marine invertebrates have made their lectins are highly specific and selective towards carbohydrates. These are essential to use invertarates' lectins as diagnostic tools for early detection of carbohydrate profiles changes that accompany many pathological processes. The use of mannan-binding C-type lectin from Far-Eastern holothurian *Apostichopus japonicus* (MBL-AJ) and galactose-specific lectin from the mussel *Crenomytilus grayanus* (CGL) have been proposed for recognizing aberrant glycans. The lectin MBL-AJ was successfully applied for the non-invasive assessment of carcinoembryonic antigens (CEA) in cervical specimens for the early differential diagnosis of a malignant condition. The presence and distribution of the lectin CGL ligands, pregnancy specific beta-1-glycoprotein 1 and CEA, were analyzed in the human placental trophoblast pathology and colorectal adenocarcinoma, respectively. For developing the functional tools for the *in situ* identification of glycosylation patterns, the lectins were fused to the highly active alkaline phosphatase of marine bacterium *Cobetia marina* (*Cm*AP) with the use of NcoI/SalI fragment of pET-40b(+) vector and linker $(G_4S)_3$. High efficiency and the facility of the cofactor-independent activity assay, broad pH-stability and a high stability against helate agents as well as monomeric station of *Cm*AP have advantaged rapid monitoring and optimization of various aspects of the recombinant chimeric lectins production. The completely soluble chimeric proteins, comprising the alkaline phosphatase domain which is capable of enzymatic digesting of p-nitrophenyl phosphate and the lectin domain which is able to bind a ligand-bearing target, were produced by *E. coli* Rosetta(DE3) strain in the presence of 0.2 mM IPTG and the temperature of 16 °C for 12 h. The bifunctional chimeras exhibited a high level of the lectin-binding activity towards embryonic alpha-1-acid glycoprotein, CEA, mucin. The 3-D structure modeling and mutagenesis have demonstrated that the lectin and *Cm*AP modules function independently, and revealed the essential amino acid residues for the interaction with ligands. The genetically engineered *Cm*AP-labeled invertebrate lectins will provide an improved method for biomarkers detection.

Recombinant virus-like particles with inserted segment of viral glycoprotein represent an efficient carrier to generate glycoprotein-specific antibodies

A. Zvirbliene, I. K. Kodze, A. Razanskiene, A. Gedvilaite
Institute of Biotechnology, Department of Immunology and Cell Biology, Vilnius University, Vilnius, Lithuania

Monoclonal antibodies (MAbs) against viral glycoproteins have important diagnostic and therapeutic applications. In most cases, the MAbs specific to viral glycoproteins are raised against intact virus particles. The biosynthesis of viral glycoproteins in heterologous expression systems such as bacteria, yeast, insect or mammalian cells is often problematic due to their low expression level, improper folding and limited stability. To generate MAbs against hantavirus glycoprotein Gc, chimeric virus-like particles (VLPs) harbouring a segment of PUUV Gc glycoprotein were expressed in yeast *Saccharomyces cerevisiae* and used as an immunogen. A 99 amino acid (aa)-long segment of Gc protein was inserted into the major capsid protein VP1 of hamster polyomavirus at previously defined positions: either site #1 (aa 80–89) or site #4 (aa 280–289). The chimeric proteins were found to self-assemble to VLPs as evidenced by electron microscopy. Chimeric VLPs induced an efficient insert-specific antibody response in immunized mice. Monoclonal antibody of IgG isotype specific to hantavirus Gc gly-

© 2014 The Authors. FEBS Journal © 2014 FEBS

coprotein was generated. It recognized recombinant full-length PUUV Gc glycoprotein both in ELISA and Western blot assay and reacted specifically with hantavirus-infected cells in immunofluorescence assay. Epitope mapping studies revealed the N-terminally located epitope highly conserved among different hantavirus strains. In conclusion, our approach to use chimeric VLPs was proven useful for the generation of virus-reactive MAb against hantavirus Gc glycoprotein. The generated broadly-reactive MAb #10B8 might be useful for various diagnostic applications.

This research was funded by the European Social Fund under the Global Grant measure (Grant No. VPI-3.1.-SMM-07-K-03-004).
Keywords: antibodies, chimeric virus-like particles, hantavirus glycoprotein.

Revealing new antimicrobial peptides in *Leymus arenarius* based on transcriptome sequencing

A. Shelenkov[1], A. A. Slavokhotova[2]
[1]Department of Genetics and Biotechnology, [2]Department of Plant Genetics, Vavilov Institute of General Genetics, Moscow, Russian Federation

Lyme grass (LG, *Leymus arenarius*) is a perennial weed plant from *Poaceae* family. The distinctive property of LG is its high tolerance to adverse environment factors (AEF) like soil salinification, drought etc.

Earlier we have obtained a number of LG antimicrobial peptides (AMP) using biochemical methods. AMPs are an important component of plant innate immunity system, so their investigation could help in understanding the plant tolerance mechanisms to AEF and pathogens, that will be especially useful for crops. However, biochemical investigations of AMP are laborious and expensive and do not allow investigating all available proteins. Thus the goal of the current research was to analyze the transcriptome of LG sprouts that allowed to investigate the LG RNAs coding for AMPs.

LG transcriptome was obtained by sequencing on Illumina HiSeq 2000 and was assembled *de novo* using various software packages. The AMPs have very low primary structure similarity, but they are characterized by presence of several cysteine residues arranged in rather rigorous order called a 'motif', This is why a novel method was developed for AMP searching. The search for potential AMPs was made by 6-reading frame translation of the transcripts obtained and looking for cystein motifs known to be common for various AMP groups in the resulting amino acid sequences. Also, a filtration step for the sequences with motifs was performed that involved taking only 1 open reading frame, checking the presence of methionine at the beginning of peptide sequence and checking for the presence of signal peptide in a sequence (SignalP program). All these conditions are mandatory for AMPs according to the current data. In addition, the sequences were filtered based on their length (≤150 amino acids).

The data from all assemblies were combined and repetitions were removed. The search was performed for 31 known cysteine motifs. 18964 sequences containing at least 1 motif were found. At the end of filtration step 202 potential AMPs were revealed satisfying the stringent conditions described above. The well-known SPADA software has revealed only 99 proteins in this dataset. Earlier only 10 LG AMPs were obtained by biochemical methods, and all of them were among 202 sequences described above. 55 potential AMPs had significant similarity with cysteine-rich proteins of other members of *Poaceae* family.

A new *in silico* method for AMP search in plant transcriptomes was developed which allowed to reveal novel potential AMPs from LG. The presence most AMPs was confirmed by gene isolation and cloning. The method developed can be applied to any plant transcriptome and its results will greatly facilitate the investigation of plant immune system and obtaining of crops with higher tolerance to AEF and pathogens.

Revision of genus *Polygonum* L.s.l. in flora of Armenia

H. Ter-Voskanyan
Plant Geography and Systematics, Institute of Botany, Yerevan, Armenia

The account of genus Polygonum L. in 'Flora of Armenia' was made more than five decades ago. After that many expeditions have been carried out in different regions of Armenia and a huge herbarium material has been collected. The genus included 5 sections with 20 species. Since then many authors accepted the sections as separate genera on the basis of anatomical, morphological, palynological and molecular data. According to the above mentioned it became clear, that the taxonomy of Armenian representatives of Polygonum s. l. also needs revision. New literature data and our investigations of live and herbarium material (ERE, LE) with specification of the morphological characters, distribution, ecology, flowering and fruiting terms brought us to conclusion, that genus Polygonum s. l. has to be split into 5 different genera (Aconogonon (Meisn.) Reichenb., Bistorta (L.) Scop., Fallopia Adans., Persicaria Mill., Polygonum L. s. s.). The number of species has been reduced to 16 species. For each genus new determination keys has been created.

Keywords: Flora of Armenia, Genus Polygonum.

Selection of DNA aptamers to *B. anthracis* lethal factor

A. V. Kolesnikov, A. V. Kozyr, A. K. Ryabko, A. E. Khlyntseva, O. N. Krasavtseva, I. G. Shemyakin
Laboratory of Molecular Biology, State Research Center for Applied Micrbiology and Biotechnology, Obolensk, Russian Federation

We obtained a panel of DNA aptamers binding to *B. anthracis* lethal factor (LF) with high affinity. LF was produced in *E. coli* as a fusion with SUMO peptide, tagged at the N-terminus by the 16 amino acid *in vivo* biotinylated peptide. The fusion protein was immobilized on streptavidin-coated paramagnetic particles and mixed with random DNA aptamer library followed by washing of the particles to remove unbound DNA. LF with bound aptamers was cleaved off the complex by SUMO protease. DNA was amplified by PCR with 5'-FAM-labeled primer and subsequently treated by 5′ lambda phage exonuclease to obtain single-stranded DNA for further round of selection. After 4 rounds, selected DNA pool was cloned into plasmid vector. Individual aptamers were isolated from the selected pool using PCR with biotinylated primer and tested for LF-specific binding by solid phase assay with neutravidin peroxidase.

Binding constants of the most efficiently binding aptamers were determined by surface plasmon resonance technique. High-throughput sequencing and subsequent analysis of the selected pool using DNA multiple alignment tools, clearly identified 4 aptamer families sharing clearly identifiable primary structure motifs. The developed panel of LF-specific DNA aptamers can be further applied for elaboration of therapeutic and diagnostic tools for prophylaxis and treatment of anthrax.

siRNA-bioportide conjugates as a Chronic Myeloid Leukemia gene therapy targeting the BCR/ABL fusion gene

J. M. Freire[1], I. Rego de Figueiredo[1], B. G. de la Torre[2], A. S. Veiga[3], D. Andreu[2], F. Enguita[3], M. Castanho[3]
[1]*Biochemistry, Instituto de Medicina Molecular, Lisbon, Portugal,* [2]*Pompeu Fabra University, Barcelona, Spain,* [3]*Instituto de Medicina Molecular, Lisbon, Portugal*

Chronic Myeloid Leukemia (CML) is a myeloproliferative disorder caused by a single genetic mutation, a reciprocal translocation that originates the BCR-ABL gene with constitutive tyrosine kinase activity. Because there is a specific gene associated to this pathology it is an optimum therapeutic target for RNA silencing therapy (siRNA). We developed a siRNA-based therapeutic approach in which the siRNA is delivered by Dengue Virus Capsid Protein-derived Cell penetrating peptides (CPP), pepM and pepR. Moreover these peptide vectors have dual role in this technology, to deliver siRNA into cells and act as bioportides, cell-penetrating peptides with bioactive intracellular properties by targeting signaling events.

Dengue virus-peptides ability to transfect the positive BCR-ABL^{+} Cell Line (BV-173) was evaluated by confocal microscopy following GFP fluorescence emission after plasmid expression. Anti-BCR-ABL siRNA design was performed using a siRNA design web-tool and the BCR-ABL downregulation kinetics (48 h to 168 h) after transfection by Dengue virus-peptides was evaluated by RT-PCR. The bioportide action of DENV vectors was assessed by genome-wide analysis microarray and further validated by testing BV 173 cell cycle and cell proliferation.

siRNA design for BCR-ABL retrieved 148 potential siRNA sequences, which were reduced to 5 BCR-ABL siRNA for *in vitro* analysis after thorough screening. Positive efficacy of siRNA targeting BCR-ABL was tested using a commercial transfection agent. Significant BCR-ABL gene knockdown were observed for siRNA #3 when delivered by pepM with maximum decrease at 120 h. Both pepM and pepR showed downregulation effects on proliferative CML cancer-related signaling pathways having direct impact on BV 173 cell cycle and proliferation.

With this work we showed the potential therapeutic technology of combining a drug delivery system (CPP) with bioportide properties to deliver functional siRNA into CML cell models. Acting in synergism, these conjugates significantly decreased BCR-ABL gene expression levels, and perturbed leukemogenic cells homeostasis, revealing a potential scaffold to develop an alternative CML therapy.

siRNA-Bioportide conjugates as a Chronic Myeloid Leukemia gene therapy targeting the BCR/ABL fusion gene

J. M. Freire[1], I. Rego de Figueiredo[1], B. G. de la Torre[2], A. S. Veiga[3], D. Andreu[2], F. Enguita[3], M. Castanho[3], CML
[1]*Biochemistry, Instituto de Medicina Molecular, Lisbon, Portugal,* [2]*Pompeu Fabra University, Barcelona, Spain,* [3]*Instituto de Medicina Molecular, Lisbon, Portugal*

Chronic Myeloid Leukemia (CML) is a myeloproliferative disorder caused by a single genetic mutation, a reciprocal translocation that originates the BCR-ABL gene with constitutive tyrosine kinase activity. Because there is a specific gene associated to this pathology it is an optimum therapeutic target for RNA silencing therapy (siRNA). We developed a siRNA-based therapeutic approach in which the siRNA is delivered by Dengue Virus Capsid Protein-derived Cell penetrating peptides (CPP), pepM and pepR. Moreover these peptide vectors have dual role in this technology, to deliver siRNA into cells and act as bioportides, cell-penetrating peptides with bioactive intracellular properties by targeting signaling events.

Dengue virus-peptides ability to transfect the positive BCR-ABL^{+} Cell Line (BV-173) was evaluated by confocal microscopy following GFP fluorescence emission after plasmid expression. Anti-BCR-ABL siRNA design was performed using a siRNA design web-tool and the BCR-ABL downregulation kinetics (48 h to 168 h) after transfection by Dengue virus-peptides was evaluated by RT-PCR. The bioportide action of DENV vectors was assessed by genome-wide analysis microarray and further validated by testing BV 173 cell cycle and cell proliferation.

siRNA design for BCR-ABL retrieved 148 potential siRNA sequences, which were reduced to 5 BCR-ABL siRNA for *in vitro* analysis after thorough screening. Positive efficacy of siRNA targeting BCR-ABL was tested using a commercial transfection agent. Significant BCR-ABL gene knockdown were observed for siRNA #3 when delivered by pepM with maximum decrease at 120 h. Both pepM and pepR showed downregulation effects on proliferative CML cancer-related signaling pathways having direct impact on BV 173 cell cycle and proliferation.

With this work we showed the potential therapeutic technology of combining a drug delivery system (CPP) with bioportide properties to deliver functional siRNA into CML cell models. Acting in synergism, these conjugates significantly decreased BCR-ABL gene expression levels, and perturbed leukemogenic cells homeostasis, revealing a potential scaffold to develop an alternative CML therapy.

Solution NMR study of viral macro domains

G. A. Spyroulias
Department of Pharmacy, University of Patras, Patras, Greece

Macro domains are evolutionarily conserved in eukaryotic organisms, bacteria and archaea, indicating important basic biological function. Furthermore, they are found in nonstructural proteins (nsPs) of several positive-strand RNA viruses, including hepatitis E virus, rubella virus and coronaviruses, as well as alphaviruses. There are limited information on the viral macro domains' but it has been suggested that they act as an ADP-ribose-binding module, while they are also involved in ADP-ribose metabolism and post-translation modification.

In this study we apply NMR spectroscopy to investigate the conformational properties and dynamics of four macro domains: (a) two from New World alphavirus (Mayaro & Venezuelan equine encephalitis virus), (b) one Old world alphavirus (Chikungunya virus) and (c) one from the Hepevirus genus (HEV-1).

The four macro domains are cloned and expressed with Poly (His)tag, in high yields in *E. Coli*. All protein constructs are soluble and, using *E.coli* culture supplements prior to induction in typical (M9) minimal media, the bacteria growth rates and protein yield were generally increased. Initial 1D ^{1}H & 2D ^{1}H-^{15}N HSQC NMR experiments suggest that all four macro domains are folded in solution. Acquisition and analysis of 2D/3D homo/heteronuclear NMR data are underway.

Spherical virus-like particles generated by thermal denaturation of helical Potato virus X

E. A. Trifonova, N. A. Nikitin, E. K. Petrova, O. V. Karpova, J. G. Atabekov
Department of virology, Lomonosov Moscow State University, Moscow, Russian Federation

Recently the spherical particles (SPs), generated by thermal denaturation and structural remodeling of rigid rod-like tobacco mosaic virus (TMV) were obtained and described [1]. The evidences that SPs are stable, highly immunogenic and biologically safe were provided. The size of SPs is possible to be controlled. The ability to bind target proteins of different nature on the surface of SPs was demonstrated. The immunogenicity of target protein within complexes with SPs was examined by subcutaneous and intraperitoneal immunization of mice. In both cases of immunizations the titers of serum antibodies to target protein increased dramatically. Thus, adjuvant properties of TMV spherical particles generated by thermal treatment of virions were demonstrated [2]. In this work the possibility of thermal transition of helical filamentous Potato virus X (PVX, genus *Potexvirus,* family *Alphaflexiviridae)* virion to structural remodeling particles was examined. The formation of virus-like particles (VLP) with morphology similar to the spherical shape by thermal treatment at 90 °C was demonstrated. In the case of PVX, spherical VLPs thermal transition requires a lower treatment temperature in comparison with TMV. The diameter of the VLPs was in ranges of 50 nm and more. Unlike TMV SPs, the size of structural modified PVX VLPs does not depend on the initial virus concentration. PVX RNA was degraded and completely released following VLPs generation. However no degradation or fragmentation of PVX coat protein occurred upon PVX heating and VLPs formation. The VLPs and native PVX virions densities were compared and significantly difference of density values was registered. The high adsorption property of structural modified PVX VLPs was founded. PVX-generated spherical particles are capable forming compositions with model protein bound to PVX SPs surface. Represented spherical virus-like particles generated by thermal treatment of helical filamentous PVX virions as well as TMV-generated SPs could become a promising platform for the design and assembly of functional active complexes.

One of the most sophisticated aspects in the design of artificial antibodies is to provide for their proper catalytic function, which requires accurate structural information. Here, the results showing how the antibody domain structure affects its functionality, is presented. The previously designed organophosphate-metabolizing *reactibody* A17 has been re-engineered by replacing its constant κ light chain by the l chain, and the A17 l X-ray structure has been solved at 1.95Å. It has been found that the active center of A17 l, compared to A17κ, is displaced, stabilized and becomes more rigid due to interdomain interactions involving the CDR loops from the V_L and V_H domains. These V_L/V_H domains also display lower mobility as was deduced from the atomic displacement parameters of the crystal structure. The Trp-L92 residue is flipped out to form a lid over the entrance to active center pocket. The antibody elbow angle is decreased to 126°, compared to 138° in A17κ. These structural differences leads to subtle changes in catalytic efficiency and thermodynamic parameters determined with two organophosphate ligands, as well as in affinity for peptide substrates selected from combinatorial cyclic peptide library, between A17κ and A17 l variants. Presented data will be of interest and relevance to researchers dealing with the design of antibodies with tailor-made functions.

Study on binding of signal recognition particles to signal-peptides

K. Hamada[1], K. Etchuya[1], Y. Mukai[2]
[1]*Dept. Electr., Grad. Sch. Sci. & Tech.,* [2]*Dept. Electr. & Bioinfo., Sch. Sci. & Tech., Meiji University, Kawasaki, Japan*

Many proteins are biosynthesized in ribosomes and have endoplasmic reticulum (ER)-targeting signals. The ER-targeting signals in the N-terminus, called signal-peptides, are separated from mature proteins by signal-peptidase after being transported to the ER. In the early phase of protein translation, biosynthesized signal-peptides appear on the surface of ribosomes, and signal recognition particles (SRP), cytosolic ribonucleoprotein complexes, recognize and interact with signal-peptides. The SRP-signal-peptide-ribosome complex binds to the SRP receptor on the ER membrane and is then transported to the translocons in the ER membrane. By means of these steps, mature proteins are transported first into the ER by translocons and then located to the appropriate subcellular localization based on the transport mechanism of each protein by intracellular vesicular traffic.

Many varieties of signal-peptide sequences exist and have regions with high hydrophobicity (h-region), however, the reasons why signal-peptide sequences are not unique have not been clarified. Nevertheless, SRP can bind signal-peptides which have many varieties of sequences. SRP54, one component of SRP, is thought especially to bind to signal-peptides. As SRP54 has a hydrophobic groove formed between the three alpha helices (h1,

© 2014 The Authors. FEBS Journal © 2014 FEBS

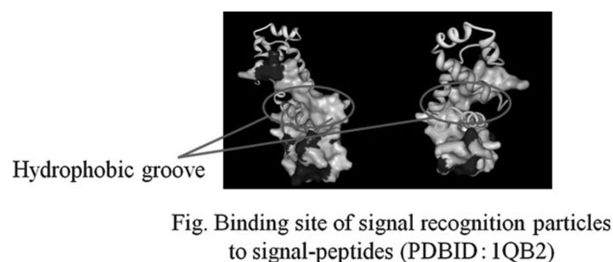

Fig. 1. Binding site of signal recognition particles to signal-peptides (PDBID : 1QB2).

h2 and h3) and the loop stemming from h2 and h3, SRP54 is thought to bind the h-region of each signal-peptide by hydrophobic interactions [1].

In this study, the characteristics of the amino acid sequences upstream from h-regions in signal-peptides were extracted, and the probability of whether or not the sequences were recognized by SRP was examined. The sequence dataset of mammalian proteins which have signal-peptides was first extracted from UniProt Knowledgebase/Swiss-Prot release 2014_01. Based on the fact that the length of the h-region in each signal-peptide was different, the h-region sequences were defined by the annotation of the length of the transmembrane region. Taking into consideration, the propensities, physicochemical properties and hydrophobicity of the amino acids, extracted sequences were classified into clusters. The correlation between the signal-peptide clusters and the subcellular localization of mature proteins was investigated in this study.

The in vitro micro-environment interface: macromolecular crowding meets cell-sheet tissue engineering

A. Satyam[1], P. Kumar[1], X. Fan[1], Y. Rochev[1], L. Joshi[2], H. Peinado[3], D. Lyden[3], B. Thomas[4], B. Rodriguez[5], M. Raghunath[6], A. Pandit[1], D. Zeugolis[1]
[1]*Network of Excellence for Functional Biomaterials (NFB),* [2]*Alimentary Glycoscience Research Cluster, National University of Ireland, Galway, Ireland,* [3]*Weill Cornell Medical College, New York, NY, USA,* [4]*Central Proteomics Facility, Oxford University, Oxford, UK,* [5]*University College Dublin, Dublin, Ireland,* [6]*National University of Singapore, Singapore, Singapore*

Introduction: Advancements in biology and chemistry have enabled development of scaffold-free substitutes; a technology termed as Tissue Engineering by Self-Assembly (TESA). Despite efficacious *in vitro* and *in vivo* results, few products have been commercialised, primarily due to prolonged culture time. It has been demonstrated that macromolecular crowding (MMC) enhances deposition of extracellular matrix (ECM). Here, we assessed the potential of combining MMC technology with TESA approach.

Materials and Methods: Human fibroblasts, tenocytes and osteoblasts were cultured under various MMC conditions [dextran sulphate (DxS); Ficolls & carrageenan (CR)] in a range of fetal bovine (FBS) and human serum (HS) concentrations. ECM deposition was verified by SDS-PAGE, immunocytochemistry

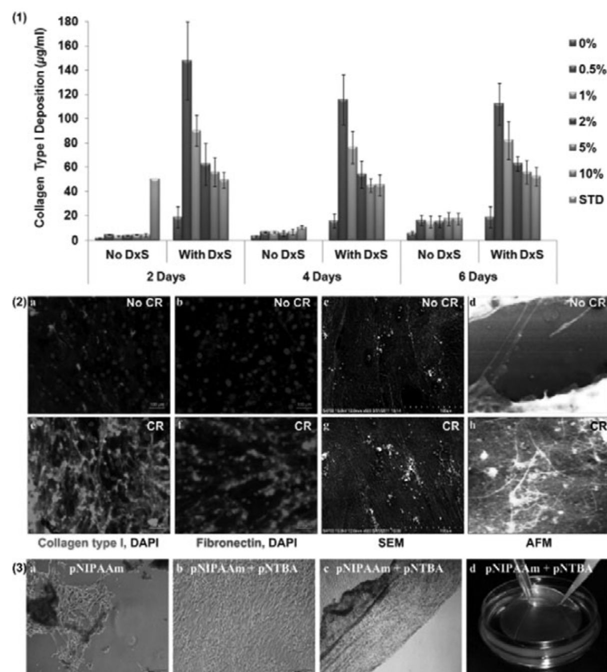

Fig. 1.

(ICC), mass-spectrometry (MS), atomic force (AFM), scanning electron microscopy (SEM). The MMC molecules were characterized by dynamic light scattering (DLS) and nanoparticle tracking analysis (NTA). The cell morphology, cell viability and metabolic activity were evaluated using phase-contrast microscopy, Live/Dead® and alamarBlue® assays respectively. NIPAM based thermo-responsive polymers were developed to facilitate detachment of ECM-rich cell-sheets.

Results: SDS-PAGE demonstrated that MMC significantly increase type-I collagen deposition ($p < 0.001$) at all tested serum (figure-1). ICC, AFM and SEM further confirmed enhanced deposition of fibrillar ECM in presence of MMC (figure-2, a-h). DLS and NTA demonstrated that CR has highest polydispersity among all tested crowders. The cellular morphology, viability and metabolic activity were not affected by MMC. Thermo-responsive coating with Poly(N-isopropylacrylamide) and Poly (N-tert-butylacrylamide) facilitated detachment of ECM rich cell-sheet (figure-3, a-d). Complementary ICC for MS validation confirmed the enhanced deposition of collagens (III, IV, V, VI) and other ECM molecules (laminin, fibronectin, hyaluronic acid, decorin, lysyl oxidase), without changing collagen-VII, elastin, fibrillin-1, transglutaminase-2, α-actin, keratin, tubulin, chondroitin sulphate, keratin sulphate, heparin sulphate, aggrecan, biglycan, CD248 and IL-10.

Discussion & Conclusions: Modulation of the *in vitro* microenvironment with polydispersed macromolecular crowders enhances ECM deposition even under low serum supplementation and facilitates the production of intact ECM rich cell-sheets.

The influence of atrial cardioactive peptides isolated from pigs heart on ECG components under condition of recording of neuronal pulse activity of bulbar cardiovascular center

G. S. Chailyan[1], H. Aganyants[2]
[1]Institute of Biochemistry of NAS RA, [2]SPC 'Armbiotechnology', Yerevan, Armenia

Problem statement: Morphological and biochemical studies allowed defining a fact of the peptides synthesis in contractile cells of atria myocardium released to blood, which control and regulate hemodynamic in the organism. Discovery and further intense study of the peptide regulatory system of heart carried out by A.A.Galoyan, R.M Srapionyan. and coworkers, appeared in essence to be an answer to the question about the role of the peptide nature synthesized and released by atria. From the point of view of the above mentioned issue, our goal of primary importance was the isolation, purification, structural and functional characteristics of cardioactive compounds of peptide nature from atria and auricular region of pig heart, which possess exceptionally high specificity in reference to different aspects of functional activity of cardio-vascular system.
Methods: The studied issue is rather than actual, being complicated and requesting high quality platform in methodology. There were used various systems allowing to control the purity level of the preparations including HPLC, mass-spectrometry, etc. The estimation of amino acid sequence was done by steps in an Edman degradation method and NMR-analysis, which resulted in defining the structure of one of the atriopeptides, conditionally named AP-7.
Results: In spite of an intense search on cardioactive compounds the further studies related to cardiopeptides, remain relevant. In turn, of a particular importance are drugs that act on the individual components of the ECG or its complexes related to diseases. Seven samples of cardioactive peptides obtained by us were tested. Sample 1 equally increases the amplitude of P, R, S, T teeth, QRS complex, and somewhat reduces the amplitude of the wave Q. Sample 2 increases the amplitude of all peaks and QRS, dramatically reduces the amplitude of the Q wave and increases the duration of the complexes. Sample 6 unevenly overestimates the amplitude of all teeth, especially the T, with the exception of «Q», the amplitude of which is greatly reduced by the end of the test. Sample 7 unevenly and slightly decreases and overestimates the amplitude of all components, except for Q, the amplitude of which is greatly reduced and overestimated the duration of complexes.

Transport pathway of GFP protein including signal-peptide and GPI-attachment signal

N. Takachio[1], T. Konishi[2], H. Takata[2], T. Terasaki[3], N. Kato[3], Y. Mukai[3]
[1]Dept. Electr. Grad. Sch. Sci. & Tech., [2]Meiji University, Kawasaki, Japan, [3]Dept. Electr. & Bioinfo., Meiji University, Kawasaki, Japan

Glycosylphosphatidylinositol (GPI) is a post-translational modification molecule which can anchor proteins to the plasma membrane. Proteins modified by GPI, called GPI-anchored proteins (GPI-APs), are localized to microdomains known as rafts via the endoplasmic reticulum (ER). GPI-APs have two signal sequences, signal-peptides (SP) and GPI-attachment signals (GPI-AS). These are N-terminal ER localization sequences and C-terminal signal sequences for GPI modification, respectively. Localization signals are able to transport proteins to specific organelles, one of them being SP which transports proteins to the ER. Most GPI-APs are transported to the ER according to the function of their SP and then modified GPI. GPI-AS is necessary for the post-translational GPI modification and also plays an important role as a raft localization signal.

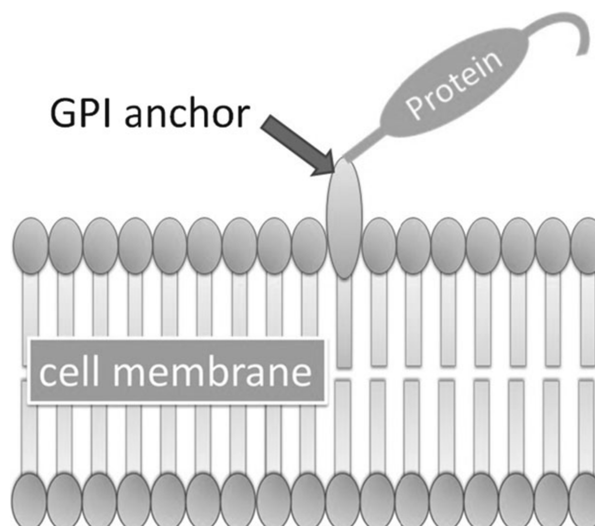

Fig. 1.

When lacking GPI modification, intractable blood diseases and anemia often appear. The relationship between excessive synthesis/loss of GPI-APs and cancers has also been noted, thus GPI modification is thought to have a strong relation with human disease. Therefore the control of GPI modification is expected to be applicable for medical and pharmaceutical fields.

In this study, to understand the sequence patterns for GPI modification in detail, artificial signal sequences were designed based on the amino acid propensities of known SP and GPI-AP sequences. The green fluorescent protein (GFP) which includes two artificial signal sequences, SP and GPI-AS, was expressed in HeLa cells. Subcellular localization of GFP fusion protein was observed by confocal laser fluorescence microscope. As a result, variation in signal sequences has a direct relation to transport pathway patterns. Two signal sequences-GFP/mCherry fusion proteins were expressed in HeLa cells, and the transport pathways of these fusion proteins were monitored by fluorescence observation.
Keywords: Signal sequence.

Using AraC variants to analyse protease activity in vivo by means of selecting for growth on arabinose

N. R. Poulsen, J. R. Winther, K. Lindorff-Larsen, M. Willemoës
Department of Biology, University of Copenhagen, Copenhagen, Denmark

The AraC protein is a dimeric transcriptional regulator involved in control of arabinose metabolism in *Escherichia coli*. The structure and function of this protein has been analyzed in great detail by Robert Schleif and co-workers (1) over the last four decades. Each monomer consists of an N-terminal dimerization domain linked to a C-terminal DNA binding domain. In the presence of arabinose, the two DNA binding domains of the AraC dimer bind to the two adjacent direct repeats sites in the pBAD promoter, I1 and I2 and induce transcription of the adjacent araA,

© 2014 The Authors. FEBS Journal © 2014 FEBS

araB and araD (araBAD) genes. Because the AraC molecule and its function is so well characterized, both as a functional unit in itself but also in various artificial variants it serves as an attractive template for tailoring selection systems in our case based on the ability of *E. coli* to grow on arabinose when combining the function of AraC and the activity of any protease activity as outlined below.

We attached an extra DBD to the C-terminus of the WT AraC monomer (AraC-DBD) and showed that this protein induce transcription of araBAD. We then introduced a H213Y mutation in both DNA binding domains (H213YAraC-DBD), a mutation known to change the properties of other artificial AraC analogs towards being a repressor instead of activator (2) and showed that this fusion protein indeed does not induce transcription of araBAD but probably converts the AraC-DBD protein into a repressor of araBAD. The H213Y modification of the AraC itself (H213YAraC) results in only slightly weaker induction of transcription from pBAD compared to wild type AraC.

However, cells expressing the H213YAraC-DBD variant were able to grow on arabinose although much slower than the AraC-DBD variant suggesting that two H213YAraC-DBD proteins still may dimerize, bind DNA and induce transcription of araBAD, but only to a low extent due to the binding competition between the additional DBD in H213YAraC-DBD and that of another molecule of H213YAraC-DBD.

By inserting protease sites in the linker region connecting the H213YAraC-DBD DNA binding domains we aim to design plasmids that in combination with the relevant protease will allow for fast growth of *E. coli* on arabinose. Results from this work establishing such a system will be presented.

CSIII-07 – Education, training and career planning in molecular life sciences

MON-511
A European safety sciences for medicines education and training

S. Dragovic[1], M. Jochimsen[2], **H. Linden**[3], N. Vermeulen[1], M. Kansy[4], SafeSciMET
[1]Molecular Toxicology, VU University Amsterdam, Amsterdam, Netherlands, [2]University of Konstanz, Konstanz, Germany, [3]EUFEPS, Stockholm, Sweden, [4]F. Hoffmann-La Roche Ltd., Basel, Switzerland

Safety issues are major reasons for discontinuing otherwise promising drug candidates from pharmaceutical development. Being able to better forecast unacceptable adverse events is mandatory to avoid failure in later development phases and unnecessary costs. This requires informed use of knowledge and methodologies in different phases in drug discovery and development by trained safety specialists with a strong focus on integrative and translational strategies.

The IMI project SafeSciMET (www.SafeSciMET.eu) has been initiated to address the needs for a pan-European education and training program for such specialists with a holistic view. The partnership between 16 European universities and 14 leading pharmaceutical companies ensures that cutting-edge knowledge in academia and industry is combined with modern competence-directed learning approaches, which will also include e-learning and distance-learning lectures. In autumn 2014, the successful training program will continue with its third course cycle, delivering 20 modular courses between September 2014 and August 2016. Emphasis lies on integrative, translational and 3Rs aspects of safety assessment, covering the whole process of safety sciences in drug development, from first discovery of an component via pre-clinical and clinical phases to end usage and post-marketing safety issues. The modular setup of the programme allows scientists from industry, academia and regulatory authorities to attend selective courses for building up a continuing professional development portfolio or to follow a pre-defined course package with the possibility to receive an Advanced MSc degree in Safety Sciences issued by the German Excellence University of Constance. In a new collaborative effort, called IMI-TRAIN, and supported by an ENSO grant of IMI, several innovative aspects, such as blended learning and CPD competence development, will be implemented in SafeSciMET.

Highlights of every course are the real-life, industry partner provided case studies that are presented and discussed by industrial experts. By transporting and delivering the European perspective, regulations and methodologies in safety sciences and drug approval, this programme is also highly interesting for safety scientists from countries outside Europe.

Anti-aging effects of vitamin E in perennials

B. Simancas[1], Fisiología Vegetal, Facultad de Biología, Universitat de Barcelona
Facultat de Biología, Departamento Biología Vegetal, Universitat de Barcelona (UB), Barcelona, Spain

Compared with our knowledge of aging processes in animals, little is still know about age-related changes in plants, especially in perennials. The aim of this poster is to deepen into our present understanding of the mechanisms underlying aging in perennials, with a special emphasis on the function of vitamin E in various aging processes (seed aging, leaf senescence and meristem aging) by using a physiological, biochemical and molecular approach. We study the function of vitamin E in meristematic tissues of perennial plant by using *Cistus albidus* as model plant. We will determine in these studies the function of vitamin E in meristematic tissues, leaf and flower buds in plants of various ages, with a special emphasis on the role of tocopherols as antioxidants and in cellular signaling, by measuring the hormonal profile an expression levels of JUNBRUNNE1 and ERF1 in the regulation of the vitamin E mediated signaling processes. These studies will undoubtedly help us not only to better understand the biochemistry and physiology of vitamin E in plants but also establish the basis to establish a key anti-aging role for vitamin E in perennial plants at different levels of complexity, including seeds, leaves and meristematic tissues.

Keywords: anti-aging, vitamin E, perennials.

Anti-thrombotic activity of Corilagin, an ellagitannin isolated from *Phyllanthus niruri* L.

N. A. Puspita, D. Pye
School of Life Sciences and Environtment, University of Salford, Manchester, UK

Phyllanthus niruri L. is an indigenous plant of tropical areas which is known to possess various therapeutic properties and thereby has been used widely as a traditional remedy in many countries. In our study, we tested methanol, ethanol, hexane and chloroform extracts of this plant to inhibit *in vitro* platelet aggregation. The result showed that all extracts possessed the activity in preventing the formation of platelet aggregates upon platelet activation by ADP. The potency of inhibition is 68.8% ± 6.7, 43.5% ± 6.6, 40.1% ± 5.6, 44.7% ± 2.7, respectively, for methanol, ethanol, hexane and chloroform extracts.

Moreover, using high performance liquid chromatography, we have isolated Corilagin (beta-1-O-galloyl-3,6-(R)-hexahydroxydiphenoyl-d-glucose) as one of the major compounds contained in methanol extract that significantly inhibited ADP-induced platelet aggregation *in-vitro*, with the IC50 of 42.8 ± 0.9 μg/mL.

However, there are only a limited number of reports available so far to explain the anti-thrombotic activity of Corilagin and therefore the mechanism of this inhibitory effect are still not clear. To address this question, we have taken a proteomics approach to investigate protein alterations in the aggregation event with or without the presence of Corilagin. The ultimate goal of this study is to reveal anti-thrombotic properties of Corilagin from *Phyllanthus niruri L.*

Keywords: Anti thrombotic, Corilagin, Phyllanthus niruri L.

The lesion is located in the right high frontoparietal lobe and shows mass effect and some degree of vasogenic edema. The T2 hyperintensity is more homogeneous. T1 with contrast injection image shows the mixed solid nodular appearance. High contrast: necrotic radio, low choline levels on MRS, displacement of the tracts on DWI, moderate elevation of rCBV.

to development of target specific biological molecules and methods to image the evolution of cancer and image the antitumor effect of these newer therapeutic agents. At the same time there is a paradigm shift happening in the field of cancer imaging from structural imaging to multifunctional imaging at molecular and functional level. Anatomical imaging has been playing a critical role in cancer screening, diagnosis, stating, management, prognosis, assessing success to therapy and follow up. At the same time the evolving molecular functional imaging using molecular targets and ligands has a great potential in translational research, giving specific and quantitate information regarding involved in the screening, diagnoses and management. Molecular functional Imaging has taken a key place in the present era of translational cancer research making an important tool to study targeted receptor therapies, gene therapies and in cancer stem cell research that helps to translate the on-going research into clinical practice. There is need for scientific developments in imaging to match the progresses in the field of the translational research and targeted imaging needs to be developed in close association between the biotechnology, information technology and translational scientists for its best usage. We will review the current role of molecular functional imaging as one of main pillar of translational research that may be translated into clinical applications in the near future for comprehensive cancer management.

Developing biochemistry laboratory experiments for different professional and occupational groups: alternative experiments for biochemistry

A. Sepici Dinçel[1], Y. Özkan[2], **S. Eksioglu**[3], F. Erkoç[4]
[1]Central Campus Biochemistry Laboratory, Gazi University, Faculty of Medicine, [2]Department of Biochemistry, Faculty of Pharmacy, Gazi University, Ankara, [3]Department of Educational Sciences, Sakarya University, Education Faculty, Sakarya, [4]Department of Biology Education, Gazi University, Ankara, Turkey

There are considerable differences in the way of biochemistry theoretical courses and biochemistry laboratory practicals are taught among different faculties, colleges and vocational schools. In addition programs and curricula vary extensively. Many disiplines of the sciences, life sciences and bioengineering have similar program headings; however presently no agreed upon standardization is available. In order to ensure the compliance requirement (harmonization) of the diploma equivalency for everyone for the European Union Lifelong Learning (LLP) and the Bologna Process, review of the biochemistry laboratory to ensure that needs of private sector, health sector, R&D institutions and finally undergraduate and graduate education are met. Students of biochemistry laboratory, similar to all other fields of study, are often from very diverse backgrounds and different levels of basic knowledge/skills and therefore new teaching methods, program approaches and resource materials are keys and tools to reach the biochemistry harmonization, standardization and competency goals. Initial step could be to elaborate new 'easy-to-implement' experiments with common materials and equipment to chemistry laboratory studies. Along this line, the new approach is expected to bring quality assurance and educational reforms through international cooperation. Biochemistry's interdisciplinary character, placed biochemistry laboratory in a central role. The need for developing new applications using alternative materials leads to modern experimentation to be employed in teaching biochemistry laboratory at different educational establishments. Although biochemistry laboratory education can be implemented in fully equipped laboratories (including molecular biology and biotechnology laboratories); basic biochemistry conceptions and applications that is known to be difficult, can be taught in high quality with the help of principle biochemistry methods/approach and using easily available and low-cost materials, basic laboratory equipment and tools via a new look: These program approaches and new teaching methods facilitate the use of alternative model organisms, promote active student participation, improve students scientific thinking skills, aid innovation, familiarize with scientific research culture. Experiments in the present study were designed and tested in modular form to these aims and are expected to satisfy quality insurance while taking into account the multidisplinary character of biochemistry laboratory studies.

Keywords: biochemistry laboratory education, easy-to-implement experiments, harmonization, standardization.

Didactic sequence for teaching structural molecular biology to various educational levels, through practical and ludic teaching resources

L. M. Beltramini, N. Bossolan
Physics Institute of São Carlos, University of São Paulo, São Carlos, Brazil

The understanding of the structure and function of proteins is closely linked to the development of structural biology and an understanding of the whole process involving in 'central dogma of molecular biology', including the importance of structure/function of the molecules involved, is essential for learning this subject. However, students often find difficult to visualize the structures of biomolecules through schematic drawings of figures from textbooks or computer. To help this understanding, we elaborated a didactic sequence, using didactic materials developed by our team, which involved the following practical activities: 1) DNA extraction (from fruits and using domestics reagents, when taught to high school students); 2) building the nucleotides and DNA/RNA structures using the kit of plastic pieces 'Building the molecules life: DNA/RNA'. The kit was used to make also DNA duplication and its transcription to RNA. The translation process used additional materials like as the Amino Acid Disc and the Kit 'Building amino acids and proteins' (primary and secondary structures). In addition, the kit 'Protein Folder' was used with undergraduate and graduate students who could build secondary and tertiary protein structures. This didactic sequence was applied to the following groups in years 2010–2013: a) continuing education courses to basic school teachers (about 1200 teachers); b) undergraduation courses of biological sciences; c) graduation courses of structural biology areas; d) students from high school (more than 2000 students). The courses for teacher included three video conferences, discussion about themes to be proposed for their students, experimental proceedings and two or three face-to-face meetings to build three-dimensional molecules using the kits. In undergraduation courses the students were encouraged to propose and develop a practical activity using the kits. The 'Protein folder' kit was used with graduate students to teach basic and applied concepts on secondary and tertiary structures of different proteins. The courses were evaluated by teachers who pointed out that they became more confident, independent and critical of their own practices, since they had the responsibility in elaborate their teaching strategies as well as evaluating it with their students. The impact in the students learning was made by comparative analysis between a pre- and post-test answered by some of their students (aged 14–17). The results were encouraging, reaching a value of about 76% of correct responses after the activity. The undergraduate and graduate students pointed out that the kits would help them to learn and teach those subjects in a more attractive way, awaking students' curiosity and implementing a dynamic in the classes.

Keywords: didactic resources, protein, structural molecular biology teaching.

Identification of phenolic components of *Rosa heckeliana* Tratt roots

N. Ozdogan[1], N. Coruh[2]
[1]Biochemistry, [2]Chemistry, Graduate School of Natural and Applied Sciences, Ankara, Turkey

Medicinal plants reveal their therapeutic effects due to high amount of phenolic compounds confined abundantly in roots, fruits, leaves and, flowers. *Rosa heckeliana* Tratt, as a member of Rosa was recently discovered as one of the important medicinal plants used in folk medicine. In this study, the therapeutically notable *R. heckeliana* was selected for the analysis of important phenolic components particularly confined in the roots. The roots were first extracted in methanol, then phenolic constituents were partitioned according to polarity by fractionation method. The method was also supported by the total amount of phenolic compounds. The highest total phenolic content as gallic acid equivalent (8.80 ± 19 μ g/mg) was obtained in the ethyl acetate fraction. Hence, that fraction was further analyzed for the identification of phenolic constituents using a diode array detectors equipped HPLC. Structural information about the compounds was confirmed by high-resolution mass spectrometry. Accordingly, catechin, caffeic acid, epicatechin, p-coumaric acid, scopoletin, ellagic acid, and quercetin were identified in the ethyl acetate fraction. To the best of our knowledge, this is the first detailed effort for the fractionated analysis of phenolic constituents in the roots of *R. heckeliana*.

Keywords: Catechin, HPLC analysis, Rosa heckeliana.

Impact and sustainability of hands-on training in the analysis of next-generation sequencing data

G. Rustici[1], S. L. Morgan[2]
[1]School of the Biological Sciences, Cambridge University, Cambridge, [2]EMBL-EBI, Hinxton, UK

Next-generation sequencing technologies are widely used in the field of functional genomics and applied in an increasing number of applications. For many 'wet lab' scientists, the analysis of the large amount of data generated by such technologies is a major bottleneck that can only be overcome through very specialized training in advanced data analysis methodologies and the use of dedicated bioinformatics software tools.

Here we will discuss the hands-on training activities in the analysis of high-throughput sequencing data that we have developed at the European Bioinformatics Institute and Cambridge University. We will present a snapshot of the audience that we have trained over the last five years, discuss the challenges that we have faced in developing training solutions that fits the needs of this very specialized user community and the best practices that we have embraced to tackle such challenges. We will also provide evidence of the impact such training has had on the research community and discuss our recipe for sustainability.

Keywords: Bioinformatics training, Education, Next-generation sequencing.

Multidisciplinary study area molecular nutrition: viewment from nutrition and dietetics postgraduate students

C. Gezer
Department of Nutrition and Dietetics, Institute of Health Sciences, Nicosia, Cyprus

Background: Nutrition and Dietetics (ND) not only closer to biomedical sciences but also social sciences, since nutrients, phytochemicals, biochemistry, genes and lifestyles interact in human biology. Therefore, it is very important for human wellbeing, quality of life and disease prevention. In this study, it is aim to analyse strengths, weaknesses, opportunities and threats of specializing attempts and efforts of ND postgraduate students on molecular nutrition (MN).

© 2014 The Authors. FEBS Journal © 2014 FEBS

Method: In this study, the doctoral (Phd) research project on molecular nutrition and the experiences of the ND Phd student were analysed by SWOT Analyse. This analysis was used to determine strengths, weaknesses, opportunities and threats of MN applications of ND postgraduate students.

Results: ND education brings students to combine epidemiological data and molecular mechanisms skills and this gives the strength to transmit the knowledge from molecular based to public. However, lacks at laboratory (lab) applications cause spend much more time and effort to be successful is a weakness. However, at this point while learning new techniques it gives an opportunity to seize new scientific perspectives. Besides that there are some threats. First one is that a few number of ND postgraduate students study on this area since difficulties of the lacks on lab application background. Another threat is that the students who studying on MN can focus much more on lab techniques since improve themselves on lab applications and this can let them away to translation of molecular data to suggestions for public health.

Conclusion: MN which includes nutrigenomics has the potential to lead to evidence-based dietary intervention strategies and related with health, diet, and genomics. This study area requires an understanding of nutrition, genetics, bioinformatics, human physiology, pathology and biochemistry as well as lab techniques and technologies. So, it is often difficult to lead all multidisciplinary information together and translating into prevention and delay of diseases and improve human wellbeing and life quality. According to our previous study, 85.6% of ND bachelor students think that nutritional biochemistry course needs lab applications to be more beneficial. Therefore, there is a need more courses and lab applications on MN in specific topics during ND education at bachelor level. This will give the new scientific perspectives and experiences to students and let them to be much more aware while planning their career. In addition, while dieticians will be encouraged and participated in this research area this will be improved the connection between molecular data and nutritional suggestions to public health.

Keywords: laboratory applications, molecular nutrition, nutrition and dietetics education.

Multidisiplinary biochemistry laboratory education; student centered real learning process

A. Sepici Dinçel[1], Y. Özkan[2], M. Selvi[3], F. Erkoç[3]
[1]Central Campus Biochemistry Laboratory, Gazi University, Faculty of Medicine, [2]Department of Biochemistry, Gazi University, Faculty of Pharmacy, [3]Department of Biology Education, Gazi University, Ankara, Turkey

Along with developments in every field in recent decades, need for re-evaluating the systems and reconstructing educational tools has arisen in the field of higher education; and educational reforms were inevitable. Student centered, flexible modules were developed aiming at 'real learning process' for the biochemistry lab. When multidisciplinary character of biochemistry is considered; students from very diverse fields and levels of basic knowledge/skills are required to complete the course and therefore a need for education programmes and resource materials arises. Modular programming for biochemistry laboratory applications/ concepts were designed and tested using one-group pretest posttest design (model). The implementation of the study was realized in Biochemistry Laboratory Course given in third year in Biology Teaching Department. The sample of the study consisted of 43 Biology Teaching students enrolled in their third year of study during the fall semester. All students took the laboratory course for the first time; and had no prior familiarity with biochemistry experimentation. Each module consists of: basic knowledge, materials, necessary equipment, experimental steps, results/discussion. In total three modules were applied to the students. Module 1: Working principles and safety in Biochemistry Laboratory, biochemical calculations. (4 weeks), Module 2: pH meter, acid-base titrations, buffer solutions. (2 weeks), Module 3: Spectrophotometric analysis. (4 weeks). Modules consist of two alternative problem sets and/or experiments presented to the students' choice. In the end of the module, there are self evaluating tools of different question types (open-ended questions, short assays, definitions, pH and solution problems, multiple choice, graphical presentation and interpretation) for the students. Assessment of modular teaching results with the pre- and posttests revealed that there is a significant difference in students' biochemistry academic success after learning with the module ($t(42) = 11.70$, $p = 0.000$). Before learning with the module, average of the students' biochemistry academic achievement points was $X = 9.86$; after implementation of the learning with modules, the mean score increased to 15.02. Modular programming enables active student participation; instructors are mostly limited in guiding the learning process. Each module ensured the dynamic and student centered learning environment where recently preferred new pedagogical strategies were applied. Students with different mental properties were able to learn concepts, knowledge and schemes in similar ways leading to improve biochemistry education.

Reproducibility in science: how video journals increase research validity and productivity

K. M. Henderson
Journal Development, Journal of Visualized Experiments - JoVE, Cambridge, MA, USA

Several high-impact studies indicate that an astoundingly low 11–30% of published scientific research is reproducible. The media has implied that scientists are actively practicing poor conduct and falsifying data under the pressure of career considerations. We reject this speculation and instead question the traditional, text-based format of scientific communication. As research methods incorporate new technologies and become increasingly complex, the platform for sharing new techniques remains relatively unchanged. Researchers currently present their dynamic methods as static snapshots manipulated to fit within the limitations of text-based journals. A new generation of science journals is changing that – it employs video technology to capture and share complex research techniques in a dynamic format. Here, we present an overview of the growing field of video publication and discuss its technical challenges, implications for scholarly communication and its adoption by the scientific community. Results from recently conducted case studies will be shared, such as the experiences of research groups at Purdue University and University of Alaska, which indicate that video publications can save a lab up to $15,000 per experiment.

EMTRAIN: the European medicines research training network

C. Brooksbank[1], C. Janko[2], M. Hardman[3], The EMTRAIN Consortium
[1]Training, EMBL-EBI, Cambridge, UK, [2]Clinical Pharmacology, Medial University Vienna, Vienna, Austria, [3]Innovative Medicines, AstraZeneca, Macclesfield, UK

Well-trained professionals, who are committed to staying at the leading edge of developments in their field, are the underlying foundation of successful biomedical research. Europe is taking leadership to retain global competitiveness in medicines research and development by building the right environment for innovative education and training. This environment needs to address several challenges. Firstly, lack of mobility across national borders is a major hurdle to Europe's competitiveness: highly qualified professionals may have to undergo retraining to enable them to advance their careers outside of the country or sector in which they received their training. Secondly, there is a perceived gap between the competencies that graduates come out of university with and the competencies that employers need. Thirdly, established mechanisms for maintaining professional competency are being challenged by: the increasingly rapid development of new technologies that unexpectedly displace established ones; the cross-disciplinary, team-working nature of modern science; and

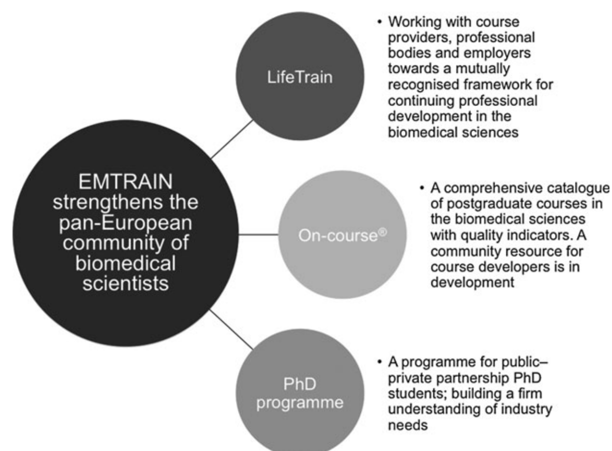

Fig. 1. xxxxxxx.

the need for greater communication and collaboration across traditional boundaries. EMTRAIN is developing a pan-European platform to begin to address some of these issues.

Training in data, tools and resources for molecular life scientists

S. L. Morgan, L. Emery, R. Grandison, T. Hancocks, M. Adams, K. Costa, C. Brooksbank
EMBL-European Bioinformatics Institute, Hinxton, Cambridge, UK

With the wealth of data being generated by laboratories worldwide, and the depositing of such data into publically accessible databases, there is an increased need for bench biologists to gain the skills required to mine, analyse and interpret this data.

EMBL-European Bioinformatics Institute develops and maintains a variety of data tools and resources for application across the life sciences, but also provides a number of mechanisms for scientists to learn how to become better users of biological data through a range of training opportunities.

Our trainees are diverse, many are from a bench background and at PhD / Postdoctoral level, but whilst they have expertise in their area of scientific interest they are often lacking in computational skill and knowledge of the tools available to them. Our aim is not to produce a new generation of bioinformaticians, but rather to develop a group of scientists who are more confident users of data tools and resources.

We have created a programme that delivers training in three modes – on-site, off-site and on-line. This enables us to provide training to a wide audience, and to provide different focus for courses, from subject specific analysis through to advanced use of a specific resource.

Providing such a programme is challenging due to the diverse nature of our potential trainees, but we present here the approach we take to meeting these challenges and to providing training that enables life scientists to become more confident data users.

14-3-3 sigma regulates epithelial-mesenchymal transition through c Jun-Slug aixs

K. Raychaudhuri, M. Gurjar, S. N. Dalal
Sorab Lab, KS215, Advanced Centre for Treatment Research & Education in Cancer, (ACTREC), Tata Memorial Centre, Navi Mumbai, India

The role of 14-3-3 proteins has been well established in regulation of cell cycle, DNA damage, regulation of gene expression, cytoskeletal dynamics, regulation of cell to cell adhesion, cancer progression etc.

We have used HCT116 based 14-3-3 σ wild type and null cells to determine the effect of 14-3-3 σ loss in the context of cancer progression. We observed that 14-3-3 σ loss leads to loss of epithelial markers e.g. E-cadherin, cytokeratin, plakoglobin and gain of mesenchymal markers e.g. N-cadherin and vimentin. Re-expression of 14-3-3σ in these cells leads to a reversal of these phenotypes, suggesting that the observed phenotypes are due to loss of 14-3-3σ.

We also observed an increase in cell migration, decrease in cell to cell adhesion and decreased cell to extra cellular matrix adhesion on loss of 14-3-3σ. These results suggested that loss of 14-3-3σ lead to EMT.

Next we determined the expression levels of Snail, Slug, Zeb and Twist as EMT specific transcription factors. We observed increased expression of Slug and Zeb1 in 14-3-3σ null cells as compared to 14-3-3σ wild type cells. We have also identified c-JUN, as an upstream transcription factor which is found to be stabilized at protein level in 14-3-3 σ null cells, whereas, in 14-3-3σ wild type cells c JUN was targeted to proteasomal degradation. c- JUN is known to bind slug promoter and up-regulate Slug at transcriptional level. We have also demonstrated in vitro and in vivo interaction of 14-3-3 σ and c JUN. This interaction might be important for c JUN degradation.

Our results have identified a novel mechanism suggesting presence of a c JUN-slug axis which can promote EMT on loss of 14-3-3 σ. In this conference we will discuss on how 14-3-3 σ regulates c JUN protein stabilty.

Keywords: 14-3-3 Sigma, c Jun and Slug, Epithelial-Mesenchymal Transition.

TUE-003
A genetically encoded biosensor to monitor Tumour Suppressor PTEN function in living cells

S. Misticone[1], E. Lima-Fernandes[2], C. Boularan[3], J. S. Paradis[4], H. Enslen[1], M. Bouvier[4], G. S. Baillie[5], S. Marullo[1], M. G. Scott[1]
[1]*Inserm, U1016, CNRS, UMR8104, Institut Cochin, University Paris Descartes, Sorbonne Paris Cité, Paris, France,* [2]*Structural Genomics Consortium, University of Toronto, Toronto, ON, Canada,* [3]*Inserm U1048, Institut des Maladies Métaboliques et Cardiovasculaires, University Paul Sabatier, Toulouse, France,* [4]*Molecular Biology Program, Institute for Research in Immunology and Cancer, Université de Montréal, Montréal, QC, Canada,* [5]*Molecular Pharmacology Group, Institute of Neuroscience and Psychology, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, UK*

Tumour Suppressor PTEN is a non-redundant phosphatase that is an essential negative regulator of the oncogenic pro-survival PI3K/AKT pathway. The ability to directly monitor PTEN conformation and function in a rapid, sensitive manner is a key step towards developing anti-cancer drugs aimed at enhancing or restoring PTEN-dependent pathways. We developed an intramolecular bioluminescence resonance energy transfer (BRET)-based biosensor, where PTEN is inserted between the energy donor *Renilla* luciferase and the acceptor yellow fluorescent protein. The biosensor retains intrinsic biological properties of PTEN and enables both structure-function and kinetic analyses in live cells. BRET shifts, indicating conformational change, were detected following mutations that disrupt intramolecular PTEN interactions, promoting its targeting to the plasma membrane, and also following physiological activation of PTEN. Using the biosensor as a reporter we unveiled PTEN activation by several G protein-coupled receptors, previously unknown as PTEN regulators. Trastuzumab, an antibody used to treat ERBB2-overexpressing human breast cancers, also produced activation-associated PTEN conformational rearrangement. We propose the biosensor can be used to identify signalling pathways that regulate PTEN or molecules that enhance its anti-tumour activity.

Keywords: Biosensor, PI3K/Akt, PTEN.

TUE-004
A mitochondrial switch promotes tumor metastasis

P. E. Porporato[1], V. Payen[2], J. Pérez-Escuredo[2], C. De Saedeleer[2], P. Danhier[3], O. Feron[2], C. Michiels[4], B. Gallez[3], P. Sonveaux[2]
[1]1Institute of Experimental and Clinical Research (IREC), Pole of Pharmacology, [2]Institute of Experimental and Clinical Research (IREC), Pole of Pharmacology, [3]Laboratory of Magnetic Resonance Imaging (REMA), Université catholique de Louvain, Bruxelles, [4]URBC-NARILIS, University of Namur, Namur, Belgium

Cancers evolve a subpopulation of tumor cells that metabolically rely on glycolysis uncoupled from oxidative phosphorylation irrespectively of oxygen availability (aerobic glycolysis). Given that most metastases are abnormally avid for glucose (which is the rationale for their clinical detection using FDG-PET) and because clinical data show a positive correlation between lactate production and tumor metastasis, we reasoned that cells performing aerobic glycolysis could constitute a population of metastatic progenitor cells that would remain glycolytic in the blood stream. We found a different metabolic phenotype, though. Indeed, using serial rounds of *in vitro* selection of highly invasive tumor cells (starting from wild-type SiHa human cervix adenocarcinoma cells) and in vivo selection of supermetastatic tumor cells (starting from B16-F10 mouse melanoma cells), we identified a mitochondrial switch corresponding to an overload of the TCA cycle with preserved mitochondrial functions (including ATP production) but increased mitochondrial superoxide production. The switch provided a metastatic advantage which was phenocopied by moderate OXPHOS inhibition associated with mild mitochondrial superoxide increase. Thus, two different events, OXPHOS overload or moderate OXPHOS inhibition, promote superoxide-dependent tumor cell migration, invasion, clonogenicity, and metastasis; demonstrating the central role of mitochondrial superoxide generation in the pathogenesis of metastasis. Consequently, we report that mitochondria-specific superoxide scavenging (using mitoTEMPO or mitoQ) inhibits metastatic dissemination from primary mouse and human tumors, which opens a new avenue for the therapeutic prevention of tumor metastasis.

Study supported by ERC starting grant #243188-TUMETAB-O, Belgian Belspo-IAP grant #UP7-03, FWB ARC 09/14-020, F.R.S.-FNRS, and Télévie.

TUE-005
A novel small molecule inhibitor suppresses tumor angiogenesis through targeting vascular endothelial growth factor receptor signlaing

S.-W. Huang, T.-F. Huang
Graduate Institute of Pharmacology, National Taiwan University, Taipei, Taiwan

Angiogenesis occurs during tissue growth and development, and tumour angiogenesis plays an essential in cancer progression. Vascular endothelial growth factor (VEGF) plays a critical factor in the induction of angiogenesis, which therefore has become an attractive target for anticancer treatment. In this study, we evaluated the effect of Wth02, a henna extract derivative, and its inhibitory mechanisms on angiogenesis of human umbilical vascular endothelial cells (HUVECs). Wth02 concentration-dependently inhibited VEGF-induced proliferation, migration and tube formation of HUVECs. Wth02 also suppressed VEGF-induced microvessel sprouting from aortic rings *ex vivo* and suppressed neovascularization of implanted matrigel plugs *in vivo*. Wth02 inhibited VEGF-induced phosphorylation of VEGFR2 and the downstream protein kinases including Akt, focal adhesion kinase (FAK), ERK and Src. Results from in vitro kinase assay further demonstrated that Wth02 suppressed the kinase activity of VEGFR2. Using a colorectal cancer mouse xenograft model, we found that Wth02 treatment caused a decrease in both tumor volume and tumor weight in Balb/C nude mice. Consequently, the inhibitory effect of Wth02 on these pathways resulted in the inhibition of tumor angiogenesis as demonstrated by the decrease of microvessel density in tumor tissues. Altogether, our findings suggest that Wth02 inhibits VEGF- and tumor cells Hep G2 and HCT116-induced angiogenesis and is a potential drug candidate in anti-cancer therapy. Downregulation of VEGFR2-mediated signaling may contribute to its anti-angiogenic actions.

Keywords: angiogenesis, human umbilical vascular endothelial cells (HUVECs), vascular endothelial growth factor (VEGF).

TUE-006
A recombinant protein PinX1 suppresses proliferation of breast cancer cells via telomerase inhibition

Y. Shi, L. Sun, G. Chen, D. Zheng, G. Chen
Shanghai Advanced Research Institute, Shanghai, China

Significantly increased levels of telomerase expression and activity have been observed in nearly 90% of the cancer cells, making it a potential target for anti-cancer drugs. Serval anti-tumor drugs targeting telomere and telomerase such as GRN163L were developed and enter into clinical trials (phase I/II), but there are some disadvantages such as low specify and high toxicity in small molecule drugs, protein drugs become a novel way to anti-tumors because of their high specificity and low toxicity. The PinX1 protein binds directly to the hTERT and suppresses telomerase activity, so PinX1 might be developed as a protein anti-tumor drug. The small HIV Tat peptide of 11 amino acids (YGRKKRRQRRR, TAT) is capable of translocating cargoes of different molecules across the cell membrane. In this study we have generated a recombinant TAT-PinX1-C protein and examined the efficiency and mechanism of the protein in suppression of breast cancer cell growth and tumorigenicity. The protein inhibits telomerase activity in vitro and decreases TRF Length of breast cancer cells, inhibits proliferation via inducing apoptosis and altering cell cycle distribution of breast cancer cells. We will test the anti-tumor activity in xenograft nude mice next. These results suggest the potential of TAT-PinX1-C in targeted therapy of breast cancer.

Keywords: breast cancer, PinX1, telomerase inhibition.

TUE-007
A selective activator of protein kinase C discovered using yeast

C. Bessa[1], N. Harilal[1], C. Pereira[1], C. Maciel[1], J. Gonçalves[2], P. Rijo[3,4], M. F. Simões[3,4], L. Saraiva[1]
[1]REQUIMTE, Laboratório de Microbiologia, Departamento de Ciências Biológicas, [2]REQUIMTE, Laboratório de Farmacologia, Departamento de Ciências do Medicamento, Faculdade de Farmácia, Universidade do Porto, Porto, [3]iMed.UL, Faculdade de Farmácia, Universidade de Lisboa, [4]CBIOS, Universidade Lusófona, Lisboa, Portugal

The Protein Kinase C (PKC) is a family of serine/threonine kinases with at least ten isoforms divided into three major subfamilies: classical (cPKCα, βI, βII and γ), novel (nPKCδ, ε, η and -θ) and atypical (aPKCζ and $\lambda\backslash\iota$) [1]. In recent years, PKC isoforms have emerged as striking anticancer drug targets. Particularly, PKCδ

© 2014 The Authors. FEBS Journal © 2014 FEBS

has been the focus of intense study due to its well-known pro-apoptotic functions [1]. Therefore, the discovery of selective modulators of individual PKC isoforms has proved to be a promising strategy in anticancer treatment. In this way, *Saccharomyces cerevisiae* cells expressing individual mammalian PKC isoforms have been used by our group to search for isoform-selective PKC modulators. In this yeast assay, PKC activators cause growth inhibition, without affecting the growth of control yeast (transformed with the empty vector) [2].

In this work, the yeast assay was used to study the modulatory activity of four semisynthetic diterpenic compounds (C1 - C4), from the Simões' research group (iMed. UL), on mammalian PKCα, βI, δ, ε and ζ. The obtained results showed that C1 had no effect on PKCs, whereas C2 and C3 induced a significant growth inhibition in yeast cells expressing PKCα, βI, δ, ε or ζ, without affecting the growth of control yeast. Notably, C4 significantly inhibited the growth of yeast expressing PKCδ, without interfering with the growth of yeast expressing PKCα, βI, ε or ζ, and control yeast. At the same time, the C4-induced growth inhibition in yeast expressing PKCδ was associated with an increase of DNA fragmentation (apoptosis), without loss of plasma membrane integrity (necrosis). The selectivity and direct activation of PKCδ by C4 was further confirmed using an *in vitro* PKC assay. Moreover, it was shown that C4 was a potent inhibitor of tumour cell growth, an effect associated to the induction of apoptosis.

In conclusion, a putative PKCδ selective activator (C4) was identified in yeast. Promising pharmacological applications may be therefore envisaged for C4, as the first non-peptide selective activator of PKCδ, and as a potential anticancer agent.

Achillea teretifolia Willd. extracts trigger the apoptosis by suppressing bcl-2 expression and activating caspase-3 and bax genes in prostate cancer cell lines

E. B. Bali[1], L. Açık[2], P. Elçi[3], M. Sarper[3], F. Avcu[4], M. Vural[2]

[1]*Health Services Vocational School, University of Gazi,* [2]*Department of Biology, Faculty of Science, University of Gazi,* [3]*Cancer and Stem Cell Research Center, Gulhane Military Medical School,* [4]*Department of Hematology, Cancer and Stem Cell Research Center, Gulhane Military Medical School, Ankara, Turkey*

The species of *Achillea* L. belonging to *Asteraceae (Compositae)*, the largest family of vascular plants, have been widely used by local people as folk or traditional herbal medicines since ancient time and most of them have therapeutic applications. *Achillea teretifolia* Willd. is an endemic plant for Turkey. In this study, its water and methanol extracts were investigated for apoptosis induction on prostate cancer (DU145, PC-3) and gingival fibroblast cells as control group. Normal and cancer cells were treated with IC50 value of the extracts detected by MTT [3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide] assay. For the detection of apoptotic and antiapoptotic effects, quantitative real-time polymerase chain reaction (RT-PCR) was used to detect the relative expression levels of *bax, caspase-3* and *bcl-2* genes. All experiments were performed in triplicate. RT-PCR analysis demonstrated that following exposure of DU145 and PC-3 cells to water and methanol extracts of *A.teretifolia*, the level of mRNA expressions of pro-apoptotic proteins (*bax* and *caspase-3*) were significantly up-regulated ($p < 0.05$), whereas the expression of anti-apoptotic proteins (*bcl-2*) were down-regulated ($p < 0.05$). In gingival fibroblast cells, apoptosis induction triggered by *A.teretifolia* extracts was not detected. Furthermore, methanol extract had more powerful apoptotic effect on prostate cancer cells than water extract. As a conclusion, it is the first report showing that *A. teretifolia* extracts triggered the apoptosis in DU145 and PC-3 cancer cells via protein activation of *bax* and *caspase-3*.

Keywords: Achillea teretifolia, apoptosis, cytotoxicity.

Adaptor protein Ruk$_l$/CIN85 overexpression results in the development of stemness characteristics of MCF-7 breast adenocarcinoma cells

G. Pasichnyk[1], O. Povorozniuk[1,2], I. Horak[1,3], D. Gerashchenko[1], D. Petukhov[1], A. Samoylenko[1], N. Byts[1], J. McCubrey[4], L. Drobot[1]

[1]*Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine,* [2]*Kyiv National Taras Schevchenko University,* [3]*National University of Kyiv-Mohyla Academy, Kyiv, Ukraine,* [4]*Department of Microbiology and Immunology, East Carolina University, Greenville, NC, USA*

According to modern concept of basic cancer biology, tumors consist of many cell populations with different characteristics and functions. Recent studies indicate that subpopulation of tumor cells with tumor-initiating ability (cancer stem cells, CSCs) play an important role in acquired resistance to chemotherapy and radiation, tumor dissemination and metastasis. A number of agents capable of targeting CSCs in preclinical models are currently entering clinical trials. Beyond all doubt, the further identification of signaling components that regulate biology of these cells will lead to the development of new anti-tumor drugs for comprehensive treatment of oncological diseases. Our previous data demonstrate that overexpression of adaptor/scaffold protein Ruk$_l$/CIN85 in weakly invasive MCF-7 breast adenocarcinoma cells result in their conversion into a more malignant phenotype. The aim of this study was to elucidate the possible role of Ruk$_l$/CIN85 in the development and maintaining of MCF-7 CSCs' population. Overexpression of Ruk$_l$/CIN85 in MCF-7 cells was accompanied by increased manifestation of CSCs' characteristics such as the ability to form mammoshperes, the high number of CD44$^+$/CD24$^-$ cells as well the resistance to chemotherapy drugs. We suggest that enhanced chemoresistence of Ruk$_l$/CIN85-overexpressing cells can be connected with activation of aldehyde dehydrogenase enzyme, ABC membrane transporters, Akt, and mTOR kinases, NF-κB transcription factor and increased resistance to apoptosis. Interestingly, knocking down of Ruk$_l$/CIN85 using specific *shRNA* lentivirus partially reversed the observed effects of Ruk$_l$/CIN85 overexpression on MCF-7 stemness characteristics. The data obtained indicate the involvement of adaptor protein Ruk$_l$/CIN85 in the development and maintaining of stemness potential of breast adenocarcinoma MCF-7 cells.

Keywords: adaptor/scaffold protein Rukl/CIN85, breast adenocarcinoma MCF-7 cells, cancer stem cells.

Adaptor proteins intersectin 1 and 2 bind similar proline-rich ligands but are differentially recognized by SH2 domain-containing proteins

O. Novokhatska[1], M. Dergai[1], L. Tsyba[1], J. Moreau[2], A. Rynditch[1]
[1]*Institute of Molecular Biology and Genetics NASU, Kyiv, Ukraine*, [2]*J. Monod Institute, Paris, France*

Background: Scaffolding proteins of the intersectin (ITSN) family, ITSN1 and ITSN2, are crucial for the initiation stage of clathrin-mediated endocytosis. These proteins are closely related but have implications in distinct pathologies. To determine how these proteins could be segregated in certain cell pathways we performed a comparative study of ITSNs.

Methodology/Principal Findings: We have shown that endogenous ITSN1 and ITSN2 colocalize and form a complex in cells. A structural comparison of five SH3 domains, which mediate most ITSNs protein-protein interactions, demonstrated a similarity of their ligand-binding sites. We showed that the SH3 domains of ITSN2 bound well-established interactors of ITSN1 as well as newly identified for ITSNs protein partners. A search for a novel interacting interface revealed multiple tyrosines that could be phosphorylated in ITSN2. Phosphorylation of ITSN2 isoforms but not ITSN1-S was observed in various cell lines. EGF stimulation of HeLa cells enhanced tyrosine phosphorylation of ITSN2 isoforms and enabled recognition by the SH2 domains of the Fyn, Fgr and Abl1 kinases, the regulatory subunit of PI3K, the adaptor proteins Grb2 and Crk, and phospholipase C gamma. Mentioned SH2 domains were unable to bind ITSN1-S.

Conclusions/Significance: Our results indicate that during evolution of vertebrates ITSN2 acquired novel protein-interaction interface that allows its specific recognition by the SH2 domains of signaling proteins. We propose that these data could be important to understand the functional diversity of paralogous ITSN proteins and establishing their roles in diseases.

Keywords: adaptor protein, protein-protein interactions, tyrosine phosphorylation.

Adenylate kinase 2, an associated activator of DUSP26 phosphatase, regulates FADD phosphorylation for cell growth

H. Kim, H.-J. Lee, Y. Oh, S.-G. Choi, **Y.-K. Jung**
[1]*Biological Science, Seoul National University, Seoul, Korea*

Adenylate kinase 2 (AK2), which balances adenine nucleotide pool, is known as a multi-functional protein. Here we show that AK2 negatively regulates tumor cell growth. AK2 forms a complex with DUSP26 phosphatase, and stimulates DUSP26 activity independently of its adenylate kinase activity. AK2/DUSP26 phosphatase protein complex dephosphorylates phospho-$FADD_{Ser194}$ to regulate cell growth. AK2 deficiency enhances cell proliferation with cell cycle alteration and induces tumor formation in xenograft assay, and this anti-growth function of AK2 is associated with its DUSP26-stimulating activity. Down-regulation of AK2 expression is frequently found in tumor cells and human cancer tissues showing high level of phospho-$FADD_{Ser194}$. Moreover, reconstitution of AK2 in AK2-deficient tumor cells retards cell proliferation. Further, $AK2^{+/-}$ mouse embryo fibroblasts exhibit enhanced cell proliferation with significant alteration in phospho-$FADD_{Ser191}$. These results suggest that AK2 is an associated activator of DUSP26 and suppresses cell proliferation via FADD dephosphorylation, postulating AK2 as a suppressor of tumor growth.

Keywords: AK2, DUSP26 activator, FADD.

ALK rearrangements in Turkey series lung adenocarcinoma

E. I. Atli[1], A. Akin[2], C. Yakicier[3]
[1]*Molecular Biology and Genetic, Acibadem University,* [2]*Molecular Biology and Genetic, Acibadem Genetic Diagnosis Center,* [3]*Acibadem University Molecular Biology and Genetic Department, Istanbul, Turkey*

Abstract Purpose: To establish the frequency of ALK translocation in lung cancer (adenocarcinomas) at a Turkish population level.

Experimental Design: Between 2011–2013, 157 paraffin embedded tumour tissue have been performed by our hospitals. 40 patient chosen from this group were also scanned for EGFR mutations. FISH technique is performed to paraffin embedded tissues were cut 4 micron thick. Vysis ALK Break apart FISH probe kit *[Vysis LSI ALK (2p23) Dual Color, Break Apart Rearrangement Probe; Abbott Molecular]* is used to detect rearrangement of ALK gene.

Results: 157 adenocarcinoma tumor tissue were analyzed. In 20 patients (12.7%) were found positive for ALK. In our study ALK-positive and-negative patients, there is a difference between the 5.69 percent year. The results of ALK-positive patients compared to negative patients showed that younger patients.

Conclusion: In summary, our study is the first study to investigate the ALK status in lung cancer in Turkish patients. Lung adenocarcinoma patients with ALK translocation, which has been reported to be younger age than carrying wild-type allele. According to result ALK breaks observed more frequently in patients at an early age. FISH analysis is the standard method for detecting ALK rearrangements. ALK gene rearrangements in patients with lung cancer, recent studies conducted on personalized treatment increases the success was observed. ALK gene rearrengements by FISH analysis has a leading role to Crizotinib treatment. Thus, wild type EGFR gene results and ALK gene rearrangements plus patients is related to increased survival after crizotinib treatment.

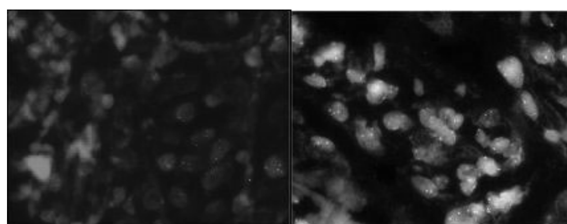

Fig. 1. Fluorescent in situ hybridization (FISH) reveals a split of red and green probe in an *ALK*-positive tumor.

Further studies about ALK gene is important to get more efficient cure result and figure out the molecular mechanism and structure.

Keywords: ALK, Fluorescent *in situ* hybridization, lung adenocarcinoma.

TUE-013
Alpha 1 syntrophin protein plays a suspicious role in cell migration and carcinogenesis

H. F. Bhat[1,2], F. Khanday[2]
[1]SKUAST-K, [2]University of Kashmir, Srinagar, India

We have studied the expression of alpha-1-syntrophin (SNTA1) protein in histologically confirmed human breast cancerous tissue samples. our results suggest a significant increase in the expression of SNTA1 adaptor protein as compared to its expression in the corresponding normal tissue samples. Our results suggested a role for SNTA1 in carcinogenesis and its possibility as a novel diagnostic or prognostic marker in breast cancers. Taking a lead from here and the earlier works we learnt that SNTA1 has also been implicated in the activation of RhoGTP'ase Rac1 protein. However the underlying mechanism has not been explored. We used co-immunoprecipitation assays to show a complex formation, involving SNTA1 and GRB2 proteins, that was shown to significantly increase the active Rac1 levels within human breast cancer cell lines (HBL 100, MCF 7), while SiRNA and ShRNA were used to down regulate the expression of these proteins. Various Rac1 activation assays were performed. Our results showed a significant increase in the activation when SNTA1 and P66shc proteins were overexpressed, whereas their depleation not only effectively reduced the levels of active Rac1 but also showed a negative effect on the migratory potential of human breast cancer cells. Taken together, we propose a possible mechanism of Rac1 activation involving SNTA1 and emphasize its role in breast cancer cell migration, and carcinogenesis.

Keywords: breast cancer, migration, rac1.

TUE-014
AMTB, an inhibitor of calcium permeable ion channel TRPM8 and its effect on breast cancer cells

K. Yapa[1], G. R. Monteith[1], S. J. Roberts-Thomson[1], A. A. Peters[1], I. Vetter[2]
[1]School of Pharmacy, [2]Institute of Molecular Biology, University of Queensland, Brisbane, Australia

Introduction: Calcium channels are involved in a wide range of cellular functions, and studies show that aberrant expression of these channels is a characteristic of some breast tumours. The calcium permeable transient receptor potential cation channel subtype M, member 8 (TRPM8) is reported to be over-expressed in tumours of the prostate; however few studies have evaluated the role of this channel in breast cancer. AMTB is reported to be a selective inhibitor of TRPM8 ion channels. The present study aims to investigate TRPM8 ion channel as a potential therapeutic target in breast cancer using a pharmacological inhibitor of this channel: AMTB (N-(3-aminopropyl)-2-[(3-methylphenyl)methoxy]-N-(2-thienylmethyl)-benzamide hydrochloride (1:1) hydrate).
Aim: To evaluate the effect of pharmacological inhibition of TRPM8 ion channel by AMTB on the proliferation of breast cancer cells.
Methods: Cells from two human breast cancer cell lines: MDA-MB-231 and SK-BR-3 were treated with 0.1 μM – 100 μM of the TRPM8 inhibitor: AMTB (Sigma-Aldrich). The cells plated in 96-well plates were incubated with AMTB for 72 hours and an MTS assay (Promega) was performed to determine cell viability. A high-throughput fluorescent imaging plate reader (FLIPR) membrane potential assay assessed the effect of AMTB on voltage gated sodium channels (Nav). HEK293 cells stably expressing hNav isoforms (Scottish BioMedical) were briefly incubated with AMTB and then activated by veratridine to measure depolarisation of Nav channels. The mRNA expression of TRPM8 and Nav channel subtypes 1.1–1.9 in breast cancer cell lines was determined using real-time RT-PCR (Life Technologies).
Results: AMTB (100 μM) decreased cell viability in both MDA-MB-231 and SKBR-3 cell lines by >70%. However, real-time RT-PCR analysis showed very low (SKBR3) or no (MDA-MB-231) TRPM8 mRNA in both breast cancer cells lines. Analysis of TRPM8 activity using FLIPR membrane potential assay revealed an inhibitory effect of AMTB at Nav channel subtypes 1.1–1.8. Multiple Nav subtype mRNAs were present in breast cancer cell lines: Nav subtypes 1.3, 1.5, 1.7 mRNA were present in MDA-MB-231 breast cancer cells and Nav 1.4, 1.6, 1.9 mRNA was detected in SK-BR-3 breast cancer cells.
Conclusion: The pharmacological activity of AMTB includes blockage of TRPM8 and most subtypes of Nav channels. The effect of AMTB on the proliferation of breast cancer cells may be mainly due to its action on Nav channels. Further studies are required to assess the role of Nav channels

Keywords: breast cancer, calcium channels.

TUE-015
Analysis of association of variations in p53 gene with breast cancer risk in Kazakhstan population

A. Khodayeva, T. Miroshnik, A. Neupokoeva, T. Balmukhanov
Aitkhozhin Institute of Molecular Biology and Biochemistry, Almaty, Kazakhstan

The association of *p53* gene polymorphisms with breast cancer (BC) varies in different races and nationalities. The aim of this study was to evaluate the associations of polymorphisms in codon 72 exon 4 (Arg72Pro), in intron 3 (16 bp duplication) and intron 6 (G/A) of *p53* gene with BC in Kazakh and Russian ethnic groups in Kazakhstan.

The case-control study included 468 BC patients (267 Kazakhs, mean age 49.1 years, 201 Russians – 51.1 years) and 466 of controls (229 Kazakhs – 49.6 years, 237 Russians – 49.7 years). Genotyping was performed by PCR-RFLP analysis. The Pearson χ^2, p-value (P), Fisher exact test's permutation p-value (P_f), and odds ratio (OR) with 95% confidence intervals (95% CI) criteria were applied to data analysis. Combined effect of allele variations was carried out using algorithm APSampler.

The association of two polymorphisms in intron 3 and intron 6 with BC was shown in Russian group. Significant differences in alleles frequency and genotypes distribution were detected for polymorphism in intron 6 ($\chi^2 = 9.02$, P = 0.003 for alleles; $\chi^2 = 8.64$, P = 0.01 for genotypes); in intron 3 ($\chi^2 = 6.31$, P = 0.01 for alleles; $\chi^2 = 5.90$, P = 0.05 for genotypes) between patients and corresponding controls.

The associations with BC risk were evaluated for 16 bp duplication in intron 3 (OR = 1.83; 95% CI = 1.14–2.93) and for allele A in intron 6 (OR = 1.93; 95% CI = 1.25–2.97) in Russians. Association with BC risk was found by means of APSampler for the combination of allele A in intron 6 with the absence of 16 bp duplication in intron 3 in Russian group (OR = 2.29, $P_f = 5.86*10^{-7}$).

The differences in allele frequencies and genotypes distribution between cases and controls in codon 72 exon 4 (Arg72Pro) in Russian group and in all tested sites in the Kazakh group were not found.

Keywords: breast cancer, p53 gene.

The wnt/β-catenin pathway regulates stem cell pluripotency and plays a pivotal role in cell fate decisions during development. The central molecule of this pathway is β-catenin, a multifunctional protein principally involved in two functions: cadherin dependent cell-cell adhesion function at the cell membrane and transcription of wnt-specific genes in the nucleus. β-Catenin, a 781 amino acid long protein has three domains folding in an unknown three dimensional structure with a structured central armadillo domain. Mutations and/or overexpression of β-catenin are associated with many cancers including liver cancer, colorectal cancer, lung cancer, ovarian cancer and malignant breast tumours. In this study we have generated many variants of this protein for understanding its role in cancer development and progression, stem cell biology and also for the biophysical studies. We have cloned and purified β-catenin N-terminal deletion mutants to homogeneity using *E. coli* expression system and we are establishing protein based assays for screening small molecule inhibitors of wnt/β-catenin signalling pathway. β-Catenin interacts with vast array of proteins in the cytosol and many transcription factors in order to regulate various functions. Some of the proteins that interact with β-catenin include Oct4, KLF4 and Sox2, these proteins are known to be critical proteins in stem cell biology. We have generated deletion mutants of the C-terminal domain, also called transcriptional activation domain, of β-catenin in order to analyze their mechanistic studies and their association with Oct4, KLF4 and Sox2. In conclusion, we have generarted many constructs of β-catenin for understanding its biophysical properties and for analyzing its nuclear functions.

Keywords: beta catenin, stem cells, biophysical studies, SOX, KLF.

Anti-angiogenic mechanisms of WMJ-S-001, a novel aliphatic hydroxamate derivative

M.-J. Hsu[1], W.-J. Huang[2], Y.-F. Hsu[3], P.-T. Chiu[4]
[1]*Department of Pharmacology,* [2]*Graduate Institute of Pharmacognosy, Taipei Medical University, Taipei,* [3]*Department of Surgery, Landseed Hospital, Taoyuan,* [4]*Graduate Institute of Medical Sciences, Taipei Medical University, Taipei, Taiwan*

The metastatic spread of tumor cells is the leading cause of death for cancer patients. Angiogenesis, one of the major routes for tumor invasion and metastasis, thus represents a rational target for therapeutic intervention. Recent development in drug discovery has highlighted the diverse biological and pharmacological properties of hydroxamate, a key pharmacophore. In this study, we explored and characterized the anti-angiogenic activities of a novel aliphatic hydroxamate, WMJ-S-001, in an effort to develop novel angiogenesis inhibitors. WMJ-S-001 inhibited vascular endothelial growth factor (VEGF)-induced proliferation, migration and endothelial tube formation of human umbilical endothelial cells (HUVECs). WMJ-S-001 suppressed VEGF-induced microvessel sprouting from aortic rings and attenuated VEGF- or HCT116 colorectal cancer cells-induced angiogenesis *in vivo*. In addition, WMJ-S-001 inhibited the phosphorylations of VEGFR2, Src, FAK, Akt and ERK in VEGF-stimulated HUVECs. WMJ-S-001 caused an increase in SHP-1 phosphatase activity, whereas NSC-87877, a SHP-1 inhibitor, restored WMJ-S-001 suppression of VEGFR2 phosphorylation and cell proliferation. Furthermore, WMJ-S-001 inhibited cell cycle progression and induced cell apoptosis in HUVECs. These results are associated with p53 activation and the modulation of p21 and survivin. Taken together, WMJ-S-001 was shown to modulate vascular endothelial cell remodeling through inhibiting VEGFR2 signaling and induction of apoptosis. These results also support the role of WMJ-S-001 as a potential drug candidate and warrant the clinical development in the treatment of cancer.

Keywords: Angiogenesis, Endothelial cells, VEGF.

Antioxidative and cytoprotective effects of proanthocyanidins in mitomycin C – treated cells

N. Pavlović[1], J. Katanic[2], K. Stankov[3], B. Stanimirov[1], V. Kojić[4], G. Bogdanović[4]
[1]*Department of Pharmacology, Toxicology and Clinical Pharmacology,* [2]*Department of Biochemistry, Faculty of Medicine, University of Novi Sad,* [3]*Clinical Center of Vojvodina, Faculty of Medicine, University of Novi Sad,* [4]*Department of Experimental Oncology, Oncology Institute of Vojvodina, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia*

Mitomycin C (MMC) is a quinone based bioreductive drug that alkylates DNA upon metabolic reductive activation. Since it contains a quinone moiety, MMC can suffer a one-electron reduction by a range of cellular oxidoreductases, resulting in the production of semiquinone anion radical. In the presence of oxygen, the semiquinone enters into a redox cycle, which leads to formation of different ROS that interact with cellular macromolecules. This mechanism is generally accepted as not being critical for antitumor activity, but crucial for toxic effects. Therefore, the application of cytoprotective antioxidants may increase the efficacy of MMC, together with decrease of its toxicity towards normal cells. The aim of our study was to compare the viability and antioxidant status of the cells exposed to MMC alone or in combination with proanthocyanidins (PACs) and standard cytoprotective agent - N-acetyl cysteine (NAC).

PACs were extracted from grape seeds by ethylacetate and 10% water, and they represent the mixture of monomers, dimers and small oligomers of catechin and epicatechin. We carried out our experiments in two cell lines – human erythroleukemia (K562) and Chinese hamster ovary (CHO) cells. Cell viability was determined by MTT assay and parameters of oxidant status - activity of antioxidant enzymes superoxide dismutase (SOD), glutathione reductase (GR) and glutathione-S-transferase (GST) were tested by spectrophotometric kinetic methods.

MMC exerted concentration-dependent cytotoxic activity towards both cell lines. Pretreatment with PACs resulted in more pronounced cytoprotection of malignant K562 cells than normal CHO cells. Growth inhibition of CHO cells treated with MMC in combination with PACs showed a biphasic dose response, suggesting the importance of selection of appropriate dose of PACs for desirable cytoprotective effects. PACs and NAC exerted the antioxidative activity and comparative analysis of activities of antioxidant enzymes SOD, GR and GST in malignant and normal cell lines showed diverse modulation of oxidant status of cells when treated with MMC, alone or in combination with PACs and NAC.

© 2014 The Authors. FEBS Journal © 2014 FEBS

PACs and NAC exert cytoprotective effects in MMC-treated both malignant and normal cell line. Our results indicate the complexity of biological response on PAC-induced effects and further investigation is needed to get more detailed insight into mechanisms of antioxidant defense mediated by PACs.

TUE-020
Identification of KLF17 as a novel epithelial to mesenchymal transition inducer via direct activation of TWIST1 in endometrioid endometrial cancer

P. Dong
Gynecology, Hokkaido University, Sapporo, Japan

Krüppel-like factor 17 (KLF17), a member of the KLF transcription factor family, is an inhibitor of the epithelial-mesenchymal transition (EMT) and tumor growth. However, the expression, cellular function and mechanism of KLF17 in endometrioid endometrial cancer (EEC; a dominant type of endometrial cancer) remains elusive. Here, we report that among the KLF family members, KLF17 was consistently upregulated in EEC cell lines compared with immortalized endometrial epithelial cells. Overexpression of KLF17 in EEC cell lines induced EMT and promoted cell invasion and drug resistance. In contrast, KLF17 suppression reversed EMT, diminished cell invasion and restored drug sensitivity. We determined whether KLF17 could affect the expression of known EMT/CSC-related genes in EC cells by qRT-PCRs. Overexpression of KLF17 in EC cells dramatically increased endogenous mRNA levels of the EMT inducers TWIST1 and BMI-1, and moderately and significantly increased expression of ZEB1, Snail and Slug. On the other hand, levels of the epithelial markers E-cadherin and CK-18 were significantly reduced compared with control cells. Moreover, the mRNA levels of CSC markers (NANOG, SOX2 and CD133), and chemoresistance-related genes (MDR-1 and MRP-1) were also highly elevated in KLF17 vector-transfected cells. Furthermore, luciferase assays, site-directed mutagenesis and transcription factor DNA binding analysis demonstrated that KLF17 transactivates TWIST1 expression by directly binding to the TWIST1 promoter. Knockdown of TWIST1 prevented KLF17-induced EMT. Consistent with these results, both KLF17 and TWIST1 levels were found to be elevated in EECs compared to normal tissues. KLF17 expression positively correlated with tumor grade, but inversely correlated with estrogen and progesterone receptor expression. Thus, KLF17 may have an oncogenic role during EEC progression via initiating EMT through the regulation of TWIST1.

Keywords: drug resistance, EMT, tumor invasion.

TUE-021
Antitumor effects of antibodies to the E2 extracellular loop of connexin-43 in high-grade gliomas

V. Baklaushev, G. Yusubalieva, V. Chekhonin
Medicinal Nanobiotechnology, Pirogov National Research Medical University, Moscow, Russian Federation

We studied the effect of intravenous administration of monoclonal antibodies to the second extracellular loop of connexin 43 (MAbE2Cx43) on the dynamics of glioma growth and survival of experimental animals. Volumometric analysis of glioma via MRI data showed that weekly intravenous administration of MAbE2Cx43 in a dose of 5 mg/kg significantly reduced glioma volume starting from day 21 after tumor implantation. By day 29, the mean volume of glioma in the experimental group (therapy with specific antibodies) was 2-fold lower than in controls. Deceleration of glioma growth in rats receiving MAbE2Cx43 was accompanied by a significant prolongation of rat lifespan (according to Kaplan-Meier test) and even led to complete recovery without delayed relapses in 19.23% animals. The mechanism of tumor-suppressing effects of antibodies can be related to inhibition of specific functions of connexin 43 in glioma cells in the peritumoral zone.

Keywords: connexin 43, glioma, monoclonal antibodies.

The progesterone receptor (PR) is known to participate in breast cancer cell proliferation and to cross-talk with the estrogen receptor alpha (ERα), yet its role in resistance to anti-estrogen therapy is not fully understood. In the present work, we studied the effects on cell proliferation of the synthetic progestin medroxyprogesterone acetate (MPA) alone or in combination with tamoxifen (Tam), a commonly used selective ER modulator. We found that Tam inhibited MPA-induced activation of the c-Src/MAPK signaling pathway in BT474-HR cells sensitive to Tam antiproliferative effects. Importantly, Western blot and chromatin immunoprecipitation assays revealed that Tam abrogated MPA-induced c-Src/MAPK phosphorylation and recruitment of the transcription factor AP-1 to the cyclin D1 promoter, thus preventing MPA from inducing cyclin D1 transcription and cell proliferation. Interestingly, Tam failed to block these MPA effects in BT474 cells resistant to Tam. Furthermore, we found that PR-dependent activation of c-Src/MAPK leads to the down-regulation of miR-16, a microRNA we have previously shown to act as a tumor suppressor in progestin-induced breast cancer growth (1). This decrease in miR-16 levels correlated with increased expression of cyclin D1. Co-treatment of BT474-HR cells with MPA+Tam restored miR-16 levels, contributing to the repression of cyclin D1 expression. Such inhibitory effects of Tam were not evidenced in Tam-resistant BT474 cells. Taken together these results suggest that, in Tam-resistant tumor cells, Tam fails to abrogate the PR-dependent c-Src/MAPK signaling that triggers the assembly of transcription factor complexes that control cyclin D1 expression directly at its promoter and indirectly through the modulation of microRNA levels, leading to unrestrained cell proliferation. Our results provide insight into a complex synergic mechanism underlying Tam resistance that involves the PR, a receptor not classically studied in the context of ER-targeted therapies, shown here to be a possible therapeutic target to prevent its unrestrained functions in Tam-resistant cells.

Apoptotic and synergic effect of resveratrol and EGCG combination in DU-145 prostate cancer cells

C. Çörek[1,2], E. Mutlu Altundağ[1,2], S. Batirel[1,2], N. Kartal Ozer[1,2], Y. Taga[1,2], S. Koçtürk[2,1]
[1]Department of Biochemistry, Dokuz Eylul University, Izmir, Turkey, [2]Genetic and Metabolic Diseases Research and Investigation Center GEMHAM, Marmara University, Istanbul

Prostate cancer is the second most common cause of male cancer deaths in Unites States. Multiple phytochemicals have been identified as potential anti-cancer agents from commonly consumed fruits and vegetables. Trans-Resveratrol (3,4′,5-trihiydroxy-trans-stilbene, Res) is the most widely studied stilbene found in small fruits. EGCG (epigallocatechinegallate) is the most abundant catechin in tea and is a potent antioxidant that may have therapeutic applications in the treatment of many disorders. Resveratrol and EGCG has been considered as a good anti-carcinogenic agent because of its low toxicity and capability of modulating multiple molecular pathways that play important roles in cell cycle progression, apoptosis. The aims of our study were to find apoptotic effect of Res and EGCG separately in DU-145 prostate cancer cell line and then to find a combination index of the agents, that has synergistic effect, and to evaluate and compare apoptotic effects of the groups. For these purposes cell viability and IC50 values were determined via WST-1 viability assay for 24 hour time point for groups of Res, EGCG and combination (Res+EGCG) in DU-145 prostate cell line. Apoptotic cell ratio was analyzed by Annexin V / Propidium iodide (PI) double staining and cell cyle (PI) was analyzed by flow cytometer. According to WST-1 results; Res and EGCG treatments were increased cell death as a dose dependent manner and IC50 value has been calculated as 141 μM and 58 μM for Res and EGCG respectively. Afterwards synergistic ratio and combination index value (CI) were calculated by using CalcuSyn© software. The combination effect of Res and EGCG was analyzed byChou-Talalay method. Strong synergism CI value (CI<1) was found as 0.519. Apoptosis ratio were found as 2.35%, 1.94% and 14.04% for Res, EGCG and combination groups by flow cytometry According to cell cycle analysis; apoptotic cell ratios were found 12.9% in Res group, 11.8% in EGCG group and 27.6% in combination group. All the results revealed that combination of Res and EGCG has more powerful effect in induction of apoptosis and combination leads to higher amount of apoptotic cell death than Res or EGCG treated groups. On account of Res and EGCG have low toxicity; we suggest that this nutritional combination might be a promising approach for adjuvant therapy of prostate cancer treatment.

Keywords: combination index, EGCG, resveratrol.

Apoptotic effects of methotrexate- loaded nanoparticles in prostate cancer LNCaP cell line

B. Ozel[1], N. Selvi Gunel[1], S. Kipcak[1], Ç. Aktan[1], C. Akgun[2], Ç. Biray Avci[1], S. Hamarat Sanlıer[2]
[1]Medical Biology, Ege University, School of Medicine, [2]Department of Biochemistry, Ege University, Faculty of Science, Izmir, Turkey

Prostate cancer is the most prevalent type of cancer in men that causes second rank among of death reason. Androgen hormones and androgen receptor genes, although showing a heterogeneous structure, it is known to have an important role in the prostate cancer development. Lately, Metothrexate (MTX) is used as an anticancer drug for treatment of particularly in prostate cancer. But MTX has short plasma half-life. In recent years, to enhance the efficacy and delivery of MTX and increase the half-life, nanoparticles were used as a drug delivery carrier. Nanoparticles have advantages as targeting in the tumor sites. Here, we used chitosan (CS) nanoparticles to contribute delivery of MTX.

In this study we aimed to evaluate cytotoxic and apoptotic effect of Methotrexate on LNCaP cell line with treated nanoparticles in vitro on the other hand the changes of mRNA expression in related genes with Androgene Receptor (AR) and PSA.

For this study, chitosan nanoparticles were synthesized by us. The cytotoxic effects of MTX-loaded chitosan on LNCaP cells were determined in time and dose dependent manner by using WST-1 analysis. Three groups were formed to treat Methotrexate and Chitosan alone and, in combination to evaluate the cytotoxic effects of MTX-loaded chitosan on LNCaP cells for 24, 48 and 72nd hours. Annexin V (Biovision) was used to determine the apoptotic effects of MTX-loaded chitosan and evaluated by flow cytometry. Quantitative assessment of Androgen Receptor and PSA mRNAs were analyzed by Real Time qRT-PCR.

In vitro cytotoxic studies confirmed that MTX loaded-chitosan was found to have higher cytotoxic effect on LNCaP cells compared with free MTX. IC_{50} value of (MTX)- loaded Chitosan was found 2.635 μmol/ml at 72nd hours. The obtained results indicated that MTX-loaded chitosan induced apoptosis in time-dependent manner as compared to untreated control groups. Especially 33.6% of apoptosis rate was seen at 72nd hours. qRT-PCR assays revealed that mRNA expression levels of AR and PSA genes were downregulated by the effect of MTX loaded-chitosan when compared to untreated control group in LNCaP cells.

In conclusion, these results showed that MTX-loaded chitosan could be more effective than free MTX for prostate cancer treatment. Using nanoparticles as a drug delivery promises more influential therapy to prevent progression of hormone – dependent prostate cancer.

Arf6 promotes proliferation and activates mTOR-downstream signaling of glioblastoma cells

A. Zhuravskaya, E. Tchevkina
Oncogene Regulation Department, Institute of Carcinogenesis, Moscow, Russian Federation

Small G-protein Arf6 (ADP-ribosylation factor 6) belongs to the ARF subfamily of small GTPases from the Ras superfamily. Arf6 is localized at plasma membrane and various subcellular membranes, regulating vesicular transport, actin cytoskeletal rearrangement, cytokinesis, autophagy and plasma membrane reorganization. Due to the participation in these processes Arf6 significantly contributes to the tumor progression. In particular, it participates in endocytosis and recycling of receptors (such as integrin β1 and E-cadherin) affecting cell adhesion, migration and invasion of cancer cells. Arf6 is also involved in several intracellular signaling pathways mostly through the activation of PLD and PIP5K. At the same time almost nothing is known about the role of this protein in cell proliferation.

Previously published data from our lab obtained on the model of transformed hamster fibroblasts revealed the promitogenic activity of Arf6 mediated through the activation of mTOR signaling.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Here we studied the impact of Arf6 on cell proliferation as well as on MAPK-Erk1/2 and PLD-mTOR signaling using human glioblastoma cell lines LN229 and U87. For this purpose we obtained stable derivative cell lines with overexpression of wild type Arf6 (Arf6WT), constitutively active mutant Arf6 (Q67L) and with depletion of endogenous Arf6 with two non-overlapping shRNAs.

We found increase of proliferation in LN229 Arf6 (Q67L) and U87 Arf6WT cells whereas both lines with depleted Arf6 demonstrated dramatical lowering of proliferation rate. Analysis of ERK1/2 phosphorylation status revealed decrease of phospho-ERK1/2 as a result of Arf6WT as well as Arf6 (Q67L) overexpression in both LN229 and U87 lines under the condition of EGF stimulation. Correspondingly, depletion of endogenous Arf6 led to upregulation of ERK1/2. Next, we studied the influence of Arf6 on mTOR-depedent signaling using the level of phospho-p70S6K1 as a marker of mTOR activation. We showed that overexpression of Arf6 promotes phosphorylation of p70S6K1 while Arf6 knockdown diminished the level of phospho-p70S6K1.Analysis of extracellular matrix proteinases activity demonstrated decrease of MMP2 activity in LN229 shArf6.

Presented data give the first evidence of Arf6 involvement in regulation of mTOR-downstream signaling in human tumour cells. Additionally, we elucidated the influence of Arf6 on ERK1/2 phosphorylation. We also demonstrated promitogenic effect of this small GTPase on glioma cells.

BAG-1 forms a complex to allow the phosphorylation of Bad from Ser136 to modulate cell survival in MCF-7 cells

T. Kizilboga, S. Demir, G. Dinler Doganay
Molecular Biology – Genetics and Biotechnology, Istanbul Technical University, Istanbul, Turkey

BAG-1 (Bcl-2 associated athanogene) is a multifunctional protein that interacts with diverse array of cellular targets and modulates a wide range of cellular processes, including proliferation, cell survival, transcription, apoptosis, metastasis and motility. In human cells BAG-1 exists as three major isoforms (BAG-1S, BAG-1M and BAG-1L) derived by alternative translation initiation from a single mRNA, which allows interactions with various molecular targets such as Hsp70/Hsc70 molecular chaperones, components of the ubiquitylation/proteasome machinery, Bcl-2, Raf-1 kinase, nuclear hormone receptors and DNA. Overexpression of BAG-1 isoforms was shown to affect the regulation of proliferation, cell survival and cancer progression. There are a number of possible mechanisms by which BAG-1 may mediate its pro-survival effects. In addition, drug resistance is observed with overexpression of BAG-1, causing cell rescue from apoptosis. Our work aims to investigate how altered BAG-1 expression levels affect cell survival pathways in MCF-7 and MCF-10A cell lines. We first cloned BAG-1L gene to a cloning vector, later transfected MCF-7 and MCF-10A cells with the designed vector and obtained stable cell lines overexpressing our clone. We used BAG-1 siRNA to silence *BAG-1* gene to understand BAG-1 role in cell survival. Western blot analysis and immunocytochemistry were applied to demonstrate relative expression levels of BAG-1, its interacting partners and certain proteins which are important for survival pathway. We performed XTT cell viability assay and growth assay for BAG-1 overexpressed cells to check BAG-1's role in cell survival, and we did Apoptotic Cell Death Elisa assay to show apoptosis rate in *Bag-1* gene silenced cells. We also performed co-immunoprecipitation to show co-existence of certain proteins with BAG-1 protein as a complex. This study revealed that once BAG-1 forms a complex with C-Raf/B-Raf/Hsp70/Akt/Bcl-2, phosphorylation of Bad from Ser136 occurs and this causes Bad's sequestration by 14-3-3, modulating cell survival. We believe that once the localization and molecular mechanism of BAG-1 and its isoforms are found, and the interacting partners are determined, the role of each BAG-1 isoform in cell survival can be understood better.

a wide variety of cellular processes, including proliferation, survival, transcription, apoptosis, tumorigenesis and motility. To perform these functions Bag-1 has three functionally distinct isoforms (Bag-1L (p50), Bag-1M (p46), Bag-1S (p36) and a minor isoform (p29)) that can interact with a diverse array of molecular targets such as Hsp70/Hsc70 molecular chaperones, components of the ubiquitylation/proteasome machinery, Bcl-2 apoptosis regulator, Raf-1 kinase, nuclear hormone receptors and DNA. In human malignant cells, at certain times Bag-1 interacts with distinctive set of proteins and it can form different complexes. These distinctive set of interaction partners has not been fully demonstrated yet, and thus, the role of Bag-1 in carcinogenesis is not clear. In this study, we aim to identify interaction partners of Bag-1 in MCF-7 breast cancer cells under Bag-1 altered states. We used an affinity purification method to obtain various Bag-1 complexes. After purification of Bag-1 TAP-tagged complexes from MCF-7 cells, duplicates of purified fractions were resolved by 2D gel electrophoresis. We identified several already known interacting partners of Bag-1 as well as undetermined ones. All identified interaction partners of Bag-1 will be discussed in a context of their relation to Bag-1 complex functional mechanisms in MCF-7 cells.

BAG3 regulates nucleocytoplasmic shuttling of HSF1 under heat stress

S.-A. Kim[1], Y.-H. Jin[1], S.-G. Ahn[2]

[1]Biochemistry, Dongguk University, College of Oriental Medicine, Gyeongju-si, [2]Pathology, School of Dentistry, Chosun University, Gwangju, Korea

BAG3 is the only member of BAG family to be induced by stressful stimuli, such as heat shock and heavy metal. Growing evidences have shown that BAG3 regulates cellular adaptive responses against stressful stimuli by regulating apoptosis, development, cytoskeleton organization and autophagy. Considering the association of BAG3 in cellular stress, we hypothesized that BAG3 may associated with HSF1 regulation in response to cellular stress. Therefore, in this study, we investigated the molecular action mechanism of BAG3 under the stress condition. We firstly demonstrated that under the heat stressed condition, BAG3 rapidly co-translocalized to the nucleus with HSF1. Overexpression of BAG3 down-regulated the level of nuclear HSF1 and subsequently decreased the Hsp70 promoter activity by exporting HSF1 to the cytoplasm. In accordance with these results, down-regulation of BAG3 reduced HSF1 export from nuclear to the cytoplasm. $Hsf^{-/-}$ mouse embryonic fibroblast (MEF) cells shows that the translocation of BAG3 upon heat stress is not affected by the absence of HSF1, suggesting BAG3 may act as a HSF1 regulator by nucleocytoplasmic shuttling upon heat stress.

Baicalein loaded iron oxide nanoparticles for targeted drug delivery in human breast cancer (MCF-7) cells

M. Paulpandi[1], K. Kavithaa[2], S. Sumathi[2]

[1]Zoology, Bharathiar University, [2]Biotechnology, Avinashilingam University, Coimbatore, India

Iron oxide has been widely used in biomedical research because of its biocompatibility and magnetic properties. In the present investigation elucidates the effect of baicalein loaded Fe_3O_4 nanoparticles were determine to establish whether these nanoparticles are effectively deliver the anticancer agent baicalein into the targeted MCF-7 cells. Fe_3O_4 nanoparticles were synthesized by co-precipitation method. A result of X-Ray diffraction indicates highly crystalline and no phase change confirms the purity of spherical Fe_3O_4. The interaction between the magnetite and surfactant was illustrated by FTIR, which confirms that the magnetic nanoparticles were coated by PEG, PVP and baicalein via the amino groups of hexamine. The synthesized Fe_3O_4 nanoparticles are highly monodispersed crystalline nature in a size range of 20 nm confirmed by Transmission electron microscope. The proliferation of MCF-7 cells and their cytotoxicity were evaluated by MTT assay and Western blotting analyses were performed to examine gene transcription and protein expression, respectively. The results showed that iron oxide nanoparticles dramatically enhanced baicalein-induced cytotoxicity and apoptosis in MCF-7 cells. The transcription of caspase-3 and bax gene in the group treated with baicalein and Fe_3O_4 was higher than that in the baicalein and Nanoparticles alone group. Our findings suggest a potential clinical application of a combination of baicalein loaded Fe_3O_4 in Breast cancer therapy.

Biochemical and structural insights into activation of Arf GTPases by endocytic GEFs

M. Zeghouf, K. Aizel, V. Biou, D. Padovani, J. Cherfils

Laboraroire d'Enzymologie et Biochimie Structurales, CNRS, Gif-sur-Yvette, France

Small GTPases of the Arf family control many aspects of membrane traffic and organelle structure. They are activated by guanine nucleotide exchange factors (ArfGEFs), which are modular proteins composed of a catalytic Sec7 domain that stimulates GDP/GTP exchange, and other domains that carry out regulatory and membrane targeting functions [1]. Three subfamilies - cytohesins, Brags and EFA6 - are involved in endocytic events in human and promote invasive phenotypes in cancer. They all associate the catalytic Sec7 domain with a downstream PH domain but, except for cytohesins, little is known on how these ArfGEFs couple their subcellular targeting to their activation of Arf GTPases. We present our recent results on BRAG and EFA6 GEFs. Biochemical reconstitution of Arf activation on membranes combined with structural analysis revealed that membranes dramatically affect ArfGEF efficiency [2]. These studies also uncovered an unexpected diversity of regulatory regimes, which suggest that ArfGEFs estab-

TUE-032
Biochemical indicators of cardio- and hepatotoxic actions of novel 4-thiazolidone derivatives and doxorubicin in complexes with PEG-containing polymeric carrier

L. I. Kobylinska[1], D. Y. Havrylyuk[2], A. Ryabtseva[3], N. Mitina[3], O. Zaichenko[3], R. Lesyk[2], B. S. Zimenkovsky[2], R. S. Stoika[1]
[1]Biochemistry, Institute of Cell Biology, NAS of Ukraine, Lviv, Ukraine, [2]Farmaceutical Chemistry, Lviv National Medical University, [3]Lviv National Polytechnic University

The aim of this study was to measure the activity of enzymes which reflects cardiotoxic and hepatotoxic actions in rats of novel synthetic 4-thiazolidone derivatives – 3882, 3288 and 3833 which demonstrated antineoplastic effect in vitro towards 60 lines of human tumor cells tested in frames of the program of screening new anticancer drugs at the National Cancer Institute (Bethesda, USA). Such actions of these compounds were compared with the effect of well known anticancer drug doxorubicin alone and after their conjugation with new polyethylenglycol-containing polymeric comb-like carrier that was synthesized at 2. Among the biochemical indicators of cardio- and hepatotoxic action of anticancer agents, the activity of the following enzymes in rat blood serum showed to be the most informative: aspartate aminotransferase, alanine aminotransferase, α-amylase, gamma-glutamyltransferase, alkaline phosphatase, creatine kinase, lactate dehydrogenase and concentration of total protein, urea, creatinine, calcium and iron ions. 10 times injection of doxorubicin in dose of 5.5 mg/kg of weight caused rats' death, while 3882, 3288 and 3833 substances did not possess such action. Application of the doxorubicin as a complex with polymeric carrier prolonged survival time of animals to 20 days. Thus, the injection of anticancer agents in a complex with polymeric carrier provides a significant decrease in their cardiotoxicity and hepatotoxicity that was confirmed by the corresponding changes in the activity of above mentioned marker enzymes.

Conclusions: Lower antineoplastic activity of synthetic 4-thiazolidone derivatives – 3882, 3288 and 3833 (comparing with such activity of doxorubicin) correlates with lower cardio- and hepathotoxicity of these derivatives in the experimental rats. Complexes of 3882, 3288, 3833 compounds and doxorubicin with polyethylenglycol-containing polymeric comb-like carrier considerably decreases the cardiotoxicity and hepatotoxicity of these anticancer agents in the laboratory rats. That was confirmed by the results of measuring enzymatic activity of aspartate aminotransferase, alanine aminotransferase, α-amylase, gamma-glutamyltransferase, alkaline phosphatase, creatine kinase, lactate dehydrogenase and concentration of total protein, urea, creatinine, calcium and iron ions in blood serum of treated rats.

Biochemical profiling of cervical pre-cancer and early cancer biopsies as a way of modelling carcinogenesis

O. V. Kurmyshkina[1], P. I. Kovchur[2], T. Volkova[1]
[1]Department of Molecular Biology, Biological and Organic Chemistry, [2]Department of Radial Diagnostics and Radial Therapy, Oncology, Urology and Phthisiology, Petrozavodsk State University, Petrozavodsk, Russian Federation

Cervical intraepithelial neoplasias grade 1–3 (CIN1-3) and cervical cancer (CeCa) constitute virtually an ideal *in vivo* model of virus-induced carcinogenesis: successive stages of cervical neoplasia development are clinically easily detectable, including the very early pre-cancer lesions, and morphologically are relatively well-described. Molecular profiling of biopsy material of CeCa-associated lesions is regarded as one of the most objective approaches to investigation of disruptions in signaling pathways during malignant transformation and natural cancer development. The fact that Human Papilloma Virus (HPV)-induced neoplastic lesions at certain steps of development are potentially reversible raises a fundamental question of defining a "point-of-no-return" – what molecular defects predetermine irreversibility and drive progression of pre-cancer to invasive forms. HPV-mediated mechanisms of dysregulation of the key cellular programs are being thoroughly studied *in vitro*. At the same time, it is assumed that *in vivo* CIN transitions are linked to a sequential redistribution of intracellular signaling pathways and a specific order of overall molecular phenotype changes. Regulation of apoptotic signaling pathways and its disruption are considered to play a significant part in CeCa development. Resistance to apoptosis provides a mechanism of evasion of antiviral/antitumor immune surveillance, and acquiring apoptosis-resistant phenotype at neoplastic locus may be a hallmark or a precondition of irreversible step of CeCa progression, however, experimental data on alteration of activity of components of programmed cell death pathways in pathological tissue samples at different stages of CeCa development are still insufficient. In the present work we examined biopsies of normal and pathological epithelium taken from 94 women with various stages of cervical squamous cell carcinoma progression including severe dysplasia, cancer *in situ* and microinvasive carcinoma. Changes of proteolytic activity and expression level of caspases (-3,-6,-8,-9) – essential mediators of apoptosis – were assessed in these samples with concurrent evaluation of apoptotic activity in circulating lymphocytes. We revealed a) stage-specific pattern of caspase activity, b) caspase-specific redistribution of activity, c) heterogeneity of pre-invasive stage at the level of caspases, d) general inhibition of caspase activity in carcinoma specimens suggesting accumulation of defects in apoptotic program and formation of resistant pheno-

TUE-034
Biochemical signalling of Ste20 kinase family proteins with Ras family adaptor proteins

A. Bitra, R. Anand
Chemistry, Indian Institute of Technology Bombay, Mumbai, India

Mammalian Sterile 20 kinase (MST) proteins belong to a large family of serine / threonine kinases that are involved in regulation of apoptosis and signalling of mitogen activated protein kinase pathway. Proteins belongs to this family possess an N-terminal catalytic kinase domain followed by a C-terminal SARAH (for Salvador/RASSF/Hippo) domain. The C-terminal region of MST kinase regulates its kinase activity via formation of complex with partner adaptor proteins RASSF (for Ras association domain family). These RASSF proteins are scaffolding proteins, which contain both Ras association (RA) domain via which they interact with Ras-GTP, followed immediately by the SARAH domain. The GTP-Ras activated form regulates downstream signal transduction pathways and misregulation of the GTP-Ras pool causes uncontrolled cell proliferation and leads to cancer. The GTP-Ras-RASSF-MST complex formation route is therefore proposed as a safeguard mechanism by which the misregulated activated Ras complex is sequestered and apoptosis is triggered.

Here in the present work we study the binding profile of RASSF adaptors (RASSF1, RASSF5) with various isoforms of MST (MST1 and MST2) by surface plasmon resonance technique (SPR) using GST kinetics. Our studies reveal that the SARAH domain of both MST1 and MST2 binds to RASSF1 and RASSF5 SARAH region with KD values ranging from 0.3 to 2.1 μM. The addition of RA domain to RASSF1 SARAH faintly decreases its binding affinity towards MST1-SARAH, but enormously decreases the binding to MST2-SARAH domain, where the KD value increases by tenfold (15 μM). On the other hand, RA domain containing RASSF5 has the opposite effect and it prefers MST2 (KD value of 1.2 nM) as oppose to MST1. Therefore, we conclude that while the SARAH domain of these adaptors binds indiscriminately to both MST1 and MST2, the RA domain regulates the interaction between these two proteins at the cellular level.

Furthermore, we performed radioactive kinase assays towards the two substrates of MST1, (Fork box protein O) FoxO and Histone H2B in presence of these adaptor proteins. The results show that the RASSF family of proteins have differential effect towards both the substrates. It negatively regulates the kinase activity of MST1 towards its cytosolic substrate FoxO. However, the effect is opposite for H2B that resides in the nucleus, with its activity being positively regulated. Additionally we observed that MST1 is able to phosphorylate the RASSF family proteins of proteins within their Ras binding domain. We propose that this phoshorylation may have implications towards stabilization of the GTP-Ras-RASSF-MST that controls apoptotic signalling.

TUE-035
Bisphenol A binds to ras proteins and competes with guanine nucleotide exchange: implications for GTPase-selective antagonists

R. Stoll
Faculty of Chemistry and Biochemistry, Ruhr University of Bochum, Bochum, Germany

We show for the first time that bisphenol A has the capacity to interact directly with K-Ras and that Rheb weakly binds to bisphenol A and 4,4′-biphenol derivatives. We have characterized these interactions at atomic resolution suggesting that these compounds sterically interfere with the Sos-mediated nucleotide exchange in H- and K-Ras. We show that 4,4′-biphenol selectively inhibits Rheb signaling and induces cell death suggesting that this compound might be a novel candidate for treatment of tuberous sclerosis-mediated tumor growth. Our results propose a new mode of action for bisphenol A that advocates a reduced exposure to this compound in our environment. Our data may lay the foundation for the future design of GTPase-selective antagonists with higher affinity to benefit of the treatment of cancer because K-Ras inhibition is regarded to be a promising strategy with a potential therapeutic window for targeting Sos in Ras-driven tumours.

C/EBPβ expression is an independent predictor of overall survival in breast cancer patients by MHCII/CD4-dependent mechanism of metastasis formation

E. Kurzejamska[1], J. Johansson[2], K. Jirström[3], J. Fuxe[2], P. Religa[1]
[1]*Medicine,* [2]*Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm,* [3]*Clinical Sciences, Lund University, Lund, Sweden*

CCAAT-enhancer binding protein beta (C/EBPβ) is a transcription factor playing a critical role in mammary gland development and breast cancer progression. Loss of C/EBPβ increases metastatic dissemination of mouse mammary tumor cells. However, the mechanism, by which C/EBPβ expression affects metastasis formation remains unknown.

To determine the relationship between C/EBPβ and survival of breast cancer patients, C/EBPβ expression was evaluated in 137 cases of human breast cancer and correlated with overall survival by Kaplan-Meier analysis. Additionally, the mouse 4T1 tumor model was used to elucidate the mechanism linking C/EBPβ with metastasis formation.

Here we report that decreased C/EBPβ expression is associated with shorter overall survival of breast cancer patients. We also demonstrate that in the murine 4T1 model loss of C/EBPb affects tumor growth and morphology, as well as promotes metastatic spread to the lungs. Immunohistochemical analyses showed that C/EBPβ inhibition leads to increased expression of MHCII, followed by accumulation of CD45, CD3 and CD4-positive lymphocytes in the tumors. Inflammation involvement in C/EBPβ-mediated metastasis formation was confirmed by DNA microarray and experiments on CD4+ cell-deprived nude mice. Additionally, anti-CD3 and anti-CD4 treatments of C/EBPβ-silenced tumor-bearing mice resulted in reverting C/EBPβ effect on tumor growth.

Altogether, C/EBPβ is a predictor of overall survival in breast cancer patients, and affects tumor growth, morphology and lung metastasis formation in murine 4T1 model. The mechanism of

© 2014 The Authors. FEBS Journal © 2014 FEBS

metastasis formation, we have discovered, involves immunological response depending on C/EBPβ-mediated activation of MHCII and accumulation of CD4 + lymphocytes in the tumor.
Keywords: breast cancer, inflammation, metastasis.

TUE-037
CD157/BST1 regulates cell adhesion and spreading through the interaction with the heparin-binding domains of fibronectin

S. Augeri[1], S. Morone[1], M. Cuccioloni[2], M. Mozzicafreddo[2], M. Angeletti[2], N. Lo Buono[1], A. Giacomino[1], E. Ortolan[1], A. Funaro[1]
[1]*Department of Medical Sciences, University of Torino, Torino,* [2]*School of Biosciences and Veterinary Medicine, University of Camerino, Camerino, Italy*

CD157/BST1 is a glycosylphosphatidylinisotol-anchored glycoprotein belonging to the ADP-rybosil cyclase gene family expressed in myeloid, endothelial, mesothelial cells and in epithelial ovarian cancer cells. In leukocytes, CD157 controls migration, adhesion to extracellular matrix (ECM) proteins and diapedesis. To accomplish these functions, CD157 establishes structural and functional partnership with specific members of the integrin family. In ovarian cancer, CD157 enhances cell motility and invasion of surrounding tissues, ultimately increasing tumor aggressiveness by promoting mesenchymal differentiation. To exert these receptor activities, CD157 interacts with an unknown ligand. The crucial role of CD157 in cell adhesion and migration, and its functional partnership with integrins led us to hypothesize that the non-substrate ligand of CD157 might be found in the ECM. Using solid phase and Surface Plasmon Resonance binding assays, we demonstrated that CD157 binds to fibronectin, fibrinogen, laminin and collagen I but not to vitronectin or to the polysaccharide components of ECM (such as heparin and hyaluronan). We identified the CD157 binding site within the N-terminal and C-terminal heparin-binding domains of fibronectin (HBD1 and HBD2). The CD157-HBD binding is mediated by the protein core while the glycosidic chains contribute to stabilize the interaction. Molecular docking analysis performed to predict the geometry of the interaction between CD157 and HBD1 or HBD2 of fibronectin suggested that a high number of residues (outside the catalytic domain in CD157) are involved. The CD157-ECM interaction demonstrated using purified proteins was confirmed in non-tumorigenic mesothelial Met-5A cells. Indeed, i) membrane CD157 expressed by Met-5A cells binds fibronectin and its HBDs, and ii) anti-CD157 antibodies significantly reduce cell adhesion to selected ECM proteins. Moreover, knockdown of CD157 expression in Met-5A cells reduced cell spreading and remarkably decreased the fibronectin-mediated phosphorylation of FAK, SRC and Akt tyrosine kinases. These morphological and functional changes resulted in impaired cell adhesion. It is reasonable to envision that the broad interaction of CD157 with several ECM proteins may be responsible for many of the biological effects exerted by CD157 in different physiological (e.g., leukocyte trafficking) and pathological contexts (e.g, inflammatory diseases and cancer), where the composition of the ECM dictates the final outcome.

TUE-038
CDK8 promotes DNA replication but is dispensable for cell proliferation in vivo

S. Prieto[1], A. Camasses[1], E. Hodimont[1], F. Gerbe[2], P. Jay[2], D. Fisher[1]
[1]*IGMM-UMR5535,* [2]*Institut de Génomique Fonctionelle, CNRS, Montpellier, France*

CDK8 is the most highly conserved metazoan CDK, as is its cognate cyclin, cyclin C (97% identity between Xenopus and Human). CDK8, which is essential for mouse pre-implantation development and is implicated in colorectal cancer. CDK8 is mainly thought to regulate transcription, where it functions in a sub-module of the Mediator complex. Here, we find that CDK8 is expressed in early stages of Xenopus embryogenesis when transcription is silent, it is recruited to chromatin and promotes, but is not essential for, DNA replication. To evaluate its role in cell proliferation and differentiation in somatic tissues *in vivo,* we have generated a conditional CDK8 knockout in the mouse intestinal epithelium. Induction of CDK8 knockout by tamoxifen feeding is efficient, but this does not affect intestinal morphology, cell proliferation or differentiation. Furthermore, CDK8 conditional knockout MEFs continue to proliferate and show no defects in cell cycle. Taken together we conclude that CDK8 is a multifunctional chromatin protein kinase that promotes a replication competent state, but it is not essential for cell division. The absence of a striking phenotype of loss of CDK8 in these experiments suggests functional redundancy. We have found that CDK19, a kinase conserved among vertebrates, highly related to CDK8 but which has no known function, is coexpressed with CDK8 in the intestinal epithelium and its levels increase upon CDK8 removal. We are undertaking TALEN-mediated knockout of CDK19 in wild-type and CDK8 knockout backgrounds to evaluate this potential synthetic lethality and compare the functions of these two highly related kinases.

TUE-039
CEACAM19, the latest member of the CEACAM family of cancer-related cell adhesion molecules, represents a novel biomarker for lung cancer prognosis

K. Mavridis[1], F. Gueugnon[2], A. Petit-Courty[2], Y. Courty[2], A. Scorilas[1]
[1]*Department of Biochemistry and Molecular Biology, University of Athens, Athens, Greece,* [2]*Centre d'Etude des Pathologies Respiratoires, INSERM UMR1100, Tours cedex, France*

The carcinoembryonic antigen-related cell adhesion molecule (*CEACAM*) subfamily is robustly related to lung tumor progression. *CEACAM19*, the newest member of this tumor-related family (identified by Scorilas *et al*, 2003), which also hosts the well-established cancer biomarker CEA, has been recently associated with aggressive breast cancer. In this study we comprehensively profile the expression of *CEACAM19* in non-small cell lung cancer (NSCLC), a disease with unmet clinical needs regarding prognostic indicators.

Tissue samples from a total of 121 NSCLC patients were analyzed in the present study. RNA was isolated and purified on a QIAsymphony SP workstation, including DNAse I digestion. The amount and quality of total RNA were assessed by a NanoDrop 2000c spectrophotometer and an Agilent 2100 bioanalyzer, respectively. Samples with an RNA integrity number (RIN)> 6 were considered for subsequent analysis. Following reverse transcription and after rigorous quality control, *CEACAM19* mRNA

© 2014 The Authors. FEBS Journal © 2014 FEBS

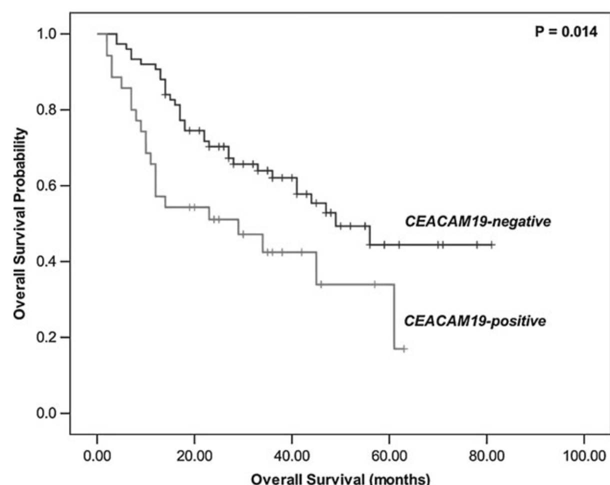

Fig. 1. Kaplan–Meier OS curves for CEACAM19 expression in NSCLC patients.

levels were quantified *via* an optimized qPCR method. SPSS Statistics software was used for biostatistical analyses.

CEACAM19 mRNA levels were slightly elevated in poorly differentiated compared to well differentiated tumors. Most importantly, patients stratified as *CEACAM19*-postitive exhibited inferior overall survival (OS) intervals compared to *CEACAM19*-negative ones (P = 0.014). The 5-year OS probability was 17.0% for *CEACAM19*-postitive patients and 49.3% for *CEACAM19*-negative ones. Univariate logistic regression corroborated the prognostic relevance of *CEACAM19* expression (HR = 1.96, 95% CI = 1.13–3.40, P = 0.016). Multivariate logistic regression analysis, adjusted for important clinicopathological parameters, including TNM stage, histotype, chemotherapy/radiotherapy administration, identified *CEACAM19* mRNA levels as a novel independent biomarker of poor prognosis for NSCLC patients (HR = 2.07, 95% CI = 1.11– 3.87, P = 0.023). The prognostic significance of *CEACAM19* was retained in the subgroup of low-risk patients (P = 0.041).

Improved risk stratification procedures are urgently needed for NSCLC. *CEACAM19* can aid in the decision-making for the management of NSCLC patients, since it has been identified by our study a biomarker that can provide important prognostic information which is independent of the currently used conventional indicators such as the TNM staging system.

Cell lineage-dependent activation of NF-κB by human T-cell leukemia virus type 1 Tax1

T. Mizukoshi, **M. Nakamura**
Human Gene Sciences Center, Tokyo Medical and Dental University, Tokyo, Japan

Human T cell leukemia virus type1 (HTLV-1) is shown to be a causative agent of adult T cell leukemia (ATL), an aggressive malignancy. HTLV-1 produces the transcriptional modulator Tax1. Tax1 exerts its activities through activation of cellular transcription factors, among which NF-kB is demonstrated to be important for T cell transformation. There are two sub-pathways in the NF-kB system, canonical and non-canonical pathways. Though both pathways have been demonstrated to be activated by Tax1, we found in this study that Tax differentially activated NF-kB sub-pathways in a cell lineage-dependent manner.

Luciferase reporter plasmids with an immunoglobulin gene NF-kB binding element (IgkB site) and an OX40 ligand gene NF-kB binding element (gpkB site) were used to monitor NF-kB activities in response to Tax1. Expression of Tax1 activated IgkB and gpkB sites in hematopoietic cell lines such as Jurkat (human T cell leukemia cell line) and K562 (human erythroleukemia cell line). Interestingly the gpkB site was not activated by Tax1 in non-hematopoietic cell lines such as MG63 (human osteosarcoma cell line) and REF56 (rat embryonic fibroblast cell line) unlike the IgkB site, and exogenous introduction of RelA activated the gpkB site in non-hematopoietic cell lines. We found that hematopoietic cell lines activated the canonical and non-canonical pathways of NF-kB in response to Tax1, while only the non-canonical pathway was activated by Tax1 in non-hematopoietic cell lines. As TNF alpha stimulated NF-kB in non-hematopoietic cell lines, the canonical pathway system was functional in those cells. Tax1 however did not induce translocation of RelA to the nucleus, resulting in failure in RelA binding to the gpkB site. Chromatin immunoprecipitation assays revealed that non-canonical pathway components RelB and p52 bound the IgkB site, but the gpkB site showed p50 binding only in those cells. These results indicate that the gpkB site may be preferentially activated by the canonical pathway at least in hematopoietic cell lines tested. Importantly HTLV-1 Tax1 activates NF-kB in more restricted conditions than we thought, presumably accounting for pathogenesis of HTLV-1 infection.

Keywords: HTLV-1, leukemia, NF-kB.

Use of nanotechnology in cancer treatment offers exciting opportunities, including the possibility of destroying tumors with minimal damage to healthy tissue by novel targeted drug delivery systems. Chitosan coated superparamagnetic iron oxide nanoparticles (CS MNPs) were *in-situ* synthesized by ionic crosslinking

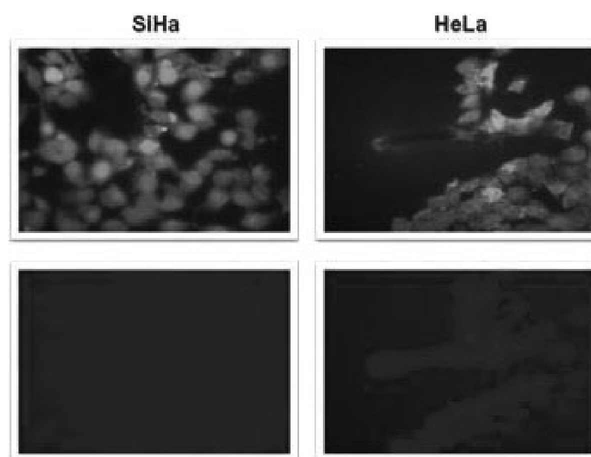

Fig. 1. Cellular internalization and localization of FITC labeled Bortezomib loaded CS MNPs on SiHa and HeLa cell lines.

© 2014 The Authors. FEBS Journal © 2014 FEBS

method as nanocarrier systems (Unsoy *et al*., 2012) and loaded with the anti-cancer drug Bortezomib (Velcade®).

Bortezomib loaded CS MNPs were labeled with FITC and visualized inside the cells by fluorescence microscopy on DAPI stained cervical cancer cell lines (SiHa and HeLa). Internalization of drug loaded nanoparticles can be clearly identified by the intensity of fluorescent color in the cells. FITC bounded Bortezomib loaded CS MNPs are successfully taken up by the cells and localized both in the cytoplasm and the nuclei of the cells (Figure 1).

Therefore, synthesized and Bortezomib loaded CS MNPs can be effectively enter to the cells and show its antiproliferative activity by inhibiting proteasome on cervical cancer cell lines.

Keywords: Bortezomib, cervical cancer, nanoparticle, FITC.

Cellular internalization of polyhydroxybutyrate coated magnetic nanoparticles in SKBR-3 cell lines

S. Yalcin[1], P. Mutlu[2], G. Unsoy[3], M. Parsian[3], **N. Taghavi Pourianazar**[3], U. Gunduz[3]

[1]Food Engineering, Ahi Evran University, Kırsehir, [2]Central Laboratory Molecular Biology and Biotechnology R&D, [3]Biotechnology, METU, Ankara, Turkey

Biodegradable polymeric nanomaterials gained importance in biomedical and bioengineering research such as drug delivery and targeting, tissue engineering, cancer diagnosis and therapy. Polyhydroxybutyrate (PHB) is a nontoxic, biodegradable, biocompatible polymer, and hence is suitable for medical applications. In this study, PHB coated magnetic nanoparticles (PHB-MNPs), were produced for targeted delivery of anticancer agent in cancer chemotherapy. PHB-MNPs were synthesized by in situ precipitation method. PHB-MNPs were incubated with breast cancer (SKBR-3) cell lines in 6 well plates and their photographs were taken with time intervals during the incubation to determine their cellular internalization. The cellular internalization of PHB-MNPs was demonstrated by fluorescence microscopy. It was revealed that these nanoparticles are efficiently internalized by the SKBR cells, and seem to be suitable for biomedical applications.

Characterization of 7-dehydrocholesterol cytotoxic effects on melanoma cell lines

F. Albano[1], M. Gelzo[1], G. Granato[2], A. Arcucci[2], A. Dello Russo[1], E. De Vendittis[1], M. R. Ruocco[1], G. Corso[3]

[1]Department of Molecular Medicine and Medical Biotecnologies, [2]Department of Public Health, University Federico II, Napoli, [3]Department of Clinical and Sperimental Medicine, University of Foggia, Foggia, Italy

Ultraviolet radiation is the main cause of skin cancers, and melanoma is the most serious form of tumor. Surgery is standard treatment for localized melanoma, while there is no therapy for advanced-stage of melanoma and its metastasis, because of the high resistance of melanoma cells to various anticancer therapies. Human skin is an important metabolic organ in which occurs photo-induced synthesis of vitamin D3 from 7-dehydrocholesterol (7-DHC). The 7-DHC, the precursor of cholesterol biosynthesis, is highly reactive and easily modifiable to produce 7-DHC-derived compounds. The intracellular levels of 7-DHC or its derivatives can have deleterious effects on cellular functionality and viability.

In this study we evaluated the effect on melanoma cell lines by 7-DHC as such and for this aim much care to minimize 7-DHC modifications was used. We found that from 12 to 72 hours of treatment 82-86% of 7-DHC entered into the cells, and the levels of 7-DHC-derivative compounds were not significant. At same time ROS production was significantly increased already after 2 hours and, after 24 hours, a reduction of cell viability was observed. Indeed, after 48-72 hours a pro-apoptotic effect of 7-DHC was detected. The cytotoxic effect of 7-DHC was associated with an increase in Bax levels, decrease in Bcl-2/Bax ratio, reduction of mitochondrial membrane potential, increase in apoptosis-inducing factor levels, unchanged caspase-3 activity, and absence of cleavage of PARP- 1. These findings could explain the mechanism through which 7-DHC exerts its cytotoxic effects. This is the first report in which the biological effects found in melanoma cells are mainly attributable to 7-DHC as such.

CHI3L1 and TSC22 proteins modulate oncogenic properties of cell under oxidative agents

T. Bukreieva[1], O. Balynska[1], V. M. Kavsan[1], T. A. Kulahava[2], G. Semenkova[2]
[1]*Biosynthesis of Nucleic Acids, Institute of Molecular Biology and Genetics of NAS of Ukraine, Kyiv, Ukraine,* [2]*Department of Biophysics, Belarusian State University, Minsk, Belarus*

Aims: Reactive oxygen species (ROS) are universal messengers of the extra- and intracellular signaling. However, the significance of ROS and antioxidant systems in tumor initiation and progression is complicated and contradictory. The inefficiency of the last years' anticancer therapies that used antioxidants to prevent progression of tumour could be attributed to the higher resistance of malignantly transformed cells to reactive oxygen species. The main goal of the present work was to reveal whether constitutive expression of *CHI3L1* oncogene leads to the resistance of malignantly transformed cells to oxidative damage. We performed this investigation to investigate the vulnerability of CHI3L1 oncogene-transformed cells to the reactive oxygen (ROS); to characterize proliferation of 293 cells stably producing CHI3L1 (293_*CHI3L1* cells) and to identify the involvement of key signaling pathways in reply to oxidants. As we showed earlier *CHI3L1* oncogene is overexpressed whereas *TSC22* oncosuppresor is down-regulated in most malignant human brain tumours – glioblastomas. So we aimed on the endorsement of TSC22 tumor suppressor protein capability to retard the proliferation and restore sensitivity of CHI3L1-producing cells to oxidants.
Methods and Results: 293 cells stably producing CHI3L1 (293_*CHI3L1*) cells had 2.7-fold higher rate constant for H_2O_2 scavenging than 293_pcDNA3.1 cells as it was shown by measurement of DCF fluorescence. Their resistance to ROS, at least partially, could be supported by the elevated level of reduced glutathione in 293_*CHI3L1* cells measured by MCB fluorescence. Ectopic expression of *TSC22* oncosuppresor diminished CHI3L1 production, retarded proliferation, and decreased the viability of CHI3L1-producing cells under oxidative stress according to the results of MTT test.
Conclusion: Our data indicate that altered expressions of *CHI3L1* oncogene and tumor suppressor gene *TSC22* contribute to ROS resistance suggesting a novel oncogene-dependent mechanism of chemoresistance in glioma.

TUE-046
Chitosan-coated magnetic nanoparticles as vehicles for the delivery of the antitumor drug gemcitabine

M. Parsian[1], G. Unsoy[1], P. Mutlu[2], S. Yalcin[3], **N. Taghavi PourianAzar**[1], U. Gunduz[1]
[1]*Biotechnology, Middle East Technical University,* [2]*Molecular Biology and Biotechnology R&D center, Central Lab. Middle East Technical University, Ankara,* [3]*Food Engineering, Ahi Evran University, Kırşehir, Turkey*

Breast cancer is a heterogeneous group of diseases that cause cells in the body to change and grow out of control.

Gemcitabine, a nucleoside analogue, has indicated experimental and clinical antitumor activity in a variety of human tumors, including breast cancer. After integration of the gemcitabine to the DNA, DNA polymerase could add just one nucleotide to the DNA chain, which leads to termination of chain elongation, and forces the cell to apoptosis. However, gemcitabine has a short biological half-life and the plasma level of this drug can quickly drop below the effective threshold level.

Tumor-specific delivery of anticancer drugs will maximize the efficacy of the drug and minimize side effects and reduce systemic toxicity. Among the various drug delivery systems, chitosan has gained considerable attention due to its biocompatibility, biodegradability, and non-toxicity.Chitosan is a natural linear polysaccharide and it has playing an important role in controlling the release of drugs and proteins.

The aim of this investigation is to produce nanoparticles with magnetic core which actively target the drug-loaded nanoparticles to the tumor site by an externally applied magnetic field.

In this study, chitosan-coated magnetic nanoparticles (CsMNPs) were in situ synthesized in the presence of chitosan and sodium tripolyphosphate (TPP) molecules.

Gemcitabine loading in CsMNPs was performed by mixing various concentrations of the drug with CsMNP in order to optimize the loading efficiency.The loading capacity were determined by measuring the amount of remaining drug in the supernatant by UV spectrophotometer.

The drug release and stability of gemcitabine-loaded CsMNPs were determined at pH 4.2, pH 5.2, and pH 7.2.

The cytotoxicity of gemcitabine-loaded nanoparticles and drug alone was assessed by XTT assay on breast cancer cell lines.

Successful binding of gemcitabine to CsMNPs were indicated using XPS, zeta-potential, and FTIR. UV spectophotometric measurements also validated the gemcitabine loading in these particles.

The drug unbounded chitosan nanoparticles were found to have minimum cytotoxicity in the XTT analysis. *In vitro* cytotoxicity of gemcitabine-CsMNP complex is increased significantly when bounding CsMNP comparedto unloaded with the free drug toxicity.

In the present study, a new nanocarrier systemfor gemcitabine delivery was reported which showed enhanced antitumor activity on breast cancer cell lines. Binding to the chitosan nanoparticles significantly enhanced the bioavailability and increased the accumulation of the gemcitabine in cancer cells, and caused apoptosis.
Keywords: Antitumor therapy, Chitosan, Gemcitabine.

TUE-047
Circulating growth factors in patients with colorectal cancer and colorectal polyps

Y. Dincer[1], E. E. Koc[1], Y. E. Ersoy[2], A. Karataş[3], U. Akyuz[4], Y. Erzin[5]
[1]*Medical Biochemistry, Cerrahpasa Medical Faculty, Istanbul University,* [2]*General Surgery, Faculty of Medicine, Bezmialem Vakif University,* [3]*General Surgery, Cerrahpasa Medical Faculty, Istanbul University,* [4]*Gastroenterology, Medical Faculty, Yedi Tepe University,* [5]*Gastroenterology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey*

Early detection of cancer is a cruical factor for a successful therapy and increased survival rate in patients with colorectal cancer. Predictive potentials of circulating insulin like growth factor 1 (IGF-1), transforming growth factor beta 1 (TGFβ1), epidermal growth factor (EGF) and extracellular domain of c-erb-B2 (co-receptor of EGF), were examined in the present study.

Patients with colorectal cancer (n = 31), patients with colorectal polyps (n = 23) and age-matched healty volunteers (n = 30) were included by the study. Blood samples were obtained just before the operation and in the 30th postoperative day. Serum levels of IGF-1, TGFβ1, EGF and c-erb-B2 were measured by ELISA kits.

© 2014 The Authors. FEBS Journal © 2014 FEBS

The preoperative IGF-1 level in the colorectal cancer group was significantly higher than those in the colorectal polyp group and control group, whereas preoperative EGF level was significantly higher in the both colorectal cancer and colorectal polyp groups compared to control group. The preoperative TGFβ1 level in the colorectal cancer group was found to be higher than those in the colorectal polyp group and control group. In the colorectal cancer group, postoperative IGF-I level was found to be decreased but this decrease was not statistically significant. The postoperative EGF level was significantly lower in the colorectal cancer group compared to its preoperative level but it was still higher than those in the control group. In the colorectal polyp group, the postoperative EGF level significantly decreased to level of the control group. In the both colorectal cancer and colorectal polyp groups, postoperative TGF β1 levels were signicantly lower compared to their corresponding preoperative levels. There was no significant difference between study groups for preoperative and postoperative c-erb B-2 levels. A significant correlation was found between tumor size and TGF- β1 in the colorectal cancer group ($r = 0.378$ $p < 0.05$).

It was concluded that serum TGF β1 level might be a good predictor for diagnose and prognostic follow up in colorectal cancer patients. High levels of EGF and TGF β1 in patients with colorectal polyps may provide awareness to take precautions.

CK1δ affects cancer cell adaptation to hypoxia by controlling HIF-1α/ARNT complex formation

M. Kourti[1], I. Mylonis[1], N. N. Giakoumakis[2], G. Ikonomou[1], U. Landegren[3], Z. Lygerou[2], G. Simos[1]
[1]*Faculty of Medicine, University of Thessaly, Larissa,* [2]*School of Medicine, University of Patras, Patras, Greece,* [3]*Department of Immunology, Uppsala University, Uppsala, Sweden*

Hypoxia-inducible factor 1 (HIF-1) is a key regulator of cellular response to hypoxic conditions. It acts as a heterodimer, consisting of two subunits, HIF-1α and HIF-1β (or ARNT). ARNT is constantly expressed while HIF-1α stability is regulated by oxygen levels. HIF-1α is additionally controlled by oxygen-independent mechanisms including activating modification of its C-terminal part by ERK and inactivating phosphorylation of S247 at its N-terminal part by CK1δ. Previous biochemical and *in vitro* experiments have suggested that phosphorylation by CK1δ reduces the affinity of HIF-1α for ARNT[1]. To corroborate these results in living and/or intact cells, we have applied fluorescence recovery after photobleaching (FRAP) and *in situ* proximity ligation assay (*in situ* PLA) methods to study the formation of the HIF-1α/ARNT complex under conditions that stimulate or inhibit CK1δ-dependent modification of HIF-1α. Analysis of cells expressing GFP-tagged forms of HIF-1α with FRAP shows that a Ser247 to Ala247 mutation or treatment with a CK1-specific inhibitor slows down the nuclear migration of HIF-1α indicating increased formation of a DNA-binding complex. This hypothesis is further supported by *in situ* PLA in cells grown under hypoxia (1% O_2), which shows that complex formation by endogenous untagged HIF-1α and ARNT is impaired when CK1δ is overexpressed but enhanced when CK1δ is inhibited. These findings have biological significance as CK1δ inhibition enhances cancer cell proliferation under hypoxic conditions. Taken together, our data suggest that CK1δ impairs cancer cell adaptation to hypoxia by inhibiting HIF-1α/ARNT heterodimerization.

Co-financed by the European Union (ESF) and Greek national funds (Education and Lifelong Learning-NSRF, Program THALIS).

TUE-049
Clinical Relevance of TMPRSS2-ERG fusion marker for prostate cancer

S. Jain[1], A. Bansal[1], A. Kumar[2], S. Saxena[1]
[1]*National Institute of Pathology ICMR), New Delhi, India,* [2]*Department of Urology, Safdurjung Hospital, New Delhi, India*

Objectives: The novel *TMPRSS2: ERG* gene fusion is a common somatic event in prostate cancer that in some studies is linked with a more aggressive disease phenotype. Thus, this study aims to determine whether clinical variables are associated with the presence of *TMPRSS2: ERG*-fusion gene transcript in Indian patients of prostate cancer.
Methods: We evaluated the clinical variables with presence and absence of *TMPRSS2: ERG* gene fusion in prostate cancer and BPH association of clinical patients. Patients referred for prostate biopsy because of abnormal DRE or/and elevated sPSA were enrolled for this prospective clinical study. TMPRSS2: ERG mRNA copies in samples were quantified using a Taqman chemistry by real time PCR assay in prostate biopsy samples ($N = 42$). The T2:ERG assay detects the gene fusion mRNA isoform TMPRSS2 exon1 to ERG exon4.
Results: Histopathology report has confirmed 25 cases as prostate cancer adenocarcinoma (PCa) and 17 patients as benign prostate hyperplasia (BPH). Out of 25 PCa cases, 16 (64%) were T2: ERG fusion positive. All 17 BPH controls were fusion negative. The T2: ERG fusion transcript was exclusively specific for prostate cancer as no case of BPH was detected having T2: ERG fusion, showing 100% specificity. The positive predictive value of fusion marker for prostate cancer is thus 100% and the negative predictive value is 65.3%. The T2: ERG fusion marker is significantly associated with clinical variables like no. of positive cores in prostate biopsy, Gleason score, serum PSA, perineural invasion, perivascular invasion and peri prostatic fat involvement.
Conclusions: Prostate cancer is a heterogeneous disease that may be defined by molecular subtypes such as the *TMPRSS2: ERG* fusion. In the present prospective study, the T2:ERG quantitative assay demonstrated high specificity for predicting biopsy outcome; sensitivity was similar to the prevalence of T2:ERG gene fusions in prostate tumors. These data suggest that further improvement in diagnostic accuracy could be achieved using a nomogram that combines T2:ERG with other markers and risk factors for prostate cancer.

Cellular responses to oxygen play an important role in many aspects of physiologic homeostasis. Central to these responses is the hypoxia-inducible factor (HIF) transcriptional control system. Although HIF-1 is usually considered as the principal mediator of hypoxic adaptation, several tissues and different cell types

© 2014 The Authors. FEBS Journal © 2014 FEBS

express both HIF-1 and HIF-2 isoforms under hypoxia or when treated with hypoxia mimetic chemicals such as cobalt. However, the similarities or differences between HIF-1 and HIF-2, in terms of their tissue- and inducer-specific activation and function, are not adequately characterized. To address this issue, we investigated the effects of true hypoxia and hypoxia mimetics on HIF-1 and HIF-2 induction and specific gene transcriptional activity in hepatic (Huh7 and HepG2) and non-hepatic (HEp2 and Saos-2) cancer cell lines.

Both hypoxia and cobalt caused rapid induction of both HIF-1α and HIF-2α proteins in all cell lines tested. In liver cancer cells, hypoxia induced erythropoietin (EPO) expression and secretion in a HIF-2-dependent way. Surprisingly, however, EPO expression was not induced when cells were treated with cobalt. In agreement, both HIF-1- and HIF-2-dependent promoters (of PGK and SOD2 genes, respectively) were activated by hypoxia while cobalt activated the HIF-1-dependent PGK promoter, but not the HIF-2-dependent SOD2 promoter. Interestingly, the negative effect of cobalt on HIF-2 activity was not observed in non-hepatic cancer cells. Unlike cobalt, other hypoxia mimetics, such as DFO and DMOG, stimulated both types of promoters. Furthermore, cobalt impaired the hypoxic stimulation of HIF-2, but not HIF-1, activity without affecting the HIF-2α nuclear accumulation. This specific effect of cobalt on HIF-2 activation was accompanied by reduced interaction of HIF-2α with upstream stimulatory factor 2 (USF2), a HIF-2-specific co-activator.

These data show that despite similar induction of HIF-1α and HIF-2α protein expression, HIF-1 and HIF-2 specific gene activating functions respond differently to different stimuli. Also, this study suggests that the operation of oxygen-independent and gene- or tissue-specific regulatory mechanisms involve additional transcription factors or co-activators.

Co-exposure of human kidney cells to two carcinogenic mycotoxins (Ochratoxin A and Fumonisin B1): molecular mechanisms

A. Pfohl-Leszkowicz[1], K. Hadjeba-Medjdoub[1], M. Peraica[2], R. Manderville[3]
[1]Bioprocédés et Systèmes Microbiens, Laboratoire Génie chimique UMR CNRS 5503, Auzeville-Tolosane, France, [2]Occupational Health, Institute Medical Research, Zagreb, Croatia, [3]Chemistry and toxicology, University of Guelph, Guelph, ON, Canada

Fumonisin B_1 (FB_1) and ochratoxin A (OTA) are mycotoxins classified as possible human carcinogens (IARC, 1993). They coexist in human food and have been shown to act synergistically in stimulating nephrotoxicity in pigs (Diaz et al, 2001; Pfohl-Leszkowicz & Manderville, 2007; 2012). In this study the combined impact of the toxins in cultured human kidney cells (HK2) was analysed. Parameters common to both FB_1 and OTA (cytotoxicity and activation of mitogen-activated protein kinase, MAPK), and features characteristic of the individual mycotoxins (DNA adduction by OTA and release of arachidonic acid (AA) by FB_1) were measured. Treatment of HK2 cells with the combined toxin mixture (FB_1 + OTA) was found to stimulate cell proliferation. Under analogous conditions FB_1 was weakly cytotoxic while OTA showed no impact on cell viability. The conditions for cell proliferation by (FB_1 + OTA) were then examined for DNA adduction, release of AA and activation of MAPK. OTA-mediated DNA adduction, as measured by ^{32}P-postlabeling, occurred at a quicker rate in the presence of FB_1, with maximum levels being detected following 2 h incubation; with OTA alone adducts were not observed until 7 h incubation. Release of AA by FB_1 was inhibited by OTA, although levels of AA, prostaglandins (PGs) and leukotrienes (LTs) were higher for the combined toxin mixture than for OTA alone. Western blot analysis for MAPK activation showed the mycotoxins to synergistically enhance MAPK activity. Our data suggests that stronger nephrotoxic damages to human kidney are likely from combined exposure of (FB_1 and OTA) versus the individual mycotoxins, as resistance to apoptosis and stimulation of cell proliferation are key events in the development of tumors

TUE-054
Combined regulation of carbonic anhydrase 9 (CA9) expression via hypoxia and cytokines in hepatocellular carcinoma cells

H. M. Said[1], C. Hagemann[2], H. Yildrim[3], M. Flentje[1], F. Kockar[4]
[1]Radiation Oncology, [2]Neurosurgery, Medical Faculty, University of Würzburg, Würzburg, Germany, [3]Biology, Faculty of Arts and Sciences, Balikesir University, Belikesir, [4]Biology, Faculty of Arts and Sciences, Balikesir University, Balikesir, Turkey

Our aim was to study the expression of carbonic anhydrase (CA) 9 in human hepatocellular carcinoma (HCC) cells. We studied CA9 protein, CA9 mRNA and hypoxia-inducible factor-1 alpha (HIF-1α) protein levels in Hep3B cells exposed in different parallel approaches. In one of these approaches, HCC cells were exposed to extreme in vitro hypoxia (24 h 0.1% O2) without or with interleukin (IL)-1, IL-6, tumor necrosis factor alpha (TNF-α) and transforming growth factor-beta (TGF-β) stimulation for the same hypoxic exposure time or exposed to normoxic oxygenation conditions without or with cytokine stimulation.The tumour cell line analysed showed a strong hypoxic CA9 mRNA expression pattern in response to prolonged severe hypoxia with cell-line specific patterns and a marked induction of CA9 protein in response to severe hypoxia. These results were paralleled by the results for HIF-1α protein under identical oxygenation conditions with a similar expression tendency to that displayed during the CA9 protein expression experimental series. Continuous stimulation with the cytokines, IL-1, IL-6, TNF-α and TGF-β, under normoxic conditions significantly increased the carbonic anhydrase 9 expression level at both the protein and mRNA level, almost doubling the CA9 mRNA and CA9 and HIF-1α protein expression levels found under hypoxia. The findings from these experiments indicated that hypoxia is a positive regulator of CA9 expression in HCC, and the four signal transduction pathways, IL-1,IL-6, TNF-α and TGF-β, positively influence CA9 expression under both normoxic and hypoxic conditions. Our findings may potentially be considered in the design of anti- cancer therapeutic approaches involving hypoxia-induced or cytokine stimulatory effects on expression. In addition, they provide evidence of the stimulatory role of the examined cytokine families resulting in an increase in CA9 expression under different oxygenation conditions in human cancer, especially HCC, and on the role of the CA9 gene as a positive disease regulator in human cancer.

Keywords: Cancer, Carbonic Anhydrase 9 (CA9), Hypoxia.

TUE-055
Comparative expression of KLF4 in normal and tumor laryngeal tissues

M. C. J. Fadous Khalife[1], R. C. Tannous[1], G. Aftimos[2], **E. D. Hadchity**[1]
[1]Biochemistry, Holy Spirit University of Kaslik- Kaslik, Kaslik, [2]INP, Baabda, Lebanon

The kruppel like factor KLF4, overexpressed in many cancers,is involved in carcinogenesis by acting as a tumor promoter or tumor suppressor depending on the cell type and context.Overexpression of this factor is often related to the progression and tumor agressiveness and metastatic potential.

In this study, we avaluated by immunohistochemistry the expression level of KLF4 in 15 larynx cancer biopsies from different stages compared to normal tissue.the SPSS statistical analysis revealed a significant difference in the expression of KLF4 between healthy tissue and tumor tissue.The existence of a significant difference in the mean expression of KLF4 between tumor stages (I,II,III,IV)was demonstrated.No correlation was observed between the expression of KLF4 and each studied epidemiological factor(age,alcohol, all of them were heavy smokers)

These preliminary results suggest that KLF4 may be considered as a possible biomarker of larynx cancer

Keywords: immunohistochemistry, KLF4, larynx cancer.

TUE-056
Comparative study of the sensitivity of chondrosarcoma to DNA damaging agents

N. Girard[1,2], E. Lhuissier[1,2], O. Cauvard[1,2], A. Batalla[3], C. Bazille[1,2,4], C. Baugé[1,2], K. Boumédiene[1,2]
[1]EA4652 MILPAT microenvironnement cellulaire et pathologie, UNICAEN, Caen, France, [2]Normandie Univ, Caen, France, [3]Service de radiophysique, CLCC Baclesse, Caen, France, [4]Service d'anatomie pathologique, CHU de Caen, France, Caen, France

Chondrosarcomas are rare tumors, potentially fatal. No effective treatment exists since chondrosarcomas are chemoresistant and radioresistant. Current treatment consists to tumor resection which may lead to amputation. The aim of this work is to study the resistance mechanisms of chondrosarcoma to different DNA damaging agents.

Different chondrosarcoma cells lines with different origin and grade were used. Their sensitivity to DNA damaging agents (X-ray irradiation or cisplatine treatment) was evaluated by carrying out survival curve obtained after cell counting or clonogenicity assay. Cell cycle was studied by flow cytometry after staining cells with propidium iodide. Apoptosis investigated by monitoring the Apo 2.7 release by flow cytometry (marks of early stages of apoptosis).

Cisplatin and irradiation induces different responses following the treatment. Some chondrosarcomas are more sensitive than others. DNA damage treatments lead to an increased sub-G1 fraction correlated to increased Apo 2.7 expression of the sensitive cell lines. These data confirm apoptotic death of cells to cisplatin and irradiation of the sensitive chondrosarcomas.

Our study shows that chondrosarcoma cell lines have different responses to DNA damaging agents. Chondrosarcomas cells lines sensitive to cisplatine aren't the same than these sensitive to irradiation. However, treatments induce apoptotic death of the sensitive chondrosarcomas cells lines. It is therefore essential to use multiple chondrosarcomas (cells lines or primary cultures) with different grade or origin in order to investigate the response of these tumors to conventional (radiotherapy, chemotherapy) or emerging treatment as hadrontherapy.

Keywords: chondrosarcoma, cisplatin, X-ray.

TUE-057

Comparison of two polymeric nanocarriers for targeted CpG-ODN delivery: chitosan- and poly (amidoamine) dendrimer-coated magnetic nanoparticles

N. Taghavi Pourianazar[1], M. Parsian[1], G. Unsoy[1], S. Yalcin[2], U. Gunduz[1]
[1]Biotechnology, Middle East Technical University, Ankara, [2]Food Engineering, Ahi Evran University, Kır ehir, Turkey

The field of gene delivery has experienced rapid growth due to its application in the treatment of various diseases such as cancer.

Unmethylated cytosine-phosphate-guanosine oligodeoxynucleotides(CpG-ODNs) have antitumor activity via interaction with Toll-like receptor 9.Successful transfer of CpG-ODNs to the tumor site is dependent on loading them in a suitable nanocarrier to protect CpG-ODN from serum nucleases and facilitating its bioavailability.

Poly(amidoamine) (PAMAM) dendrimers and chitosan have been proposed as biocompatible polymers for gene delivery. PAMAM is a dendrimer with surface amine groups which form stable complexes with ODNs.On the other hand, chitosan is a biodegradable,and biocompatible polymer with minimum toxicity.

Active magnetic targeting strategies applied on nanoparticles enhance the intracellular drug concentrations in cancer cells and avoid toxicity in normal cells (Fig. 1).

In this research, the aim is to synthesize chitosan- and G5PAMAM dendrimer-coated nanoparticles (CsMNP and DcMNP), to be used in targeted cancer therapy and to compare them in four aspects, CpG-ODN loading efficiency,complex stability, CpG-ODN release behavior,and cytotoxicity.To achieve this purpose, in situ synthesis of CsMNP was performed. For synthesizing G5DcMNP, magnetite was produced with coprecipitation method and coated with PAMAM dendrimer.

The CsMNPs and DcMNPs were mixed with CpG-ODN and their ability of binding was evaluated. Moreover, these nanoparticles were characterized and compared to each other in terms of cytotoxicity, particle size, and CpG-ODN release.

DcMNPs showed greater ability to form a complex with CpG-ODN and showed more suitable physicochemical properties as delivery system. The sufficient surface amine groups enable DcMNPs to interact with DNA through charge-based interactions.Lower loading efficiency of the chitosan may also depend on other factors,such as the chemical structure, nanoparticle size, and composition.

DcMNP is found to be more toxic compared to CsMNP, due to the amine groups on the PAMAM dendrimer surface, which can be reduced by surface modification.The availability, noncytotoxicity, ease of modification are the advantages of CsMNPs.For DcMNPs, the interest arises from their ease of synthesis with controlled size, and high transfection efficiencies.

In conclusion, these results suggest that DcMNPs seem to be a better candidate with higher loading of CpG-ODN which make it suitable for targeted gene delivery.Using DcMNPs as a suitable nanocarrier may lead the CpG-ODN a powerful agent for tumor therapy.

Keywords: Chitosan polymer, CpG-oligodeoxynucleotides, PAMAM dendrimer-coated magnetic nanoparticles.

TUE-058

Conjugation of gemcitabine to PAMAM dendrimer-coated magnetic nanoparticles for targeted delivery

M. Parsian[1], **N. Taghavi PourianAzar**[1], S. Yalcin[2], P. Mutlu[3], U. Gunduz[1]
[1]Biotechnology, Middle East Technical University, Ankara, [2]Food Engineering, Ahi Evran University, Kırşehir, [3]Molecular Biology and Biotechnology R&D Center, Central Lab., Middle East Technical University, Ankara, Turkey

Magnetic iron oxide nanoparticles (MNPs) as carriers for delivering chemotheraptic drugs to tumors have been described well.Efforts in implementing magnetic particles for medical applications are based on their lack of toxicity, biodegradability, biocompatibility, and absorption. In addition, controllable size and targeting ability to the desired site by an external magnetic field are the advantages of MNP.

A new model of MNPs coated with Polyamidoamine (PAMAM) dendrimer could overcome the side effects of chemotherapy. Modifiable surface functionality, monodispersity and nanosize of PAMAM make these dendrimers attractive candidate for drug delivery (Fig 1).However, biomedical applications of PAMAM dendrimers limited due to their toxicity associated with the terminal-NH2 groups and multiple cationic charges. Surface engineering by modifying the surface of dendrimers with various functional groups is a satisfactory strategy for producing less toxic PAMAM dendrimers.

Gemcitabine (2′, 2′-diflurodeoxycytidine) being an analogue of deoxycytidine, is an effective anticancer drug against several solid tumors, including breast cancers.

However, clinical benefits of gemcitabine are limited due to some aspects, such as short plasma half-life after intravenous administration resulting from rapid metabolism by cytidinedeaminase, which represents a major disadvantage of this anticancer compound. Gemcitabine hydrophilicity is another limitation of using this drug, since it can not cross the plasma membrane and not accumulate into the cancer cells. Additionally, when the drug is administrated alone, significant damage to non-cancerous tissues is caused due to the lack of target specificity. This results in

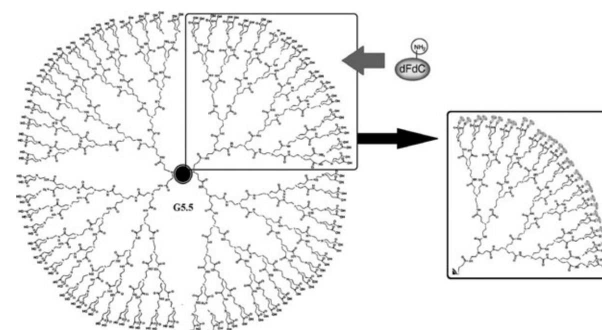

Fig. 1. Gemcitabine (dfdc)-loaded DcMNP.

© 2014 The Authors. FEBS Journal © 2014 FEBS

serious side effects such as hair loss, anemia, vomiting, and loss of appetite.

The aim of this study is to obtain an effective targeted delivery system for gemcitabine. MNPs were synthesized by co-precipitation method. The different generations of PAMAM dendrimer coated magnetic nanoparticles (DcMNPs) were conjugated with gemcitabine.

The results show that best loading efficiency was obtained for generation 5.5 of DcMNPs. The FTIR and XPS analysis supported the conjugation of drug and dendrimer. TEM images show nanoscale size of the nanoparticles before and after conjugation. The zeta-potential analysis indicated a decreased negativity of surface charge in drug bound dendrimer. Thus, it was shown that Gemcitabine was conjugated onto the surface of PAMAM coated magnetic nanoparticles successfully. Further in vitro studies have indicated higher cytotoxicity of drug bound nanoparticles on breast cancer cell line compared to free Gemcitabine.

Keywords: Gemcitabine, magnetic nanoparticles, PAMAM dendrimer.

TUE-059
CRBP1 could be a new tumor suppressor gene in cervical cancer

M. G. Mendoza[1,2], H. Serna[3], G. Gómez[4], M. Salcedo[2], M. A. Meraz[1]
[1]Biomedicina Molecular, Centro De Investigación Y De Estudios Avanzados Del Ipn, [2]Unidad De Investigación Médica De Enfermedades Oncológicas (UIMEO), Centro Médico Nacional IMSS-SXXI, México Distrito Federal, [3]Clinica de colposcopía, Hospital General de México, Mexico Distrito Federal, [4]Clinica de colposcopía, Hospital General de México, México Distrito Federal, Mexico

Aims: Cervical Cancer (CC) is one of the most important health problems in women. CC shows genetic changes at chromosome region 3q21. This region contains the Cellular Retinol Binding Protein 1 gene (*CRBP1*). This protein has been implicate as a key element in the development of other types of cancer. The main goal of the present work was to determine the molecular alterations of *CRBP1* and its relationship to CC.

Methods: To determine the molecular alterations of *CRBP1* gene in CC; twenty-six CC and twenty-six healthy cervix samples were evaluated for: 1) Copy number gain by real-time PCR analysis, 2) expression levels by an immunohistochemistry assay on tissue microarray, and 3) the methylation status of the *CRBP1* promoter region.

Results: The increase in *CRBP1* copy number was observe in 10 out of the 26 CC samples analyzed, while healthy cervices samples showed no changes in the copy number. In addition, there was a lack of expression of the *CRBP1* gene in an important number of the CC samples (17/26), and the *CRBP1* gene promoter was methylate in 15/26 of the CC samples. Interestingly, there was a significant association between the lack of expression of the *CRBP1* gene and its methylation status. Conclusions: The data indicates that, both activating and inactivating changes in the *CRBP1* gene could be significant events in the development and progression of CC, and a lack of expression of the CRBP1 protein could be related with to the development of CC. We believe that there is enough evidence to consider the *CRBP1* gene as a tumor suppressor gene for CC.

TUE-060
Cx43 expression in endothelial cells determines prostate cancer cell diapedesis†

M. Kosińska[1], K. Piwowarczyk[1], D. Ryszawy[1], Z. Madeja[1], M. Siedlar[2], J. Czyż[1]
[1]Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, [2]Department of Clinical Immunology, Polish-American Institute of Pediatrics, Jagiellonian University Medical College, Kraków, Poland

Metastatic niche is defined as the microenvironment of cancer cells at the place of their prospective extravasation. Efficiency of cancer cell diapedesis is determined by intercellular communication between cancer and endothelial cells, which among others depends on the function of connexin (Cx)43. Using an in vitro model of "metastatic niche" based on co-cultures of prostate cancer (DU-145) and endothelial cells (HUVEC), we assessed the role of Cx43-dependent mechanisms in the regulation of endothelial cell mobilization during prostate cancer cell diapedesis. The involvement of Cx43 in DU-145 cell diapedesis and endothelial mobilization was illustrated by the attenuation of transendothelial migration of DU-145 cells and of DU-145-induced HUVEC motility observed upon Cx43 silencing in cancer cells. Concomitantly with HUVEC mobilization, an induction of Cx43 expression was observed in endothelial continuum proximal to DU-145 cells. Apparently, it sensitized the endothelium to Cx43-mediated signals from cancer cells and facilitated their transendothelial migration. Cx43 silencing in DU-145 by siRNA, but not chemical block of GJIC, reduced this effect, which indicates the involvement of GJIC-independent Cx43 signaling in this process. Moreover, peripheral blood monocytes modulated DU-145-induced Cx43 expression changes in HUVEC in response to DU-145 cells, suggesting the involvement of paracrine loops within the metastatic niche. Because the effect of DU-145 and monocytes on Cx43 expression was partially eradicated by ERK1/2 inhibitor PD98059, ERK1/2-dependent pathway seems to be involved in the regulation of Cx43 expression in HUVEC. When extrapolated to in vivo situation, these data explain how Cx43 confers selective advantage on the cells during their invasion and confirm the significance of Cx43 for prostate cancer cell diapedesis.

TUE-061
CYLD downregulation in human hepatocellular carcinoma cells antagonizes p53-mediated apoptosis

P. Kotantaki, G. Mosialos
Department of Genetics, Developmental and Molecular Biology, School of Biology, Aristotle University of Thessaloniki, Thessaloniki, Greece

Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related death worldwide, since its highly chemoresistant nature renders chemotherapy with conventional cytotoxic agents ineffective. Shedding light to the molecular mechanisms and signaling pathways involved in hepatocarcinogenesis, will lead to novel successful therapies.

CYLD is a deubiquitinating enzyme that was originally identified as the tumor suppressor of familial cylindromatosis. CYLD's deficiency has been shown to promote the development of several types of malignancies including HCC. Hepatoma cell lines display significantly lower CYLD expression compared to primary human hepatocytes, while its inactivation in murine hepatocytes can lead to fibrosis, inflammation and cancer. Therefore, loss of

© 2014 The Authors. FEBS Journal © 2014 FEBS

CYLD expression may contribute to HCC development and progression, highlighting CYLD as a new target for therapeutic intervention. *Cyld*'s silencing involves DNA methylation, histone deacetylation and direct recruitment of Snail to *Cyld*'s promoter whereas, recruiment of NF-κB, SRF and BAF57 to *Cyld* promoter promote transcription. However, the mechanisms of *Cyld's* silencing in HCC remain still ellusive.

We previously identified the tumor suppressor p53 as a putative transcriptional regulator of *hCyld* and demonstrated that both its exogenous expression and treatment of wt-p53 HepG2 cells with drugs like doxorubicin and etoposide, upregulate CYLD's protein and mRNA levels. ChIP analysis reveals now that CYLD's upregulation upon etoposide treatment is not employed via direct binding of p53 to three putative p53-binding sites on *hCyld* promoter,. Since p53 is frequently mutated in HCC and p53-dependent apoptosis primarily determines the efficacy of chemotherapy, we investigated further the role of CYLD in p53-mediated apoptosis. We treated HepG2 cells with p53 Activator III, RITA, a specific acivator of p53 that disrupts the MDM2-p53 complex and recorded an early upregulation of CYLD followed by a gradual decline, where apoptosis was evident. Using viability assays and RNAi silencing we show that *Cyld's* knockdown in HepG2 cells antagonizes RITA induced decline in cell survival. Our experiments thus far reveal a possible implication of CYLD in p53-mediated cell death of HCC cells that may be of potential therapeutic importance.

Keywords: CYLD, Hepatocellular carcinoma, p53-mediated apoptosis.

TUE-062
CYLD down-regulation promotes oncogenic phenotypic characteristics in breast cancer cells

T. Orfanidou[1], K. Xanthopoulos[1], A. Pseftogkas[1], D. Dafou[1], E. G. Hatzivassiliou[2], G. Mosialos[1]
[1]Department of Genetics, Developmental and Molecular Biology, School of Biology, [2]Department of Biological Chemistry, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

The cylindromatosis gene (*Cyld*) is a tumor suppressor that is mutated in familial cylindromatosis, a rare autosomal dominant disorder associated with numerous benign skin adnexal tumors. However, a number of reports have indicated a role for CYLD in growth suppression of different types of cancer including breast cancer. CYLD is a deubiquitinating enzyme which hydrolyzes preferentially K63-linked and linear polyubiquitin chains. It is a known regulator of several signaling pathways including the NF-kB, MAPK and Wnt/β-catenin pathways. This study investigated the role of CYLD in the growth characteristics of breast cancer cell lines. We assessed mRNA and protein expression profiles of CYLD in two basal (MDA-MB-231, HCC1937) and two luminal (MCF7, T47D) breast cancer cell lines and in a non-tumorigenic mammary epithelial cell line (MCF10A). All breast cancer cells exhibited significantly reduced CYLD mRNA expression compared with MCF10A cells. Next, stable monoclonal cell lines with varying levels of CYLD downregulation were established by lentiviral mediated expression of short-hairpin RNAs (shA, shB), and one non-silencing RNA control (NS). CYLD downregulation resulted in statistical significant enhancement of oncogenic characteristics as measured by cell viability (MTT assay), cell migration (wound healing assay) and anchorage-independent growth in semi-solid substrate. At the molecular level CYLD downregulation enhanced JNK activation whereas additional signaling pathways are currently being analyzed in breast cancer cell lines with downregulated CYLD expression. Our findings indicate that downregulation of CYLD contributes to multiple phenotypic characteristics of breast cancer cells.

TUE-063
Cysteine protease cathepsin X regulates the function of gamma enolase in malignant progression

T. Vižin[1], A. Pišlar[1], I. J. Christensen[2,3], H. J. Nielsen[4,5], P. Meško Brguljan[6], J. Kos[1]
[1]Department of Pharmaceutical Biology, Faculty of Pharmacy, Ljubljana, Slovenia, [2]Biotech Research and Innovation Centre (BRIC), University of Copenhagen, [3]The Finsen Laboratory, Rigshospitalet, Copenhagen, [4]Department of Surgical Gastroenterology, Hvidovre Hospital, Hvidovre, [5]Institute of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, [6]University Clinic for Respiratory and Allergic Diseases Golnik, Golnik, Slovenia

Gamma enolase (neuron specific enolase) has been used as a tumor marker in neuroendocrine tumors, however, its role in cancer is not well understood. As a glycolytic enzyme it can be involved in increased aerobic glycolysis in cancer cells and thus their enhanced proliferation. On the other hand, it can act as a prosurvival factor, as demonstrated for neuronal cells, where gamma enolase can activate PI 3-K/Akt and MAPK/ERK signaling pathways. This effect is achieved through the active site at the C-terminal part of the molecule. Gamma enolase prosurvival activity is regulated by cysteine protease cathepsin X, which sequentially cleaves amino acids from the C-terminal end. In clinical practice, total gamma enolase, including the uncleaved (active) and the C-terminally cleaved (inactive) forms is evaluated in cancer samples. The levels of active uncleaved gamma enolase may provide additional information on patient's status.

To prove that, we performed a prospectively accrued multicenter observational cohort study on 264 patients with colorectal cancer. Blood samples were collected before preoperative large bowel endoscopy. Uncleaved gamma enolase was measured in sera by ELISA and the total gamma enolase by ECLIA (Elecsys NSE assay). Univariate survival analysis showed that the increased levels of total ($HR = 1.40$, $p = 0.0004$) and uncleaved gamma enolase ($HR = 1.11$, $p = 0.025$) were related to poor prognosis. In multivariate analysis however, only total gamma enolase levels had independent, significant ($p = 0.03$) value. Additionally, in stage IV patients we observed that total gamma enolase levels may predict response to palliative chemotherapy.

The levels of total and uncleaved gamma enolase were evaluated also in the CaCo2 cell line. The uncleaved form of gamma enolase was significantly upregulated, when the cells were cultured in serum-starvation medium. Its upregulation was even more evident in the presence of the cathepsin X specific inhibitor AMS-36 or in cells silenced for cathepsin X by siRNA.

Our results demonstrate that besides glycolytic activity of gamma enolase its prosurvival function is important for progression of malignant diseases. Cathepsin X, a protease impairing the prosurvival function, represents a possible tool for regulation of malignant processes.

Keywords: cancer signalling, cathepsin X, gamma enolase.

TUE-064
Cytotoxic effect and apoptosis induction by *Cerastes cerastes* and *Macrovipera mauritanica* venoms and evaluation of their antimicrobial profile

B. Makran[1], L. Fahmi[1], B. El-Amraoui[1], H. Ait Mouse[2], A. Zyad[2], M. Lkhider[3], N. Ghalim[4]
[1]Biotechnology, Biochemistry and Nutrition Laboratory, Faculty of Sciences El Jadida, Chouaib Doukkali University, El Jadida, [2]Laboratory of Biological Engineering, Faculty of Sciences and Technology, Béni-Mellal, [3]Department of Biology, Faculty of Science and Technology, Mohammedia, [4]Venoms and Toxins Laboratory, Pasteur Institute of Morocco, Casanblaca, Morocco

Viperidae venoms contain a variety of pharmacologically active substances which are recognized for their therapeutic properties. The present study aims to highlight the antibacterial and antitumoral activities of Moroccan viper Cerastes cerastes and Macrovipera mauritanica venoms and their purified fractions.

The antimicrobial potential of both venoms and their fractions was evaluated against strains of bacteria and yeast by the disk diffusion method. The results showed that both venoms and their toxic fractions have dose-dependent antibacterial activity against the majority of Gram positive and negative bacterial strains used, with the exception of Pseudomonas aeruginosa and yeasts tested which have been found to be resistant.

Venoms and fractions were evaluated for their cytotoxicity and their capacity to activate apoptosis in the cancer cell line P815. The results of the MTT assay have shown a differential cytotoxic effect between both venoms and their fractions. Both venoms appear to inhibit the proliferation and cell adhesion in a dose and time dependent 24, 48 and 72 h after incubation. Morphological changes were also observed along the post-treatment period compared with untreated control cells. The DNA fragmentation test and cells marking with Annexin V-Biotin were found positive for both venoms indicating the involvement of apoptosis in the inhibition of cell proliferation.

In conclusion, this work provides the first experimental evidence showing the antibacterial and antitumor potential of Moroccan viper venom in vitro. Further studies are needed to elucidate the molecular mechanism implicated in these activities.

Keywords: Antibacterien activity, antitumoral activity, viperidae venom.

TUE-065
Deciphering triple negative breast cancer driven pathways via multi-omic networks

K. Karagoz[1], R. Sinha[2], K. Y. Arga[1]
[1]Department of Bioengineering, Marmara University, Istanbul, Turkey, [2]Biochemistry and Molecular Biology, Penn State College of Medicine, Hershey, United States

Triple negative breast cancer (TNBC) constitutes approximately 15% of breast cancers that is characterized by lack of expression of both estrogen receptor (ER) and progesterone receptor (PR) together with absence of human epidermal growth factor 2 (HER2) over expression. TNBC has attracted more attention due to its aggressiveness such as large tumor size, high proliferation rate and metastasis. The absence of efficient molecular targets is still challenging in the treatment of TNBC patients. To understand the complexity of TNBC, comprehensive and integrative transcriptomics and proteomics analyses were performed including 4 publicly available gene expression datasets, which encompassed 201 non-TNBC tumors compared with 157 TNBC tumor samples. Differentially expressed genes (DEGs) were identified through statistical analysis. 23 down-regulated and 17 up-regulated DEGs (called core DEGs) were detected. The protein-protein interaction networks of associated core DEGs were constructed and down-regulated interaction network consisted of 672 edges between 615 nodes and up-regulated interaction network included 837 edges between 755 nodes. The highly connected proteins (hubs) on which different pathways converge were ascertained by applying the degree and betweenness criteria. The down-regulated GATA3, FOXA1, MYB and up-regulated ATF5, CEBPB, FOXC1, MYC, STAT5A, RELA transcriptional factors from the hub list were utilized to reveal a potential transcriptional control mechanism of TNBC which leads to TNBC driven molecular pathways such as JAK-STAT and TNF signaling pathways. These approaches not only provided novel candidate biomarkers of TNBC but also pointed out the TNBC driven pathways that can be used to design targeted therapies.

Keywords: Triple negative breast cancer, transcriptional regulatory network, protein-protein interaction network.

TUE-066
Dependency of translationally controlled tumor protein degradation on mammalian target of rapamycin complex 1/polo-like kinase-1 signaling in human lung cancer cells

Y. G. Park, J. E. Kim, M. H. Jeong, J. W. Yun, Y. B. Yu, J. Sohn
Department of Biochemistry and Molecular Biology, Korean Institute of Molecular Medicine and Nutrition, Korea University College of Medicine, Seoul, Korea

TCTP protein is highly expressed in human cancer cell lines of various tissue origins as well as in tumor tissues and sera of cancer patients. However, the signaling mechanisms underlying TCTP overexpression in cancer are still unknown. Based on a preliminary study in which mammalian target of rapamycin (mTOR) might be involved in the regulation of TCTP expression in lung cancer cell lines, the role of mTOR complex 1 (mTORC1) in TCTP expression was investigated. The protein levels of TCTP in various lung cancer cells were decreased without changes in mRNA levels when mTORC1 activity was selectively inhibited. mTORC1 inhibition induced protein degradation of TCTP through the ubiquitin-proteasome system without affecting TCTP translation. PLK1 activity was required for TCTP protein degradation by mTORC1 inhibition. Furthermore, Selective inhibition of polo-like kinase-1 (PLK1) activity completely blocked the increased TCTP ubiquitination upon mTORC1 inhibition. Ser46 and Ser64 were necessary for proteasomal degradation of TCTP by mTORC1 inhibition. TCTP phosphorylation at Ser46 depended on PLK1, indicating that mTORC1 down-regulated PLK1 activity. In addition, the levels of TCTP expression were proportional to malignancy in a set of four cell lines comprising a human lung carcinogenesis model. The mTORC1/PLK1 signaling was also required for the reported inhibitory effect of sertraline and thioridazine on TCTP protein expression. These results demonstrate that mTORC1/PLK1 signaling is essential for the increased expression of TCTP in lung cancer and provide the first evidence, to our knowledge, that mTORC1 can negatively regulate PLK1 activity.

Keywords: mTOR, PLK1, TCTP.

TUE-067
Design and development of alpacas VHH-antibodies specific to CD47 protein on cancer cells

N. Ratnikova[1], S. Chumakov[2], P. Chumakov[1]
[1]Engelhardt Institute of Molecular Biology of the Russian Academy of Sciences, [2]Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation

In the end of twentieth century antibodies with uncommon structure were detected in mammals of Camelidae family (which include camels, llamas, alpacas) along with traditional type of IgG antibodies. These antibodies were designated VHH (variable heavy-heavy) and have an antigen-binding pocket containing heavy chain variable region and lacking light chain.

Recombinant VHH-antibodies have several advantages over single-chain antibodies derived from conventional molecules of IgG such as simplicity of genetic manipulation, high expression in different systems, good solubility, high stability in a wide range of conditions and better tissue penetration due to smaller size (15–30 kDa). Structural properties of VHH-antibodies facilitate in construction of immune phage libraries which has great potential for precise engineering of antibodies specific to target proteins. Variable domains of VHH-antibodies may be used in particular as a framework for design of synthetic libraries since only three CDR-fragments of VHH-antibody are required for high affinity binding.

It is known that CD47 protein is expressed at high level on the surface of many cancer cells. CD47 interacts with SIRPa receptor which is present on macrophages resulting in phagocytosis inhibition. Thus cancer cells can escape their recognition by the host immune system. CD47-SIRPa interaction is considered as a promising target for cancer therapy. One approach comprises of using of monoclonal antibodies which block CD47 protein allowing macrophages to engulf cancer cells. However, antibodies with properties suitable for clinical application are still under development. Our aim is to develop a new high affinity anti-CD47 VHH-antibody which has a better blocking action, smaller size and minimal toxicity. To achieve this goal we immunized alpacas with extracellular fragment of human CD47 protein, isolated mRNA from PBMCs and generated PCR-fragments with VHH sequences to obtain VHH library. Further we performed selection of specific antibodies using phage display technology. Now we are studying the characteristics and functional activity of such VHH-antibodies. We suggest that these new anti-CD47 VHH-antibodies might prove perspective and suitable for cancer therapy.

Keywords: CD47, phage display, VHH single domain antibodies.

TUE-068
Design and synthesis of nitric oxide releasing acridone carboxamide derivatives as reverters of doxorubicin resistance in MCF7/dx cells

D. R. R. Gade, R. P. VVS
[1]Medicinal Chemistry Research Division, Vishnu Institute of Pharmaceutical Education and Research, Narsapur, India

Objective: In the present investigation, based on our earlier observations we have designed new NO donating acridones as MDR modulators, capable of releasing NO in controlled manner into P-gp and/or BCRP that could reverse the doxorubicin resistance in cancer.

Methods: We prepared an essentially complete set of *N10*-substituted acridone-4-carboxamides whose amide fragments were formed by the alkyl groups or aryl ring systems bearing exocyclic groups at different ring positions. The *in vitro* cytotoxic effects against Drug sensitive and resistant human cancer cell lines [MCF7, (P-gp and BCRP), MCF7/dx (P-gp expressed) and MCF7/mr (BCRP expressed)] are studied by using SRB assay. Selected molecules were also screened for their cytotoxic properties against SW1398, WIDR and LS174T cell lines. Doxorubicin accumulation and efflux studies were performed and *in vitro* levels of formed nitrate/nitrite were determined by the colorimetric assay.

Results & Conclusion: NO releasing acridones showed activity against MCF-7/wt (0.7–3.1 μM), MCF7/mr proved to be sensitive towards the compounds 1, 2, 3, 7, 10, 11 and 16 with IC_{50} ranges of 0.7–2.3 μM. MCF7/dx sensitivity was observed with compounds 1, 10 and 11 with IC_{50} range of 1.9–2.9 μM. Compounds 1, 10 and 11 showed significant cytotoxic activity against SW1398, WIDR and LS174T cell line. The results indicate NO-acridones are potent against both the sensitive and resistant cells and significantly correlated with rate of *in vitro* nitric oxide release. The results of accumulation studies showed that intracellular accumulation of doxorubicin is significantly dependent on the rate of nitric oxide release.

Keywords: Acridones, Nitric oxide, Multidrug Resistance.

TUE-069
Detection of BRAF mutation in colorectal cancer patients and compare the tumors and normal tissues with PNA clamp qPCR

H. Tuncel[1], F. Shimamoto[2], S. Erdamar[3]
[1]Biophysics, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey, [2]Prefectural University of Hiroshima, Hiroshima, Japan, [3]Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Colorectal cancer (CRC) is one of the most common malignancies in the world and a heterogeneous disease with multiple underlying genetic mutations resulting in different phenotypes. *BRAF* plays an important role in the activation of RAS–RAF–MEK–ERK signaling pathway, is one of the targeted genes in colorectal cancers. Most known BRAF mutation in colorectal cancer occurs when valine is substituted for glutamate at codon 600 on chromosome 7, referred to as the V600E mutation. V600E mutant B-Raf not only plays a important role in uncontrolled cellular proliferation through spontaneous ERK signalling, but also controls apoptosis via NF-κB signaling. Uncontrolled NF-κB signaling also related with angiogenesis, invasion and metastatic processes. The aim of this work was to assess BRAF mutations in the Turkish population with CRC. We also compared the clinicopathological data from CRC patients with the mutational status of in their cancer and normal tissues to determine a relationship to outcomes.

A total of 40 paraffin-embedded colorectal cancer and normal specimens were obtained from department of pathology in Cerrahpasa Medical Faculty. Ten-micrometer-thick tissue sections were placed on a glass slide. The tissue sections were dehydrated in graded ethanol solutions and dried without a cover glass. DNA was extracted from the tissues with 50 μl of extraction buffer at 55°C overnight. The tubes were boiled for 15 min to inactivate the proteinase K. Investigate the possibility of *BRAF* mutations, PNA clamp qPCR was performed using the PNA Clamp BRAF Mutation Detection kit (Panagene Inc., Daejeon, Korea) according to the manufacturer's instructions. The PNA probe was designed to hybridize completely to the wild-type *BRAF* allele. PNA probe hybridization securely inhibited amplification of the wild-type *BRAF* allele, whereas the PNA/mutant allele hybrid was unstable due to a base pair mismatch and there-

© 2014 The Authors. FEBS Journal © 2014 FEBS

fore did not inhibit extension by Taq polymerase. The Ct was automatically calculated from PCR amplification plots in which fluorescence was plotted against the number of cycles.

A BRAF mutation increases the risk of mortality in colorectal cancer patients over twofold. In this study, we explore BRAF mutations in the colorectal tissues, not only tumors but also normal, which may play a role in carcinogenesis in some cases, and this will require further large sample sizes study.

Keywords: BRAF, Colorectal Cancer, QPCR.

TUE-070

Detection of Pirh2-interacting proteins using GST-pulldown followed MALDI-TOF mass spectrometry

A. A. Daks, O. A. Fedorova, N. A. Barlev
Laboratory of Molecular Pharmacology, St. Petersburg State Institute of Technology, St. Petersburg, Russian Federation

Ubiquitin-dependent proteasomal degradation is one of the major pathways of non-lysosomal protein degradation in the cell. The ubiquitination process involves several enzymatic reactions and includes the following enzymes: E1 — activating, E2 — conjugating, and the third — E3 — ligating enzymes. E3 ligases determine the specificity of ubiquitination reaction, i. e. what target protein will be subjected to the covalent modification by ubiquitins.

Pirh2 (RCHY1) is the E3 ubiquitin ligase that promotes ubiquitination and subsequent proteasomal degradation of the p53 tumor suppressor protein. Phosphorylation of human p53 at serine 15 occurs after DNA damage and this leads to reduced interaction of p53 with its main negative regulator Mdm2. However, Pirh2, unlike Mdm2, targets the activated form of p53 after DNA damage, when the activity of Mdm2 is attenuated by post-translational modifications.

Beside its interaction with p53, Pirh2 interacts with other proteins involved in cell cycle regulation, DNA-damage response (DDR) and apoptosis such as Cdk9, p27, PolH.

Overexpression of Pirh2 is frequently detected in many clinical tumor tissues including hepatocellular carcinoma (HCC), prostate cancer, and lung cancer. Despite evidence of PIrh2 participation in tumorigenesis its specific role in this process remains unclear and requires further investigation. Our work is aimed toward better understanding of the molecular mechanisms of tumorigenesis involving Pirh2 protein.

For extraction and identification of proteins interacting with Pirh2 we carried out GST pull-down assay followed by MALDI-TOF mass spectrometry. To this end, a GST-Pirh2- expression vector was generated and the respective protein was purified from *E. coli* lysate. Subsequently, we incubated GST-Pirh2 with nuclear extract prepared from p53-negative H1299 cells treated with 1 μM Doxorubicin for 6 h to induce DNA Damage. Bound proteins were then separated by 1D SDS-PAGE gel electrophoresis and then analyzed by means of MALDI-TOF mass spectrometry.

Analysis of mass-spec peaks revealed about 30 novel significant proteins interacting with Pirh2. Several identified proteins are known to play role in splicing processes: hnRNP M, hnRNP K, Aly/REF etc. Some other proteins are involved in apoptosis regulation: DDX5 (p68), cytochrome c etc. Such proteins as DDX3, VDAC, PRKDC, and several others have shown to directly participate in tumorigenesis. These interactions certainly need further validation by other means. However, this work provides the ground for investigating the role of Pirh2 in apoptosis and cancer.

Work was supported by the RFBR (No. 13-04-01024A, 12-04-01397a and 14-04-32242 mol-a), MCB Program of RAS Presidium and Russian Government Programme 11.G34.31.0069.

Keywords: cancer, Pirh2, protein interactions.

Detrimental and cell death effects of organic selenium treatment on human glioblastoma cells

D. Harmanci[1], Z. Erbayraktar[2], G. Guner[1,2]
[1]*Molecular Medicine,* [2]*Medical Biochemistry, Dokuz Eylul University Graduate Scholl of Health Sciences, Izmir, Turkey*

Glioblastoma multiforme (GBM) is caused by the central nervous system-derived glial cells and is the most common (50-60%) form of primary brain tumor. The aim of this study was to investigate *in vitro* effects of selenium on human glioblastoma multiforme cells.

In the present study, GMS-10 and DBTRG-05MG human GBM cell lines were used as a model to examine, in the selenomethionine treated and non-treated groups; proliferation, cytotoxicity, DNA fragmentation and apoptosis. The organic source of selenium, selenomethionine stimulated effects on cell proliferation and cytotoxicity, as these were assessed with WST-1 and lactate dehydrogenase (LDH) tests, respectively. DNA fragmentation was using cell death ELISA kit and apoptosis was determined by Annexin V staining.

This is the first study to examine SeMet effects on cell growth and death in GMS-10 and DBTRG-05MG cells. According to the results of our research, cells respond to seleno-L-methionine in a dose-dependent and time-dependent manner for both cell lines. As a result of WST-1 test cell proliferation increased at 50 and 100 μM doses, which were considered as low doses by us. With the analyzis of the DNA fragmentation, SeMet induced apoptosis after 72 h incubation on these GBM cells. In this study, SeMet, in the *in vitro* environmental conditions, has decreased proliferation and has shown cytotoxicity in a dose and incubation period dependent manner in both DBTRG-05MG and GMS-10 cells and also SeMet induced apoptosis on these GBM cells. Our results suggest that SeMet may be key therapeutic target for GBM. This study will yield further studies focusing on the possibility of using SeMet against some types of GBM.

Acknowledgement: We thank Dr. Nurten Saydam and Dr. Okay Saydam (Vienna Medical University) and Dr. Memduh Bülbül (Dokuz Eylul University, R-LAB) for kindly support.

TUE-072

Development and optimization of a novel assay for studying protein kinase CK2 enzyme interactions using quartz crystal microbalance with dissipation monitoring (QCM-D)

E. Senkara-Barwijuk[1], G. Mosieniak[2], M. Bretner[1], J. Cieśla[1]
[1]*Faculty of Chemistry, Warsaw University of Technology,*
[2]*Laboratory of Molecular Bases of Aging, Nencki Institute of Experimental Biology PAS, Warsaw, Poland*

Protein kinase CK2 is a ubiquitous, highly pleiotropic and constitutively active kinase that phosphorylates mainly serine/threonine residues. It has been observed, that an elevated CK2 activity underlies global human diseases, with special reference to cancer and tumor pathologies. Six major hallmarks for cancer have been reported and protein kinases, especially CK2, can contribute to each of these steps. Therefore, screening for selective CK2 inhibitors is of great importance. The standard method for study of CK2 and most protein kinases activity is based on a radiometric filtration binding system, involving the use of radioactive ATP as a phosphate donor. Radioactivity methods require special han-

© 2014 The Authors. FEBS Journal © 2014 FEBS

dling and involve high cost of waste disposal. Therefore, availability of non-radiometric technique is highly desirable.

The aim of this study is to develop and optimize a novel assay for investigating enzyme inhibition and protein-protein interactions using CK2 as a model substrate. This technique might serve as a powerful tool for fast and sensitive evaluation of potential anticancer agents. Our research includes a full analysis of the mechanism and kinetics of kinase-catalyzed phosphorylation and enzyme inhibition by known and novel CK2 inhibitors.

In our studies we use a quartz crystal microbalance with dissipation monitoring (QCM-D), a unique tool which can be applied for studying biomolecular interactions. Its main advantage is ultra-sensitivity and ability to simultanously measure frequency and dissipation changes in real time. In other techniques, applied for studying enzyme assays, only the result of the reaction is investigated. Here, it is possible to monitor changes in mass and viscoelastic properties of the adsorbed layer throughout the whole process. This gives novel insights into the structural and kinetic properties of the reactions investigated.

Our studies of CK2 activity have shown that QCM-D is a suitable device for this assay, as it allowed us to determine all enzyme-reaction kinetic parameters. Moreover, we have investigated the influence of inhibitors on CK2 activity and measured the inhibitor-CK2 interactions kinetic parameters. For this assay we have used two types of quartz crystal sensors: i) Au surface and ii) modified with Cu^{2+} chelated ions for HisTag label capturing. Finally, the influence of CK2 inhibitors on colonal cancer cells HCT 116 was analyzed using a QCM-D device equipped in a window module enabling simultaneous optical access to the sensor surface.

The study was co-financed by NCN grant No 2011/01/B/ST5/00849 and by Warsaw University of Technology.

TUE-073
Differential regulation of pyrimidine nucleotide biosynthesis by Rheb and mTOR

T. Sato, S. Hattori
Pharmaceutical Sciences, Kitasato University, Minato-ku, Japan

Rheb small GTPases, which consist of Rheb1 and Rheb2 (also known as RhebL1) in mammalian cells, are unique members of the Ras superfamily and play central roles in regulating protein synthesis and pyrimidine nucleotide synthesis by activating mTOR. Although extensive studies have been carried out on Rheb activation of mTOR, little is known about other downstream effectors of Rheb. As multiple effectors have been identified for each of many small GTPases, it is reasonable to assume that Rheb may also activate multiple downstream effectors. We analyzed proteins co-immunoprecipitated with Rheb and found that Rheb binds to CAD (carbamoyl-phosphate synthetase 2, aspartate transcarbamoylase and dihydroorotase) protein, a multifunctional enzyme required for the *de novo* synthesis of pyrimidine nucleotides. CAD binding to Rheb is specific to GTP-bound active form of Rheb and is dependent on the effector domain of Rheb. Immunostaining reveals that Rheb recruits CAD to the lysosomes, while CAD is mislocalized when HeLa cells are treated with a farnesyltransferase inhibitor, which blocks the membrane targeting of Rheb. *In vitro* assays showed that Rheb increased CPSase activity of CAD. Although it has been reported the CAD phosphorylation at S1859 by S6K1, a downstream effector of Rheb-mTOR signaling, is a key event in regulating pyrimidine biosynthesis, the phosphorylation of CAD did not alter its enzymatic activity in our hands. In addition, elevated levels of intracellular pyrimidine nucleotides were observed in TSC2-knockout cells, which persisted even when the cells were treated with rapamycin. These results suggest that Rheb regulates *de novo* pyrimidine nucleotide synthesis by binding and activating CAD, independent of mTOR.

Keywords: mTOR, pyrimidine biosynthesis, Rheb.

TUE-074
Differential sensitivity of human gliomas to nonpathogenic oncolytic enteroviruses

A. Poteryakhina[1], D. Kochetkov[1], A. Chumakova[2]
[1]Engelhardt Institute of Molecular Biology RAS, [2]Department of Neurotrauma, Burdenko Neurosurgery Institute, Moscow, Russian Federation

Background and Aims: Viral oncolysis is a promising approach for the therapy of human malignant tumors. However, therapeutic response of a patient to a particular oncolytic virus strain is difficult to predict because of the substantial genetic variability within cancer types. A development of a diagnostic test for confident personalized prediction of the response would facilitate the success of therapy. Malignant gliomas are generally more susceptible to viruses, as tumor cells commonly have defective antiviral mechanisms. Non-pathogenic eneroviruses can efficiently replicate and kill some malignant glioma cells, but the efficiency may vary. One of the critical determinants of the efficiency is linked to host cell receptors that are used for entry of the virus. The goal of the study was to develop a diagnostic method for prediction of individual gliomas sensitivity for oncolytic enterovirus treatment.

Material and Methods: Standard stocks of four non-pathogenic enteroviruses (Polio Type 1 vaccine, ECHO-12, Coxsaxkie B2 and B5) were examined for self-replication in human glioblastoma cell lines U87, U251, A172 and in normal asctrocytes cell culture. Organ cultures of 15 biopsies from patients with low- and high-grade primary and recurrent gliomas were also tested for viral replication in 48 hours after infection with their stocks. Cell viability was measured by the metabolic XTT test. Relative expression levels of viral receptors were obtained using RT-PCR.

Results:

1 Human astrocytes, as nontumor cells, were not susceptible for any of the viruses from the panel. By contrast, the glioblastoma cells lines displayed differential sensitivity to the viral strains.
2 Organic cultures demonstrated individual sensitivity to the viruses in wide range.
3 The sensitivity is strongly correlated with relative expression levels of enterovirus receptors, such as CD155, CD112, CD55, ICAM-1 and CAR.

Conclusion: We suggest a rapid RT-PCR based test as a novel personalized approach for selection of the most effective oncolytic virotherapy for individual glioma patients treatment.

Keywords: oncolytic enteroviruses.

TUE-075
Double role of CacyBP/SIP N-terminal domain in the MAP kinase signaling pathway

A. M. Topolska-Woś[1,2], W. J. Chazin[2], A. Filipek[1]
[1]Department of Molecular and Cellular Neurobiology, Nencki Institute of Experimental Biology, Warsaw, Poland, [2]Center for Structural Biology, Vanderbilt University, Nashville, TN, USA

CacyBP/SIP plays an important role in various cellular processes such as cells differentiation and cytoskeleton re-organization through the interaction with its binding partners: S100A6, Siah-1, actin, tubulin and tropomyosin [Schneider and Filipek, 2011, Jurewicz et al., 2013]. It has been also shown that CacyBP/SIP

© 2014 The Authors. FEBS Journal © 2014 FEBS

participates in down-regulation of the MAP kinase cascade *via* dephosphorylation of ERK1/2 [Schneider and Filipek, 2011; Kilanczyk et al., 2011].

In this work we show that apart from the C-terminal domain, also the N-terminal domain of CacyBP/SIP is capable of ERK1/2 binding and dephosphorylation. That phenomenon is related to the presence of a double Kinase Interacting Motif (KIM) in CacyBP/SIP sequence, one in the C-terminal domain, previously reported [Kilanczyk et al., 2009], and second in the N-terminus, a newly found. Both domains exhibit comparable phosphatase activity, slightly lower than the full-length protein but modification of very conservative residues in the N-terminal KIM motif, K25 and R26, utterly abolishes the activity of CacyBP/SIP. Furthermore, we found that the N-terminal domain of CacyBP/SIP participates in homodimerization of this protein. Mutants D11-E14 with disturbed dimerization efficiency do not exhibit significant loss of activity. This may suggest that the activity does not depend directly on the oligomerization state but rather on the functionality of the KIM motif and other factors, such as post-translational modifications, which affect also dimer formation.

To support the *in vitro* analyses we determined the level and localization of CacyBP/SIP in neuroblastoma NB2a cells. Since the MAP kinase cascade is activated during oxidative stress, NB2a cells were treated with H_2O_2. Interestingly, we have found that after H_2O_2 treatment the CacyBP/SIP level increases and the functional monomer-dimer equilibrium is altered. Under control conditions CacyBP/SIP is present in the dimeric form mainly in the cytoplasm of NB2a cells. Even though under oxidative stress the protein translocates to the nucleus, the dimer is not found in that compartment. Thus, it seems that dephoshorylation of ERK1/2, which takes place in the nucleus, is catalyzed by the monomer of CacyBP/SIP, which is a prevalent active form of the protein in this compartment.

Concluding, we showed, using *in vitro* methods and experiments on cells, that the N-terminal domain of CacyBP/SIP is engaged in two processes – protein homodimerization and down-regulation of ERK1/2 signaling pathway. Changes in CacyBP/SIP oligomerization state, imposed by the N-terminal domain, are strongly dependent on its subcellular localization and phosphatase activity toward ERK1/2.

Keywords: CacyBP/SIP, dimerization, ERK1/2.

TUE-076
Doxorubicin induces G2/M arrest, Ca2+ release, oxidative stress and apoptosis in human leukemia Jurkat cells at clinical doses and dose rates

R. G. Sandu, I. Baran, D. Ionescu, A. Filippi, R. Babes, A. Goicea, A. Garaiman, R. Irimia, A. Dimancea, M. Gaman, C. Ganea, A. Murgoci
Department of Biophysics, Carol Davila University of Medicine and Pharmacy, 050474 Bucharest, Romania

Doxorubicin, an effective anticancer drug, has benn reported to induce either apoptosis or necrosis in various cancer cell lines, in function of dose and treatment duration. We investigated the antiproliferative effects of doxorubicin at clinical doses (50–100 nM) and duration (24 h, 72 h) in human leukemia JUrkat cells. Doxorubicin induced G_2/M arrest and significant apoptosis (up to 54% after 72 h of exposure), as assessed by flow cytometry analysis of the DNA content. However, cellular viability determined by flow cytometry on propidium iodide labeled cells was 1.6% after the 72 h treatment with 100 nM doxorubicin, indicating a significant fraction of necrotic cells as well. Neither quercetin nor menadione or their combination at clinical concentrations (10–15 μM) enhanced doxorubicin-induced apoptosis, despite their apoptigenic effects reported in the Jurkat cell line [1, 2]. Fluorimetric measurements on fura-2 loaded cells showed that doxorubicin (7.5 μM) induced Ca^{2+} release at slow rate and elicited a three-fold, progressive increase in cytosolic Ca^{2+} concentration over the next 55 min. from drug addition. However, since the fluorescence of internalized doxorubicin displayed a considerable and rapid increase after extracellular addition, this result indicates a sustained but indirect activation of the Ca^{2+} release channels. The observed Ca^{2+} increase was partly mediated by ryanodine receptors, so that the presence of the specific inhibitor, ryanodine (200 μM), consistently inhibited the doxorubicin-evoked Ca^{2+} signal. We also found by spectrofluorimetry that doxorubicin at clinical doses and dose rates generates oxidative stress, which is enhanced by menadione (10-15 μM), but is alleviated by both quercetin (10-15 μM) and the quercetin-menadione combination. However, these agents did not improve cellular viability following the doxorubicin treatment. In addition, quercetin did not affect the cell cycle distribution of doxorubicin treated-cells, whereas menadione and the quercetin-menadione concentration apparently abolished the doxorubicin-induced without further progression through the cell cycle phases.

D-propranolol anti-tumoral effects in B16F10 mouse melanoma

R. Shaughnessy[1,2], A. Soza[1,2], F. Segovia[1,2], C. Oyanadel[1,2], C. Metz[1,2], A. González[1,2]
[1]*Departamento de Inmunolgía Clínica y Reumatología,* [2]*Centro de Envejecimiento y Regeneración (CARE), Facultad Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile*

We recently reported that D-propranolol, used as a phosphatidic acid (PA) phosphohydrolase (PAP) inhibitor to increase cellular PA levels, may underlie a novel anti-tumoral strategy (Shaughnessy et al. FEBS J-2014). The evidence was based on a perturbation of EGFR endocytic traffic leading to both an accumulation of empty/inactive and ligand-activated receptor in recycling endosomes and a decreased proliferation/survival rate in tumoral cell lines bearing EGFR as an oncogenic trait. Here we study the effect of D-propranolol *in vitro* and *in vivo* using the B16F10 melanoma mouse model. *In vitro,* D-propranolol-treated B16F10 cells, which express low levels of EGFR, showed a reduced proliferation rate and increased apoptosis. *In vivo*, tumor progression in C57BL/6 mice inoculated with B16F10 cells was significantly decreased by intraperitoneal (IP) treatment with D-propranolol once a day. Tumors showed an increased total mass of EGFR and c-MET (hepatocyte growth factor receptor) in D-propranolol-treated mice. Both receptors were internalized under D-propranolol treatment. These results provide further evidence to consider PAP inhibition with D-propranolol as a plausible anti-tumoral approach, counteracting the tumorigenic contribution of growth factor receptors through the protein trafficking machinery. (Financed in part by CONICYT Doctoral Scholarship to RS and CONICYT PFB12/2007 to AG).

TUE-078
eEF1A1 and eEF1A2 hetrodimerization by confocal microscopy and fret analysis

N. Migliaccio[1], N. M. Martucci[1], I. Ruggiero[1], V. Quagliariello[2], F. Papale[2], P. Arcari[1], A. Lamberti[1]
[1]Department of Molecular Medicine and Medical Biotechnology (DMMBM), University of Naples Federico II, [2]Department of Anaesthesiological, Surgical and Emergency Sciences, Second University of Naples, Naples, Italy

The eukaryotic translation elongation factor 1A (eEF1A) catalyzes the first step of the protein synthesis elongation cycle [1]. Two isoforms of the protein (eEF1A1 and eEF1A2), sharing 92% amino acid homology, are known expressed in a tissue specific manner: eEF1A1 is widely expressed in almost all tissues whereas eEF1A2 is normally expressed only in non-proliferative tissues (brain, heart, skeletal, muscle). Beyond their canonical role in protein synthesis, both isoforms have been reported to be involved in other non-translational functions. eEF1A1 isoform seems to play a pro-apoptotic role whereas eEF1A2 appears to protect from apoptosis suggesting its potential function as putative oncogene [2]. Previous studies identified eEF1A Raf-mediated phosphorylation sites (S21 and T88) during survival response mediated by epidermal growth factor receptor (EGFR). However phosphorylation of S21 occurs only in presence of both eEF1A isoforms, suggesting that the eEF1A isoforms can heterodimerize. A docking model supported the formation of a possible heterodimer between eEF1A1 and eEF1A2. In particular, this model showed that the M-domain of one isoform was in contact to the G-domain of the other and vice versa. The heterodimer formation somehow could induce a conformational change in one or in both eEF1A isoforms that allows the phosphorylation of S21 [3]. The heterodimerization hypothesis was investigated by carrying out sensitized emission FRET experiment that involves the non-radiative transfer of energy from an excited state donor fluorophore to a nearby acceptor and the energy transfer efficiency ($FRET_{eff}$) was evaluated using FRET and colocalization analyzer ImageJ plug-in software [4]. HeK293 cells were transfected with pcDNA3.1 construct containing the human eEF1A2 cDNA ingineered with a C-terminal His_6-tag. FRET measurements via confocal microscopy, was carried out using mouse anti-His antibody and rabbit anti-human EF1A-1 antibody. Confocal analysis showed colocalization of the eEF1A isoforms within the cytoplasm with a stronger merge signal at the level of plasma membrane. FRET analysis indicated a specific interaction between endogenous eEF1A-1 and transfected eEF1A1-2 at the level of the plasma membrane. These results strongly confirmed that the eEF1A isoforms might interact by possibly forming a dimer that undergo to phosphorylation regulated by C-Raf [3].

TUE-079
Effect of down-regulation of STEAP1 by siRNA in cell cycle and apoptosis of human LNCaP prostate cells

I. Gomes, C. Gaspar, M. I. Alvelos, C. Santos, C. Maia
Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal

Introduction: The six transmembrane epithelial antigen of the prostate 1 (STEAP1) is over-expressed in several types of tumors, particularly in prostate cancer. STEAP1 can be found in the plasma membrane of epithelial cells, at cell–cell junctions, but also in the cytoplasm with less intensity. Although its physiological functions are yet to be ascertained, STEAP1 appears to take part on intra- and intercellular communication. Several studies have pointed out that STEAP1 has a great potential as an immunotherapeutic target, highlighting its role on prostate pathophysiology. It is well known that sex steroid hormones, namely dihydrotestosterone (DHT), are not only involved in maintenance of prostate physiology but also promote proliferation of prostate cancer cells. In addition, it was recently demonstrated that DHT is involved in regulation of STEAP1 gene. This way, we hypothesized that the effect of DHT on cell proliferation and apoptosis may be dependent on STEAP1 levels in cancer cells.
Materials and Methods: LNCaP prostate cancer cell line was cultured under an atmosphere of 5% CO_2 and 37°C. To access the effects of DHT and STEAP1 on cell proliferation and apoptosis, cells were transfected with STEAP1 siRNA and either treated with 0 or 10 nM DHT for 48 h. Control group included non-transfected LNCaP cells and treated with 0 nM DHT. Cell cycle and apoptosis analysis was performed by flow cytometry, using propidium iodide and FITC annexin V staining, respectively. Cell proliferation was also investigated through MTS assay.
Results and Discussion: STEAP1 gene silencing with a specific siRNA appears to induce cell cycle arrest and decrease proliferation when compared to control group. Hormonal treatment with DHT induces proliferation in the non-silenced cells, as it was previously described by others. When comparing siRNA transfected cells treated with DHT with non-transfected cells, it appears that DHT impairs cell proliferation, diminishing the number of cells on S-phase. Apoptosis analysis is underway.
Conclusions: STEAP1 may influence prostate cell proliferation, and the effect of DHT on prostate cells seems to be dependent of STEAP1 levels. However, more assays are being carried out in order to clarify the role of STEAP1 in cell proliferation and apoptosis.

Keywords: prostate cancer, STEAP1.

Effect of doxorubicin loaded CS MNPs on cell proliferation in sensitive and doxorubicin resistant MCF-7 cell lines

G. Unsoy[1], R. Khodadust[1], S. Yalcin[2], P. Mutlu[3], **N. Taghavi Pourianazar**[1], M. Parsian[1], U. Gunduz[1]
[1]Biotechnology, Metu, Ankara, [2]Food Engineering, Ahi Evran University, Kırsehir, [3]Central Laboratory Molecular Biology and Biotechnology R&D, Metu, Ankara, Turkey

Targeted drug delivery is a promising alternative in cancer therapy to increase the efficacy of drugs and reduce the destructive side effects of classical chemotherapy. In order to obtain an effective targeted delivery system for Doxorubicin, chitosan coated magnetic nanoparticles (CS MNPs) were synthesized (Unsoy *et al*, 2012). CS MNPs maintain pH dependent drug delivery while providing targeting of drugs to the tumor site under magnetic

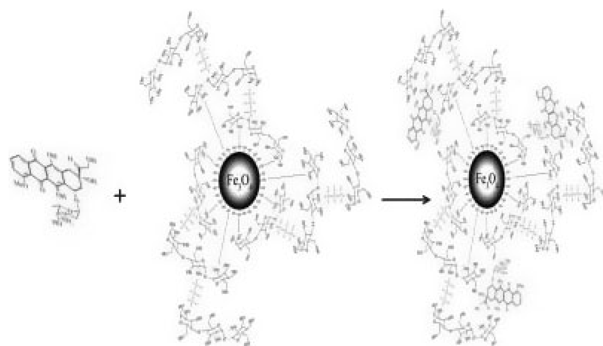

Fig. 1. Schematic representation of Doxorubicin (a), CS MNP (b) and of Doxorubicin loaded CS MNP (c).

field. The anti-cancer agent Doxorubicin, which is an antracycline antibiotic, was loaded onto CS MNPs (Figure 1). As maintained from drug loading, release, and stability characterization studies, CS MNPs have pH responsive release characteristics and are quite stable at physiological pH.

Anti-proliferative effects of Doxorubicin loaded CS MNPs were investigated by XTT cell proliferation assay on MCF-7 and MCF-7/Dox cells at increasing concentrations. IC_{50} values of free Doxorubicin and Doxorubicin loaded CS MNPs indicated that drug loaded nanoparticles not only increase the efficacy of drug but also overcome Doxorubicin resistance in MCF-7/Dox cells. Consequently, CS MNPs can be effectively used for the pH dependent release of Doxorubicin in cancer cells. Results of this study can pave the way for the development of pH responsive targeted drug delivery systems to overcome the limitations of conventional chemotherapy.

Keywords: Doxorubicin, drug resistance, breast cancer, cytotoxicity.

Effect of holothurians triterpene glycosides, cucumariosideA2-2 and frondoside A, on human prostate cancer

E. Menchinskaia[1,2], S. Dyshlovoy[1,2], C. Jacobsen[1], S. Venz[3], C. Scharf[4], D. Aminin[2], F. Honecker[5,†], G. von Amsberg[1,†]
[1]Department of Oncology, Haematology and Bone Marrow Transplantation, Section Pneumology, Hubertus Wald -Tumorzentrum, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Far-East Branch of the Russian Academy of Sciences, Vladivostok, Russian Federation, [3]Department of Medical Biochemistry and Molecular Biology and Interfacultary Institute of Genetics and Functional Genomics, Department of Functional Genomics, University of Greifswald, Greifswald, Germany, [4]Department of Otorhinolaryngology, Head and Neck Surgery, University of Greifswald, Greifswald, Germany, [5]Tumor and Breast Center ZeTuP, St. Gallen, Switzerland

Prostate cancer is the most common malignancy among men and the second leading cause of cancer related deaths. In the beginning the metastasized stage can be controlled by hormone deprivation. However, the vast majority of tumors become castration-resistant in the course of treatment. Although new drugs e.g. Abiraterone, Cabazitaxel and Enzalutamid have been successfully applied in this situation, cancer cells again acquire resistance to these substances with patients facing a dismissal prognosis. Thus, the search for new natural or synthetic compounds with selective anticancer properties remains a high scientific priority.

Holothurians triterpene glycosides cucumarioside A_2-2 and frondoside A were isolated from the holothurian *Cucumaria japonica* and *Cucumaria frondosa* and kindly provided by Drs. Avilov and Silchenko (PIBOC FEB RAS, Vladivostok, Russian Federation). Anticancer properties and mechanism of action were evaluated in the castration-resistant human prostate cancer cell line PC3: Trypane blue staining, MTT test and colony formation assay were applied for cytotoxicity and cell proliferation studies. Influences on cell cycle and apoptosis were evaluated by flow cytometry and western blotting analysis. The effect of triterpene glycosides on protein expression was analysed by 2D-gel electrophoresis followed by MALDI-MS.

EC_{50} for cucumarioside A_2-2 and frondoside A was 3 μM and 2,5 μM determined by trypane blue method and 3,3 and 3,0 μM by MTT assay, respectively. Cucumarioside A_2-2 and frondoside A caused cell cycle arrest in G2/M phase. A relative increase of the cells in the Sub-G_0 phase of the cell cycle was observed indicating cell death. Indeed, both glycosides induced apoptosis in concentrations equalling EC_{50} or less reflected by caspase-3 and caspase-9 activation. Inhibition of tumor cell colony formation of up to 40% was observed after glycoside treatment when compared to controls. In addition, incubation of PC3 cells with triterepene glycosides resulted in a distinct regulation of protein expression: Both substances up-regulated Keratin, type II cuticular Hb1 and Interleukin-1 beta, and down-regulated expression of Cathepsin B and Heterogeneous nuclear ribonucleoprotein A/B, which are involved in metastatic formation, tumor cell invasion and malignant growth.

In conclusion, cucumarioside A_2-2 and frondoside A are promising novel substances showing high efficacy in castration-resistant prostate cancer.

This research was supported by the Eppendorfer Krebs- und Leukämiehilfe.

Keywords: Anticancer activity, Cell cycle, Triterpene glycosides.

TUE-082
Effect of phytoestrogen emodin on doxorubicin-induced cytotoxicity and apoptosis on tumorigenic MCF-7 and non-tumorigenic MCF-10A human breast cells

P. Uyar[1], B. Kaya[2], T. N. Güray[2]
[1]Biology, Selcuk University, Konya, [2]Biology, Middle East Technical University, Ankara, Turkey

Emodin (3-Methyl-1,6,8-trihydroxyanthraquinone), is a phytoestrogenic component of *Rheum and Polygonum* plant extracts which has been used to treat several diseases since ancient times. It has been shown to have anti-microbial, anti-oxidant and anti-cancer effects in nature. The anti-tumor drug doxorubicin, a widely used chemotherapeutic agent, is used for the treatment of many cancer types including lung, gastric, ovarian and breast cancer. In this study, the effects of pre-, co- and alone treatment of doxorubicin and emodin in MCF-7 and MCF-10A cell lines were investigated.

MCF-7 and MCF-10A cells were cultured in the presence of various concentrations of emodin and doxorubicin at 6, 24 and 72 hours. The effect of emodin varies according to the presence of doxorubicin (pre-treatment, co-treatment, post-treatment) on both cell lines. Emodin pre-treatment (0.4 and 4 μM) for 24-hour prior to doxorubicin treatment (0.1, 0.83, 2.5 μM) caused to increase in cell viability of MCF-10A cells, comparing to doxorubicin alone treatment. Whereas no effect was observed in MCF-7 cells. Emodin post- and co-treatment with doxorubicin for 72-

© 2014 The Authors. FEBS Journal © 2014 FEBS

hour inhibited the survival of MCF-7 and MCF-10A cells in a concentration dependent manner, shown by trypan blue and XTT.

Apoptotic effects of doxorubicin and emodin were investigated by flow cytometer. While emodin (0.4 μM) did not induce apoptosis in both cell lines, doxorubicin alone, pre- and co-treatment (0.83 μM) with emodin (0.4 μM) induced late apoptosis/necrosis in MCF-7 and MCF-10A cells. Mitochondrial membrane potential loss was not observed after doxorubicin and emodin treatment in both cell lines.

Keywords: Apoptosis, Doxorubicin, Emodin.

TUE-083
MAPK inhibitor treatments in human Malignant Mesothelioma cells

Z. Ulupinar, **A. Demiroglu-Zergeroglu**
Molecular Biology and Genetics, Gebze Institute of Technology, Gebze/Kocaeli, Turkey

Malignant mesothelioma (MM), is lethal tumor, originates from mesoderm-derived tissues of serosal cavities. The worldwide incidence of MM has risen dramatically as a result of widespread exposure to asbestos together with industrialization. In our country, the disease is a serious public health problem in rural areas of Anatolia particularly, Central and South-eastern parts. The failures of conventional chemotherapeutic regimens have made the search for new approaches and drugs critically important. It is known that disturbed protein kinase activities are associated with human malignancies making these proteins attractive targets for cancer therapy. Therefore, we investigated the effect of stress activated and mitogen activated protein kinase inhibitors including SP600125 and SB203580 (JNK and p38 inhibitors, respectively), and U0126 (ERK inhibitor), in two different MM cells lines. We observed that SPC111 and SPC212 cell proliferation were inhibited at dose and time dependent manner with all inhibitors. SPC111 cells were found more sensitive than SPC212 cells to SP600125 and U0126 compounds. In addition SB203580 inhibitor (<50 μM) reduced both cell number in 72 h. These results suggest involvement of ERK and JNK pathway in cell proliferation. However, decreased cell number with high doses of SB203530 may indicate that proliferation of malign cells also, depend on either highly activated p38 MAP pathway or PKB pathway, which can be blocked by SB203580 approximately 10-fold higher than those required to inhibit p38 pathway. Thus, in turn much more specific p38 and/or PKB pathway inhibitors aimed to be use in order to clarify our result.

Keywords: malignant mesothelioma, MAPK.

TUE-084
Effect of the small GTPase Rheb on the regulation of LKB1 kinase

A. Castro, M. E. Armijo, R. J. Pincheira
Biochemistry and Molecular Biology, Universidad De Concepcion, Concepcion, Chile

The small GTPase Rheb activates the mTORC1 kinase, which promotes cell growth and is implicated in metabolic deregulation in cancer cells. The LKB1-AMPK pathway senses intracellular energy levels, and negatively regulates Rheb-mTORC1 signaling in response to metabolic stress. However, our group recently demonstrated that Rheb activates AMPK through a mTORC1-independent mechanism. This observation suggests that a negative feedback loop between Rheb and AMPK exists, but how Rheb activates AMPK remains elusive. Here, we show that Rheb is unable to induce AMPK activation in LKB1 kinase-null HeLa cells. Since LKB1 kinase is known to induce full activation of AMPK by phosphorylation, we tested whether Rheb regulates LKB1 function. We found that Rheb co-immunoprecipitates with endogenous LKB1 in HEK 293T cells, but GST-pull down assays demonstrated that the interaction between these proteins is not dependent on Rheb's activation state. These results suggested that Rheb forms a complex with LKB1 to affect its function. LKB1 is known to form different complexes in the cell, affecting its stability and catalytic activity. We then analyzed whether Rheb affects LKB1 stability. We transiently co-transfected LKB1 and Rheb in HeLa cells, and the effect of Rheb on LKB1 stabilty was analyzed by pulse-chase and cycloheximide experiments. We found that Rheb increases LKB1 stability. Consistent with this result, shRNA-mediated depletion of Rheb was correlated with a decrease in LKB1 expression in Colo320 cancer cells. Altogether, our results suggest that Rheb induces AMPK activity by interacting with and increasing the stability of LKB1.

Keywords: Rheb, AMPK, LKB1 stability.

TUE-085
Effect of transition metals on sequence-specific binding of p53 family proteins

P. Bazantova[1], M. Adamik[2], L. Navratilova[2], V. Tichy[2], **J. Cerven**[3], M. Brazdova[2], P. Pecinka[3]
[1]*Faculty of Science, University of Ostrava, Ostrava,* [2]*Institute of Biophysics, Bron,* [3]*Institute of Environmental Technologies, University of Ostrava, Ostrava, Czech Republic*

The p53 protein family that is coded by TP53, TP63 and TP73 genes play an important role in many cell proesses. For correct function as tumor supresors, sequene specific binding to responsive elements of target genes is required. DNA binding domain (DBD) is responsible for this. It was found, that in all p53 family members oxidation of cysteins in DBD lead to inhibition of sequence specific binding, which is conected with loosing of zinc ions. Zn^{2+} ions are essential for stable conformation of the protein. Another studies showed, that excess of Zn^{2+} ions, simillarly as ions of other heavy metals inhibit sequence specific binding of the p53 protein. It is known, that zinc homeostasis is the result of a coordinated regulation and intracelular zinc concentration is in corelation to cell fate. While absence of zinc ions doesn't allow synthesis of functionable proteins, excess of zinc is cytotoxic.

In our work we focused on effect of two-valent cations of zinc, cobalt, nickel and cadmium on sequence specific binding of p53, p63 and p73 proteins. Ihibition of this binding was detected in micromolar concentrations. Our experiments with DNA fragments and oligonucleotides containing sequences of promotor regions of p53 family target genes (e.g. *p21, MDM2)* confirms inhibition effect of Zn^{2+}. It is interesting, that interaction of p63 and p73 with DNA was inhibited less then p53. Other studied heavy metals inhibited sequence specific binding in similar concentrations as p53.

Keywords: DNA-protein interaction, heavy metals ions, p53 family.

TUE-086
Effects of plant phenolic compounds tannic acid and resveratrol on prostate cancer metastasis

S. Karakurt[1], M. Akkulak[2], E. Evin[2], O. Adali[2]
[1]Department of Biochemistry, Faculty of Science, Selcuk University, Konya, [2]Department of Biological Sciences, Middle East Technical University, Ankara, Turkey

Background: Prostate cancer, a heterogeneous cancer, is the third most common cause of male cancer deaths in developed countries, with castration resistance. Current therapeutic approaches for prostate cancer generally have variable efficiency, develop metastasis and drug-resistance, and have high toxicity to normal tissues. Hence, the searching for more effective strategies with moderate or any adverse effects for the chemopreventive intervention of those cancers remains one of the important issues in cancer research. Increasing popularity towards traditional medicine such as herbal remedies or dietary supplements leads the investigators to examine the actions of phytochemicals on xenobiotic metabolism and their antioxidant, antitumor, anti-carcinogenic, and anti-mutagenic effects. For these reasons, this study was aimed to determine the effect of tannic acid and resveratrol on prostate cancer proliferation, metastasis and invasion.
Methods: PC-3 and LnCaP cell lines were grown in Hams' F-12 medium and RPMI-1640, respectively supplemented with 10% fetal bovine serum and 2 mM glutamine. Cytotoxicity of tannic acid and resveratrol on PC-3 and LnCaP cell lines were determined with Alamar blue and IC50 value was calculated. The effects of tannic acid and resveratrol on proliferation, invasive potential and metastasis of cancer cell lines were analyzed by wound healing, colony formation and matrigel chamber assays, respectively.
Results: In this study, we found that tannic acid and resveratrol on has the potential to inhibit the proliferation of PC-3 and LnCaP cell lines in a concentration-dependent manner. Tannic acid and resveratrol inhibited proliferation of PC-3 cell line with IC50 of 35 μM and 78.4 μM while LnCaP cell line's proliferation was determined as 29.1 μM and 76.2 μM, respectively. Both tannic acid and resveratrol treatment of cells led to a significant inhibition in motility and metastasis of PC-3 and LnCaP cell lines ($p < 0.0001$).
Conclusions: The data obtained from this study will supply valuable information about usage of those phenolic compounds in treatment of prostate cancer since tannic acid and resveratrol are found plenty amounts in vegetables and fruits. These results show that tannic acid and resveratrol significantly inhibit the proliferation, invasive potential and metastasis of prostate cancer cell lines, PC-3 and LnCaP.

This work was supported by a grant from TUBITAK, Project No:113Z488, TURKEY.

TUE-087
Effects of selected growth factors and their receptors inhibitors on invasiveness of two differentially migrating lines of colon cancer cells

A. Simiczyjew, M. Podolska, A. J. Mazur, M. Malicka-Blaszkiewicz, D. Nowak
Department of Cell Pathology, University of Wroclaw, Wroclaw, Poland

Cell migration plays an important role in metastasis. A better understanding of the molecular mechanisms of cell locomotion is therefore of high clinical relevance.

Epidermal growth factor receptor (EGFR) as well as hepatocyte growth factor receptor (c-Met) are tyrosine kinases which are abnormally overexpressed in numerous tumors of epithelial origin, including colon cancer, where it is connected with high risk of metastasis occurrence. Activated by ligand binding EGFR and c-Met induce activation of two main intracellular pathways - the MAPK pathway and the PI3K/AKT pathway. These pathways lead to the activation of various transcription factors that impact cellular responses such as proliferation, migration, differentiation, and apoptosis. Additionally, some patients with colon cancer have a point mutation in B-Raf, a component of the RAF/MEK/ERK signaling pathway. That's why we decided to use c-Met (crizitinib), EGFR (erlotinib, gefitinib, lapatinib) and B-Raf (vemurafenib) inhibitors to test how two differentially migrating lines of colon cancer cells will react to these treatments. There are also some reports indicating that EGFR inhibitors and c-Met inhibitor as well as B-Raf inhibitor have synergistic effects on viability of some types cancer cells. That's why we decided to test also the influence of these compounds mixes on examined cells.

In this study we used human colon carcinoma cells BE, moving in mesenchymal way and LS174T, moving in ameboid way. At first we showed that EGF as well as HGF influenced positively protrusions formation activity of these cells and their invasion abilities. Then we focused on viability of cells after inhibitors treatment. We observed that for both cells lines lapatinib and crizotinib are the most effective ones in decreasing viability of examined cells. Other EGFR inhibitors as well as vemurafenib didn't influence significantly this parameter. Invasion assay gave similar results – crizotinib and lapatinib were the most potent in inhibiting migration of both colon cancer cells. We noticed also some changes in cytoskeleton of these cells upon inhibitors treatment. Actin cytoskeleton organization and cortactin distribution was observed using confocal microcopy. Cells treated with higher concentrations of lapatinib and crizotinib rounded up and didn't form any protrusions. Usage of lower concentrations of selected inhibitors caused changes in cells morphology and formation of new protrusions. We noticed subtle differences between mesenchymally and ameboidally migrating colon cancer cells after inhibitors treatment.

TUE-088
Effects of syntenin expression levels and growth factor stimulation on exosomal protein content

N. S. Imjeti[1,2], S. Audebert[1], R. Ghossoub[1], F. Lembo[1], A. Rubio[1], E. Baudelet[1], L. Camoin[1], P. Zimmermann[1,2]
[1]Centre de Recherche en Cancérologie de Marseille (CRCM), Marseille, France, [2]Department of Human Genetics, KU Leuven, B-3000 Leuven

Exosomes are small secreted vesicles of endosomal origin that have been shown to play a role in various aspects of trans cellular signaling. They are of particular importance during cancer progression because they suppress immunity and stimulate tumor angiogenesis and metastasis. Little is known on the impact of growth factor signaling on exosomal protein content. Also it is unclear whether specific components of the exosomal machineries can differentially affect the content of exosomes.

Here, we compared secreted exosomal proteins from MCF-7 cells upon different growth factor stimulation by proteomic approach. We also tested for the effect of syntenin, a scaffolding protein stimulating exosomal production. For the analysis, we divided our exosomal proteins into 10 families. Interestingly, we observed that upon syntenin gain of function, exosomes contain high amounts of nuclear proteins involved in transcription and

© 2014 The Authors. FEBS Journal © 2014 FEBS

translation and proteins involved in the metabolism. Upon FGF2 stimulation, exosomes contain mainly proteins involved in trafficking, cytoskeleton remodeling, and polarity proteins as well as junctional and adhesion molecules. These data indicate that cells drastically change their secreted material depending on internal and external stimuli. We are currently optimizing protocols for proteomic analysis of exosomes from MCF-7 cells grown in the presence of various concentrations of serum. By these approaches, we hope to clarify to what extend internal and external stimuli affect exosomal content and to better understand trans cellular signaling.

Keywords: exosomes, syntenin.

TUE-089

Electrical, metabolic and genetic communication between laryngeal squamous cell carcinoma cells via membranous tunneling tubes

I. Antanaviciute[1], K. Rysevaite[1,2], L. Rimkute[1], A. Marandykina[1], R. Sveikatiene[1], V. Liutkevicius[1,3], V. Uloza[3], V. A. Skeberdis[1]

[1]Institute of Cardiology, [2]Institute of Anatomy, [3]Department of Otorhinolaryngology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Intercellular membranous tunneling tubes (TT) are recently discovered form of communication between remote cells. In the present study, we demonstrate that human laryngeal squamous cell carcinoma (LSCC) cells in culture form a dense network of non-adherent tunneling tubes that differ in length, thickness and composition. We observed extremely long (up to 1 mm) and thick (up to 5 μm) epithelial bridge-like connections (Zani, 2010), containing F-actin together with α-tubulin, and shorter (up to 100 μm) but extremely thin (less than 0.2 μm) tunneling nanotube-like formations (Rustom, 2004), containing only F-actin. Using fluorescence microscopy and dual whole-cell patch-clamp technique we performed a quantitative evaluation of TT electrical properties permeability to fluorescent dyes of different molecular weight and charge. We found that the thickest and longest intercellular TTs formed during cell dislodgement after division provided open-ended connections able to permit at least 3 kDa molecules, while TTs formed by filopodia or secondary lamelipodia outgrowth mechanism establish intercellular connections through the formation of connexin 43 based gap junctions with consequent voltage gating properties and permeability to smaller molecules < 1 kDa. TTs, containing F-actin together with α-tubulin transported mitochondria, accommodated DAPI stained vesicles and were capable of transmitting double-stranded small interfering RNA between cells. In addition we demonstrated the existence of TTs in the microsections of LSCC tissue samples.

Our findings may contribute to better understanding of intercellular communication between normal and tumor cells providing possible guidelines for the cancer treatment and future drug design.

Keywords: intercellular communication, laryngeal squamous cell carcinoma, tunneling tubes.

TUE-090

Endoplasmic reticulum stress-mediated activation of p38 MAPK, caspase-2 and caspase-8 leads to abrin-induced apoptosis

R. Mishra, A. A. Karande

Department of Biochemistry, Indian Institute of Science, Bangalore, India

Abrin from *Abrus precatorius* plant is a potent protein synthesis inhibitor and induces apoptosis in cells. However, the relationship between inhibition of protein synthesis and apoptosis is not well understood. We initiated studies to examine if abrin can induce endoplasmic reticulum (ER) stress which finally leads to mitochondrial membrane potential (MMP) loss and apoptosis.

Imunoblotting was employed to analyse the activation of ER stress markers such as eIF2α (eukaryotic initiation factor 2α), CHOP (CAAT/enhancer binding protein (C/EBP) homologous protein), p38 mitogen-activated protein kinase (p38 MAPK) and c-Jun N-terminal kinase (JNK) upon abrin treatment. Additionally, caspase-2 and caspase-8 have been reported as key molecules linking ER stress to apoptosis. Therefore, flow cytometry and immunoblotting was done to analyse the activation and involvement of p38 MAPK, JNK, caspase-2 and caspase-8 using specific inhibitors. We also checked for the phosphorylation of H2AX which is a marker for double strand DNA breaks to investigate any direct DNA damage caused by abrin.

Significant phosphorylation of eIF2α, p38 MAPK, JNK and upregulation of CHOP was observed suggesting activation of ER stress signaling in the cells treated with abrin. Further, studies with the help of inhibitors showed that abrin-mediated cleavage of caspase-2 and -8 was found to be dependent on p38 MAPK but not JNK. The cleavage of caspase-2 and caspase-8 triggered Bid cleavage leading to MMP loss clearly delineating the link between ER stress and mitochondrial damage leading to abrin induced apoptosis. We also found significant phosphorylation of H2AX and ATM after abrin treatment which was completely abrogated in the presence of broad spectrum pan-caspase inhibitor suggesting that DNA damage was not a cause but consequence of apoptosis induced by abrin. Therefore present study demonstrates the significance of inhibition of protein synthesis in abrin induced apoptosis.

We acknowledge Council of Scientific and Industrial Research (CSIR) and Department of Biotechnology (DBT) Government of India for the support.

Epigenetic therapy: a promising treatment for chondrosarcoma?

N. Girard[1,2], C. Bazille[1,2,3], E. Lhuissier[1,2], H. Benateau[1,4], K. Boumédiene[1,2], C. Baugé[1,2]

[1]EA4652 MILPAT Microenvironnement Cellulaire et Pathologie, UNICAEN, Caen, France, [2]Normandie Univ, Caen, France, [3]Service d'anatomie Pathologique, CHU de Caen, France, [4]Service de chirurgie Maxillo-Faciale, CHU de Caen, Caen, France

Chondrosarcomas are rare tumors, potentially fatal since they are chemo- and radioresistant. Current treatment consists to tumor resection which may lead to amputation. The development of new therapeutic approaches is necessary. Among emerging strategies, the targeting of Enhancer of Zeste Homolog 2 (EZH2), the enzyme responsible for the methylation of histone H3 on lysine 27 (H3K27) seems promising. The objective of this work is to validate the concept of epigenetic therapy targeting H3K27 methylation using 3-Deazaneplanocin A (DZNep), an S-adenosyl-L homocysteine hydrolase inhibitor which induces EZH2 protein depletion, to treat chondrosarcomas.

EZH2 expression was determined by immunohistochemistry on high grade chondrosarcomas, enchondromas (benign tumors) and adult articular cartilages from human patients, and western blot on chondrocytes and chondrosarcomas cells lines. SW1353 and CH2879 chondrosarcomas cells lines were cultured in the presence of DZNep, and their growth and survival were evaluated by counting adherent cells periodically. Cell cycle analysis was analysed by flow cytometry. Apoptosis was evaluated by

© 2014 The Authors. FEBS Journal © 2014 FEBS

Apo2.7 expression using flow cytometry. Cell migration was assessed by wound healing assay. *In vivo* experiments were done with implantation of CH2879 chondrosarcoma cell line in nude mice.

EZH2 is expressed in high grade chondrosarcomas but not in enchondromas or adult articular cartilage. *In vitro*, DZNep reduces EZH2 protein expression and H3K27me3 level. It reduces growth of chondrosarcomas *in vitro* and *in vivo*. DZNep also induces cell death by apoptosis, and reduces migration of chondrosarcomas.

These results confirm the interest of the DZNep for the treatment of chondrosarcomas. Further experiments are required to better understand mechanisms responsible of its effects on tumoral cells, and to determine its putative effects on normal cells.
Keywords: chondrosarcoma, epigenetic therapy, EZH2.

TUE-092
Epithelial transiton of gastric cancer cells by KRC-108

Y. J. Jeong, **S.-Y. Han**
College of Pharmacy, Gyeongsang National University, Jinju, Korea

Investigation of the resistance mechanism in targeted therapy is important because resistance acquired during the treatment can be the cause of relapse or refractoriness to the therapy. The small molecule compound KRC-108 has been developed in an effort to identify an anticancer agent with c-met inhibitory activity in the previous study. Gastric cancer cell lines resistant to KRC-108 were established, and the changes that accompanied resistance were explored. Increased expression of the c-met protein was observed in KRC-108-resistant cells. The phosphorylation of c-met also increased in cell lines resistant to KRC-108. Resistance to the c-met inhibitor resulted in cell morphological changes. Parental cells with a round and poorly differentiated morphology changed to an epithelial cell-like phenotype. Consistent with the transition to an epithelial morphology, the expression of E-cadherin was increased in resistant cells. In an immunoprecipitation study, an interaction between E-cadherin and the c-met protein was observed in the KRC-108-resistant cells. These results suggest that the epithelial transition in KRC-108-resistant cells is mediated by recruiting E-cadherin to c-met protein. This study was supported by grants from the Ministry of Trade, Industry and Energy (MOTIE), Korea Institute for Advancement of Technology (KIAT) through inter-ER cooperation projects (A004500005)
Keywords: c-met, drug resistance, E-cadherin.

TUE-093
ERK-dependent association of HIF-1α with chromatin via a peptide that can inhibit HIF-1 activity when over-expressed in hepatocellular carcinoma cells

M. Kourti[1], N. N. Giakoumakis[2], Z. Lygerou[2], G. Simos[1], **I. Mylonis**[1]
[1]*Faculty of Medicine, University of Thessaly, Larissa,* [2]*School of Medicine, University of Patras, Patra, Greece*

A major aspect of carcinogenesis is the development of hypoxic regions due to increased cell proliferation and limited blood supply. Hypoxia further promotes tumor progression by facilitating angiogenesis and metabolic adaptation of cancer cells. HIF-1α is the regulatory subunit of Hypoxia-Inducible Factor-1, a key transcriptional activator that mediates the cell response to hypoxia. HIF-1α represents an attractive therapeutic target because it is expressed in many cancers and is associated with poor patient prognosis. HIF-1α is regulated by oxygen as well as oxygen-independent mechanisms that involve its phosphorylation. We have previously shown that ERK phosphorylates HIF-1α at Ser641/643 in a domain termed ETD (ERK-Targeted Domain). In the absence of this phosphorylation, HIF-1α is exported from the nucleus in a CRM1-dependent manner while ETD phosphorylation enhances nuclear accumulation and activity of HIF-1. To investigate further the function of ETD, wild-type GFP-tagged HIF-1α or 42-amino acid long ETD forms carrying mutations that either prevent or mimic modification by ERK were analyzed by fluorescence recovery after photobleaching (FRAP) in Huh7 hepatocarcinoma cells. The phosphomimetic mutant full-length HIF-1α or ETD exhibited lower intranuclear mobility than their wild-type counterparts suggesting that phosphorylation of ETD by ERK stimulates its interaction with chromatin components, the identification of which is currently under progress using pull-down assays. Over-expression of the wild-type and phosphomimetic mutant flag-tagged ETD forms, but not the phospho-deficient mutant ETD form, drastically inhibited HIF-1 activity under hypoxia in Huh7 and HepG2 cells, suggesting that exogenous ETD peptides can compete with endogenous HIF-1α for binding to chromatin. We conclude that the ETD mediates ERK-dependent interaction between HIF-1α and chromatin and it can be used as an efficient peptide inhibitor of HIF-1 activity in cancer cells.

Supported by the “ARISTEIA II “ Action of the “OPERATIONAL PROGRAMME EDUCATION AND LIFELONG LEARNING” to G.S. and is co-funded by the European Social Fund (ESF) and National Resources.

TUE-094
Ethanol influences MICA/B surface expression and release from the cells

M. Streltsova, A. Kuchukova, L. Kanevskiy, E. Kovalenko
IBCH RAN, Moscow, Russian Federation

Expression of proteins MICA and MICB(MIC), the ligands for immunoreceptor NKG2D, has been proposed to play an important role in the detection and elimination of tumor and other damaged cells. The result of the interaction of surface MIC with NKG2D is the increase of cytotoxic activity of NK and T cells and the subsequent killing of affected cells. On the other hand, soluble MIC can depress NK cell functions particularly because of decrease of NKG2D surface expression. We studied in several cell models the influence of ethanol on the expression of MIC and on their release from the cells. MIC expression was analyzed in a model of ethanol-induced cell stress using K562, Jurkat and THP-1 cell lines, as well as human peripheral mononuclear cells. Surface MIC expression was measured by flow cytometry. C1R-MICA transfected line was used as a positive control. Significant levels of spontaneous surface MIC were registered in all lines. Surface expression of MIC increased under the influence of ethanol (0.5-1.5%) and decreased with ethanol dose increasing up to 2% and above. The later process was corresponded to cell death elevation. We did not find spontaneous surface expression of MIC in lymphocytes, but discovered it in CD14-positive cells, increased under the influence of ethanol-induced cellular stress (0.12-1%). Those cells, which have no spontaneous MIC surface expression, have a considerable level of MIC mRNA (detected by RT-PCR). A cause of the increase of MIC expression in cells may be the oxidative stress induced by ethanol resulting in DNA damage. We used ATM/ATR kinase inhibitor for detection DNA damage in cells under the ethanol influence, and we did not detect considerable changes in MIC surface levels at indi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

cated ethanol doses. With confocal microscopy it was shown, that the inner pool of MIC decreased and the surface pool increased in comparison with the control cells. We can assume that under the influence of ethanol the proteins MIC move from the cytoplasm to the cell surface (detected by ELISA). It has been shown that under the influence of ethanol MIC were released from the cells as soluble proteins and consisting of microparticles and exosomes. The increase of soluble MIC level after cell treatment with methyl-cyclodextrin supports the role of lipid rafts in release MIC from the cells. Thus, ethanol may decrease MIC amount on the cell surface by the elimination of cholesterol and disintegration of lipid rafts in plasma membrane. Thus, we have shown that ethanol can alter MIC expression in some cell lines and normal monocytes and have analysed mechanisms underlying this alteration. Changes in MIC surface and extracellular content induced by ethanol may have amodulating effect on the immune system. This work is supported by RFBR, grant # 14-04-32342.

TUE-095

Evaluation of anticancer properties of an endemic geophyte species from Turkey, Muscari muscarimi

C. Özay[1], E. R. Karagur[1], A. Demiray[2], H. Akca[2], R. Mammadov[1]

[1]Department of Biology, [2]Department of Medical Biology, School of Medicine, Pamukkale University, Denizli, Turkey

The genus *Muscari* (Hyacinthaceae) is represented by nearly 50 species on the Earth. In Turkey, it is represented with about 30 species. Among them, *M. muscarimi* have been used in traditional medicine as antirheumatic, stomachic, diuretic and expectorant. In addition to this, it has also been used as food for humans and animals, ornamental plants in gardens.

The chemical composition of the *M. muscarimi* is composed of polysaccharides, homoisoflavanons, glycosides and pyrrolizidine alkaloids. Also, many kinds of flavonoids have been identified. Phenolic compounds including flavonoids and phenolic acids are known to be responsible for antioxidant capacities in plants. In our previous studies, total antioxidant activity of ethanolic and methanolic bulb extracts of *M. muscarimi* was determined by β–carotene/linoleic acid assay and we found at 69.43% and 61.55% respectively. The phenolic contents of the both extracts were found 21.8 and 18.3 mg/g GAE respectively. A positive correlation was observed between antioxidant activity and amount of phenolic contents.

Recent studies showed that *Muscari* species have different biological and pharmacological activities such as anti-inflammatory, antimicrobial, antioxidant and antimutagenic. Nevertheless, no reports on the investigaton of anticancer properties. In this respect, the aim of the present study is evaluate the anticancer properties of ethanolic and methanolic bulb extracts of *M. muscarimi* against various human cancer cell lines (MCF-7, H1299, HeLa). Plant samples were collected and their cytotoxic effects on the cancer cell lines were examined at different concentrations (16, 31, 62.5, 125, 250, 500, 1000 μg/mL). Cytotoxicity in plant extract-treated and untreated control groups was measured by the luminometric method using a CytotoxGlo kit. Values for the concentration at which 50% inhibition occurred (IC_{50}) were calculated for all extracts. For the detection of the induction of apoptosis of each extract, cells were treated with IC_{50} values of each plant extract for 24 h. At the end of the incubation period late apoptotic events were analyzed by terminal transferase dUTP nick end-labeling (TUNEL) analysis. Apoptotic cells were counted under the microscope. According to results, both ethanolic and methanolic extracts have the strongest cytotoxic effects on the H1299 cells (IC_{50}: 62.5 μg/mL) in a dose-dependent manner than MCF-7 and HeLa cells. Among the three cell lines, *M. muscarimi* has the biggest effect on induction of apoptosis on MCF-7 cells. Based on the in vitro data, it is suggested that consumption of this plant may impart anticancer effects especially in the breast, lung and the cervix.

Keywords: Apoptosis, MCF-7, H1299 and HeLa cells, Muscari muscarimi.

TUE-096

Evaluation of KRAS gene expression and gene variant in genomic and cell free DNA of Iranian women with endometriosis

S. Shahbazi[1], R. Mahdian[2], M. Shahrabi-Farahani[1]

[1]Medical Genetics Department, Faculty of Medical Sciences, Tarbiat Modares University, [2]Molecular Medicine Department, Pasteur Institute of IRAN, Tehran, Iran

Purpose : Endometriosis is a complex gynecological disease which is defined as the presence of endometrial–like tissue outside the uterus. The pathology of endometriosis remains unknown, although genetic components have been suggested by numerous studies. Among them, KRAS considered as a crucial gene, because its activation results in de novo endometriosis in mice. It has been reported recently that 31% of women with endometriosis as opposed to 5% of control population have KRAS let-7 microRNA binding site variant (rs61764370).

Methods: We screened genomic and cell free DNA of Iranian women with endometriosis for this SNP, whether is associated with the risk of endometriosis. We investigated 58 patients with histopathologically confirmed endometriosis and 60 control group women who were surgically proven to have no endometriosis and 100 randomly selected Iranian people. Quantitative real-time RT–PCR was performed to determine expression of KRAS transcripts in eutopic endometrium tissue samples.

Results: The KRAS variant allele frequency distribution in controls and normal population was in agreement with previous reports. Our results suggest that the variant is not associated with development of advanced endometriosis in Iranian women. We obtained the higher level of KRAS expression in eutopic endometrium of patients with endometriosis compare to healthy women.

Conclusions: The LCS6 let-7 miRNA binding site variant of the KRAS is neither a genetics nor somatic marker for endometriosis risk in Iranian population. However, the higher expression ratio of KRAS mRNA in endometriosis indicates its role in transferring endometrium outside uterine cavity.

Keywords: Endometriosis, KRAS gene, let-7 microRNA, Cell free DNA, Single nucleotide polymorphism.

TUE-097

Evidence for anti-proliferative properties of the anti-diabetic agent 1,1-dimethylbiguanide hydrochloride (metformin) on human ovarian cancer cells

M.-I. Christodoulou[1], P. Samara[2], O. Tsitsilonis[2], E. Fragoulis[1], A. Scorilas[1]

[1]Department of Biochemistry and Molecular Biology, [2]Department of Animal and Human Physiology, National and Kapodistrian University of Athens, Attica, Greece

It is widely supported that the use of metformin (1,1-dimethylbiguanide hydrochloride) in patients with type-2 diabetes mellitus is associated with lower risk of ovarian cancer development and that metformin-treated diabetic individuals with ovarian cancer display enhanced response to chemotherapy and progression-free survival.

© 2014 The Authors. FEBS Journal © 2014 FEBS

However, the exact molecular pathways underlying this anti-ovarian cancer profile of metformin have not yet been elucidated.

Scope: We sought to investigate the anti-proliferative effect of metformin in human tumor cells of ovarian origin.

Methods: Six human ovarian cancer cell lines (TOV-21G, TOV-112D, ES-2, SK-OV-3, OV-CAR-3, MDAH-2774) were cultured and subjected to metformin treatment. Cell-growth curves and IC50 values were estimated using the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) cell-viability assay. Metformin was tested in concentrations ranged from 1μM to 50 mM, in 24 h and 48 h. Induction of apoptosis was estimated by flow-cytometry using annexin-V-FITC/propidium iodide staining, in a FACSCanto™ Flow Cytometer (Becton Dickinson, Germany).

Results: At 24 hr, the IC50 values were found to be: 50 mM for TOV-112D, 30 mM for ES-2, 50 mM for SK-OV-3, and 30 mM for OV-CAR-3, while in the TOV-21G and MDAH-2774 lines reduction of cell viability was not higher than 25% in any of the concentrations tested. The 48 hr-IC50 values were: 30 mM for TOV-21G, 15 mM for TOV-112D, 10 mM for ES-2, 5 mM for SK-OV-3, 10 mM for OV-CAR-3, and 50 mM for MDAH-2774. Moreover, preliminary flow-cytometry experiments marked a significant increase in early-(~8-fold), late-apoptotic (~3-fold) and necrotic cells (~4-fold) in TOV-21G cells after metformin treatment (30 mM, 48 hrs).

Conclusion: Our preliminary results indicate the pro-apoptotic capacity of metformin on ovarian cancer cells. Results from the other cell lines, and further analyses on cell-cycle arrest, pro- and anti-apoptotic gene-expression and immune patterns, as well as possible synergistic effects with standard chemotherapeutics used in ovarian cancer treatment, are needed to elucidate the potentiality of this anti-diabetic drug as an adjuvant anti-ovarian cancer agent.

The project is co-funded by the European Union (ERDF) & Greek national funds: Operational Program *Competitiveness & Entrepreneurship*, National Strategic Reference Framework-Research Funding Program: COOPERATION 2011-11ΣΥΝ-10-1821, and partially (presentation expenses) by the Athens University Special Research Account (#10812).

Keywords: apoptosis, metformin, ovarian cancer.

TUE-098

Exome and transcriptome analysis of cancer cells in chronic myeloid leukemia

A. V. Lavrov[1,2], S. Smirnikhina[1], E. Adilgereeva[1], E. Chelysheva[3], O. Shukhov[3], A. Turkina[3], S. Kutsev[1,2]
[1]Laboratory of Mutagenesis, Research Center for Medical Genetics of Rams, [2]Department of Molecular Genetics and Cytogenetics, Pirogov Russian National Research Medical University, [3]Hematological Research Centre, Moscow, Russian Federation

Tyrosine kinases inhibitors (TKI) are highly effective in treatment of chronic myeloid leukemia (CML). However long-term clinical studies demonstrated that about 20% of the CML patients are primary resistant to TKI. Activation of *BCR-ABL*-independent mechanisms could explain this resistance. Here we tried to find exomic variants and expression differences associated with optimal response or failure of the therapy. This approach can both benefit therapy efficiency and understanding of cancer pathogenesis. Exome sequencing was done with Ion PGM technology using Exome Enrichment Kit from LifeTechnologies. Gene expression profiles were analyzed using Illumina HT-12 Expression Bead Chip. According to European Leukemia Net (2013) criteria patients were divided into resistant to TKI therapy – molecular response >10% in 6 months of therapy and optimal responders with molecular response <1% in 6 months of therapy. Exome analysis revealed from 36153 to 38636 single nucleotide variants (SNV) and indels in patients with optimal response. Filtering procedures allowed us to select only 3 homozygous SNVs common for all three examined patients. One of these variants was found to be a frameshift deletion in NCAM1. This gene is an essential marker of T-lymphocytes and its expression is associated with T-NK lymphomas and both acute and chronic myeloid leukemias. It was also found in studies of small-cell carcinomas and lethal median granuloma. Two other variants were registered in SLC4A3 associated with dendrite-cell carcinoma and 28S_rRNA-related gene. Comparative transcriptome analysis revealed 26 differently expressed genes in patients with optimal response and failures. Ten of these genes (*DAZAP2, UBA52, PRR13, ATG7, LOC387820, PAK1, RAB11A, EMP3, GSTM1, GSTM2*) are associated with other cancers and another 4 (*RSAD2, MAP3K11, COMMD1, TNFRSF1A*) are the key members of regulatory pathways including NF-kappa-B, MAPK, JNK and other thought to be disbalanced in many cancers. Enrichment analysis of the differently expressed genes showed the following molecular networks involved ($p < 0.05$): glutathion, drug and xenobiotic methabolism, chemical mutagenesis, glycosaminoglycan degradation and MAPK signaling pathway. According to expression levels we may suggest that these pathways are activated in patients resistant to TKI therapy while. We found two exomic variants and 14 differently expressed genes potentially involved in cancer signaling pathways responsible for differences in patient's response to TKI treatment.

Exosome mediated Glioma cell-endothelial cell cross talk increase angiogenesis in glioblastoma

A. Sharma, A. Shiras
NCCS, Pune, India

The organ specific heterogeneity of endothelial cells points toward their ability to adapt to the tissue environment and become genetically or phenotypically unique from other endothelial cell types of the body. In glioblastoma, high amount of angiogenesis is a result of steadily proliferating endothelial cell populations via paracrine interactions with glioma cells. Here, we show that human glioblastoma derived endothelial cells (hGECs) are auto-angiogenic, but remain untransformed in nature and that cross-talk of endothelial cells-glioma cells enhance angiogen-

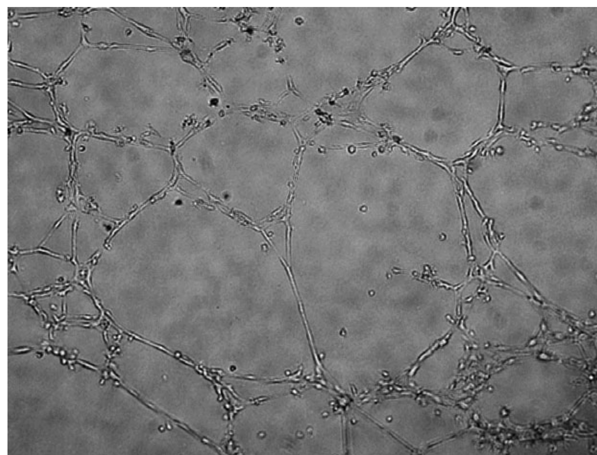

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

esis via exosome mediated pathway. Although, hGECs showed resistant to glioma chemotherapeutic drug temozolomide induced apoptosis, they remain dependent on glioma cell secreted factors for their survival during in vitro matrigel tube formation assay. Interestingly, when incubated with glioma cell derived exosomes, hGECs showed upregulated angiogenesis as a result of increased initial endothelial cell migration. Also, we show that glioma cells can activate normal brain endothellial cells thus making them proangiogenic in nature.

TUE-100
Expression of AID in malignant melanoma with BRAFV600E mutation

M. Nakamura, R. Okura, H. Yoshioka, M. Yoshioka, K. Hiromasa, D. Nishio
Department of Dermatology, University of Occupational and Environmental Health, Kitakyushu, Japan

BRAF-activating somatic mutations often exist in malignant melanoma. Malignant melanoma is classified into four subtypes: skin melanomas without chronic sun-induced damage (non-CSD), skin melanomas with chronic sun-induced damage (CSD), acral melanomas, and mucosal melanomas. A previous Japanese study has revealed that *BRAF* mutations were found in 26.7% of Japanese melanoma patients: 71.4% in CSD, 55.2% in non-CSD, 9.1% in acral melanoma, and 5% in mucosal melanoma. The underlying molecular mechanism of somatic *BRAF*-mutation inductions remained to be clear.

Activation-induced cytidine deaminase (AID), a member of a cytidine deaminase family, is essential for somatic hypermutation and class-switch recombination, in immunoglobulin genes. Recently, several studies have shown that abnormally expressed AID acts as a genome mutator that contributes to malignancy such as adult T cell leukemia/lymphoma (ATLL) and chronic active Epstein-Barr virus infection (CAEBV). Another protein APOBEC3B was reported to be an enzymatic source of mutation in breast cancer.

Chronic ultraviolet ray irradiation may play a role in causing *BRAF* mutations in CSD, however, *BRAF* mutations in non-CSD cannot be explained by the ultraviolet ray irradiation.

To explore the correlation between the AID and APOBEC3B expression and *BRAF* mutations, we performed the immunohistochemical study for 16 Japanese melanoma patients. As the previous report from a Japanese group, $BRAF^{V600E}$ mutation was predominant in malignant melanoma patients in our department and any other mutation was not found. Nine out of 10 AID malignant melanoma specimens with high AID expression in our study contained $BRAF^{V600E}$ mutation, while none of the 6 malignant melanomas with low AID expression had $BRAF^{V600E}$ mutation. All 9 melanomas with $BRAF^{V600E}$ mutation in our study took place in the region without chronic ultraviolet irradiation.

In contrast, 5 out of 9 malignant melanoma specimens with high APOBEC3B expression contained $BRAF^{V600E}$ mutation, while 4 of the 7 malignant melanomas with low APOBEC3B expression had $BRAF^{V600E}$ mutation.

We next examined the prognosis of each malignant melanoma patient for one to 4 years. Eight out of 10 malignant melanoma patients with high AID expression develop multi-organ metastases and/or multiple lymph node metastases afterwards during the follow-up, while no metastasis has been observed in melanoma patients with low AID expression during our follow-up until now. However, the sample size was not large enough in this study to perform multivariate analysis to show the relationship between AID expression and the prognosis of malignant melanoma.
Keywords: AID, BRAF, melanoma.

TUE-102
Expression of CRABP1 and CRABP2 in non-small cell lung cancer

I. Favorskaya, Y. Kainov, E. Tchevkina, I. Zborovskaya, **A. Komelkov**
N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Retinoic acid (RA) is the most active derivative of vitamin A and regulates proliferation, differentiation and apoptosis of normal and transformed cells. Cellular retinoic acid binding proteins (CRABP1 and CRABP2) are important modulators of RA-dependent signaling. Despite the role of RA in carcinogenesis seems to be well defined, participation of CRABPs in tumor development remains poorly investigated. Several studies showed abnormal expression of CRABPs in human tumors and its association with clinicopathological features. Up to date, almost nothing is known about CRABP1 and CRABP2 expression in non-small cell lung cancer (NSCLC).

Here we studied the simultaneous mRNA expression of CRABPs in 48 NSCLC samples using quantitative real-time PCR. Data were analyzed with respect to clinicopathological characteristics. We observed elevated expression of CRABP1 and CRABP2 in 42% and 56% cases, respectively. Decrease of CRABP2 expression was significantly associated with the presence of lymph node metastases ($P < 0.05$). We also revealed significant positive correlation between expression of CRABP1 and CRABP2. The strongest correlation was detected in well and moderately differentiated tumors (Spearman‘s rank correlation coefficient was 0.6, $P < 0.05$).

Overall, we found the significant alterations in CRABP1 and CRABP2 expression in NSCLC samples. Obtained results provide the first evidence of possible implication of CRABPs to lung cancer progression.
Keywords: CRABP1, CRABP2, non-small cell lung cancer.

TUE-103
Fad104, a regulatory factor of adipogenesis, negatively regulates invasion and metastasis of cancer cells.

D. Katoh, M. Nishizuka, S. Osada, M. Imagawa
Mol. Biol., Grad. Sch. of Pharm. Sci., Nagoya City University, Nagoya, Japan

Fad104 (Factor for adipocyte differentiation 104) is a regulator of adipogenesis. Previously, we showed that *fad104* regulated cell adhesion, migration and proliferation. Since *fad104* regulated cell migration, it was thought that *fad104* regulated invasion and metastasis of cancer cells. In the present study, we clarified the role of *fad104* in invasion and metastasis of melanoma cells.

Using quantitative PCR and Western blotting, we first analyzed the expression levels of *fad104* in highly metastatic A375SM cells and poorly metastatic A375C6 cells. The expression level of *fad104* in A375SM cells was lower than that of A375C6 cells. Next we assessed the effect of *fad104* on invasion of cancer cells using transwell assays. A375C6 cells transfected with *fad104* siRNA increased in the number of invaded cells compared with control cells transfected with luciferase siRNA. In contrast, *fad104*-expressing adenovirus-infected A375SM cells showed a reduction in invasion compared with b-galactosidase-expressing adenovirus-infected A375SM cells (control cells). Furthermore, the expression of matrix metalloproteinase 2 in *fad104* overexpressing A375SM cells was lower than that of control cells. These results suggest that *fad104* suppresses invasion of cancer cells. We next investigated

© 2014 The Authors. FEBS Journal © 2014 FEBS

whether *fad104* contributed to metastasis. We first produced murine melanoma cells B16F10 stably expressed *fad104* and we assessed the ability of *fad104* to form colonization in lung *in vivo*. As a result, *fad104* over expressing B16F10 cells showed a reduction in lung colonization. This result suggests that *fad104* negatively regulates metastasis of melanoma cells.

Next, we investigated the molecular mechanism by which *fad104* regulated invasion and metastasis of cancer cells. In melanoma cells, various signaling pathways, such as janus activated kinase (JAK)-signal transducer and activator of transcription (STAT) play essential role for invasion and metastasis. Therefore, we verified the effect of *fad104* on JAK-STAT signaling pathway. Overexpression of *fad104* reduced the phosphorylation level of STAT3. Furthermore, depletion of *fad104* increased phosphorylation level of STAT3. These results suggest that *fad104* inhibits JAK-STAT signaling pathways.

In summary, we demonstrated that *fad104* suppressed activation of STAT3 and controlled invasion and metastasis of melanoma cells.

Keywords: metastasis, signal transducer and activator of transcription 3 (STAT3).

TUE-104

Fragment of mucin MUC1 extracellular domain enhances metastatic potential of cancer cells in vitro

M. Syrkina[1,2], M. A. Rubtsov[2], J. D. Kondratenko[2], V. P. Veiko[1]

[1]*Laboratory of Molecular Engineering, A.N.Bakh Institute of Biochemistry RAS,* [2]*Department of Molecular Biology, Lomonosov Moscow State University, Moscow, Russian Federation*

The speculations about the role of MUC1 which is known to be overexpressed in glandular cancers on metastatic potential of cancer cells originate from the data indicating that cell malignization correlates with the change of apical mucin MUC1 localization to peripheral [1]. But the role of MUC1 in cancer metastasizing is not clear yet [2-4]. The major problem is the absence of adequate cell models. The aim of this study was to create cell models presenting different fragments of human mucin MUC1 extracellular domain on cell surface.

Genetic constructions were generated on the basis of plasmid vector pEGFP-N3. These constructions contain fusion genes coding chimeric proteins composed of different combinations of mucin MUC1 functional domains and identification markers – FLAG-epitope located at the N-terminus and EGFP located at the C-terminus of the chimeric proteins. The constructions were used for stable transformation of human cancer cells HT-29. Transformants obtained were characterized by means of flow cytometry. Low expression level of endogenous mucin MUC1 and high expression level of the recombinant proteins were confirmed by real-time PCR. Microscopic examination of transformed cells confirmed localization of fusion proteins on its plasmatic membrane. Cells obtained are used to be a quite applicable model of MUC1-expressing cancers and might be used for study the role of different functional fragments of mucin MUC1 in metastasizing.

Cells obtained were tested for the ability to penetrate and migrate through the endothelium by using an artificial system. It was shown that the expression of fragments of mucin MUC1 extracellular domain leads to an increase in the proportion of cells capable to overcome the endothelial barrier. Furthermore, a fragment has been identified, the presentation of which on the cell surface leads to the greatest increase in the proportion of cells migrated.

This work is partially supported by: RFBR grant 12-04-31721 and MSERF grant 8800.

From ancient formula to modern drug: exploring the Chinese herbal medicine toward cancer therapy

Y.-H. Liu[1,2], J.-Y. Lin[3,4]

[1]*Graduate Institute of Integrated Medicine, China Medical University,* [2]*Department of Medical Genetics and Medical Research, China Medical University Hospital, Taichung,* [3]*Institute of Biochemistry and Molecular Biology, College of Medicine, National Taiwan University,* [4]*Department of Life Science, National Taiwan Normal University, Taipei, Taiwan*

Chinese herbal medicine (CHM) has been historically used in cancer therapies by skillful Chinese medical doctor for thousands of years. Some clinical used anti-cancer therapeutic agents such as camptothecin, taxol or vinblastine, are derived from CHM that recorded as poisonous herbs. Although the current agents show promising to fight cancers, most of them are with significant side effects including killed the normal cells concomitantly, prompting increased interest in discovering more safety formula or compound toward alternative anti-cancer therapy.

In others and our previous studies, several cancer-associated genes have been identified. CD74, a nonpolymorphic integral membrane protein which has several functions in MHC class II-restricted antigen presentation, is up-regulated in various kinds of cancers thus been suggested to play an important role in oncogenic functions suchas as cancer cell growth and motility. Here we will address the roles of CD74 in oncogenic functions of cancer cells in vitro and in vivo. The regulatory effects and the signaling transduction pathways will be discussed. In addition, we will further show our new findings about CD74-targeted CHM and compound screening: from all selected 400 CHM extracts, more than 40 CHM extracts are identified as high-ranking cell-permeable, low-toxic ones by the two-dimensional high throughput living cell-based screening platforms. Based on the results

© 2014 The Authors. FEBS Journal © 2014 FEBS

aforementioned, one potential formula, JYCE-102, is selected at the first notch as a potential CD74-targeted agent using cell-based enzyme-linked immunosorbent approaches. The regulatory mechanisms and the signaling transduction pathways of JYCE-102 and its compounds toward oncogenic functions are compared in vitro and in vivo, suggesting its potential as a therapeutic option.

Functional potential of sulfonamide derivative compounds in the regulation of hypoxia induced carbonic anhydrase 9 (CA9) in human brain cancer

H. M. Said[1], C. Hagemann[2], F. Carta[3], A. Katzer[1], M. Flentje[1], C. T. Supuran[3]
[1]Radiation Oncology, [2]Neurosurgery, Medical Faculty, University of Würzburg, Würzburg, Germany, [3]Organic Chemistry, Faculty of Science, University of Firenze, Firenze, Italy

Genes regulated by Hypoxia induced HIF-1α are mainly responsible for tumour resistance to radiation- and chemo-therapy. Among these genes, carbonic anhydrase isoform IX (CA9) is highly over expressed in many types of cancer especially in high grade brain cancer like Glioblastoma (GBM). Inhibition of the enzymatic activity by application of specific chemical CA9 inhibitor sulphonamides (CAI) like Acetazolamide (Aza.), the new Sulfonamide derivative carbonic anhydrase inhibitor (SU.D2) or indirect inhibitors like the HIF-1a inhibitor Chetomin or molecular inhibitors like CA9-siRNA are leading to an inhibition of the functional role of CA9 during tumorigenesis. Human GBM cells were treated with *in vitro* hypoxia (1, 6, or 24 h at 0.1%, O_2). Aza. application was at a range between 250 and 8000 nM and the HIF-1α inhibitor Chetomin at a concentration range of 150–500 nM. Cell culture plates were incubated for 24 h under hypoxia (0.1% O_2). Further, CA9-siRNA constructs were transiently transfected into GBM cells exposed to extreme hypoxic aeration conditions. CA9 protein expression level was detectable in a cell-type specific manner under normoxic conditions. Whereas U87-MG exhibited a strong aerobic expression,. Aza. as well as SU.D2 displayed inhibitory characteristics to hypoxia induced CA9 expression for 24 h of hypoxia (0.1% O_2) at concentrations between 3500 and 8000 nM, on both the protein and mRNA level. Chetomin application under similar oxygenation conditions led to a sharply reduced expression of both CA IX protein and CA9 mRNA levels, indicating a clear glucose availability involvement. In GBM therapy, either the tumour is eradicated or to convert it into a controlled, quiescent chronic disease. Aza., SU.D2, Chetomin or CA9-siRNA possesses functional CA9 inhibitory characteristics when applied against human cancers with hypoxic regions like GBM. Therefore, they can applied as potential optimal tools for the development of a developed anti cancer therapy in human brain cancer patients.
Keywords: Cancer, Hypoxia, Carbonic Anhydrase 9 (CA9).

TUE-107
FUT11 as a potential biomarker of clear cell renal cell carcinoma progression based on meta-analysis of gene expression data

E. Zodro[1], M. Jaroszewski[1], A. Ida[2], T. Wrzesiński[1], Z. Kwias[2], J. Wesoy[1]
[1]Laboratory of High Throughput Technologies, Adam Mickiewicz University, [2]Department of Urology, Poznań University of Medical Sciences, Poznań, Poland

Background: Renal cell carcinoma (RCC) is the most common type of kidney cancer that accounts for 2% of the world total of all adult malignancies. The majority of ccRCC cases are detected incidentally and diagnose at the late stage due to asymptomatic course of the disease. As a result it is difficult to treat and rarely cured once spread beyond the kidney.
Observation: We provide a comprehensive summary of available clear cell renal cell carcinoma (ccRCC) microarray data in the form of meta-analysis of genes differentially regulated in tumors as compared to healthy tissue, using effect size to measure the strength of a relationship between the disease and gene expression. Twelve Affymetrix studies of biopsy confirmed, primary ccRCC samples with TNM, F grades, or WHO classifications were included. The data, in the FLEO format, were obtained from ArrayExpress and Gene Expression Omnibus. Arrays were normalized using the Robust Multichip Average method. Eight studies fulfilled inclusion criteria and 222 tumor and 85 control samples were subjected to the analysis. For each array type, the probes were mapped to version 14 Unigene gene identifiers. Moreover, tumors from patients from Western Poland who were diagnosed with urological carcinomas were collected. The tissues were histopathologically verified as ccRCC and screened for VHL mutations, promoter methylation, expression of VHL, HIF1A and EPAS1, and LOH.
Results: We identified 725 differentially regulated genes, with a number of interesting targets, such as TMEM213, SMIM5, or ATPases: ATP6V0A4 and ATP6V1G3, of which limited or no information is available in terms of their function in ccRCC pathology. Downregulated remodeling, blood clotting, vasodilation, and energy metabolism, while upregulated genes were classified into pathways generally deregulated in cancers: immune system response, inflammatory response, angiogenesis, and apoptosis. One hundred fifteen deregulated genes were included in network analysis, with EGLN3, AP-2, NR3C1, HIF1A,and EPAS1 (gene encoding HIF2-α) as points of functional convergence, but, interestingly, 610 genes fail previously identified molecular networks. Furthermore, we validated the expression of 14 top deregulated genes in independent sample set of 32 ccRCC tumors by qPCR and tested if it could serve as a marker of disease progression. We found a correlation of high fucosyltransferase 11 (FUT11) expression with non-symptomatic course of the disease, which suggests that FUT11's expression might be potentially used as a biomarker of disease progression.

TUE-108
Gain-of-function PDGFRB mutations associated with familial infantile myofibromatosis are sensitive to imatinib

F. A. Arts[1], D. Chand[2], A. Velghe[1], B. Hallberg[2], J.-B. Demoulin[1]
[1]De Duve Institute, University of Louvain, Brussels, Belgium, [2]Department of Molecular Biology, Umea University, Umea, Sweden

Infantile myofibromatosis is the most prevalent tumor of soft tissue of childhood. It is characterized by the presence of nodules in the skin, the subcutaneous soft tissues, the bones or the viscera. Recently, germline and somatic heterozygous *PDGFRB* mutations have been associated with familial infantile myofibromatosis (FIM) but have not been functionally characterized. Platelet-derived growth factor receptors (PDGFRA and PDGFRB) are tyrosine kinase receptors that stimulate cell proliferation and motility. Until now, no activating point mutation in *PDGFRB* has been described in cancer. Therefore, the aim of this work was to characterize these new mutations. For this purpose, we transiently expressed three PDGFRB mutants associated with FIM (R561C, P660T and N666K) in HT-1080 cells, a fibrosar-

© 2014 The Authors. FEBS Journal © 2014 FEBS

coma-derived human cell line. The analysis of the signaling pathways downstream these mutants showed that, in the absence of ligand, the somatic N666K mutant strongly activated mitogen-activated protein kinases (ERK), phospholipase Cγ and signal transducer and activator of transcription 3 (STAT3). The germline R561C mutant was less active than the N666K mutant whereas the P660T mutant showed no difference with the wild-type receptor. Moreover, in foci formation assays with NIH3T3 cells, we observed that the N666K mutant and, to a lesser extent, the R561C mutant were able to transform cells, unlike the P660T mutant. Interestingly, both activated mutants, namely R561C and N666K, were sensitive to imatinib (Gleevec®). Altogether, our results indicate that two of the three reported FIM-associated mutations, R561C and N666K, activate PDGFRB, supporting the hypothesis that these mutations cause the disease. The lower activity of the R561C mutant compared to N666K is consistent with the fact that the first mutation is a germline one whereas the second mutation is somatic. Moreover, imatinib seems to be a promising treatment for patients with visceral tumors carrying these two mutations. To our knowledge, these are the first confirmed gain-of-function point mutations of *PDGFRB* in human cancer.

Gastrointestinal cancer risk associated with PARP1 (ADPRT) Val762Ala polymorphism

D. Uslu[1], M. A. Korpinar[1], F. Shimamoto[2], S. Erdamar[1], H. Tuncel[1]
[1]*Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey,* [2]*Prefectural University of Hiroshima, Hiroshima, Japan*

Poly (ADPribose) polymerase 1 (PARP-1) is a DNA double strand break recognizing protein. and its activation is one of the early responses to DNA damage. PARP-1 gene consists of 23 exons and spans about 47.3 kb which is localized on chromosome 1q41–42. Several SNPs have been found in PARP1 gene, but only for the Val762Ala (rs1136410) a functional analysis has been performed. PARP-1 Val762Ala was well-known to be associated with increased risk of several cancers. Colorectal cancer is one of the most common human malignancies in the world.

A total of 120 paraffin-embedded colorectal cancer and normal specimens were obtained from department of pathology in Cerrahpasa Medical Faculty. These normal tissues were used from same cases as a control group. Archival formalin-fixed, paraffin wax-embedded tissue was used. A single block representative of the tumor was selected in each case and the same block was used for PCR-RFLP. Tissue sections (10 μm) were prepared from formalin fixed, paraffin-embedded colorectal tissues. The sections were stained with hematoxylin and eosin (HE) for histologic examination. Tissue sections were dehydrated in a graded ethanol series, and then dried without a cover glass. Tissue samples from 60 tumors and corresponding 60 normal tissues were cut with sterile needles, and the DNA was extracted with 50 μl extraction buffer (100 mmol/L Tris-HCl, pH 8.0, 2 mmol/L EDTA, 400 μg/mL proteinase K) at 55°C overnight. The tubes were boiled for 15 min to inactivate proteinase K, and 5 μl of each extract was used for polymerase chain reaction (PCR). The primers used in the amplification were: PARP-F -TTTGCTCCTCCAGGCCAACG-3, and PARP-R 5-CATCGATGGGA TCCTTGCTGCT-3, which produce a 110-bp fragment. Polymerase chain reaction–restriction fragment length polymorphism (PCR–RFLP) method was used to detection of the polymorphism in PCR products by digestion with 10 units of Acc II restriction endonuclease. Fragmented PCR products, stained with ethidium bromide, were analyzed after agarose gel electrophoresis. All analyses were performed using the Statistical Package for the Social Sciences (SPSS).

Overall, this updated our previous study allowed us to provide a more precise relative risk estimate regarding the association between PARP1 Val762Ala polymorphism and cancer susceptibility. These findings suggested that the PARP1 Val762Ala polymorphism may play a role in gastrointestinal cancer development.

Genome wide investigation of genes regulated by Beta-catenin in AML

T. Ozkan[1,2], B. Altinok Zaim[2,3], A. Karadag[1], H. Ozdag[2], N. Sayinalp[4], B. Doganay Erdogan[5], A. Sunguroglu[1]
[1]*Department of Medical Biology, Faculty of Medicine, Ankara University,* [2]*Biotechnology Institute,* [3]*Vocational School of Health, Ankara University,* [4]*Department of Internal Medicine, School of Medicine, Hacettepe University,* [5]*Department of Biostatistics, School of Medicine, Ankara University, Ankara, Turkey*

Acute Myeloid Leukemia (AML) is a disease characterized with impairment of normal hematopoetic proliferation, differentiation and accumulation of abnormal immatured myeloid cells in bone marrow and periferic blood which occurs as a result of genetic changes in early hematopoietic stem cells. Wnt/β-catenin signaling is an evolutionarily conserved signal transduction pathway that governs cell fate decisions during embryogenesis at the stem cell level. Wnt signaling which is known to be activated both in the early embryonic period and various cancer types has been taking serious attention because it is known that lots of genes in this pathway causes neoplastic transformation. β-catenin plays the central role in this pathway. β-catenin is a cytoplasmic protein which translocates to the nucleus via Wnt signal activation. Thus it activates transcription of lots of genes most of which are oncogenes. ChIP-chip is a new technology which combines chromatin immunoprecipitation (ChIP) and microarrays (chip) to determine DNA-protein interactions in cells. It has become an ideal approach to define genome-wide transcription factor targets or chromatin modification regions. In this study, genome-wide promotor binding regions of β-catenin translocated to nucleus was identified by ChIP-chip method. For this purpose, CD34 + hematopoietic stem cells of AML patients with high β-catenin gene expressions were cultured and genome-wide promotor binding sites of β-catenin were determined. It was found that β-catenin binded approximately 16.000 target genes in AML patients and 8000 target genes in the control group. The results showed all probable genome-wide targets of β-catenin protein in AML for the first time.

Keywords: AML, β-catenin, ChIP-chip.

Growth hormone-releasing hormone (GHRH) activates E-cadherin/β-catenin signalling pathway in human prostate cells

M. J. Carmena, L. Muñoz Moreno, J. Prieto, A. M. Bajo
Sistems Biology, Universidad de Alcalá, Alcala de Henares, Spain

Growth hormone-releasing hormone (GHRH) and its receptors have been implicated in a variety of cellular phenotypes related with tumorigenesis. The E-cadherin/β-catenin complex is involved in the regulation of processes including growth, migration and adhesion in various cancers. The aim of this work was to study

© 2014 The Authors. FEBS Journal © 2014 FEBS

the involvement of GHRH in E-cadherin/β-catenin signalling pathway. We used three human cell lines: non-tumour prostate epithelial cells (RWPE-1) and prostate cancer cells (LNCaP, androgen-dependent; PC3, androgen-independent). GHRH (0.1 μM) significantly decreased E-cadherin levels, following a time-dependent pattern, in LNCaP and PC3 cells but not in RWPE-1 cells. Conversely, GHRH up-regulated the expression of β-catenin in tumour cells but not in non-malignant cells. In addition, we analysed the subcellular localization of β-catenin in PC3 cells. The results show that the decrease of the cytoplasmic expression of β-catenin is linked to increased protein level into the nucleus after treatment with neuropeptide. The increased level of β-catenin protein into the nuclei of PC3 cells may induce the transcription of target genes involved in the progression of cell cycle. Thus, we assessed the mRNA expression levels of CD44, c-myc, and cyclin D1 in GHRH-treated PC3 cells. Results show that GHRH increased mRNA levels of the three genes evaluated in a time-dependent manner. The present findings shed more light on the involvement of GHRH and E-cadherin/β-catenin signalling pathway in prostate carcinogenesis process.

TUE-112
Growth hormone-releasing hormone (GHRH) and GHRH antagonists JMR-132 and JV-1-38 modulate metastatic processes in human prostate cells

L. Muñoz Moreno[1], J. Prieto[1], M. J. Carmena[1], A. V. Schally[2], A. M. Bajo[1]
[1]Biology of Sistems, Univesity of Alcala, Alcalá de Henares, Spain, [2]Division of Oncology and Hematology, Veterans Administration Medical Center and Departments of Pathology and Medicine, University of Miami Miller School of Medicine and South Florida Veterans Affairs Foundation for Research and Education, Miami, FL, USA

Prostate cancer accounts with 29% of all new cancer cases and is the second leading cause of cancer-related deaths among men in the Western world. New treatment options are needed to prevent the progression of prostate cancer toward androgen-independent stage. The aim of this work was to compare the expression of GHRH receptors (pGHRHR) and their splice variants (SVs) as well as the effect of GHRH and its antagonists (JMR-132 and JV-1-38) on viability, proliferation and adhesion in human prostate cells. We used two cell lines: non-tumor human prostate epithelial cells (RWPE-1) and androgen-dependent prostate cancer cells (LNCaP). Higher expression levels of pGHRHR and vice versa for their SVs were detected in LNCaP cells as compared with those in RWPE-1 cells using Western blot analyses and immunocytochemistry. We subjected the cells to a mitochondrial enzymatic (methylthiazoletetrazolium; MTT) assay and a bromodeoxyuridine (BrdU)-incorporation assay in order to assess their viability and proliferation, respectively. After treatment with GHRH (0.1 μM), significant increases of viability and proliferation were observed in both types of cells. Conversely, viability was significantly decreased after treatment with GHRH antagonists (0.1 μM) in RWPE-1 cells as well as after treatment with JMR-132 in LNCaP cells. In addition, GHRH antagonists induced a significant decrease in the proliferation of LNCaP cells. Cell adhesion to collagen decreased after exposure to GHRH, while it was augmented after treatment with GHRH antagonists, JMR-132 and JV-1-38.

The antagonists used block GHRH receptors and, in turn, reduce tumor progression induced by autocrine/paracrine mechanisms of GHRH. The results shed light on the effect of GHRH and its antagonist in non-tumor prostate cells and androgen-dependent prostate cancer cells. These findings support the effectiveness of JMR-132 and JV-1-38 on proliferation and adhesion in androgen-dependent prostate cancer.

This work was supported by the Junta de Comunidades de Castilla-La Mancha [grant number PII10-0189-3222 to A.M.B.] and by the University of Alcalá [FPU/UAH grant to L.M.M.].

GSK-3beta kinase controls Notch3 protein stability and subcellular localization in EMT phenotype acquisition of cancer cells

G. Diluvio[1], G. Franciosa[1], F. Del Gaudio[1], S. Checquolo[2], I. Screpanti[1]
[1]Medicina Molecolare, Univesità La Sapienza Di Roma, Rome, [2]Scienze E Biotecnologie Medico-Chirurgiche, Università La Sapieza Di Roma, Latina, Italy

Notch receptors participate in a highly conserved signalling pathway that regulates different cellular processes including cell proliferation, differentiation, apoptosis and survival. Deregulated Notch signaling has been implicated in the development of many diseases, including cancer. Moreover, increasing evidence correlates Notch pathway with drug-resistance of many tumors, through different mechanisms including the acquisition of the epithelial-mesenchymal transition (EMT) phenotype, which is critically associated with tumor invasion and metastatis. In EMT, epithelial cells acquire fibroblast-like properties, reduced intercellular adhesion and increased motility. This process is associated with the functional loss of E-cadherin. Down-regulation of Notch signalling leads to partial reversal of the EMT phenotype, through the decreased expression of members of the Snail family of transcription factors, known to repress E-cadherin expression. Recent evidence reports that the specific activation of Notch3 (N3) in ovarian cancer cells causes a spindle and fibroblast-like morphology, induces the expression of smooth muscle α-actin, Slug and Snail and decreases the expression of E-cadherin, indicating that Notch3 activation is able to induce EMT in ovarian cancer cells. However, the general mechanisms that govern the acquisition of the EMT phenotype in cancer cells remain to be elucidated. We have previously demonstrated that Notch3 protein expression and/or stability can be modified by different post-traslational modifications and this is correlated with the regulation of leukemia development and progression. However, the mechanisms that modulate its expression levels, subcellular localization and function remain still elusive, even in solid tumors. Here, we demonstrate that N3 protein is regulated by Glycogen synthase kinase-3β (GSK-3β), a widely expressed and highly conserved serine/threonine protein kinase that plays important roles in several signaling pathways, including Notch signaling. Preliminary results obtained by using insertional mutants of N3 show that GSK-3β is able to interact with and to phosphorylate N3 at specific consensus motifs located inside its intracellular domain ($N3^{IC}$), leading to a regulation of $N3^{IC}$ function in terms of both protein stability and subcellular localization. Our subsequent studies will be focused to understand how the observed Notch3/GSK-3β relationship could be involved in controlling the EMT phenotype associated to tumour invasion and metastasis of breast cancer, in the purpose to improve future strategies for developing effective cancer treatments.

TUE-114
Haponin promotes cell death in oxidative stress by upregulating p53 transcriptional activity

E. Vorobyeva[1], N. Sharonova[1], A. Litvinenko[1], T. Rakitina[1,2], **E. V. Smirnova**[1], V. Lipkin[1]
[1]*Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry,* [2]*NRC Kurchatov Institute, Moscow, Russian Federation*

The excessive production of "reactive oxygen species" (ROS) in the cell results in nonhomeostatic state referred to as "oxidative" stress. ROS generated in response to endogenous or environmental stimuli have been shown to be implicated in aging, carcinogenesis, and the progression of various pathologies, such as cardiovascular diseases, neurodegenerative disorders, and inflammatory disorders.

Previously we have shown that cellular sensitivity to the oxidative stress directly correlates with the expression level of nuclear protein haponin [1]. Given the involvement of haponin in the cell death under the oxidative stress conditions [2] in conjunction with the previously demonstrated haponin ability to bind GAPDH [3] we have suggested that haponin appears to be involved in GAPDH-mediated p53-dependent apoptosis induced by oxidative stress [4].

Using the panel of cell lines with the altered levels of haponin expression we showed that silencing of haponin expression with siRNA decreased cell death induced by oxidative stress. On the contrary, haponin overexpression promoted cell death under oxidative conditions. Furthermore, we have demonstrated that in oxidative stress nucleus condensation and nucleosomal ladder accumulation are dependent on the hapopnin expression level suggesting that haponin modulates apoptotic cell death. We have found that haponin overexpression stabilizes p53 in the cells and increases its presence in the nucleus. In addition we have shown that haponin siRNA inhibits p53 transcriptional targets activation induced by oxidative stress. Taken together these data indicate that haponin is involved in the regulation of p53 transcriptional activity supposedly through GAPDH-mediated acetylatin of p53.

Growth factors, such as the Platelet-derived growth factor (PDGF) or the Fibroblast-growth factor (FGF), induce cell proliferation, migration and differentiation through the activation of different signaling mediators such as the phosphatidylinositol-3 kinase-AKT pathway. Downstream growth factor receptors, AKT inhibits the activity of the Forkhead box O transcription factors (FOXO1, FOXO3, FOXO4 and FOXO6) and represses their expression. The transcription factors FOXO are involved in cell cycle arrest, DNA damage repair, apoptosis and resistance to oxidative stress. They also play an important role in the control of cell proliferation in response to PDGF. Our results showed that FOXO regulated the HMG-box protein 1 (HBP1) expression in different cell types including normal fibroblasts and cancer cells. HBP1 is a transcription factor that plays a role in the control of cell cycle, in premature senescence induced by an oncogene and in cell differentiation.

The analysis of different microarray data led us to the identification of HBP1 as a target gene downstream of the growth factors – PI3K – AKT - FOXO pathway: its expression was down-regulated by PDGF, FGF4 and by two oncogenic forms of the PDGF receptors (Fip1L1-PDGFRα and TEL-PDGFRβ), by constitutively-activated PI3K and AKT, and it was up-regulated by FOXO3 and FOXO4. These results were confirmed by quantitative RT-PCR and Western blot in several cellular models. To further investigate the regulation of HBP1 by FOXO, we analyzed the HBP1 promoter and we identified a potential FOXO-binding site. We cloned the promoter of HBP1 in a luciferase reporter vector and we showed that FOXO1, FOXO3 and FOXO4 induced the activity of HBP1 promoter. We confirmed the localization of the binding site by mutating two residues, which abolished the promoter activity in response to FOXO. The binding of FOXO on HBP1 promoter was then confirmed by chromatin immunoprecipitation (ChIP) and by ChIP-sequencing. Using two HBP1-specific shRNA, we showed that HBP1 played a role in cell proliferation in normal fibroblasts: indeed, HBP1 down-regulation promoted cell proliferation. Finally, HBP1 and FOXO1 expression was decreased in breast cancer. To investigate a possible link between FOXO and HBP1 in these tumors, we analyzed data from The Cancer Genome Atlas (TCGA) and showed that tumors with decreased FOXO1 expression expressed less HBP1, in agreement with our data.

In conclusion, our study identifies HBP1 as a mediator of the PI3K-AKT-FOXO pathway and a regulator of proliferation downstream growth factor receptors in normal and tumor cells.

Glioblastoma, the most common primary brain tumor, is characterized by high invasive potential and short survival. It is known that invasion depends on tumor microenvironment characteristics. Proteoglycans, complex glycosylated molecules, are key components of tumor microenvironment, playing critical role in cell-cell and cell-matrix interactions. Malignant brain tumors have individual proteoglycan profiles, which are closely associated with their differentiation and biological behavior. One of the causes of

© 2014 The Authors. FEBS Journal © 2014 FEBS

proteoglycans profiles changes may be dysregulation of their biosynthetic system.

In this study we examined the expression pattern of heparan sulfate proteoglycan metabolic enzymes in human brain tumors by RT-PCR and immunohistochemical analysis. Expression level of the most of the enzymes (EXT1/2, NDST1/2, OST1, SULF2) were consistent for different patients. But, interestingly, we showed the significant patient-to-patient variability of GLCE, SULF1 and HPSE expression, enzymes which have been shown to affect proliferation and invasion characteristics of tumors. We showed loss of GLCE expression for 70% of the patients. All of the anaplastic astrocytoma samples were characterized by loss of GLCE and SULF1 expression, but did not change HPSE expression. Analysis of glioblastoma patients showed consistent level of SULF1 expression and heterogeneity of GLCE and HPSE expression. Analysis of expression of these three enzymes revealed discrete groups of patients that can be associated with the clinical prognosis.

From these results, we suggest a new approach for the individualization of brain cancer diagnostics based on the expression pattern of heparan sulfate proteoglycan biosynthesis and degradation enzymes. It will result in more accurate diagnosis and personalized therapeutic strategy for brain cancer.

Hepatitis C virus suppresses HNF4α expression and modulates HNF4α-miR feedback circuit

I. Vallianou[1], N. Vassilaki[2], D. Dafou[1], P. Mavromara[2], M. Hadzopoulou-Cladaras[1]
[1]Department of Genetics Development and Molecular Biology, School of Biology, Aristotle University of Thessaloniki, Thessaloniki, [2]Molecular Virology Laboratory, Hellenic Pasteur Institute, Athens, Greece

Hepatitis C Virus (HCV) infection presents with a disturbed lipid profile and can evolve to hepatic steatosis and hepatocellular carcinoma (HCC). Hepatocyte Nuclear Factor 4α (HNF4α) is the most abundant transcription factor in the liver and the master transcription factor in hepatic lipid metabolism. We have previously shown that transient inhibition of HNF4α initiates transformation of immortalized hepatocytes through a feedback loop consisting of miR-24, miR-629, IL6 receptor (IL6R), STAT3, and miR-124, suggesting a central role of HNF4α in HCC. To investigate the effect of HCV replication on HNF4α circuit, Huh7-Lunet cells were electroporated with JFH1 isolate (genotype 2a). During the time course of HCV replication a decrease was observed in both RNA and protein levels of HNF4α. The decrease was also reflected in the downregulation of downstream targets, HNF1α and MTP (Microsomal Triglyceride Transfer Protein). HCV also up-regulated IL6R and activated STAT3 protein phosphorylation. Furthermore, the inverse correlation between HNF4α and miR-24 or miR-629 expression levels in HCV RNA electroporated cells was confirmed. Suppression of HNF4α expression was also validated in Huh7.25/CD81 cells inoculated with JC1 virus strain (genotype 2a) at m.o.i.: 2 (multiplicity of infection). HCV nucleocapsid core protein apart of its role in capsid formation is responsible for many virus-host interactions including usurping the host lipid metabolism mainly by modulating the activity of transcription factors involved in hepatic lipid metabolism. We therefore evaluated the effect of HCV core protein on the expression of HNF4α. Core protein overexpression also reduced HNF4α protein levels implying that HCV might exert its effect through core. Finally, the possible effect of viral proteins, core, non-structural (NS) 5A protein and the whole NS region (NS3-NS5B) on HNF4α promoter activity is being investigated using HNF4α promoter-luciferase constructs. Our findings demonstrated that HNF4α-miR circuit operates in HCV infection and confirm a pivotal role of HNF4α in HCC.

HNF4α silencing induced epithelial-to-mesenchymal transition (EMT) in 3D in vitro models of liver cancer

D. Dafou[1], I. Vallianou[1], P. Hytiroglou[2], T. Poutahidis[3], M. Hadzopoulou-Cladaras[1]
[1]Development Genetics and Molecular Biology, [2]Pathology and Anatomy, [3]Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Hepatocellular Carcinoma (HCC) represents the third most common cancer in mortality worldwide. The deregulation of the molecular signaling network of HNF4α-miR24, plays an important role in the mechanism of hepatocarcinogenesis. We aimed to study the process of Epithelial-to-Mesenchymal transition (EMT) in stable monoclonal HNF4α knock down (KD) liver cancer cells. We established monoclonal liver cancer cell lines (HepG2, Huh7) with different expression levels of HNF4α (KD) using lentiviral transduction methods followed by analysis of HNF4α expression levels in RNA (Real-Time qPCR) and protein (Western). HNF4α_KD cells were then cultured as multicellular spheroids, which better recapitulate the 3 Dimensional (3D) tissue microenvironment *in vitro*.

Quantification of EMT markers revealed a correlation of increased HNF4α_KD with increased expression of mesenchymal (N-cadherin, Vimentin), reduced expression of epithelial markers (E-cadherin) and altered expression of EMT master inducers (SNAIL, ZEB1/2, TWIST). Clones were further analyzed for: size of 3D spheroids, cellular context by immunohistochemistry for hepatic protein markers (a-fetoprotein, HEPAR1), viability (Ki67), and apoptosis (Live/Dead Assay) and changes in migratory and metastatic ability (Scratch Assay, Anchorage Independence Growth Assay, Invasion Assay), respectively. Similar gene expression profiles were analyzed in 3D *in vitro* models of HNF4α silencing by transient overexpression of miR24 in liver cancer cells followed by validation of protein expression by immunohistochemistry. Furthermore, we observed for the first time the induction of the Notch and TGFβ signaling pathways in these cellular models by Real Time qPCR Arrays, thus contributing to induction of EMT. The data collectively indicate that reduced expression of HNF4α induces EMT in liver cancer cells.

HNRNPK protein profile in acute promyelocytic leukemia cell lines (NB4 and NB4-R2): role in cell differentiation and survival

K. Stringhetta[1,2], L. J. Greene[2], E. M. Rego[2,3], C. Curti[4], A. M. Leopoldino[1,2]
[1]Department of Clinical Analyses, Toxicology and Food Sciences, School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, [2]CEPID-FAPESP, Center for Cell Therapy, Hemotherapy Center of Ribeirão Preto, [3]School of Medicine of Ribeirão Preto, University of São Paulo, [4]Department of Physics and Chemistry, School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Heterogeneous nuclear ribonucleoprotein K (hnRNPK) participates in several processes such as chromatin remodeling, transcription, RNA splicing and translation. Recently, hnRNPK has been considered a prognostic marker in different types of cancer and implicated in the progression of chronic myeloid leukemia. The role of hnRNPK in leukemogenesis and cell differentiation in acute promyelocytic leukemia (APL) has not been established. APL is mainly caused by t(15,17), which generates an oncoprotein capable of blocking the differentiation of myeloid progenitors at the promyelocyte phase. Treatment with all-trans retinoic acid (ATRA) restores the process of cell differentiation, but fails to produce the same effect in patients with syndrome of resistance to ATRA. The aim of this study was to establish the role of hnRNPK in the APL using NB4 and NB4-R2 cell lines, which are responsive and resistant to the treatment with ATRA, respectively, as well as a possible role of hnRNPK in ATRA-induced cellular differentiation. Analysis by western blotting revealed that hnRNPK level in NB4 cells is lower than in NB4-R2 after ATRA treatment (96 h). In addition, changed the subcellular location of hnRNPK in NB4 cells increasing the isoform b in the cytoplasm in association with cellular differentiation, as evidenced by increase in the Cd11b marker; this suggests a role of hnRNPK in ATRA-induced cellular differentiation. Both cell lines revealed higher level of hnRNPK than control samples (bone marrow, polymorphonuclear cells obtained from donors); this reinforce that the increase of hnRNPK protein is involved in leukemogenesis of APL. The knockdown of hnRNPK (shRNA) in NB4 e NB4-R2 cells promoted massive loss of cell viability due to induction of apoptosis; this suggests that hnRNPK is essential for NB4 and NB4-R2 cell survival and maintenance. NB4 and NB4-R2 cells with knockdown of hnRNPK revealed a decrease in hnRNPK downstream targets such as c-Myc, an oncogene, and Bcl-xL, an anti-apoptotic protein. Our findings appoint hnRNPK protein as up-regulated in APL and suggest its involvement with differentiation and survival.

HOXB5 promotes the proliferation and invasion of breast cancer cell

J.-Y. Lee[1], H. Hur[2], H. J. Yun[1], Y. Kim[3], S. I. Kim[2], M. H. Kim[1]
[1]Department of Anatomy, [2]Department of Surgery, Yonsei University College of Medicine, Seoul, [3]Department of Pathology, National Health Insurance Corporation Ilsan Hospital, Goyang, Korea, Republic Of

HOX transcription factors play an important role in determining body patterning and cell fate during embryogenesis. There has been accumulating evidence that these genes act as positive or negative modulators in many types of cancer, including breast cancer, in a tissue-specific manner. We have reported earlier that HOXB5 is aberrantly overexpressed in certain breast cancer cell lines and breast cancer tissues. Here we investigated the biological role and clinical relevance of HOXB5 in breast cancer. Immunohistochemical analysis of HOXB5 on tissue microarray (TMA) including 34 normal and 62 breast cancer (invasive ductal carcinoma) specimens revealed that HOXB5 was highly expressed in cancer tissues, particularly from ER-positive breast cancer patients. An online survival analysis confirmed the correlation between HOXB5 expression and poor distant metastasis-free survival in ER-positive, but not in ER-negative, breast cancer. In vitro study indicated that HOXB5 silencing in T47D cells significantly decreased cell proliferation and anchorage-independent cell growth. In contrast, MCF7 cells overexpressing HOXB5 displayed EMT characteristics with a greater invasive ability, cell proliferation and colony formation in soft agar. In conclusion, we suggest that HOXB5 acts as a positive modulator most likely by promoting cell proliferative response and invasiveness in ER-positive breast cancer.

Keywords: breast cancer, ER-positive, HOXB5.

TUE-121
Human glioblastoma cells are auxotrophic for arginine and sensitive to recombinant arginase I (Co)-PEG5000 [HuArgI (Co)-PEG5000]-induced arginine depletion

O. Khoury[1], A. Bekdash[1], E. Stone[2], A. E. Frankel[3], **R. J. Abi-Habib**[1]
[1]Department of Biology, Lebanese American University, Beirut, Lebanon, [2]Department of Biomedical Sciences, University of Texas, Austin, TX, [3]Simmons Comprehensive Cancer Center, UT Southwestern, Dallas, TX, USA

In this study, we attempt to target arginine auxotrophy in glioblastoma (GBM) cells using a recombinant human Arginase I cobalt [HuArgI(Co)] coupled with polyethylene glycol 5000 [HuArgI (Co)-PEG5000].

HuArgI (Co)-PEG5000 was tested on a panel of 9 human GBM cell lines (U251, U87-MG, T98, U118, Hs683, SF, A172, H4 and SW1088) and on normal human fetal glial cells (SVG p12).

All GBM cell lines tested were sensitive to HuArgI (Co)-PEG5000-induced arginine depletion with IC_{50} values ranging from 128-985 pM and a percent cell kill > 80%. Addition of exogenous L-citrulline failed to rescue cells from arginine depletion-induced cytotoxicity at doses of 1.14, 11.4 and 114 μM and led to the rescue of only 6 GBM cell lines at the highest concentration of 11.4 mM, reflecting the extent of arginine auxotrophy in GBM cells. The ability of excess L-citrulline to rescue cells was dependent on the expression of argininosuccinate synthetase-1 (ASS1) with the 3 cell lines that were not rescued by L-citrulline lacking ASS1 expression. In addition, siRNA Knock down of ASS1 reversed the ability of L-citrulline to rescue GBM cells from argi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

nine depletion-induced cytotoxicity, further illustrating that the lack of ASS1 expression is the underlying mechanism of complete arginine auxotrophy in these cells. Normal human fetal glial cells, on the other hand, expressed ASS1 and were not sensitive to the HuArgI (Co)-PEG5000-induced arginine depletion, demonstrating the selective toxicity of arginine depletion to GBM cells. Inhibition of autophagy increased GBM cell sensitivity to HuArgI (Co)-PEG5000 indicating that, under arginine deprivation, autophagy plays a protective role in GBM. Analysis of the type of cell death showed a lack of AnnexinV staining and caspase activation, in addition to positive PI staining and a high degree of fragmentation following HuArgI (Co)-PEG5000-induced arginine depletion. This demonstrates that arginine deprivation induces caspase-independent, non-apoptotic cell death in GBM cells.

In this study, we demonstrate that GBM cells are auxotrophic for arginine and are, subsequently, sensitive to HuArgI (Co)-PEG5000-mediated arginine depletion. We also demonstrate that lack of ASS1 expression is the underlying mechanism for complete arginine auxotrophy in GBM cells. Arginine depletion is, therefore, a novel targeted therapy for the potential treatment of GBM.

Human metastatic melanoma cells secrete pro-apoptotic 15d-PGJ2, when stressed with HMG-CoA reductase inhibitor, simvastatin

M. Hohenegger, C. Wasinger, M. Künzl
Pharmacology, Medical University Vienna, Vienna, Austria

Advanced stage melanoma treatment is still a challenge. Autocrine and paracrine signalling plays a crucial role in tumour cell communication, involving small immunogenic molecules like cytokines or prostaglandins. The atypical prostaglandin 15-deoxy-12,14-prostaglandin J_2 (15d-PGJ_2) is an endogenous agonist at the peroxisome proliferator-activated receptor gamma mediating inhibition of the NFkB pathway. Moreover, 15d-PGJ_2 shows anti-tumour activity in melanoma by suppression of metastasis and interaction with the tumour microenvironment.

Here we show that simvastatin evokes apoptosis in human metastatic melanoma cells in a p38 and COX2 dependent manner. Moreover, inhibition of the lipocalin prostaglandin D synthase also prevented activation of the mitochondrial pathway of apoptosis and guided us to the identification of 15d-PGJ_2 as the responsible mediator. Simvastatin treatment resulted in significant concentrations of 15d-PGJ_2 in the medium and cytosol of the melanoma cells, sufficient to activate caspase 8 and 9. Application of 15d-PGJ_2 triggered ROS formation and caspase 9 activation, which were grossly prevented by ROS scavenger N-acetylcysteine. Finally, 15d-PGJ_2 also activated caspase 8 and thereby confirmed 15d-PGJ_2 as the postulated suicide factor triggered by simvastatin in human metastatic melanoma cells.

Given the fact that statins are well tolerated, our results provide novel evidence and supportive rational for usage in adjuvant cancer therapy.

This work was supported by Herzfelder′sche Familienstiftung and the Austrian Science Foundation FWF (P-22385).
Keywords: 15d-PGJ2, apoptosis, melanoma.

TUE-123
Hypoxia impacts on adenosine metabolism and chemoresistance in glioblastoma stem like cells

C. A. Quezada, W. X. Garrido, R. Rocha, D. Uribe, C. Oyarzun, R. San Martín
Instituto De Bioquimica Y Microbiologia, Universidad Austral De Chile, Valdivia, Chile

Background: Glioblastoma multiforme (GBM) is the most common nervous system primary tumour with one of the worst prognosis of all cancers. Consistent studies have shown glioblastoma stem-like cells (GSCs) to be the tumourigenic population in GBM. Further, their particular properties are required for the extreme chemoresistance of this tumour. One of the most important mechanisms conferring chemoresistance is the overexpression of the ATP-binding cassette (ABC) family transporters, which extrude anticancer drugs from tumour cells, essentially Mrp1 in GBM. We have identified the nucleoside adenosine as a key endogenous modulator of Mrp1 in GBM cells. In addition, it has been recognized that hypoxia promotes therapeutic resistance in GBM. Consequently, our aim was to determine the role of hypoxia on both the adenosine production and the chemoresistant phenotype in GSCs.

Methods: Glioblastoma Stem-like Cells were derived from U87 cell line. Hypoxia was obtained in a chamber at 1% oxygen. The contents of Mrp1, Mrp3, adenosine A_3 receptor and 5′-ectonucleotidase were measured by western blots, flow cytometry and immunofluorescence. Mrp1 activity was estimated measuring the extrusion of the fluorescent substrate CDFA from cells. Adenosine levels were quantified in Tyrode's buffer in regulated oxygen conditions. 2-chloroacetaldehyde derivatives were quantified by HPLC. Cell viability was assayed by the MTT reduction method and flow cytometry. Cells were treated with AOPCP (50 μM, inhibitor of 5′-ectonucleotidase) and MRS1220 (10 μM, selective antagonist of adenosine A_3 receptor).

Observations: We quantified an increased capability for extracellular adenosine production in GSCs compared to differentiated cells. Correspondingly, we determined a higher expression of the 5′-ectonucleotidase, the rate limiting enzyme for adenosine production, and the adenosine A_3 receptor in GSCs under hypoxic conditions (20% vs 1% oxygen). We also found that the expression of the ABC transporters Mrp1 and Mrp3 were influenced by hypoxia. The expression and activity of Mrp1 were reduced under the treatment with a 5′-ectonucleotidase activity inhibitor or an adenosine A_3 receptor selective antagonist. Importantly, the viability of GSCs decreases by 50% under the vincristine treatment, an antitumour drug substrate of Mrp1, when combined with the antagonist of the A_3 receptor.

Conclusions: We have demonstrated the role of the purinergic signaling on the chemoresistance of GSCs. Furthermore, we validated *in vitro* the efficacy of targeting adenosine A_3 receptor to sensitize GSCs to antitumour drugs substrates of Mrp1. We propose a new therapeutic alternative to the treatment of this tumor targeting the GSCs chemoresistance.

TUE-124
Ibulocydine sensitizes human cancers to radiotherapy by induction of mitochondria-mediated apoptosis

S. S. Park, E. J. Ju, S. H. Shin, J. Choi, J. Park, J. H. Lee, K. J. Lee, J. Park, H. J. Park, E. J. Ko, S. Y. Song, S.-Y. Jeong, E. K. Choi
ASAN Medical Center, Seoul, Korea

Background and Purpose: Ibulocydine (IB), a novel prodrug of CDK inhibitor, has been reported to have anti-cancer effect in human hepatoma cells. In order to address its feasibility as a radiosensitizer to improve radiotherapeutic efficacy for human cancers, this study was designed.
Material and Methods: Human cancer cells of lung and colon were treated with IB and/or radiotherapy (RT). The cellular effects were assessed by CCK-8, clonogenic, flow cytometric, and western blotting assays. *In vivo* radiotherapeutic efficacy was evaluated using xenograft mouse model.
Results: Combined treatment of IB and RT significantly reduced viability and survival fraction of the cells. Apoptotic cell death accompanied with activation of caspases, decrease of Bcl-2/Bax expression, loss of mitochondrial membrane potential (MMP) leading to release of cytochrome *c* into cytosol was observed. Recovery of Bcl-2 expression level by introducing Bcl-2 expressing plasmid DNA compromised the loss of MMP and apoptosis induced by IB and RT. *In vivo* therapeutic efficacy of combined treatment was verified in the xenograft mouse model, in which tumor growth was markedly delayed by RT with IB.
Conclusions: IB demonstrated the property sensitizing human cancer cells to RT by induction of mitochondria-mediated apoptosis, suggesting that IB deserves to be applied for chemoradiotherapy.
Keywords: Ibulocydine, radiotherapy, apoptosis.

Introduction: Acute myeloid leukemia(AML)is a clonal disease resulting from a malignant transformation of a hematopoetic stem or progenitor cell.Recently,many studies confirmed that dysregulations in the Wnt/b-catenin signaling have been identified in AML cases.About gene expression levels of the b-catenin,which is the key element of Wnt pathway,carried out many studies in the literature and variations in b-catenin gene expression levels have been identified among AML patients.It is aimed to identify the related genes with b-catenin and the downstream pathways in AML patients through determining the differences between the AML patients classified according to gene expression levels of b-catenin and healthy control groups.
Materials and Methods: This study has been performed on 19 AML patients and 3 healthy individuals.RNA was extracted from CD34 + hematopoietic cells using Trizol reagent.QRT-PCRassays were used to determine the expression of β-catenin.RNA was used to generate cRNA,subsequently hybridized to HGU133Aplus2.0arrays according to the Affymetrix Genechip Expression Analysis Technical manual.
Results: We found that β-catenin was overexpressed in 8 out of 19 AML patients in compared with controls($p < 0.05$).β-catenin levels in AML samples were determined to be varied.According to these results in patients with high and low β-catenin compared with controls of gene profiles,it has been reached different conclusions.
Discussion: It is the first study to identified the transcriptome profile in the AML cases which is divided into two groups depending on the b-catenin levels.In this study,detection of b-catenin related genes and pathways will put forward an important data about the molecular biology of AML as well as providing diagnostic,prognostic and therapeutic new candidate molecules.

TUE-127
Identifying modifiers of Wnt and EGFR/RAS/MAPK signaling through quantitative *C. elegans* genetics

S. Maxeiner[1], T. Schmid[1], L. B. Snoek[2], M. Rodriguez[2], F. Largey[1], L. van der Bent[2], J. E. Kammenga[2], A. F. Hajnal[1]
[1]*Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland,* [2]*Laboratory of Nematology, Wageningen University, Wageningen, Netherlands*

A number of studies aim at investigating the origin and potential treatment of monogenic diseases. However, polygenic diseases arising from an interplay between several malfunctioning signaling pathways are the predominant cause of up to 60% of deaths in the human population. Quantitative genetic approaches provide a powerful tool to elucidate genetic risk factors underlying such complex diseases.

We use two isolates of *C. elegans*, N2 Bristol and CB4856 Hawaii to study the influence of naturally occurring polymorphisms on mutant genetic backgrounds well-known to promote diseases such as cancer. We chose the development of the *C. elegans* vulva as the phenotypic readout of Wnt and EGFR/RAS/MAPK signaling activity, where changes in signaling result in either a multivulva or vulvaless phenotype that can be quantified at single-cell resolution.

Previous work has established comprehensive QTL maps spanning the entire genome. We generated these maps by comparing an N2 strain carrying a mutation in *ras/let-60* or β-*catenin/bar-1* to animals carrying the *let-60* or *bar-1* mutation in a mixed N2/CB4856 background (so called mutation included recombinant inbred lines, miRILs). Interestingly, one QTL on the first chromosome (LGI) is shared between the two mutant backgrounds suggesting a link between Wnt and Ras signaling. We are currently identifying polymorphic modifier genes of the two pathways. To this aim, we narrow down a genomic region containing the QTL by generating N2 strains carrying well-defined CB4856 introgressions and by performing RNAi knockdown of candidate genes followed by mutant analysis.

TUE-128
IDH1 mutations in a Turkey series of primary glioblastoma

R. Kalkan[1], E. I. Atlı[2]
[1]Department of Medical Genetics, Near East University Faculty of Medicine, Nicosia, Cyprus, [2]Department of Molecular Biology and Genetics, Acıbadem University, İStanbul, Turkey

Purpose: To establish the frequency of IDH1 mutations in primary glioblastomas at a population level.
Experimental Design: We screened primary glioblastomas in a population-based study for IDH1 mutations and correlated them with clinical data.
Results: IDH1 mutations were detected in 5 of 40 primary glioblastomas (12,5%). Primary GBM patients carrying IDH1 mutations were significantly younger, mean age of 41 ± 5.06 years, than patients with wild-type IDH1, mean age of 57 ± 2.29 years, p = 0.011. The mean survival time of all GBM patients with and without IDH1 mutations was 19 months (5 cases) and 16 months (35 cases), respectively (P > 0.05).
Conclusion: In summary, our study is the first study to investigate the IDH1 status in primary GBMs in Turkish patients and confirmed IDH1 mutation as a genetic marker for GBM, and therefore as complementary information to help predict to the outcome of patients with GBM. We have shown consistent IDH1 status and younger age and lack of association between IDH1 mutation and survival time.
Keywords: Glioblastoma Multiforme, IDH1 mutation, Turkey.

TUE-129
IDH2 mutations in primary glioblastoma

E. I. Atli[1], R. kalkan[2], S. Artan[3]
[1]Molecular Biology and Genetic, Acibadem University, Istanbul, Turkey, [2]Molecular Biology and Genetic, Near East University, Nicosia, Cyprus, [3]Eskişehir Osmangazi University Medical Genetic Department, Eskişehir, Turkey

Purpose: To establish the frequency of IDH2 mutations in primary glioblastomas at Turkısh population level. In this study GBM patients studied with IDH1 gene mutation analysis was performed samples. Evaluated IDH2 gene mutations, compared with clinicopathological features.
Experimental Design: We screened primary glioblastomas in a population-based study for IDH2 mutations and correlated them with clinical data. We studied the frequency of IDH2 mutations in a series of 40 primary GBM patients from the Turkish population according to patient age, gender, GBM type and survival time. Tumor samples were collected during surgical procedures by the Department of Neurosurgery of Eskisehir Osmangazi Uni-

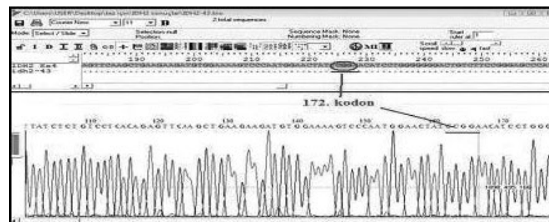

Fig. 1. Fluorescent in situ hybridization (FISH) reveals a split of red and green probe in an *ALK*-positive tumor.

versity. The samples included frozen tissues, collected upon surgical removal. DNA was extracted from the frozen tissues by Magna Pure Compact DNA isolation kit. Polymerase chain reaction (PCR) followed by DNA sequencing was applied to detect IDH2 mutation. The mean age of 40 GBM patients was 54,89 ± 3.34 years, with 51,71 ± 3,98 females and 58,07 ± 2,71 males. A total of 40 cases were primary GBMs. Calculations were performed using SPSS 15.0 software (SPSS, Chicago, IL, USA), with statistical significance of $p < 0.05$.
Results: No IDH2 gene mutation was detected in tumor samples. Since the analysed tumors were the primary GBMs, the data of undetected IDH2 gene mutation was in agreement with the literature. All of our cases, the average survival time of 17 months, respectively.
Conclusion: In summary, our study is the first study to investigate the IDH2 status in primary GBMs in Turkish patients. Anaplastic astrocytoma or glioblastoma patients with IDH1/IDH2 mutations, which has been reported to be younger age than carrying wild-type allele. According to result IDH1/IDH2 mutations observed more frequently in patients at an early age. In our study, mutations were not detected in our study group for this reason could not be made to such a statistical ratios. But all of our samples were wild-type allele therefore the average age was 54.5 ± 2, respectively.

TUE-131
Impact of CYP1A2 gene polymorphisms in adenocarcinoma lung cancer risk among tunisian population

F. B'chir
Laboratoire des Substances Naturelles, Institut NationaL de Recherche et D'analyses Physico-Chimique, Tunis, Tunisia

Four single nucleotide polymorphisms (SNPs) of CYP1A2 gene were analysed in 109 healthy smokers and in 101 lung cancer cases, including 63 with squamous cell carcinoma (SCC) and 41 with adenocarcinoma (AD). The genotyping for the SNPs -3860 G>A, -2467delT, -739T>G and -163C>A was performed by polymerase chain reaction (PCR)-restriction fragment length polymorphism analysis.

The results showed that smokers with CYP1A2 gene polymorphisms were associated with an increased risk for the development of lung AD. There was however no significant increased risk of developing lung SCC in smokers having CYP1A2 gene polymorphisms. An increased risk of developing AD was observed in smokers who are carriers of at least one copy of -3680A or -739G giving a significant odds ratio (OR) of 6.02 (CI = 2.91–12.9) and 3.01 (CI = 1.54–5.98), respectively.

These genotyping data are consistent with the hypothesis that tobacco-specific-N-nitrosamines (TSN) such as 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) are major contributors to the development of lung AD and that CYP1A2 gene product

© 2014 The Authors. FEBS Journal © 2014 FEBS

plays an important role in the metabolic activation of NNK. This study suggests that SNPs of CYP1A2 could be considered as promising biomarkers in the aetiology of lung AD in smokers.
Keywords: CYP1A2 gene, Polymorphisms, Lung cancer.

In vitro and in vivo analysis of the oncogenic role of Otx2 in medulloblastoma

A. Chakroun[1,2,3], S. El Nagar[1,2,3], B. Fant[1,2,3], T. Lamonerie[1,2,3], N. Billon[1,2,3]
[1]Institut de Biologie Valrose, University Nice Sophia Antipolis, [2]CNRS, UMR7277, [3]Inserm, U1091, Nice, France

Medulloblastoma (MB) is a malignant and invasive tumor of the *cerebellum*. It comprises four distinct molecular variants: Wnt and Sonic hedgehog (Shh) groups, in which Wnt and Shh signalization are deregulated, respectively, Group 3 (also known as Myc-medulloblastoma) characterized, among other genomic deregulations, by the overexpression and/or amplification of the Myc gene and of the transcription factor Orthodenticle homeobox 2 (Otx2) gene, and Group 4, which is not well characterized. Recently, Kawauchi et al. generated an animal model of Myc-medulloblastoma using orthotopic transplantation of granule cell precursors (GCPs) overexpressing Myc and a dominant negative form of the tumor suppressor protein P53 into the cerebellar cortex of the mouse.

Otx2 is overexpressed in 74% of medulloblastomas and it is also frequently amplified in type 3 MB. In the adult cerebellum, this transcription factor is expressed posteriorly by granule cells, which represent the most abundant neuronal cell type in the CNS. During cerebellum development, Otx2 is expressed by GCPs, which have a high proliferation rate. Deregulation of GCPs proliferation may favor oncogenic processes, as seems to occur in the Shh group of MB.

Our objective is to study the role of Otx2 in normal and oncogenic development of the cerebellum. We are investigating the role of Otx2 in the control of GCPs proliferation and differentiation using a mouse genetic model where Otx2 is co-expressed with the green fluorescent protein GFP, allowing identification and purification of Otx2-expressing (Otx2+) GCPs from developing cerebellum. Purified cell populations are subjected to different tests of proliferation (Ki67 expression, Edu incorporation) to assess the proliferation rate of Otx2+ versus Otx2- GCPs. Preliminary results show that Otx2+ GCPs have an increased proliferation rate compared to Otx2- GCPs, suggesting that Otx2 may have an oncogenic role in the establishment of medulloblastoma through the regulation of GCPs proliferation. We are now studying the effect of Otx2 overexpression or silencing on the proliferation rate of Otx2+ GCPs in *in vitro* studies. Finally, we will test the oncogenic potential of Otx2 in Myc-medulloblastoma using the transplantation model described above.
Keywords: granule cell precursors, medulloblastoma, Otx2.

TUE-133
In vitro modulation of enzymatic processes using biologic active substances with relevance for cancer therapy

M. L. Craciun, L. Olariu, M. D. Ene, L. Zglimbea
[1]Research and Development, Biotehnos SA, Otopeni, Romania

The therapeutic possibilities offered by plants and insects have been known to mankind for centuries; the pharmaceutical companies continue to invest enormous resource in identifying agents, to define and understand their most appropriate therapeutic uses.

Using an original patented technology, we have obtained a bioactive complex (Etno P) from entomological source which can be used in drugs and cosmetics industry. The complex is rich in proteins, essential amino acids, essential fatty acids and mineral salts (Ca, Na, K, Fe, Mg, Se, Ni, Cu, Si).

Determination of the relation between antioxidant effect and enzymatic activity of MMP-2, MMP-9 and Hyaluronidase, under the action of Etno P, is important for in vitro evaluation of potentially chemotherapeutical agents. Matrix metalloproteinases (MMPs) and hyaluronidase are involved in the degradation of the extra-cellular matrix under normal physiological conditions and during the metastatic process. Is well known that MMP-9 is a key effector molecule that promotes tumor cell invasion through type-IV collagen degradation and its expression has been observed in tumors of various organs, including the prostate. Hyaluronidase (HYAL-1) degrades hyaluronic acid into proangiogenic fragments that support tumor progression. If free radicals are not inactivated, they can accumulate in time and chemical reactivity of this species can damage cellular macromolecules including proteins, carbohydrates, lipids and nucleic acids. Because reactivity of free radical species are associated with several forms of tissue damage and disease, people had been trying to evolve a highly sophisticated and complex antioxidant protection system, that functions interactive and synergistic to neutralize free radicals before they attack the cells.

In order to emphasize the potential preventing antitumoral ability of the biologic active substances isolated and purified in ours laboratories from entomological source, enzymatic studies were done on the cell line DU 145. The biochemical parameters monitored was the enzymatic activity of catalase, SOD, MMP-9, MMP-2 and Hyaluronidase.

The experimental data demonstrated that bioactive substances are favourable to modifying enzymatic activity (MMP-2, MMP-9 and Hya) and presenting antioxidant activity. This study indicated that our bioactive complex can be included in pharmaceutical preparations, used individually or synergistically with other bio products in order to obtain a convenient efficiency/toxicity report.

This study was funded by Romanian National Authority for SCIENTIFIC RESEARCH, INNOVATION RESEARCH PROGRAMME, CONTRACT 26 DPST / 2013
Keywords: DU145, Hyaluronidase enzyme, MMP-9.

TUE-134
In vivo tumour-suppressive effects of alpha-tocopheryl succinate in Ehrlich ascites carcinoma

B. G. Stanimirov[1], K. Stankov[2], D. Mihajlović[2], S. Stankov[3], N. Pavlović[1], M. Mikov[1]
[1]Department of Pharmacology, Toxicology and Clinical Pharmacology, [2]Clinical Center of Vojvodina, Faculty of Medicine, University of Novi Sad, [3]Health Center Novi Sad, Novi Sad, Serbia

Introduction: Tumour-specific targeting of distinct molecular pathways involved in apoptotic process of malignant cell represents the highly beneficial concept in development of novel anticancer therapeutics. Alpha-tocopheryl succinate (α-TOS) has been shown to selectively inhibit cell proliferation and to induce cell death in variety of transformed cell lines while shielding normal cells. The aim of this study was to evaluate the effects of the administration of α-TOS on the vitality of Ehrlich ascites carcinoma cells (EAC) as well as its influence on the activity of glutathione-dependent antioxidative enzymes in EAC.

Material and methods: Two days after the transplantation of EAC cells in the abdominal cavity, Swiss mice were intraperito-

© 2014 The Authors. FEBS Journal © 2014 FEBS

neally treated with 50 μl or 100 μl α-TOS (0.2 M) each third day, four days in total. Aseptic evacuation of peritoneal content on tenth day post-transplantation, enabled the collection of EAC, and cell viability and enzyme activity were assessed. All experimental procedures were approved by the Ethical Committee of the University of Novi Sad.

Results: We observed the decreased viability of EAC cells in treated animals, indicated by the leakage of cytosolic lactate dehydrogenase (LDH) into the extracellular compartment that was significantly increased in the groups treated with 50 μl ($p = 0.002$) and 100 μl ($p = 0.01$) of α-TOS compared to control. The specific activities of glutathione-dependent antioxidative enzymes showed the dose-dependent decrease in both experimental groups, however, only the decrease in specific activity of glutathione peroxidase (GPX) was statistically significant ($p = 0.003$ for 50 μl, and $p = 0.0005$ for 100 μl of α-TOS). The concentration of total intracellular proteins has also been significantly decreased in treated groups ($p = 0.053$ for 50 μl, and $p = 0.045$ for 100 μl of α-TOS) compared to control, which is in accordance with results that show the decreased activity of antioxidant enzymes as well as increased leakage of LDH.

Conclusion: The results of pro-oxidant activity of α-TOS in EAC cells using the *in vivo* model followed by decreased viability of malignant cells, may indicate the potential anti-tumour properties of α-TOS, which could be considered as promising adjuvant agent in developing novel therapeutic strategies.

Induction of apoptosis in HeLa cancer cells by Gracillaria gracilis M. Steentoft, L.M. Irvine & W.F. Farnham hexane extracts

A. Guner[1], A. Nalbantsoy[2], A. Sukatar[1], N. Karabay Yavasoglu[3]
[1]*Depatment of Biology, Faculty of Science, Ege University,* [2]*Department of Bioengineering, Faculty of Engineering, Ege University,* [3]*Center for Drug Research & Development and Pharmacokinetic Applications, Ege University, İzmir, Turkey*

Background/Aim: The extracts from red seaweeds possess broad spectrum therapeutic properties such as anticancer and antigenotoxic effects. Recently, much attention has been paid to the anticancer activity of seaweeds. Hence, the aim of the study was to evaluate the *in vitro* genotoxic and cytotoxic/pro-apoptotic potency of the hexane extracts of *Gracillaria gracilis* (Rhodophyta) from the Coast of Urla in Aegean Sea.

Materials and Methods: Field collections of algae were made from several reefs (depths of 1–2 m) along the Izmir (Urla) coast during April 2013. Algae samples were dried at 45°C. Powdered material was extracted with n-hexane at room temperature and stored at 40°C. Cytotoxic effects of extracts have been tested in 5 different human cancer cell lines (CaCo-2, HeLa, MCF-7, A549, U87MG) and a healthy cell line (HEK 293) by MTT assay. The most effective cancer cell line was selected for apoptosis panel according to the IC_{50} results. To exhibit the expression profile of 84 genes involved in apoptosis, derived cDNAs from treated each cell line with the extract applied to RealTime ready Human Apoptosis Panel 96 (Roche, Germany). The genotoxicity of the extract was evaluated by Ames test that was conducted by the pre-incubation method using *Salmonella typhimurium* strain TA 98 and TA 1537 for the detection of frameshift mutations and TA 100 and TA 1535 for pair substitution.

Results: MTT results indicated that while hexane extract have significant cytotoxic activity against HeLa cells with IC_{50} values of 22.4 μg/mL, it showed cytotoxicity against other cancer cell line with IC_{50} values of >50 μg/mL. We found that comparing changes in expression of apoptosis related genes as fold change the hexane extract negatively modulated HeLa cancer survival, according to untreated control cells which might be mediated through up-regulation of BAK1 and down-regulation of NF-kB. Furthermore, this compound can extrinsic or intrinsic pathway induce apoptosis on HeLa cells, which might be mediated through both pro-apoptotic and anti-apoptotic Bcl-2 family and caspase family. When the chemical concentrations and resulting his^+ revertants produced by the extracts were compared with those produced by controls, even 5 mg/mL dose of the all extracts demonstrated no mutagenicity in the Ames test.

Conclusion: Cytotoxicity and genotoxicity results and gene expression assays demostrating that this extract may have potential in servics cancer treatment.

E. Kavetsky Institute of Experimental Pathology, Oncology, Radiobiology, Kyiv, Ukraine*

Nowadays stem cells participation in tumor growth has been extensively discussed in anticancer therapy. In vitro was investigated, mesenchymal stem cells (MSCs) produced the transient arrest of tumor cells in the G_1 phase of cell cycle; this was accompanied by a reduction in the apoptotic rate. However, previous studies have produced controversial results regarding whether MSCs promote or inhibit tumor growth and progression. In view of these controversial data, we conducted a study on the impact of allogeneic MSCs on biological properties of the primary tumor cells of Lewis lung carcinoma.

The investigation was carried out in C57Bl/6 male mice weighing 20-22 g aged 2 to 3 months. Mice of experimental group received the course of inoculation of MSCs (in concentration $1{,}25x10^4$ cells). The primary culture was obtained from transplantable Lewis lung carcinoma. Cell cultivation was conducted under standard conditions. The number of living cells was determined using MTT-colorymetric test. Apoptotic level and distribution of cells primary culture in phases of cell cycle were assessed by cytofluorimetry.

In order to determine MSCs influence on biological characteristics of tumor cells they were isolated from primary tumor, incubated 24 hours and then apoptotic level was assessed in control (20 days after tumor transplantation) and test samples (intravenous administration of allogeneic MSCs). The number aneuploid cells increased in 1.3 times upon MSCs influence on transplantable lung Lewis carcinoma. According to morphological characteristics, growth of subpopulation of cells of non-adhesion fraction with increase of nucleocytoplasmic ratio was detected in primary culture. Among aneuploid cells population, increase of cells of proliferative pool were detected after MSCs administration in comparison with control (G_2/M+S). Decrease of per cent of diploid cells subpopulation in 1,7 times in primary culture after MSCs administration and their more than 90% synchronization G_0/G_1 phase of cells cycle was shown. Regarding aneuploid cells

© 2014 The Authors. FEBS Journal © 2014 FEBS

after MSCs influence, increase of this population to 77.02 + 3.83% versus 59.20 + 1.71% in control was accompanied by growth of proliferative pool subpopulation G_2/M+S.

Thus, biological characteristics of tumor cells under the influence of MSCs are primarily associated with the increase of aneuploidy.

Keywords: aneuploidy, mesenchymal stem cells (MSCs), tumor cells.

Influence of lumican on biological properties of selected cell lines

I. Sacewicz-Hofman[1], M. Wiktorska[1], J. Kaciak[2], K. Sobierajska[1], K. Wieczorek[1], J. Niewiarowska[1]
[1]Department of Cell Molecular Mechanisms, [2]Medical University of Lodz, Lodz, Poland

Lumican is the major leucine-rich keratan sulfate proteoglycan of the extracellular matrix in corneal stroma, skin, muscle and cartilage. As proved by knocking-out of its gene in mouse, lumican plays a critical role in collagen fibrillogenesis. Due to direct interactions with cell membrane proteins, under pathological conditions lumican influences key biological processes such as cell growth, proliferation, adhesion, migration and apoptosis. It is known that lumican by binding to α2 integrin I domain and interaction with β1 integrin subunit inhibits melanoma cell migration but increases their adhesion. Previously, we shown that lumican is an efficient protein to block MMP-9 and MMP-14 expression and pro-angiogenic activity of endothelial cells. In present study we compare its influence on biological properties of human colon adenocarcinoma cells (HT29) and human prostate cancer cells (PC-3). We demonstrate that in both cell lines the presence of lumican caused upregulation of ß1 integrin subunit level. We also provide an evidence that changes in expression of ß1 integrins cause increasing of invasion through Matrigel™ and enhance their ability to form microcapillary tubes. However, statistically significant changes in invasion of HT29 cells were not observed. Summarising, lumican causes changes in the invasive properties of human prostate cancer cells (PC-3), but not in human colon adenocarcinoma cells (HT29).

Inhibition of the Rheb/mTOR pathway in TSC2-deficient AML cells results in down-regulation of IRF7

V. Makovski, Y. Kloog
Neurobiology, Tel-Aviv University, Tel-Aviv, Israel

Lymphangioleiomyomatosis (LAM) is a rare disorder that causes obstruction of lung tissue. It occurs predominantly in young women, and is caused by mutations in one of the tuberous sclerosis (*TSC*) genes, that serve as a GTPase-activating protein for the small GTPase Rheb. As a result, Rheb and mTORC1 are chronically activated in TSC1- or TSC2-deficient cells, and this activation can be diminished using the appropriate inhibitors. Rapamycin (sirolimus) is a known specific inhibitor of mTORC1, while S-trans,trans-farnesylthiosalicylic acid (FTS; salirasib) has been shown to inhibit Rheb. To examine the effect of the Rheb/mTOR inhibition pathway and further establish FTS as a potential treatment for LAM, we used human TSC2-deficient angiomyolipoma cells. FTS indeed inhibited Rheb in these cells and attenuated their proliferation. After comparative treatments with FTS or rapamycin or by re-expression of TSC2 we carried out a gene array analysis. This yielded a substantial number of commonly altered genes, many of which we identified as downstream targets of the interferon regulatory factor 7 (IRF7) transcription factor, a central activator of the interferon (IFN) type 1 immune response. Furthermore, nuclear localization of IRF7 was impaired by each of the three treatments. Interestingly, the phenomena seen on FTS or rapamycin treatment were selective for TSC2-deficient cells. Moreover, knockdown of IRF7 by siRNA mimicked the decrease in number of the abovementioned genes and also inhibited angiomyolipoma (AML) cell proliferation. Altogether, these findings support FTS as a potential treatment for LAM and IRF7 as a novel target for treatment.

Keywords: mTORC1, Rheb, TSC2.

TUE-139
Inhibitory effect of liposomal bovine lactoferrin (LbLF) on DSS-DMH-induced rat colorectal tumors

F. Shimamoto[1], H. Tuncel[2], G. Qi[3], A. Isikado[4], H. Imanaka[5], T. Takata[6]
[1]Faculty of Human Culture and Science, Prefectural University of Hiroshima, Hiroshima, Japan, [2]Istanbul University, Istanbul, Turkey, [3]Gulin Medical University, Gulin, China, [4]Department of Research and Development, Sunstar Co., Osaka, [5]Department of Research and Development, Osaka, [6]Department of Oral pathology Hiroshima University, Hiroshima, Japan

The Ulcerative Colitis (UC) increases year by year, and colorectal cancer cancer occurs in 7–8 years. Bovine lactoferrin (bLF), a member of the transferrin family, is an 80-kDa ironbindeng glycoprotein abundant in exocrine secretion of mammals, including milk, saliva, and neutrophils. Because bLF is present at high concentrations in cow's milk(1.9 mg/ml), it is regarded as a safe food-derived substance. Moreover, bLF is a multifunctional protein with anti-inflammatory, anti-bacterial, anti-viral,anti-tumor, and immunoregulatory effects. In this study, we used LbLF which encoded in soybean lecithin raising rate of absorption of LF, and investigated the anti-infammatory and anti-tumor effect of LbLF on DMH-induced rat colon cancer after the dosage with Dextran Sulfate Sodium (DSS) and on cultured colon cancer cells.

Method: 36 male F344 rats were divided into 3 groups (Control, 500 mg/kg/day LbLF and 1000 mg/kg/day LbLF group). After all the experimental rats drank 1% of DSS solution for one week, DMH(20 mg/kg) was injected to them for 8 weeks. All the rats were sacrificed 26 weeks after commencement of DMH administration, and aberrant crypt foci (ACF) and the colorectal tumors were examined. RKO 5000 cells were plated on 24 well plates and were preincubated with 0, 1, 10 and 100 ug/ml bLF and 100ug/ml LbLF, and trypsinized cells counted at 0, 1,2 and 3 day by Cell Counter. RKO cells were preincubated with 100ug/ml bLF for 4 h before LPS(100 ng/ml) stimulation, and cells were carefully washed twice with PBS. Cells were then cultured in medium with or without LPS, TNF-α mRNA expression was analyzed LPS stimulation.

Results and Conclusion: 500 or 1000 mg/kg/day LbLF group compared with control group showed statistically lower number of ACF, adenoma and adenocarcinoma of the colon. 1000 mg/kg/day LbLF group compared with 500 mg/kg/day LbLF group showed statistically lower number of adenoma. LbLF inhibits the development of colon tumor in DSS induced UC, and may be suggested to be useful for prevention of colitis cancer.

Keywords: cancer, colon, lactoferrin.

Insight into the comprehension of prolactin receptor mechanistic activation by a structural approach

M.-B. Lascombe[1], J. van Agthoven[2], B. B. Kragelund[3], V. Goffin[4], G. Phan[5], **I. Broutin**[1]
[1]Laboratoire de Cristallographie et RMN Biologiques, Faculté de Pharmacie, CNRS UMR 8015, Université Paris Descartes, Paris, France, [2]Department of Medicine, Harvard Medical School, Massachusetts General Hospital, Massachusetts, Charlestown, MA, USA, [3]Structural Biology and NMR Laboratory, Department of Biology, University of Copenhagen, Copenhagen, Denmark, [4]Centre de Recherche "Croissance et signalisation", Faculté de médecine, site Necker, NSERM U845, Université Paris Descartes, [5]Structural Biology and NMR Laboratory, Department of Biology, CNRS UMR 8015, UNIVERSITÉ PARIS DESCARTES, Paris, France

Based on accumulating evidence suggesting that prolactin receptor (PRLR) signalling may be involved in breast and prostate tumorigenesis, there is a real need to develop new therapeutic strategies to block the activation of this receptor. The active complex between prolactin (PRL) and its receptor is a heterotrimer involving two receptor moieties and one hormone molecule, interacting at binding sites 1 and 2. The classical approach that proved to be efficient to inhibit activation of the homologous growth hormone receptor consists in the development of competitive receptor antagonists engineered by substituting an Arginine for the natural Glycine residue lying at the bottom of the site 2 cavity in the ligand. For the PRL/PRLR system, however, this strategy generated a mild (partial) PRLR antagonist (G129R-hPRL) displaying residual agonism. An additional modification, i.e. the deletion of the 9 N-terminal residues, was necessary in order to obtain a pure PRLR antagonist (Jomain, JBC 2007). We also investigated an alternative strategy, consisting in the mutation of Glycine 129 into various types of amino acids while maintaining the N-terminus intact. Interestingly, this resulted in PRL analogs exhibiting very different antagonistic potency. G129P-hPRL was even less potent than G129R-hPRL while G129V-hPRL appeared as potent as Del1-9-G129R-hPRL, indicating that deletion of the N-terminus is not mandatory to achieve pure antagonism. Although these variants were shown to exhibit different stabilities, their specific biological properties remained poorly understood.

In order to give some light on the activation mechanism of the receptor and to explain the versatile antagonistic properties of the various G129 analogs, we undertook a systematic crystallographic study of the different prolactin mutants and of PRL/PRLR complexes (van Agthoven JBC 2010), and submitted them to a normal mode analysis. We did performed an in-depth comparative structural analysis of all the obtained structures, showing that binding of the hormone at site 1 leads to conformational changes within the PRL which may facilitate (or allow) the interaction at binding site 2. We also highlighted the importance of flexibility and allosteric movements for the activation of the receptor.

Intracellular CHI3L1 production promotes malignant transformation of 293 cells

E. N. Golubeva, T. A. Kulahava, N. G. Krylova, G. N. Semenkova, T. Kuznetsova, O. V. Balynska, V. M. Kavsan
Department of Biophysics, Belarusian State University, Minsk, Belarus

High levels of chitinase-3-like-1 oncoprotein (CHI3L1) were found to accompany development of glioblastoma and some other malignant tumors. In present study it was established that transfection of plasmid with *CHI3L1* cDNA insert led to appearance of several new morphological and functional properties typical for malignantly transformed cells. By means of atomic force microscopy and fluorescent confocal microscopy the enlargement of cell volume and cell surface square, modification of cells shape, increased amount of filopodia, and decreased amount of long outgrowths in 293_*CHI3L1* cells, stably producing CHI3L1 protein, compared to 293 cells transfected with "empty" vector (293_pcDNA3.1) were established. In 293_*CHI3L1* cells distribution of filamentous actin (F-actin) was revealed to be diffusive and uniform while in 293_pcDNA3.1 cells it was localized predominantly nearby plasma membrane with actin filaments being organized in dorsal stress fibers. Size, modification of distribution, increased number and membrane potential of mitochondria in 293_*CHI3L1* cells were likely to be associated with expression of *CHI3L1*. Increased number and modification of spatial distribution of lysosomes in cells 293_*CHI3L1* being probably associated with F-actin cytoskeleton reorganization involved in exocytosis of CHI3L1 protein were observed. Constant depolarization of 293_*CHI3L1* cell plasma membrane and acidification of extracellular medium due to activation of Na^+/H^+ exchangers in these cells was revealed. Extracellular acidification was shown to be involved in filopodia formation in 293_*CHI3L1* cells. It was also ascertained that transfection of plasmid with *CHI3L1* cDNA insert into 293 cells promoted cellular redox state modification. 293_*CHI3L1* cells in comparison to 293_pcDNA3.1 cells were characterized by decreased endogenous hydrogen peroxide and mitochondrial superoxide anion radical production, by elevated level of reduced glutathione, increased constants of H_2O_2 utilization, enhanced resistance to oxidative damage induced by H_2O_2 and menadione. Role of ERK1/2 in mechanisms of intracellular redox state regulation was established. Revealed cells functions modifications associated with CHI3L1 production are closely linked to malignant cell transformation, thus allowing consideration of CHI3L1 as one of the perspective targets for anticancer therapy.

Intracellular proteases promoting endometrial hyperplasia and carcinoma development

L. A. Lysenko[1], N. A. Ivanova[2]
[1]Institute of Biology, Karelian Research Centre of RAS, [2]Department of Obstetrics and Gynecology, Petrozavodsk State University, Petrozavodsk, Russian Federation

Endometrial disorders in fertile and menopausal women are related to estrogen stimulation resulted in hyperplasia, adenomatous hyperplasia, atypia, and even malignancy (carcinoma). In order to evaluate possible cellular biomarkers and molecular targets for rational therapy of disease progression the intracellular proteases and their inhibitors were studied. Proteolytic machinery is tightly implicated with the disorder progression and might have prognostic value as it was shown for many cancers. High-

© 2014 The Authors. FEBS Journal © 2014 FEBS

throughput approach for assaying gene expression has shown that a variety of proteolysis-related processes are overactivated in endometrial cancer patients. Despite extracellular processes of physiological importance (inflammation, coagulation, etc.) a wide range of inter- and intracellular proteolytic pathways such as extracellular matrix remodeling, aberrant cell-cell interaction, proteasome-dependent protein quality control, autophagic protein degradation, apoptosis, known to be affected in disease. Carcinoma invasion requires the close interaction of tumor cells with components of the ECM. Matrix components might by degraded through a cascade of matrix metalloproteases initiated by plasmin. Plasminogen activation depends on turn on uPA and tPA activity promoting by other proteases (for example lysosomal cathepsin B). To evaluate intracellular players in damaged tissue the activity, content and mRNA expression were measured for proteases of different catalytic type and subcellular localization such as cathepsins B and D, Ca^{2+} -dependent m- and μ-calpains, caspases-3, -8, and -9. Substantial changes in protease synthesis and activity were observed in adenocarcinoma lesions when compared to normal endometrial cells. Regarding calpain function in cell motility it might reflect high metastatic potential of the tumor. Cathepsin B was upregulated both in adenomatosis and adenocarcinoma with maximal activity on lesion periphery. In this study, we found that activity of initiator and effector caspases (caspase-8, -9, and -3) were decreased in advanced endometrial tumors compared with the normal endometrium, while there was no correlation between caspase activity in patients with benign adenoma and healthy women. Due to conventional roles of proteases in cell migration and apoptotic cascade it might indicate apoptotic inefficiency in tumors due to insusceptibility of tumor cells to apoptotic signals. Further studies involving both in vivo and in vitro models will be needed to further clarify the significance of intracellular proteases in endometrial pathology and their biomarker relevancy. This work was supported by RFBR grant 12-04-01597 and “Leader Scientific Schools” grant 1410.2014.4.

Intracellular proteins controlling the activation of β1 integrins in HT29 cells overexpressing Snail

K. Wieczorek[1,2], M. Wiktorska[1], I. Sacewicz-Hofman[1], M. A. Kowalska[3], K. Sobierajska[1], J. Niewiarowska[1]
[1]Molecular Cell Mechanisms, [2]Endocrinology and Metabolic Diseases, Medical University of Lodz, [3]Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland

Snail is a key transcription factor involved in the epithelial to mesenchymal transition process (EMT) and it is known to promote proliferation, cell adhesion and migration of human cancer cells, including colorectal cancer cells (CRC). It has been shown that overexpression of Snail induces EMT but the molecular basis of how Snail regulates that process has not been fully clarified. We have focused on early changes in CRC cells - how Snail regulates adhesive properties of colon cancer cells (HT29) and how its expression influences integrin signaling since integrins, heterodimeric, transmembrane adhesion and signaling proteins, are involved in migratory and adhesive properties of cells. We reasoned that intergrins may interact with miscellaneous proteins that cause its switch from an inactive, low affinity to active, high affinity state.

We performed an analysis of the expression levels of several proteins that are known to inhibit or activate β1 integrins: talin, kindlin, migfilin, ILK, DAB-2 and filamin, in CRC cells with overexpressed Snail* *in vitro* using Western Blotting technique. We found that levels of filamin-1 (FLNA), but not filamin-3, are positively correlated with Snail overexpression, invasive phenotype and capillary structures formation. Subsequently we silenced filamin-1 expression, using specific anti-FLNA siRNA, to investigate the impact of filamin-1 on migration and adhesion processes in HT-29-Snail cell clones.

Our results show that filamin-1, apart from its numerous cell functions, may interact with Snail in cancer cells and that can lead to changes in migratory properties of the cells and their invasiveness. We believe that this study may change our understanding of the major pathophysiological processes underlying development of colon cancer metastases and possibly will help to develop future strategies to block metastasis.

HT-29-Snail clones were obtained by Joanna Boncela, PhD, Institute of Medical Biology, Polish Academy of Sciences.

This research is supported by the National Science Centre grant - DEC-2011/02/A/NZ3/00068 and HARC FP7-REGPOT-2012-2013-1.

TUE-145
Investigation of the Taspine's antiproliferative, antiangiogenic and apoptotic effects on U118 and U87 glioblastoma multiforme cell lines

S. S. Sharifi[1], S. Aydos[1], T. Ozkan[2], S. Bozkurt[3], C. Ateş[4], A. Sunguroglu[1]
[1]Department of Medical Biology, School of Medicine, Ankara University, Ankara, Turkey, [2]Ankara University Biotechnology Institute, Ankara, Turkey, [3]Institute of Oncology, School of Medicine, Hacettepe University, Ankara, Turkey, [4]Department of Biostatistics, School of Medicine, Ankara University, Ankara, Turkey.

Brain tumors are responsible for 1.5% of all cancers and 2% of cancer deaths. In adults, glioblastoma multiforme (GBM) is the most common and most malignant brain tumors. There is no curative treatment of the disease. In addition to the standard treatment protocols, herbal therapies as an alternative methods of treatment can be used in cancer therapy. Taspine as an alkaloid, not only can pass the blood-brain barrier, but also has effect on apoptosis and angiogenesis in various cancer. In our study antiproliferative, apoptotic, anti-angiogenic effect of Taspine was investigated on GBM cell lines for the first time.

In this study the effects of Taspine were investigated on two different cell lines p53 mutant U118 and p53 normal U87 GBM cell lines which were close to the *in vivo* characteristics of tumors. The sensitivity of GBM cell lines to Taspine was determined by MTT. Also the proportion of DNA fragmentation after Taspine application was analyzed by COMET assay. Expression levels of angiogenic genes, VEGF, EGFR; apoptotic genes, p53, Bim, Bad, Bax, Bcl2 and autophagic gene Beclin 1 were investigated after Taspine added to each cell lines.

Taspine addition did not change VEGF and EGFR expression in p53 normal U87 cell line however, it increased the expression level of Bcl2, VGEF, EGFR significantly in p53 mutant U118 cell line. The reason of the different sensitivity to Taspine was thought to be because of the presence and absence of p53 mutation.

It was concluded that, Taspine has antiproliferative effect on GBM cell lines. The antiproliferative effect of Taspine on p53 normal cell line was due to apoptosis, but on p53 mutant cell line, it was due to another programmed cell death, other than apoptosis and autophagy. We also showed that p53 mutation was one of the important factor in response to the treatment of GBM.

TUE-146
Investigation of potential biomarkers of biochemically recurrent prostate cancer

R. Demidenko[1], K. Daniunaite[1], A. Laurinavicius[2], F. Jankevicius[3], S. Jarmalaite[1], J. R. Lazutka[1]
[1]Division of Human Genome Research Centre, [2]Department of Pathology, Forensic Medicine and Pharmacology, [3]Department of Urology, Vilnius University, Vilnius, Lithuania

Improved diagnostic biomarkers of prostate cancer (PCa) are needed to prevent overtreatment of indolent tumors, and to ensure early detection of aggressive PCa that requires treatment. Human Gene Expression Microarrays (Agilent) have been widely used for discovery of new candidate biomarkers in cancer. This study investigates genome-wide profiling of gene expression for identification of biomarkers of biochemically recurrent (PSA >0.2 ng/ml) PCa showing the tendency to progress.

Gene expression profiling was analyzed using Agilent microarrays on cancerous prostate tissues from PCa patients with and without biochemical recurrence (BCR) after radical prostatectomy. Change in expression of 455 genes (FC>2, $p < 0.05$) was identified. Out of 34 genes showed up-regulated expression in relation to BCR. Later on, 11 genes and 5 reference genes were selected for further validation with TaqMan Low-Density Arrays (TLDA) in expanded group of PCa cases. These arrays enabled to identify changes in 5 gene expression in cancerous tissues to compare with non-cancerous prostate tissues (NCPT) from another PCa patients set. Moreover, significant ($p < 0.01$) down-regulation of 2 genes marked the PCa cases with BCR. Last step of our study was to perform QPCR with 12 TagMan Gene Expression Assays, including 2 reference genes, in new PCa patient cohort. Screening was done only in cancerous prostate tissues (≥ 60% cancerous cells per sample).

The results of our study indicate that the down-regulation of several gene expression may be important for relapse of prostate cancer and therefore, identification of these genetic biomarkers may assist for early detection of aggressive PCa cases.

Investigation of the role of CYLD in mammary gland development and tumorigenesis

A. Pseftogkas[1], K. Xanthopoulos[1], T. Orfanidou[1], A. Chatzigiagkos[2], C. Ori[1], T. Poutahidis[2], G. Mosialos[1]
[1]Department of Genetics, Developmental and Molecular Biology, [2]Laboratory of Pathology, Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Breast cancer is a leading cause of cancer-associated mortality in women. CYLD is a tumor suppressor protein that has been associated with breast cancer development. More specifically, it has been shown previously that CYLD mediates the growth suppression of the aggressive human breast cancer cell line BT549 by inducing apoptosis. Furthermore, it was recently shown that CYLD expression is downregulated in human breast cancer tissues in comparison to normal breast tissues. In order to characterize in vivo the functional role of CYLD in mammary gland development and homeostasis we have generated mice with targeted inactivation of CYLD in the mammary gland using a conditional approach. For this purpose, mice in which *Cyld* exon 9 has been flanked with loxP sites (*Cyldflx*^{9}) were crossed with mice expressing the Cre recombinase under the control of the mouse mammary tumor virus (MMTV) LTR (*MMTVCre*) in order to achieve targeted CYLD inactivation in the mammary epithelium. Exon 9 codes for an essential catalytic motif of the deubiquitination domain of CYLD and its removal places exon 10 and downstream exons out of frame after splicing to exon 8. Pathological and immunohistochemical analysis of nulliparous, female mice indicates that inactivation of CYLD in the mammary epithelium leads to marked alterations in the cellular proliferation and apoptosis as well as the gross tissue histology. *MMTVCre-Cyld*^{flx9} mice display hyperplastic luminal mammary epithelia with increased proliferation rate and low level apoptosis as opposed to control mice in which the luminal epithelium retains its monolayer architecture low level cell proliferation and extremely limited apoptosis. The increased proliferation rate in *MMTVCre-Cyld*^{flx9} mice is consistent with the observed augmented Cyclin D1 levels in the hyperplastic epithelia. Our experiments indicate that CYLD plays an important role in mammary epithelium homeostasis possibly by affecting Cyclin D1 expression.

Wnt/β-Catenin signaling is one of the most important paracrine pathways during development, tissue regeneration and stem cell regulation. After activation by Wnt ligands, a multi-protein complex assembles at the plasma membrane clustering membrane-bound active receptors and intracellular signal transducers into the so-called signalosome. However, the dynamics of signalosome formation and dissolution are unclear and how these processes are related to Wnt/b-Catenin signaling remains to be determined. Our imaging studies in live zebrafish embryos show that the signalosome is a highly dynamic structure, which is continuously assembled by Dvl2-mediated recruitment of the destruction complex to the receptors and partially disassembled after clathrin-mediated endocytosis. We suggest that the μ-subunit of the endocytic Clathrin adaptor Ap2 interacts with Dvl2 in zebrafish and that this interaction is required for signalosome formation and activation of Wnt signaling. We find that after internalization, the ligand-receptor complex and the signal-transducer complex take separate routes. While Wnt ligand follows an endocytic path, the destruction complex still bound to Dvl2 is temporarily kept inactive. Thus, blockage of Ap2μ2 function at the plasma membrane inhibits the formation of an active ligand-receptor complex and its subsequent internalization and thereby reduces Wnt signaling.

Keywords: AP2, WNT signalling, zebrafish.

Ion interactions and thrombospondins, a multiscale molecular modelling study

T. Haschka[1], C. Etchebest[1], L. Martiny[2], M. Dauchez[2]
[1]UMRS_1143 Interactions and Dynamics of Macromolecular Systems, Inserm, Paris, [2]Laboratoire SiRMA, Université de Reims, Reims, France

In this presentation we show our study around the Thrombospondin (TSP) Signature Domaine (SD). This domain is implicated in various important biological processes. One of them is nitric oxigen introduced angionesis, which highlights the molecules importance in cancer research. Mutations in the SD are further the cause for heriditary diseases that cause bone malformation such as pseudoachondroplasia (PSACH). The signature domain features around 30 calcium ions in its resolved structures. In the "in silico" study that we present, we eludicate which and how these calcium ions dissasociate from the SD. Differences in calcium concentrations have been shown to be important for various protein-protein interactions such as those with Integrin, Cluster of Differentiation (CD-47) and Collagen. Besides pointing out these interesting results of major biological relevance, we highlight developments in charge parameterization from ab-intio quantum mechanics, and cinematic visulization that we have made as a part of this mulitscale molecular modeling study.

Ionomycin/PMA treatment modifies the expression of genes involved in apoptosis, proliferation and endoplasmic reticulum stress in T cell leukemia cell line

K. Stankov[1], G. Bogdanović[2], S. Stankov[3], J. Katanic[2], I. Mikov[4], M. Mikov[2], D. Blagojevic[5]
[1]Clinical center of Vojvodina, Medical faculty Novi Sad, University of Novi Sad, [2]Medical Faculty, University of Novi Sad, [3]Health Center Novi Sad, [4]Clinical Center of Vojvodina, Medical Faculty, University of Novi Sad, Novi Sad, [5]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia

The cytokine milieu during T cell activation is one of the most important factors in determining T cell fate. Activation of T cells by direct stimulation with phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io) results in numerous downstream signals that activate pathways enabling T cells to proliferate and produce cytokines. Inducible T cell activation is regulated predominantly at the transcriptional level. Therefore, we performed the analysis of the transcriptional activity of 19 genes involved in the regulation of several important cellular processes in Jurkat T cell leukemia cell line upon Io/PMA treatment by quantitative real-time (RT) PCR method using mRNA-specific primers and SybrGreen.

Our results showed c-kit expression in Jurkat cells, further confirmed by sequencing of c-kit mRNA specific PCR product. The expected increase in interleukin (IL)-2 mRNA expression, together with moderate Ki-67 upregulation, suggests the induced proliferation of PMA/Io-treated Jurkat cells. Significant upregulation of nuclear factor (NF)-κB, JNK and the prosurvival Bcl-2 was followed by activation of only one (protein kinase RNA-like endoplasmic reticulum kinase (PERK)) out of 3 main endoplasmic reticulum (ER) stress subpathways (ATF6 and spliced XBP were downregulated). NF-κB and JNK activation, as well as ERK downregulation were reactive oxygen species (ROS)-independent, shown by the lack of activation of antioxidative enzymes (SOD, NOS, GSTP1, gGCS and GR). C-kit was downregulated in the absence of exogenous SCF (c-kit ligand).

Based on our data set it is concluded that the PMA/Io treatment of Jurkat cells induced the increased expression of IL-2, followed by upregulation of prosurvival genes belonging to the Bcl-2 family. Neither c-kit nor the antioxidative system were activated, excluding their role in Jurkat T-cell activation in the absence of exogenous c-kit ligand SCF. Based on our dataset we may suggest that the upregulation of JNK and (NF)-κB upon PMA/Io treatment in Jurkat cells was the antiapoptotic, prosurvival and proliferative signal, resulting in IL-2 overexpression followed by the transcriptional block of numerous genes involved in apoptosis induction and antioxidative ROS scavenging.

Ions and side chains: probing functional hotspots in histone deacetylase 8

N. Werbeck, J. Kirkpatrick, D. F. Hansen
Institute of Structural and Molecular Biology, University College London, London, UK

Histone deacetylases (HDACs) play a key role in a variety of cellular events including transcription, protein degradation and apoptosis. By deacetylating lysine side chains of their target proteins – histones and non-histone proteins - they constitute the counterparts of histone acetyltransferases (HATs). In this project we study human HDAC8 (42 kDa) as a model system to investigate the mechanism, activity and regulation of histone deacetylases from a structural and dynamical perspective using nuclear magnetic resonance (NMR) experiments. The challenges we are confronted with by studying HDAC8 encourage us to extend the methodological repertoire of existing NMR experiments. For example, we developed a set of new, carbon-detected NMR experiments to study arginine side chains and – via Ne-relaxation experiments - their dynamics at physiological pH, which was previously impossible for proteins of the size of HDAC8. Further, we developed a strategy for mapping and characterising potassium binding sites in potassium-binding enzymes such as HDAC8 using 15N labelled ammonium. These experiments in combination with established methods such as methyl-TROSY based approaches are used in this project to probe side chains and ions in functionally relevant parts of HDAC8.

Keywords: histone deacetylase, NMR Spectroscopy, Protein dynamics.

Leptin induces Src/ERK1/2-mediated, upregulation of sphingosine kinase 1 in ER-negative breast cancer: a potential mechanism for obesity driven cancer progression

H. Alshaker[1,2], J. Krell[1], E. Yagüe[1], D. Pchejetski[3]
[1]Department of Surgery and Cancer, Imperial College London, London, UK, [2]Department of Pharmacology and Biomedical Sciences, University of Petra, Amman, Jordan, [3]School of Medicine, University of East Anglia, Norwich, UK

Background: Obesity is a known risk factor for breast cancer. Sphingosine kinase 1 (SK1) is an oncogenic lipid kinase that is overexpressed in breast tumours and linked with poor prognosis, however its role in obesity-driven breast cancer was never elucidated.

Methods and Results: Our findings show for the first time that human primary breast tumours and associated lymph node metastases exhibit a strong correlation between SK1 and leptin receptor expression (Pearson $R = 0.78$ and $R = 0.77$, respectively, $p < 0.001$). Both these genes are elevated in metastases of ER-negative patients and show a significant increase in patients with higher BMI. Leptin induces SK1 expression and activation in ER-negative breast cancer cell lines MDAMB-231 and BT-549, but not in ER-positive cell lines. Pharmacological inhibition and gene knockdown showed that leptin-induced SK1 activity and expression are mediated by activation of extracellular signal-regulated kinases 1/2 (ERK1/2) and Src family kinases (SFKs) pathways, but not by the major pathways downstream of leptin receptor (LEPR) - janus kinase 2 (JAK2) and signal transducer and activator of transcription 3 (STAT3). Src-homology 2 domain-containing phosphatase 2 (SHP2) appeared to be key to SK1 activation, and may function as an adaptor protein between SFKs and LEPR. Importantly, leptin-induced breast cancer cell proliferation was abrogated by SK1 specific siRNA.

Conclusions: Overall, our findings demonstrate a novel SFK/ERK1/2-mediated pathway that links, leptin signalling and expression of oncogenic enzyme SK1 in breast tumours. Our data indicate the potential significance of this pathway in ER-negative breast cancer and identifies this as a new possible mechanism for obesity driven breast cancer progression.

TUE-154
Loss of heterozygosity – plausible mechanism underlying betaglycan down-regulation in primary endometrial adenocarcinomas

P. K. Zakrzewski[1], M. Nowacka-Zawisza[1], A. I. Cygankiewicz[1], A. Semczuk[2], T. Rechberger[2], W. M. Krajewska[1]
[1]Department of Cytobiochemistry, Faculty of Biology and Environmental Protection, University of Lodz, Lodz, [2]IInd Department of Gynecology, Medical University of Lublin, Lublin, Poland

TGFβ signaling pathway regulates plethora of cellular processes including proliferation, differentiation, apoptosis, angiogenesis and immunological response. Recent findings indicated the particular role of TGFβ accessory receptors in cancer development. Betaglycan is a transmembrane proteoglycan responsible for TGFβ ligands presentation to the canonical receptors TGFβRI and TGFβRII. It is encoded by *TGFBR3* gene, which is located on chromosome 1p33-p32. Our previous findings indicated significant down-regulation of *TGFBR3* gene in sporadic endometrial adenocarcinomas. Moreover, observed deregulation was associated with increased cancer malignancy characterized by cancer cell grading (WHO classification).

The aim of the study was the evaluation of allelic imbalance in *TGFBR3* locus (1p33-p32), as a potential mechanism determining betaglycan deregulation in primary endometrial adenocarcinomas. Loss of heterozygosity in *TGFBR3* locus was analyzed using D1S188, D1S435 and D1S1588 microsatellite markers. The study group comprised 48 cases of sporadic endometrial adenocarcinomas obtained from women aged from 36 to 81.

It was stated that 54% (15/28), 36% (8/22) and 35% (7/20) of informative cases displayed LOH for D1S188, D1S435 and D1S1588 microsatellite markers, respectively. Analysing summarized allelic imbalance in *TGFBR3* locus, 25/39 (64%) of informative cases (25/48 of studied cancer specimens) revealed LOH in at least one microsatellite marker. Microsatellite instability (MSI) was observed only in the case of D1S188 and D1S1588 marker, but at low extent, i.e., in two and one cases, respectively.

Loss of heterozygosity in betaglycan gene *locus* may be implicated in disruption of TGFβ signaling in endometrial cancer. However, the presence of allelic imbalance in *TGFBR3* locus seemed not to predetermine aggressiveness of the sporadic endometrial carcinomas. Correlation between LOH in *TGFBR3* locus and clinical and pathological parameters of endometrial cancer samples was not found to be statistically significant.

This work was founded by grant UMO-2011/01/N/NZ4/01723 from National Science Centre (NCN).

TUE-155

Low resolution structural characterization of the complex between protein kinase ASK1 and 14-3-3 protein

D. Kosek[1], O. Petrvalska[1], V. Obsilova[2], T. Obsil[1]
[1]Department of Physical and Macromolecular Chemistry, Charles University in Prague, [2]Institute of Physiology, Academy of Science of Czech Republic, Prague, Czech Republic

ASK1 (Apoptosis signal-regulating kinase, MAP3K5) acts as a critical initiator of the apoptosis triggered by reactive oxygen species (ROS), immune response or various anticancer agents. So far it has been connected with the development of several neurodegenerative or cardiovascular diseases, diabetes and cancer. ASK1 is a homodimeric serine/threonine kinase from MAP3K family therefore it activates MAP2K kinases which in turn activate JNK or p38 kinases promoting cellular apoptosis via caspase 3/9 dependent manner. Enzymatic activity of ASK1 is tightly regulated by phosphorylation, oligomerization and protein-protein interactions. Formation of high molecular complexes, ASK1 signalosomes, was also observed as an essential element for oxidative stress-induced cell death althought its exact composition is still unclear. The 14-3-3 protein was identified as one of the most important physiological regulator of ASK1. It binds to the phosphorylated serine 966 at the C-terminus of the kinase domain ASK1 and maintains its inactive state preventing the signaling iniciation. It has been shown previously that ASK1 is activated after dephosphorylation of serine 966 and dissociation of 14-3-3 in the presence of ROS(1). However, the structural mechanism of ASK1 activation through this interaction remains unknown. Here we present first biophysical and low resolution structural characterization of interactions between the 14-3-3 protein and catalytical domain of ASK1 using AUC and SAXS.

Mass spectrometry – based analysis of proteome components related with tumor presence and associated with risk of metastasis of breast cancer

A. Walaszczyk[1], M. Pietrowska[1], E. Nowicka[2], K. Behrendt[2], A. Zagdanski[3], J. Polanska[4], P. Widlak[1]
[1]Center for Translational Research and Molecular Biology of Cancer, [2]II Radiotherapy and Chemotherapy Clinic, MSC Memorial Cancer Center and Institute of Oncology, Gliwice, [3]Institute of Mathematics and Computer Science, Wroclaw University of Technology, Wroclaw, [4]Faculty of Automatic Control, Electronics and Computer Science, Silesian University of Technology, Gliwice, Poland

Breast cancer diagnosed at early clinical stages is relatively well cured, yet even in this group some patients are at high risk of metastasis and failure of the treatment. Optimal selection of adjuvant treatment for these patients would be facilitated if reliable prognostic markers of risk of metastasis were available in clinical practice. Serum proteomics allows characterizing processes related to progression of cancer and its influence on patient's organism. Hence, serum proteome might be a source of knowledge on factors reflecting or enhancing spread of cancer cells.

Here we aimed to identify components of serum proteome specific for early stage breast cancer, and to identify components which abundance is associated with risk of metastasis. Blood samples were collected before the start of therapy, after the surgical resection of tumors and one year after the end of therapy in a group of 92 patients with low advanced breast cancer and in a group of 100 healthy women. The low-molecular-weight fraction of serum proteome was analyzed using MALDI-ToF mass spectrometry. We found several serum proteome features specific for patients with low advanced cancer and detected changes characteristic for toxicity of adjuvant treatment that could be observed one year after the end of therapy [Pietrowska et. al. 2009; 2010]. After five years of the follow-up 15 patients from the initial group suffered metastasis or cancer relapse. Blood collected from this group of patients was analyzed together with material collected from 45 patients who benefited from successful treatment. This allowed identification of serum proteome components putatively associated with increased risk of cancer metastasis or relapse.

Mechanism of action of 9-norbornyl-6-chloropurine – a novel carbocyclic nucleoside analogue

P. Plačková, M. Šála, R. Nencka, H. Mertlíková-Kaiserová
IOCB AS CR, Praha, Czech Republic

6-Chloropurines substituted at position 9 with variously modified bicyclic skeletons have recently been reported as anti-enterovirus agents [1]. Importantly, these compounds also showed considerable cytotoxicity and could be considered as candidates for the development of new anticancer drugs. 9-[(1*R**,2*R**,4*S**)-Bicyclo [2.2.1]hept-2-yl]-6-chloro-9*H*-purine (9-norbornyl-6-chloropurine, NCP) represents the most active compound from the series and thus served as a model compound for biochemical studies. In this work we explored the mechanism of action of NCP.

As described previously, NCP was shown to be a substrate for glutathione-*S*-transferase, forming glutathione conjugate (NCP-GS) as a major metabolite, with rapid membrane permeation into cells [2, 3]. Reduced glutathione (GSH) is the most abundant low molecular weight thiol in animal cells and is involved in many cellular processes [4]. It was shown that GSH level is rapidly decreased in treated cells depending on the time of incubation. GSH depletion led to increase in oxidative stress and the induction of apoptosis. Furthermore, NCP activates Nrf2-Keap1 pathway and its downstream targets, such as NAD(P)H:quinone oxidoreductase (NQO-1) or γ-glutamylcysteine synthetase, modifier subunit (GCLm).

Altogether, the novel nucleoside analog NCP represents a promising orally available antileukemic agent, acting through lowering GSH levels in tumor cells.

The project was supported by Project NPU I, LO 1302 from Ministry of Education, the Grant Agency of the Czech Republic #P303/11/1297 and the Research Project of the IOCB #RVO:61388963.

TUE-158
Metal phthalocyanines in experimental photodynamic therapy – a proteomic evaluation of dysplastic keratinocytes apoptosis

C. Constantin[1], C. Matei[2], M. Tampa[2], G. Dumitrascu[1], R.-M. Ion[3], M. Neagu[1]
[1]Immunology, "Victor Babes" National Institute of Research-Development in the Pathology Domain and Biomedical Sciences, [2]Dermatology, "Carol Davila" University of Medicine and Pharmacy, [3]Chemistry, The National Institute for Research & Development in Chemistry and Petrochemistry, Bucharest, Romania

Photodynamic therapy (PDT) is a therapeutical approach directed to selective destruction of tumoral cells widely used in dermatology, for treatment of several muco-cutaneous tumors such as basal and squamous cell carcinoma, Bowen disease and oral dysplasia [1]. As an alternative treatment of muco-cutaneous tumors PDT uses a light source able to photoactivate a photosensitizer destroying tumoral cells mainly by induction of apoptosis. Among metal phthalocyanines, the aluminium-substituted bi-sulphonated phthalocyanines [Al(III)S2Pc] exhibit a good photosensitizing potential, however the intimate molecular apoptotic mechanisms activated by PDT with this type of phthalocyanine in dysplastic human oral keratinocytes are not completely elucidated so far.

Protein microarray technology could be an excellent proteomic tool for apoptosis quantification post-PDT procedure. We evaluate apoptotic cell death following experimental PDT in dysplastic oral keratinocytes cell line (DOK) treated with Al(III)S2Pc, using a semi-quantitative protein microarray platform for simultaneously detection of 155 proteins involved in apoptosis course. Alteration of the most important proteins in cells subjected to PDT studied with the chosen array platform, affects mainly Bcl-2, P70S6K, Raf-1 and Bad family proteins expression. Using this proteomic approach a better understanding of apoptotic tumor cell death upon PDT could be achieved, revealing also new insights and molecules as potential new targets for anti-tumoral therapies in the dermato-oncology field.

The study was partially supported by the following research projects: PN-II-ID-PCE-2011-3-0918, POSDRU/159/1.5/S/141531 and PN. 09.33-01.01.

Metastasis-promoting glycerophosphodiesterase EDI3 influences tumour cell migration, integrin-mediated adhesion and spreading

M. S. Lesjak[1], R. Marchan[1], J. Stewart[2], J. Lambert[3], H. Keun[4], E. Steiner[5], J. G. Hengstler[1]
[1]Systems Toxicology, Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany, [2]Centre for Biological Sciences, University of Southampton, Southampton, UK, [3]Leibniz Institute for Analytical Sciences, Dortmund, Germany, [4]Department of Surgery & Cancer, Imperial College, London, UK, [5]Gynaecological Clinic, GPR Clinical Centre, Rüsselsheim, Germany

Metastasis from primary tumours is the leading cause of death in cancer patients and remains a major therapeutic challenge. Recently, we have identified the glycerophosphodiesterase EDI3 (Endometrial carcinoma differential 3) as a novel factor involved in metastasis (Stewart JD, Marchan R, Lesjak MS *et al.*, *PNAS*, 2012). High expression of EDI3 is associated with metastases in both primary endometrial and ovarian carcinomas and significantly reduces tumour-free survival time in patients. EDI3 hydrolyses glycerophosphocholine to generate glycerol-3-phosphate and choline, thereby influencing both cellular choline and lipid metabolism. Investigations using both classic scratch assays and transwell migration assays show that EDI3 has a major impact on cellular migration in different cancer cell lines, most likely via its direct influence on PKCα signalling. Further experiments using MCF-7 and OVCAR-3 cells reveal that EDI3 can also have an effect on both integrin-mediated adhesion and spreading, two processes which are closely related to cellular migration. Reduced expression of the key integrin subunit β1 upon EDI3 knockdown impairs cell attachment and spreading on a fibronectin matrix, which is accompanied by delayed formation of membrane protrusions. Accordingly, stable overexpression of EDI3 in MCF-7 cells increases integrin $\alpha5\beta1$ expression and is associated with enhanced cell attachment and spreading. The underlying mechanisms remain to be elucidated; however, initial results suggest that EDI3 influences the reorganisation of the actin cytoskeleton and the formation of focal adhesions independent from the FAK-Src signalling cascade. Overall, our data provide some insight into the biological function of the poorly characterised enzyme EDI3 emphasising its importance for the metastatic process.

Mitochondriotropic carbon nanotubes for efficient tumour targeting

S. Bhargava[1], V. Bhargava[2]
[1]Manav Bharti University, [2]KRV Hospitals Pvt. Ltd., Kanpur, India

Cancer is the uncontrollable growth of cells which are devoid of apoptosis. It has a very large impact around the world as there are around 10 00 000 new cases diagnosed annually & around 3,35,000 deaths. We tried to develop a novel strategy by developing a Ligand mediated tumor targeting via carrier systems. So for the study I selected multiwalled carbon nanotubes for mitochondrial targeting as it has Central role in Apoptosis, there are Multiple activation pathways, the tumour growth depends on energy & the availability of mitochondriotropics.

Rhodamine-123 is shown to be rapidly taken up by the mitochondria in living cells and serves a triple purpose as a stain, ligand and therapeutic agent. Multiwalled Carbon nanotubes (MWCNTs) are the choice of delivery system as it directly enters into the cell without passing through endo-lysosomes, have large inner volume, have distinct inner and outer surfaces & have ability to enter the cell by spontaneous mechanism. Thus, the proposed work envisages Rhodamine-123 conjugated Paclitaxel loaded *functionalized*-CNTs to provide an enhanced cell permeation and mitochondrial localization in order to enhance mitochondrial availability of Paclitaxel.

Methods: The raw MWCNT were procured and were purified, oxidized & then conjugated with rhodamine-123 by carbodimide method. The MWCNT's were characterized *in-vitro* for shape & size by Scanning (SEM) & Transmission Electron Microscopy (TEM), FTIR analysis, X-ray diffraction and zeta potential determined. Stability studies were performed at exaggerated conditions along with Hemolytic Toxicity Study. The Cell Cytotoxicity Study- MTT Assay was done using Hela cell lines. Mitochondrial localization was determined by CLSM

© 2014 The Authors. FEBS Journal © 2014 FEBS

study. The *in-vivo* part of the study comprised of determining the distribution of drug in various organs by fluorescence microscopy.

Results: The Rhodamine-123 conjugated MWCNTs were prepared and characterized. The CNTs showed high paclitaxel loading, sustained release, and excellent biocompatibility as evident by *in-vitro* drug release and low hemolytic toxicity. MTT assay against HeLa cell lines suggested the potential anticancer activity of the developed system. Confocal microscopic study suggested that mitochondrial specific localization of Rhodamine-123 conjugated MWCNTs in HeLa cells.

Conclusion: Thus, we concluded that Rhodamine-123 conjugated Paclitaxel loaded *f*-CNTs system have potential to provide an enhanced cell permeation and mitochondrial localization for effective tumour chemotherapy.

Keywords: Cancer, nanotubes.

TUE-161
Modulation of cell motility and signaling pathways of ErbB proteins in tumor cell lines by epigallocatechin-3-O-gallate

M.-M. Mocanu[1], T. Picot[2], E. Radu[3], I. Baran[1], E. Katona[1], P. Nagy[4], J. Szöllősi[4], L. Campos[2], C. Ganea[5]
[1]Department of Biophysics, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Hematology, University Hospital of Saint-Etienne, Saint-Etienne, France, [3]Department of Cellular and Molecular Medicine, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Biophysics and Cell Biology, University of Debrecen, Debrecen, Hungary, [5]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Multiple lines of evidence support the concept that epigallocatechin-3-*O*-gallate (EGCG) displays anti-cancer activity [1, 2]. However, the complete molecular mechanisms of action of EGCG in tumor cells still remain to be clarified. We aimed to study the effect of EGCG in cancer cell lines overexpressing ErbB proteins.

We continued our previous experiments [3] and we studied the influence of EGCG on tumor cell motility and on the signaling pathway of ErbB proteins including phosphorylated focal adhesion kinase (pFAK) at S910 site, phosphorylated protein kinase B (pAkt) at S473 site, extracellular-signal regulated kinases (ERK), phosphorylated ERK (pERK) at Y204 site and a nuclear transcription factor, c-fos which is known to be overexpressed in cancers. The study of the EGCG effects on tumor cell migration demonstrated the ability of the flavonoid to inhibit the motility of the A-431 epidermoid adenocarcioma and SK-BR-3 mammary adenocarcinoma cells. The effect was further enhanced by serum starvation.

Investigations on the signaling proteins using flow cytometry method showed that 50 μM EGCG at 48 h of treatment induced partial inhibition (20 – 50%) of pFAK, pAkt and pERK in A-431, but not in SK-BR-3 cell line. Dose-response curves and clonogenic assay experiments are in progress. Our results further support the anti-cancer activity of small natural flavonoids, as EGCG.

TUE-162
Modulation of VCAM-1 and ICAM-3 in metastatic osteosarcoma cells in vitro

M. Muhamad[1], A. Mansor[2], F. H. Ramli[3], S. Ab-Rahim[1]
[1]Faculty of Medicine, Universiti Teknologi MARA, Sungai Buloh, [2]NOCERAL, Department of Orthopaedic Surgery, Faculty of Medicine, University Malaya, Kuala Lumpur, [3]Institute of Molecular Medicine and Biotechnology, Faculty of Medicine, Universiti Teknologi MARA, Sungai Buloh, Malaysia

Osteosarcoma (OS) is a rare primary bone cancer arising among the adolescence and it is worsen upon metastasis. The important biomarkers that are usually involved in the invasion and metastasis of cancer cells are the cell adhesion molecules (CAMs). Therefore, this study aims to elucidate the expression profile of the adhesion molecules involved in metastatic OS cells isolated from OS patients. Normal human osteoblast (NHOst), osteosarcoma cell line (MG-63), non-metastatic and metastatic primary cell culture are used in this study. Morphological observation was carried out using hematoxylin and eosin (H&E) staining. The expression of ICAM-3 and VCAM-1 biomarkers was assessed by imunostaining (IHC) and western blot (WB) techniques. The results of H&E staining showed that all four types of cultured cells possess distinct morphological differences. Further analysis through immunostaining and western blotting showed the expression of VCAM-1 is higher compared to ICAM-3. The IHC results showed that the expression and intensity of VCAM-1 is slightly higher compared to ICAM-3 in all cancer cell line. Comparing the normal NHOst to all cancer cell lines, both the VCAM-1 and ICAM-3 biomarkers are significantly under expressed. In conclusion, we have showed that the expression of the two biomarkers is different although both proteins are involved in OS disease. Moreover, we managed to demonstrate the different metastatic characteristic of OS primary culture in comparison to normal cell lines. These findings are important for future exploration targeting these biomarkers and their characteristics as therapeutic mediators to treat OS.

Keywords: cell adhesion molecules, osteosarcoma, protein expression.

TUE-163
Molecular genetic analysis of the *Drosophila* Mig-10/RIAM/Lamellipodin (MRL) adapter protein in experimental metastasis

N. A. Alqadri
Biochemistry and Cell Biology, University of Liverpool, Liverpool, UK

The invasion of cancer cells into surrounding tissues plays a causal role in tumour progression and is the initial step in tumour metastasis, which clinically is the most important process in the progression of cancer. For invasion to occur, cells must detach from the epithelium, acquire and regulate both their motile properties and affinity for other cell types as they migrate to a new location. Several lines of evidence indicate that the Mig-10/RIAM/Lamellipodin (MRL) family of adapter proteins transduce signals derived from growth factor receptors, via interactions with Ras GTPases and/or phospholipids, resulting in changes in the actin cytoskeleton, increased lamellipodia protrusion, cell

© 2014 The Authors. FEBS Journal © 2014 FEBS

motility and altered cell adhesion properties. *Drosophila* encodes only one MRL protein, encoded by *pico*, which we previously showed to have a role in the regulation of actin dynamics. Although aberrant recruitment of the actin cytoskeleton is implicated in the motility and dissemination of cancer cells, the contribution of specific actin regulators to cancer metastasis is not fully understood. Here we report that overexpression of Pico can promote invasion of Ras^{V12}-induced tumours in a *Drosophila* model of cancer metastasis, characterised by JNK-dependent elevation of MMP1 expression leading to basement membrane degradation at sites of cell invasion. Notably, the ability to promote invasion is shared with a subset of actin regulators, including Enabled, Scar and Chicadee/Profilin, which physically interact with Pico, and Mal/SRF, a downstream transcription factor that promotes actin reorganisation. We will also discuss data obtained using a panel of site-directed mutants in Pico designed to abolish binding to specific MRL-associated proteins, and a fluorescent SRF-dependent reporter gene, which provides a readout the activation state of transcriptional signalling. Importantly, our findings are consistent with the known roles of MRL proteins in promoting lamellipodia-like structures and in intracellular signalling, and point to the potential involvement of MRL proteins in tumour cell invasion and metastasis.

Molecular tools for ecological risk assessment of pharmaceutical drugs released in hospital waste water and surface water

A. Pfohl-Leszkowicz[1], N. Mater[1], F. Geret[2], S. Rodriguez-Mozaz[3], C. Albasi[1]

[1]*Bioprocédés et Systèmes Microbiens, Laboratoire Génie chimique UMR CNRS 5503, Auzeville-Tolosane,* [2]*Laboratoire GEODE, UMR CNRS 5602, Centre Universitaire Jean-François Champollion, Albi, France,* [3]*Catalan Institute for Water Research, Girona, Seychelles*

Most pharmaceutical compounds are excreted partially transformed or even unchanged *via* urine and faeces of patients under medical treatment. As hospital effluents reach the municipal sewer network generally without preliminary treatment, they can reach environment and affect animals, plants, but also human health *via* drinking water. Although the concentrations are low (ng/L to µg/L), no data exist concerning their ecotoxicological impact. In this study biomarkers of early effect were performed on hepatic cells (HepG2) and on mammary cells (MCF7): cell viability using cell proliferative assay and genotoxicity (DNA breaks and DNA adduct) using comet assay and DNA P^{32} post-labelling method, respectively. These data were compared with two standardized bioassays: algaltoxkit (*Solenastrum capricornutum)* and microtox® (*Vibrio fischeri*). Cells were exposed to increasing amount of individual drug or in mixture during 24, 48 or 72 h. The time-exposures of bacteria and algae were ranged between 5-30 min and 72 h, respectively. Finally, the same tests were used to check the potential toxicity of Hospital waste water. Samples from a Hospital located in Girona (Spain) were collected during 3 consecutive months. Water samples from the urban WWTP that receives Hospital wastewater were also collected (inflow and outflow). Depending of the relative proportion of the drugs/mixtures applied on cells or aquatic organisms, either antagonistic or additive effects were observed. A non-monotonic dose- response (hormesis) on cell viability was observed when HepG2 were exposed to TAM alone or in presence of CIP. CP induced antagonistic effects when it was added to mixtures. The same was observed with microtox® when the bacteria were exposed to the mixtures. Exposure of cells to individual drugs does not induce any DNA breaks, whereas when cells were exposed to drugs in mixture a dose dependant increase of DNA breaks was observed even with the lowest doses. TAM induces a dose related increase of DNA adduct formation in hepatic cells whereas a non-monotone response was observed in mammary cells. CIP and CP increased DNA adduct formation and modify also the pattern of DNA adduct.

mRNA binding proteins regulate BRCA1 mRNA translation in CML cells

M. Wolczyk[1,*], P. Podszywalow-Bartnicka[1,*], T. Skorski[2], M. Nieborowska-Skorska[2], K. Skowronek[3], K. Piwocka[1]

[1]*Nencki Institute of Experimental Biology PAS, Warsaw, Poland,* [2]*Temple University, Philadelphia, United States,* [3]*The International Institute of Molecular and Cell Biology, Warsaw, Poland*

The BCR-ABL1 oncoprotein plays a major role in the development and progression of chronic myeloid leukaemia (CML). To study the role of BCR-ABL1, we employed mouse progenitor cell line expressing high level of BCR-ABL1 corresponding to drug-resistant cells from blast crisis of the disease. We previously demonstrated that CML progression correlates with increased aneuploidy resulting from affected mitosis. This was caused by BRCA1 downregulation leading to decreased expression of protein members of spindle assemble checkpoint [1]. BRCA1 tumor suppressor regulates crucial cellular processes involved in DNA damage repair and cell cycle control. In this study we investigated the mechanisms responsible for BCR-ABL1-mediated BRCA1 downregulation. Herein we found that downregulation of BRCA1 protein is associated with enhanced half-life and increased levels of BRCA1 mRNA in a BCR-ABL1 transformed cell line and in CML primary cells from patients. Lowered luciferase synthesis level under BRCA1 3'UTR control indicated that BRCA1 mRNA translation is affected in BCR-ABL1 expressing cells. Silencing and overexpression studies suggested that mRNA binding proteins regulates BRCA1 mRNA translation and stability. Studies based on site directed mutagenesis revealed that phosphorylation pattern plays a key role in determining of HuR effect on BRCA1 mRNA translation in BCR-ABL1 expressing cells. Currently we use BRCA1 Stellaris RNA FISH probes and SmartFare RNA probes to visualize BRCA1 mRNA together with mRNA binding proteins. Altogether, we showed a novel mechanism affecting BRCA1-dependent signaling in CML, in which BCR-ABL1 expressing cells modulate translation of BRCA1 mRNA, leading to protein downregulation. This may ultimately contribute to genomic instability and provide justification for targeting PARP1 and/or RAD52 to induce synthetic lethality in CML.

TUE-166
Multitargeted tyrosine kinase inhibitors in regulation of growth and survival of acute myeloid leukemia cells

M. Lasota, W. Balwierz
Department of Pediatric Oncology and Hematology, Jagiellonian University Medical College, Polish-American Institute of Pediatrics, Krakow, Poland

In spite of continuous progress in therapy of acute leukemia, treatment failures still occur frequently. Mutations affecting genes for tyrosine kinases and their signaling pathways result in abnormal proliferation and lead to acute myeloid leukemia (AML). The application of preparations curbing the impact of this disorder might contribute to further improvement of its curability.

The aim of this work was to determine the influence of selected inhibitors of c-KIT receptor tyrosine kinase on growth and survival of AML. We compared the antitumor activities of the multitargeted tyrosine kinase inhibitors (imatinib, nilotinib, midostaurin and dasatinib) to determine which inhibitor causes the strongest cytostatic and cytotoxic effect on AML cells.

The human AML cell lines HL-60, GDM-1, Kasumi-1 and MV-4-11 were cultured in RPMI 1640 containing 10% or 20% fetal bovine serum. Cell proliferation was determined by hemocytometer counts and MTS assay. The investigated tyrosine kinase inhibitors were also examined for their cytotoxic potential and ability to induce tumor cell apoptosis or necrosis. The percentage of apoptotic cells was determined by differential staining with Hoechst No. 33258 and propidium iodide (PI) and FACS analysis using Annexin V/PI staining.

The exposure of acute myeloid leukemia cells to investigated inhibitors at the concentration ≥ 0.01 μM resulted in dose-dependent suppression of proliferation compared to the control. Imatinib, nilotinib, midostaurin and dasatinib completely inhibited growth of AML cell lines. Both differential staining and FACS analysis showed independently that investigated inhibitors induce apoptosis of AML cells. The percentage of apoptotic cells was increased in a dose-dependent manner by treatment with inhibitors.

Midostaurin and dasatinib are more potent inhibitors of cellular proliferation than imatinib and nilotinib. Moreover, they demonstrate stronger proapoptotic effects. Tyrosine kinase inhibitors such as imatinib, nilotinib, midostaurin and dasatinib represent a promising class of therapeutic agents for the treatment of AML.

Keywords: acute myeloid leukemia, receptor c-KIT, tyrosine kinase inhibitors (TKIs).

TUE-167
Muscarinic acetylcholine receptors mediate rps6 phosphorylation in SNU-407 colon cancer cells via two distinct pathways

Y.-S. Park, N. J. Cho
Biochemistry, Chungbuk National University, Cheongju, Korea

Muscarinic acetylcholine receptors (mAChRs) are involved in the regulation of diverse cellular functions, including cell growth and proliferation. In this study we examined the signaling pathways by which mAChRs activate ribosomal protein S6 kinase 1 (S6K1), a key regulator of cell growth and proliferation, in SNU-407 colon cancer cells. Treatment of the cells with carbachol stimulated phosphorylation of T389 of p70 S6K1 in a time-dependent manner. The PI3K inhibitor LY294002 or the mTOR inhibitor rapamycin almost completely blocked carbachol-stimulated S6K1 activation, indicating that mAChRs mediate S6K1 activation through the PI3K/AKT/mTOR pathway. We observed, however, that carbachol-stimulated phosphorylation of ribosomal protein S6 (rpS6), a downstream target of S6K1, was only partially inhibited by LY294002 or rapamycin. When the cells were treated with the MEK inhibitor U0126, carbachol-stimulated rpS6 phosphorylation was abolished in the presence of either of these inhibitors. These results suggest that the ERK pathway as well as the PI3K/AKT/mTOR/S6K1 pathway is responsible for mAChR-mediated rpS6 phosphorylation in SNU-407 colon cancer cells.

New anticancer compounds from sea cucumbers: molecular mechanisms of action

D. Aminin, E. S. Menchinskaya, E. A. Pislyagin, A. S. Silchenko, S. A. Avilov, V. I. Kalinin, V. A. Stonik
G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Far Eastern Branch of the Russian Academy of Sciences, Vladivostok, Russian Federation

Background: Cytotoxic activity of sea cucumber glycosides against different types of cells and cell lines including human tumor cell lines has been studied for many years. However, the molecular mechanism(s) of antitumor action of triterpene glycosides on the cancer cells remains unclear. Present work reports a continuation of investigations of monosulfated triterpene glycoside, cucumarioside A_2-2, isolated from the Far-Eastern sea cucumber *Cucumaria japonica*. It describes a study of glycoside anticancer activity *in vivo* and glycoside interaction with mouse Ehrlich carcinoma cells *in vitro*.

Methods: The cytotoxicity of cucumarioside A_2-2 and its effect on apoptosis, cell cycle, DNA biosynthesis, p53 activity, multidrug resistance (MDR), and glycoside antitumor action against Ehrlich carcinoma was studied.

Results: Cucumarioside A_2-2 influences tumor cell viability at micromolar concentrations. The EC_{50} for glycoside estimated by non specific esterase assay and MTT assay was 2.1 and 2.7 mM, respectively. Cucumarioside A_2-2 at sub-cytotoxic range of concentrations exhibits a cytostatic effect by blocking cell proliferation and DNA biosynthesis in the S phase. It may induce apoptosis in tumor cells through caspase-dependent way bypassing activation of p53-dependent segment. It was found that cucumarioside A_2-2 blocks the activity of membrane transport P-glycoprotein in the mouse Ehrlich ascites carcinoma cells. It increases the upload and intracellular concentration of cytostatic doxorubicin, and prevents in this way an efflux of acticancer drug from the cancer cells.

Conclusion: The anticancer and pro-apoptotic properties of cucumarioside A_2-2 may be due to direct interaction of the glycoside with tumor cells. The *in vivo* anticancer effect of cucumarioside A_2-2 may be associated with the ability of the drug to arrest the cell cycle in the S phase and induce programmed tumor cell death. Since the interaction with cancer cells results in decrease of MDR, this glycoside may be considered as potential inhibitor of multidrug resistance of tumor cells and can be used in combined anticancer therapy.

New benzo[b]furane and dicarboximide derivatives with anticancer activity - studies on the mechanism of action in human cells

K. Krolewska[1], M. Cieslak[1], B. Kuran[2], M. Krawiecka[2], J. Kossakowski[2], I. Wybrańska[3], B. Nawrot[1]
[1]*Department Bioorganic Chemistry, Centre of Molecular and Macromolecular Studies, Polish Academy of Sciences, Lodz,* [2]*Department of Medical Chemistry, Medical University of Warsaw, Warsaw,* [3]*Department of Genetic Diagnodtics and Nutrgenomics, Chair of Clinical Biochemistry, Medical College, The Jagiellonian University, Krakow, Poland*

There is a permanent need for new anticancer drugs with improved pharmacological profiles. Following that demand, Screening Laboratory at Department of Bioorganic Chemistry (CMMS PAS, Lodz) tested a set of 80 benzo[b]furanes or dicarboximides developed in Department of Medical Chemistry of Warsaw Medical University. Among them, several entities exhibited remarkable cytotoxic properties [1,2,3]. Interestingly, some compounds displayed selective toxicity towards human leukemia cells (K562, HL-60, MOLT-4) and were non-toxic to adherent cancer cells (HeLa, CFPAC) neither to normal endothelial cells (HUVEC). We have shown that these compounds induce the programmed cell death (apoptosis) in leukemia cells, which is the desired mechanism of action for anticancer drugs. To give further explanation of the mechanism of cytotoxicity of the novel compounds, the profiling of gene expression (TaqMan Human Apoptosis Array; Applied Biosystems) was performed in leukemia cells treated with the active compounds. The studies showed significantly increased expression (2-fold or more, $p < 0.05$) of several genes involved in regulation of apoptosis. The ability of these compounds to interact with DNA was explored by circular dichroism spectroscopy and by a plasmid DNA cleavage with restrictases. The selected compounds inducing apoptosis of leukemia cells, possibly by intercalating to DNA, can be considered promising leads for further development of anticancer drugs.

The studies were financially supported by the National Science Centre, project DEC-2012/05/N/NZ7/01174 for Karolina Krolewska.

New role for p130Cas as a regulator on the cellular responsiveness to TGF-β-induced growth inhibition in cancer cells

W. Kim[1], D. E. Jeong[1], E. Lee[2]
[1]*Department of Molecular Science and Technology, Ajou University, Suwon-si,* [2]*Department of Biochemistry, The Catholic University of Korea, Seoul, Korea*

Transforming growth factor-beta (TGF-β) suppresses the initiation of tumors by causing the cell cycle arrest and the loss of the anti-proliferative function of TGF-β is a hallmark of many cancers. Here we report that p130Cas plays a role in determining the cellular responsiveness to TGF-β-induced growth inhibition in cancer cells. Analysis of the tyrosine phosphorylation levels of p130Cas revealed higher levels of phosphorylation in cancer cell lines (MCF7 and A375) than in corresponding normal cell lines (MCF10A and MEL-STV). Contrast to normal cells, the cancer cells showed the resistance to TGF-β-induced not only Smad3 phosphorylation and p21 expression but also growth inhibition. However, silencing p130Cas was sufficient to restore Smad3 phosphorylation and p21 expression as well as the susceptibility to TGF-β-induced growth inhibition. Interestingly, overexpression of p130Cas accelerated TGF-β-induced epithelial-mesenchymal transition. In sum, our results suggest that elevated expression or/and phosphorylation of p130Cas contributes to the resistance to TGF-β-induced growth inhibition and thus to the initiation and progression of human cancers that harbor an active integrin signal.

Keywords: Cancer, p130Cas, TGF-beta.

TUE-172

NF-kB and p53-dependent signalling pathways are involved in cellular response to ionizing radiation

K. Szoltysek[1], P. Janus[1], A. Walaszczyk[1], N. Perkins[2], M. Kimmel[3], P. Widlak[1]
[1]*Center for Translational Research and Molecular Biology of Cancer, MSC Cancer Center and Institute of Oncology, Gliwice, Poland,* [2]*Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle Upon Tyne, UK,* [3]*Faculty of Automatic Control, Electronics and Computer Science, Silesian University of Technology, Gliwice, Poland*

Signalling pathways that depend on p53 or NF-kB transcription factors are essential components of cellular response to stress. Both proteins, which participate in regulation of the expression of numerous genes involved in cell cycle arrest, DNA repair, apoptosis, immune response and inflammation, can be activated by the same stimuli and the final cellular outcome is determined by the crosstalk between them. Here we aimed to characterize the effect of ionizing radiation (IR) on regulation of expression of genes controlled by these transcription factors.

U2-OS human osteosarcoma cell line was used as an experimental model. The clonogenic assay was performed to characterize its radiosensitivity, and then two doses: 4 Gy and 10 Gy (LD_{50} and LD_{100}, respectively) were used for further analyses. Activation of the NF-kB and p53 pathways was monitored by Western-blotting. Expression of selected target genes dependent on NF-kB and/or p53 was assessed by qRT-PCR at different time points after irradiation (from 30 minutes to 24 hours). Moreover, analysis of RelA (NF-kB subunit) and p53 binding to promoter regions of selected genes was performed using ChIP-qPCR.

Exposure of the U2-OS cells to IR resulted in strong activation of both NF-kB and p53 pathways, which was observed as IkBa phosphorylation (Ser32) and subsequent NF-kB nuclear translocation, and by p53 accumulation (irradiation with 10 Gy resulted in faster and stronger activation of NF-kB). As a consequence, both transcription factors were recruited to promoter regions of analyzed target genes (e.g. *IL8*, *CDKN1A*). In general, IR increased expression of NF-kB-dependent genes: exposure to 10 Gy resulted in increased activation of genes involved in negative feedback loop (e.g. *TNFAIP3*). In contrast, p53-dependent genes (e.g. *HDM2*) were activated after exposure to 4 Gy and repressed after exposure to 10 Gy.

We concluded that both p53 and NF-kB-dependent pathways were activated in cells exposed to IR, yet specific mechanism of the response was affected by dose of radiation (and putatively the level of radiation induced DNA damage).

TUE-173
Notum inhibits TRAIL-induced cytotoxicity

S. Vivarelli, E. Piddini
Gurdon Institute, Cambridge, UK

Our immune system provides a key barrier against tumour formation, for example releasing anti-tumour substances in the extracellular environment. TRAIL is a powerful factor produced by the immune cells, which selectively kills tumour cells but not normal cells.

On the other hand tumours can release molecules contributing to cancer development and progression. Notum is a secreted phospholipase with target selectivity towards specific GPI-anchored proteins such as Glypicans. It has been found to be over-expressed in tumours with constitutively active Wnt signalling but rarely in normal adult tissues.

Our results show that Notum protects cancer cells from TRAIL mediated anti-tumour activity. Here we present data on the mechanism of action of Notum on TRAIL and on the molecular players involved. These findings could contribute to explain why some tumours are resistant to TRAIL and suggest the possibility that inhibiting Notum could potentiate TRAIL based anti-tumour therapies.

Keywords: Glypicans, Notum (Notum Pectinacetylesterase Homolog - Drosophila), TRAIL (TNF-related apoptosis-inducing ligand).

TUE-174
Novel evidence that extracellular nucleotides direct Rhabdomyosarcoma metastasis and A1R identified as a novel receptor for extracellular AMP

M. Tarnowski, M. Tkacz, M. Czerewaty, A. Poniewierska-Baran, M. Z. Ratajczak
Physiology, Pomeranian Medical University, Szczecin, Poland

Purinergic nucleotides including Adenosine triphosphate (ATP) play a pivotal role in intracellular energy transfer. Evidence accumulates that they can be also released form the cells in particular if cells are damaged and cell membranes are leaky. For example both necrotic and apoptotic cells release ATP and other nucleotides that constitute 'danger signals' belonging to the family of alarmines. This happens in particular at sites of mechanical stimulation, hypoxia, tissue injury or inflammation. Extracellular nucleotides (ATP, UTP, ADP) activate specific purinergic (P2) receptors, and adenosine interacts with its own receptors called P1 receptors (A1, A2A, A2B, A3). Interestingly, the receptor for AMP is still unidentified.

Rhabdomyosarcoma (RMS) is the most common sarcoma in children. RMS accounts for approximately half of all pediatric soft tissue sarcomas and 15% of all pediatric solid tumors. Tumor microenvironment has a key role in supporting tumor growth and affects host-tumor interaction. Recent data show that solid tumors exhibit a gradient of adenosine concentration from the centre to the periphery, that is higher than the surrounding healthy tissue. In addition, many tumors over-express enzymes involved in the catabolism of extracellular nucleotides and in the generation of adenosine.

The aim of this study was to investigate the effect of purinergic nucleotides and their receptors on migration, invasion and proliferation of RMS cells. We employed in our studies several alveolar and embryonal RMS cell lines and first evaluated them for expression of membrane receptors for extracellular nucleotides. Next we performed several functional studies on cells exposed to ATP, ADP, AMP such as i) chemotactic responsiveness to purine gradient, ii) effect of purines on adhesion, iii) phosphorylation of AKT and MAPKp42/44 kinases and iii) effect of purines on cell proliferation. In some experiments we employed receptor inhibitors and applied shRNA strategy to assess involvement of A1 receptor.

We report for a first time that the purine nucleotides: ATP, ADP, AMP and adenosine, which are released during physiological stress from damaged cells, affect the migration of rhabdomyosarcoma cells. Rhabdomyosarcoma cells are characterized by high expression of purinergic receptors P2Y and adenosine receptors A1 and A2A. While ADP and ATP act through P2Y1 receptor adenosine interacts with A2A receptor. We also report for a first time employing selective inhibitors and shRNA strategy that AMP signals through A1 receptor.

Keywords: cancer, metastasis, rhabdomyosarcoma, purinergic signaling.

TUE-175
Novel mTOR isoform and tumorigenesis

O. Malanchuk, S. Palchevskyy, O. Garifulin, V. Filonenko
Cell Signalling, Institute of Molecular Biology and Genetics of NASU, Kyiv, Ukraine

The mTOR plays a striking role in signal transduction and regulates cell growth, metabolism, proliferation and survival in response to nutrients and growth factors. Deregulation of mTOR signaling pathway has been associated with numerous pathologies, including many human cancers, Alzheimer′s disease, obesity and type II diabetes.

There is only one gene encoding mTOR. Therefore the diversity of the mTOR-mediated signaling is conferred by two functionally and structurally distinct multiprotein complexes with the well known mTORalpha in their core. Previously in our Laboratory for a fist time mTOR splicing isoform (mTORbeta) was identified. This isoform differs from well known mTORalpha leaking HEAT and partially FAT domains but carrying intact Kinase domain. It has been shown that mTORbeta is an active protein kinase that mediates downstream signaling through complexing with Raptor and Rictor proteins and, significantly, is a potential oncogene.

Recently, we have identified a novel mTOR isoform – mTORdelta. Importantly, this isoform has another principle of isoform formation then mTORbeta (unpublished data). Deletion in kinase domain resulted in frame shift within 3' - region and finally translation of unique protein sequence which is absent in mTORalpha. So, current research proposal is focused on clarifying the involvement of mTORdelta in tumorigenesis. Characterization of oncogenic and signaling activities of mTORdelta and its expression in cancer will offer new perspective target for cancer therapy includes rapamycin insensitive tumor types.

Early using RT-PCR of various cell lines we have identified a novel splicing isoform mTORdelta. The aim of this study was to characterize the functional role of mTORdelta in tumorogenesis. So, initially, we have generated polyclonal antibody against mTORdelta and specific antibodies against Raptor and Rictor which are applicable in various immunoassays. Then we have shown by Western-blot analysis that mTORdelta expressed in different cell lines *in vivo*. Next, HEK293 stable cell line overexpressing mTORdelta has been generated. To examine the oncogenic potential of mTORdelta the various assays have been done: MTT assay to analyze the cellular activity and proliferation; Soft Agar Assay to measure cell anchorage-independent proliferation potential; Scratch Migration Assay to study the migration capacity of cells. In result, HEK293 stable cell line overexpressing mTORdelta demonstrates a low proliferative potential and not considerable migration capacity in compare to control HEK293 cell.

© 2014 The Authors. FEBS Journal © 2014 FEBS

In contrast to mTORbeta isoform, mTORdelta can inhibit cell proliferation. To elucidate the mechanism by which cell proliferation may be inhibited by mTORdelta now we are exploring its effect on the cell cycle progression by flow cytometric analysis.

Keywords: cell signalling, mTOR, splicing isoform.

TUE-177
Novel selective inhibitor against CDK9, a new target in antitumor therapy

A. Sipos[1,2], J. Pató[1], L. Őrfi[1], F. Waczek[1], G. Kéri[1]
[1]Vichem Chemie Research Ltd., [2]Medical Chemistry, Semmelweis University, Budapest, Hungary

Background: Cyclin-dependent kinase 9 (CDK9) was discovered in the early 1990s as a member of cdc2-like serine/threonine kinase family. In the past two decades CDK9 activation/malfunction was observed in proliferative disorders, infections, cardiological diseases and – in combination with other kinases – in inflammation. Thus CDK9 is now an attractive target for kinase inhibitor drug research in various indications including antitumor therapy.
Objective: The aim of our study was the identification and the biological evaluation of new, potent small-molecule CDK9 inhibitors as anticancer agents.
Results: In primary screen compounds from Vichem's NCL, (library of kinase inhibitors) were screened for 18 cell lines with *CellTiter-Glo* Luminescent Cell Viability Assay. The ratio of survived cells and the untreated samples (positive control) was examined. We further investigated the effective compounds which showed more than 75% inhibition in 10 μM and determined their IC_{50} values for NSCLC cell lines. Compounds which had IC_{50} value lower than 2 μM were chosen for additional experiments. Using the DiscoverX panel of KINOMEscan Technology Platform the potential target of the hit compounds was identified. We developed IMAP FP technology based in-vitro assays for screening the analogues of the hit compound on CDK2, CDK4 and CDK9 kinases. We screened these compounds at 10 μM concentration on three kinases then we determined IC_{50} values of the most effective ones. In this way the selectivity of the hit compounds were revealed also. Clonogenic assay was performed to elucidate the colony forming ability and to describe the proliferative potential of drug treated cancer cells. The apoptotic effect, inhibition of migration of tumor cells, solubility and permeability of hit compounds were also determined.
Conclusions: Promising lead molecules have been identified and characterized in order to achieve newly synthesized, selective CDK9 inhibitors.

TUE-178
Nuclear localization of formyl peptide receptor 2 in human lung cancer cells

F. Cattaneo, M. Parisi, R. Ammendola
Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy

GPCRs are the largest group of membrane receptors in eukaryotes. They exhibit seven transmembrane-spanning domains, three extracellular and three intracellular domains. Several agonists may interact with GPCRs triggering signalling cascades via G-protein-associated activation. Conventional models of GPCRs signalling describe receptor activation at plasma membrane level leading to downstream signalling. Nevertheless, GPCRs may localize to and signal at the nuclear membrane.

Formyl-peptide receptors 1, 2 and 3 (FPR1, FPR2, FPR3) belong to the GPCR super-family and are coupled to pertussis toxin (PTX)-sensitive Gi proteins. WKYMVm, a modified peptide isolated by screening synthetic peptide libraries, binds FPR2 with high efficiency. FPR2 activation results in different intracellular responses in a ligand-specific fashion[1]. These include the transactivation of many Tyrosine Kinase Receptors, such as EGFR[2], c-Met[3] and VEGFR.

We identified by analysis *in silico* of FPR2 sequence a nuclear localization signal (NLS) 227-KIHKK-231 in the third intracellular loop. Western blot analysis performed on purified nuclear proteins and immunofluorescence assays confirmed the nuclear localization of FPR2. We used a receptor binding assay to investigate specific binding of WKYMVm on purified nuclei of CaLu-6 cells. The experiments performed by using I^{125}-WKYMVm revealed a binding that was specifically displaced by increasing concentration of unlabeled ligand. The saturability of the nuclear membrane binding sites for WKYMVm was tested by adding increasing concentration of I^{125}-WKYMVm and receptor binding analysis predicted a Kd = 245pM. Moreover, exposure of purified CaLu-6 nuclei to WKYMVm for different times induced the rapid phosphorylation of Myc and c-Jun, which was prevented by WRWWWW, a selective antagonist of the receptor, supporting that FPR2 is functionally expressed onto CaLu-6 nuclei. We also performed site directed mutagenesis experiments on putative NLS to identify amino acid residues involved in the nuclear localization of FPR2. The consensus sequence 227-KIHKK-231 was mutated in 227-KIHAK-231 (FPR2mut3) and 227-KIAAA-231 (FPR2mutbis). These were transfected in HEK293T cells (FPR2 null) and both western blotting experiments and immunofluorescence assays showed that FPR2mutbis did not localize onto nuclear membrane of HEK293T transfected cells, suggesting that the sequence 229-HKK-231 plays a key role in FPR2 nuclear localization.

These data support new concepts on function and regulation of FPR2 which could have an impact on development of new therapy.

Analysis of the complete transcriptomes is complicated by the problems linked with difficulties in understanding of the overall physiological (functional) features basing on the observed large-scale gene expression profiles. We propose a new biomathemati-

© 2014 The Authors. FEBS Journal © 2014 FEBS

cal method, OncoFinder, which for the first time enables performing both quantitative and qualitative analysis of the intracellular signaling pathway activation (SPA). This method is universal and may be used for the analysis of any physiological, stress, malignancy and other user-defined conditions at the molecular level. In contrast to other techniques, OncoFinder utilizes an algorithm that distinguishes the activator/repressor role of every gene product in each pathway. This unique feature makes it possible to quantitatively characterize activation of each signaling pathway in a given biosample. We show that the relative importance of each gene product in a pathway can be assessed using kinetic models for "low-level" protein interactions. For the first time, OncoFinder technique showed a strong potential to neutralize differences between the experimental data obtained using different transcriptomic methods like NGS and microarray hybridization, using most of the commercially available platforms. This approach also allowed us to characterize new SPA signatures as the better markers of cancer progression compared to the individual gene products. OncoFinder also makes it possible to correlate SPA with the success of anticancer therapy of the individual patients. To facilitate using OncoFinder platform by the biomedical society, we created a software package available freely for the academic research community. Some aspects of the enclosing technology were published by us recently: (Buzdin et al., http://journal.frontiersin.org/Journal/10.3389/fgene.2014.00055/abstract); (Zhavoronkov et al., http://journal.frontiersin.org/Journal/10.3389/fgene.2014.00049/abstract); Suntsova et al. PNAS 2013; Spirin et al. Leukemia 2014 (In press). The additional information about the software is available upon the request at: http://www.insilicomedicine.com/ and http://pathwaypharmaceuticals.com/. The authors enthusiastically support building international scientific collaborations and partnerships

OTX2 controls the proliferation of cerebellar granule cell precursors

S. El Nagar[1,2,3], M. Delhorbe[1,2,3], T. Lamonerie[1,2,3], N. Billon[1,2,3]
[1]*Institut de Biology Valrose, University Nice Sophia Antipolis,* [2]*CNRS, UMR7277,* [3]*Inserm, U1091, Nice, France*

Transit amplification of granule cell precursors (GCPs) is one of the most important processes of cerebellar development. In a short lapse of time, each precursor will divide symmetrically, in average, eight times, making it prone to mutations which may result in medulloblastoma (MB) formation, the most common pediatric brain tumor. Otx2, a homeodomain transcription factor, is expressed in GCPs throughout their maturation with a posterior-high to anterior-low gradient. Otx2 function in cerebellum development and MB formation is still poorly understood. Otx2 overexpression is observed in 75% of MB. Ectopic expression of Otx2 in medulloblastomas cell lines increases their tumorogenicity, while Otx2 inhibition in xenograft tumors extends animal survival. Moreover, in vitro studies indicate that Otx2 may directly activate cell cycle genes and inhibit differentiation in MB cells. Together, these data suggest that this factor may act as an oncogene in MB formation by driving uncontrolled GCPs proliferation. In this study, we investigated the role of Otx2 in cerebellum development and GCPs proliferation using a conditional Otx2 KO mouse model. This system allows tamoxifen-inducible Otx2 ablation at the time of cerebellum formation (between E16.5 and P21), without affecting early development, where Otx2 plays essential functions. We triggered Otx2 ablation at postnatal day 1 (P1) and analyzed the consequences at P3 and P5. In parallel, we performed a transcriptomic analysis of Otx2 KO cerebellum to identify Otx2 targets in this organ. We show that Otx2 invalidation consistently results in a reduction of the posterior cerebellum size and in a decrease in the number of proliferating GCP. We are now assessing the function of Otx2 in a murine model of MB. Understanding the role and identifying the targets of Otx2 in normal and tumoral cerebellar GCPs will allow to develop new therapies to fight against MB.

Keywords: Cerebellum, Granule cell precursors, Otx2.

Oxidative stress induces S-glutathionylation of STAT3 and impairs its phosphorylation: in vivo and in vitro study

G. Chiavegato, E. Butturini, E. Darra, A. Carcereri de Prati, S. Mariotto
[1]*Department of Life and Reproduction Sciences, University of Verona, Verona, Italy*

STAT3 is a transcription factor constitutively activated in highly malignant solid and hematological tumor. Activated STAT3 may participate in oncogenesis by stimulating cell proliferation and inducing resistance to apoptosis, as well as promoting tumour angiogenesis, invasion, and migration. The tight association of STAT3 activation with transformation and tumor progression makes STAT3 a potential therapeutic target. Recently, we identify naturally occurring sesquiterpene lactones as potent inhibitors of both IL-6-inducible and constitutive STAT3 activation in different cells lines. These terpenes induce the drop in intracellular GSH concentration. Furthermore, the glutathione ethylene ester, the cell permeable GSH form, prevents their inhibitory action on STAT3 phosphorylation. The disturbance in the intracellular redox state induces S-glutathionylation of STAT3. These findings suggest that these compounds is able to induce redox-dependent post-translational modification of cysteine of STAT3 protein in order to regulate its function.

Many reports support the idea that STAT3 S-glutathionylation might represent the key event in redox STAT3 modulation. However, a number of questions still remain unanswered with regard to the molecular aspects of STAT3 S-glutathionylation, and it is unclear whether there is more than one cysteine residues active for glutathionylation.

In order to clarify S-glutathionylation of STAT3 we perform an *in vitro* study.

We demonstrated that the combined treatment with diamide, a thiols specific oxidant, and GSH induces S-glutathionylation of STAT3 in the recombinant purified form. This effect was completely reversed by treatment with dithiothreitol, indicating that S-glutathionylation of STAT3 was related to formation of protein-mixed disulphides.

Since STAT3 was glutathionylated in the presence of oxidants, we examined whether this modification might affect STAT3 phosphorylation using *in vitro* kinase assay. As expected, S-glutathionylation significantly decreased the level of STAT3 tyrosine phosphorylation and the addition of a reducing agent before JAK2 incubation almost completely rescued STAT3 phosphorylation level. The addition of the bulky negatively charged GSH moiety impairs JAK2-mediated STAT3 phosphorylation very likely interfering with tyrosine accessibility thus affecting protein structure and function. This suggests the possible cross-talk between phosphorylation and glutathionylation and points out that STAT3 is susceptible to redox regulation. The data presented herein confirm the occurrence of a redox dependent regulation of STAT3 but more research is needed to identify the

© 2014 The Authors. FEBS Journal © 2014 FEBS

cysteine residues mainly involved in S-glutathionylation of STAT3.

Keywords: Oxidative stress, S-glutathionylation, STAT3 signaling.

p53-specific E3 ubiquitin ligase MDM2 interacts with lysine methyltransferase Set7/9

O. Shuvalov[1], O. Fedorova[1], G. Ivanov[1], L. Lezina[2], N. Barlev[1]
[1]Institute of Cytology RAS, St. Petersburg State Technological Institute (Technical University), University of Leicester, St.Petersburg, Russian Federation, [2]St. Petersburg State Technological Institute (Technical University), University of Leicester, St.Petersburg, Russian Federation

TA53 protein is one of the most important tumour suppressors in mammals, also dubbed as 'guardian of the genome'. Acting as a transcription factor, p53 controls proliferation, metabolism, aging and apoptosis. The specificity of p53 response is controlled by a variety of post-translational modifications (PTMs). As a result, differentially modified p53 can selectively interact with various partner proteins at the same time. For example, dynamic lysine methylation of the C-terminal regulatory region in p53 by a number of lysine methyltransferases (KMTs) is one of the critical PTM that confer the specificity to the p53 activity.

One of these p53-modifying KMTs is Set7/9 (SETD7, Set9). This KMT, by methylating p53, on K372 enhances its subsequent acetylation, which, in turn, contributes to its stabilisation and activation. The main negative regulator of p53 is an E3 ubiquitin ligase MDM2, which blunts the p53-specific response by several means. Besides ubiquitinylation of p53, Mdm2 also interacts with various proteins that influence p53 activity. Given that Set7/9 increases p53 acetylation and Mdm2 decreases it, it is plausible that Set7/9 competes with Mdm2 for binding to p53.

In the present work we demonstrated a physical interaction between MDM2 and Set7/9. By using a panel of Set7/9 and MDM2 deletion mutants we have characterized this interaction in details using several approaches. At first, we expressed the recombinant GST-MDM2 and GST-Set7/9 deletion variants in bacteria and incubated the purified proteins with nuclear extract obtained from U2OS (human osteosarcoma) and H1299 (human lung carcinoma) cell lines. The interaction of MDM2 and Set7/9 was visualized by western blotting using anti-MDM2 and anti-Set7/9 antibodies. To validate these finding *in cellulo* we performed co-immunoprecipitations of co-transfected Flag-MDM2 and Flag-Set7/9 variants from U2OS and H1299 cells. Collectively, we demonstrated a novel interaction between MDM2 and Set7/9 and identified the protein regions responsible for this interaction. The role of this molecular interaction is discussed.

This study was supported by grants from the Goverment of Russian Federation no. 11.G34.31.0069, RFBR #14-04-32242 mol_a and RFBR #13-04-01024 A and from MCB Program at Russian Academy of Sciences.

PAMAM coated magnetic nanoparticles as CpG-ODN carriers for activation of toll-like receptor 9

N. Taghavi PourianAzar, U. Gunduz
Biotechnology, Middle East Technical University, Ankara, Turkey

Gene therapy is a powerful technique in the treatment of many life threatening diseases such as cancer. The major challenge in this therapy is to seek a safe and efficient delivery carrier for various gene materials. Carriers are designed to protect these molecules from degradation, improve their stability and facilitate the delivery of them to the site of action.

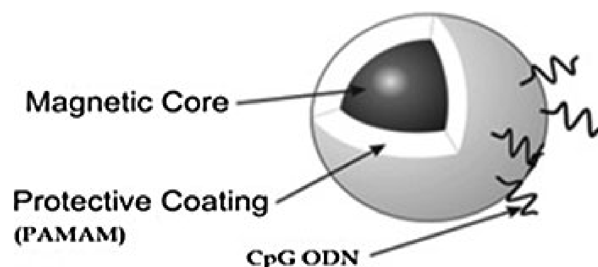

Fig. 1. Pathogen mimicking metal oxide nanoparticle.

CpG-oligodeoxynucleotide, the synthetic 24mer single stranded agonist of TLR9, containing unmethylated cytosine–phosphate–guanosine motifs (CpG-ODN) possess potential antitumor activity. This research aims to develop an appropriate carrier, with the ability of interacting with and delivering unmethylated CpG-ODNs into cells to activate toll-like receptor 9 (TLR9), which can be a very important process for therapy of cancers.

In our study, we utilized different generations of a three-layer magnetic nanoparticle composed of a Fe_3O_4 magnetic core, an aminosilane (APTS) interlayer and a cationic poly (amidoamine) (PAMAM) dendrimer to enhance the delivery of CpG-ODN molecules (Figure 1). The characterization of synthesized nanoparticles was performed by X-ray photoelectron spectroscopy (XPS), Fourier transform infrared spectroscopy (FTIR), Transmission electron microscopy (TEM), and ZETA potential analyses.

Magnetic nanoparticles at different generations were loaded with CpG-ODN. Loading of CpG-ODN onto PAMAM coated magnetic nanoparticle was followed by agarose gel electrophoresis. The characterization of CpG-ODN-loaded nanoparticles was carried out by Nanodrop spectrophotometer, X-ray photoelectron spectroscopy (XPS), Fourier transform infrared spectroscopy (FTIR), and ZETA potential analysis. Cellular internalization of bare nanoparticles and CpG-ODN-loaded nanoparticles were studied using different breast cancer cell lines, and cytotoxicity was determined by XTT analysis.

Results showed that the CpG-ODN-nanoparticles composites were successfully synthesized, can enter into tumor cells and inhibited cell growth in dose-and time-dependent means. In addition, more positive functional groups at the surface will make higher generations (G7, G6, and G5) of PAMAM coated nanoparticles a more suitable delivery system for CpG-ODN.

Taken together, our findings indicate that the developed system can be used for high transfection efficiency and effective targeting of TLR-9 in breast cancer cell lines, conferring a simple and noninvasive approach for cancer immunotherapy.

Keywords: Cancer immunotherapy, CpG-ODN, TLR-9.

Peculiarities of mTOR kinase subcellular localization in the human epithelial cells

V. Kosach, O. Cherednyk, V. Filonenko, A. Khoruzhenko
[1]Department of Cell Signaling, IMBG of NASU, Kyiv, Ukraine

The mammalian target of rapamycin (mTOR) is a highly conserved serine/threonine kinase. It is one of the central links of several signaling networks, which provide signal transduction from hormones, growth factors and nutrients into the cell. mTOR is a part of two distinct complexes mTORC1 and mTORC2, which participate in the regulation of translation initi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ation, autophagy, ribosome biogenesis, transcription, and cell survival. The specific realization of these functions is provided by separation of mTOR substrates to the different cellular compartments. Deregulation of mTOR signaling was detected in several human diseases, including different types of cancer, type II diabetes and neurodegenerative disorders. Nowadays much attention is paid to the studying of mTOR subcellular localization. It will help to understand functioning of signaling networks and its possible therapeutic correction.

Different human epithelial cell lines, such as MCF-7, MCF-10A, HeLa, HepG2, A549, and also histological sections of the normal and malignant human breast tissues were used in the research. Colocalization of mTOR and different types of the cytosceletal proteins was studied by double immunofluorescent analysis and then visualized with confocal or fluorescent microscopy. To verify interconnection of mTOR kinase and cytokeratins we performed co-immunoprecipitation and PLA.

Application of anti-mTOR N-terminal antibodies detected fibrils-like structure in MCF-7 cells. So, possible colocalization of mTOR and different cytosceletal proteins was tested. We didn't reveal obvious relation between the location of mTOR kinase and β-tubulin. The convincing colocalization of mTOR and β-actin also was not detected. However, there was a strong colocalization of mTOR and cytokeratins. Application of anti-pan-cytokeratin antibodies revealed such colocalization in a set of the human cell lines and epithelial cells of the human breast tissue samples. Also the use of a series of alternative fixation and permeabilization regimens did not alter the link between mTOR kinase and keratins. Then we compared reaction of the anti-N-terminal mTOR antibodies, generated in our laboratory, with commercially available ones. Under identical conditions of the experiment all tested antibodies recognized mTOR kinase at the fibrils of the intermediate filaments. Co-immunoprecipitation along showed that anti-mTOR antibodies precipitated keratins from lysates of MCF-7 cells. Obtained data were confirmed by PLA.

So, it was shown cytoplasmic localization of mTOR that is in accordance to results of other authors. But for the first time we discovered the colocalization of mTOR kinase and cytokeratins and revealed that it is a general phenomenon in human epithelial cells.

TUE-185
Phosphatidylcholin/sphingomyelin metabolizm crosstalk inside the nucleus chromatin after the cisplatin in vivo action

N. Hakobyan, A. Hovhanisyan, Z. Yavroyan, E. Gevorgyan
Yerevan State University, Yerevan, Armenia

It is known that the phospholipids represent a "minor component" of chromatin. It has been highlighted that these lipids are metabolized directly inside the nucleus thanks to the presence of the enzymes related to their metabolism such us neutral sphingomyelinase, sphingomyelin-synthase, reverse sphingomyelin-synthase and phosphatidylcholine–specific phospholipase C.

The present research was aimed to investigate the crosstalk of the lipid metabolisms in chromatin isolated from rat liver and thymus in vivo under the antitumour platinum drug cisplatin action. The possible mechanism of the crosstalk was discussed considering the recent literature in the field.

The in vivo 24-hour effect of cisplatin on rat liver and thymus cells nuclear phospholipids was investigated. Rat liver nuclear phospholipids were fractionated by microTLC technique. The quantitative estimation of fractionated phospholipids was carried out by computer program FUGIFILM Science Lab. 2001 Image Gauge V 4.0, which was destined for densitometry.

The small decrease of phosphatidylcholine quantity (14%) and the significant diminution of sphingomyelin (44%) in liver chromatin preparations as well as the reverse changes of these phospholipids in thymus chromatin preparations (decrease of phosphatidylcholine content over 40% and sphingomyelin quantity near 14%) was established.

The results confirm the probable influence of cisplatin on activity of sphingomyelinase and sphingomyelin-synthase and show that in chromatin exists a phosphatidylcholine/sphingomyelin metabolism crosstalk which regulates the intranuclear ceramide/diacylglycerol pool. The results also indicate that cisplatin may affect on phosphatidylcholine/ sphingomyelin crosstalk mechanism which exists in nuclei.

Keywords: chromatin, cisplatin, phospholipids.

TUE-186
Phosphorylation of CacyBP/SIP by casein kinase II – regulation by calcium binding protein S100A6

A. Filipek, B. Kądzioka, U. Wasik
Nencki Institute of Experimental Biology, Warsaw, Poland

CacyBP/SIP (Calcyclin binding protein/Siah-1 interacting protein) was originally purified from Ehrlich ascities tumor cells as an S100A6 ligand (Filipek & Wojda 1996; Filipek & Kuznicki 1998). Up to now, many papers have been published regarding tissue and cell distribution and binding partners of the CacyBP/SIP protein. Among these partners are members of calcium binding proteins from the S100 family, proteins involved in ubiquitination such as Siah-1 and Skp1, cytoskeletal proteins such as tubulin, actin, tropomyosin, and ERK1/2 kinase (Schneider & Filipek, 2011). Interestingly, the interaction of CacyBP/SIP with ERK1/2 kinase, due to phosphatase activity of CacyBP/SIP, results in dephosphorylation of ERK1/2 and has an influence on phosphorylation of the Elk-1 transcription factor. There is no data up to now as to the physiological role of the interaction between CacyBP/SIP and calcium binding protein, S100A6. Since the theoretical analysis showed that CacyBP/SIP might be phosphorylated by casein kinase II (CKII) on threonine 184, which is located close to the S100A6 binding site, in this work we examined whether CacyBP/SIP is phosphorylated by CKII and whether S100A6 has an effect on CacyBP/SIP phosphorylation/activity, and in consequence on cell growth and proliferation. CKII plays a central role in the control of a variety of pathways engaged in cell proliferation, transformation, apoptosis and senescence. Interestingly, in highly proliferating cells/tumors, an up-regulation of CacyBP/SIP and S100A6 is observed. Thus, phosphorylation of CacyBP/SIP by CKII and its regulation by S100A6 might be considered as one of the factors involved in cell proliferation/tumorigenesis. This work was supported by grant rom the National Science Center (NZ1/00595) and by statutory funds from the Nencki Institute of Experimental Biology.
Keywords: CacyBP/SIP, phosphorylation, S100A6.

Breast cancer is the most frequent cancer worldwide for females. Currently, the cancer stem cell (CSC) hypothesis suggests that

© 2014 The Authors. FEBS Journal © 2014 FEBS

many cancers, including breast cancer, are sustained by a subpopulation of cells that share common properties with embryonic and adult stem cells. CSCs are responsible for the tumor's self-renewal, heterogeneity and resistance to therapy. Because of their unique features CSCs are promising targets for novel anticancer therapeutic approaches. Recent studies showed that promyelocytic leukemia (PML) protein regulates the function of hematopoietic stem cells (HSCs) and leukemia initiating cells (LICs)[1]. Apart from the hematopoietic system, PML has been found to regulate the stem cells of the nervous system and the mammary gland[2]. PML is the core component of subnuclear structures, called PML-nuclear bodies, which are involved in various cellular functions including proliferation, apoptosis, senescence, transcription and self-renewal. PML is a well-established tumor suppressor gene and its expression is lost in primary breast cancer tissue samples[3]. However, it was recently found that PML is overexpressed in a subset of breast cancers[4]. In an effort to understand the molecular mechanisms underlying the involvement of PML in breast CSCs regulation we studied the effect of PML overexpression in breast cancer cell lines. Using two different experimental conditions, monolayer and mammosphere culture (CSCs enrichment), we compared the gene expression profile of breast cancer cells overexpressing PML. Primary data show that PML overexpression represses proliferation of breast cancer cells cultured in both conditions. Differentially expressed genes involved in proliferation, apoptosis, DNA repair and differentiation are analyzed by transcriptome profiling.

Potential side effects of resveratrol and baicalein in prostate cancer at physiological levels: a whole-transcriptome study using LNCaP cell line

M. Suhorutshenko[1,2,3], K. Tamm-Rosenstein[3,4], J. Simm[4], A. Salumets[1,3], M. Metsis[2,3]
[1]University of Tartu, Tartu, [2]Tallinn University, Tallinn, [3]Competence Centre on Reproductive Medicine and Biology, Tartu, [4]Centre for Biology of Integrated Systems, Tallinn University of Technology, Tallinn, Estonia

Introduction: Most flavonoids are known for their antioxidant qualities. These compounds act as agonists or antagonists of ligand-dependent transcription factor called aryl-hydrocarbon receptor (AHR). Besides direct transcriptional regulation, antioxidants can interacts with estrogen receptor (ER) and alters the expression of ER responsive genes. The mechanism of this is yet not well understood, whereas it was reported to be dose-dependent. The current study focuses on the processes affected by flavonoids at physiological levels that can lead to male reproductive system dysfunction. In the study, ER and AHR positive human prostate cancer cell line LNCaP was used as a model to investigate global gene expression in male reproductive cells, exposed to two natural AHR ligands, baicalein and resveratrol, in presence and absence of oestradiol.

The Study: RNA was extracted from cells, treated with oestradiol, baicalein, resveratrol at physiological concentrations at several time points, following cDNA synthesis. Chromatin was immunoprecipitated using ERα antibodies and HTP sequencing was applied for all samples. Analysis of the sequencing data revealed that the expression of thousands of genes was significantly regulated in LNCaP cells after treatment with baicalein and resveratrol. Among the genes with the highest expression rate change after resveratrol and baicalein treatments were such genes as *CCND2, CDH11, COL1A2, DLC1, EPHA4*. In addition, baicalein showed remarkable influence on ER ability to bind DNA and the expression of ER regulated genes. Interesting gene expression patterns ($p < 0.05$) were observed for the genes associated with carcinogenesis, endocrine disruption and spermatogenesis. RNA-seq and ChIP-seq results refer to the direct action of baicalein and resveratrol on ER signaling, without the need for AHR activation and suggest a set of ER-responsive genes directly regulated by baicalein and resveratrol.

Conclusions: A set of unique genes regulated by baicalein and resveratrol demonstrate the specific action of flavonoids at physiological concentrations in male reproductive tissues, whereas the ER-responsive genes, directly regulated by baicalein reveal their potential role in endocrine disruption, male infertility and prostate cancer. The results of whole transcriptome study suggests both positive and potential side effects of studied flavonoids. *In vivo* studies are currently being performed to analyse the results of the current study.

Keywords: baicalein, LNCaP, resveratrol.

Prediction of Bevacizumab drug efficacy on the treatment of colon cancer using bioinformatic algorithm OncoFinder

K. Lezhnina[1,2], N. Borisov[2], A. Zhavoronkov[1,2,3], A. Aliper[1,2], M. Korzinkin[1,2], A. Buzdin[1,2,3,4]
[1]Laboratory of Bioinformatics and Medical Information Technology, D. Rogachev Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [2]Pathway Pharmaceuticals, Wan Chai, Hong Kong, [3]Biogerontology Research Foundation, London, UK, [4]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation

One of the major problems of modern oncology deals with the efficiency of choosing of anticancer therapy that would be successful for treatment of an individual patient. A recently developed bioinformatic platform termed OncoFinder makes it possible to create a model of individual target drug efficacy to the patient basing on the high-throughput gene expression data. Microarray or Next Generation Sequencing – based gene expression profiles of tumor samples are investigated against datasets obtained for the normal tissue samples isolated from healthy donors. OncoFinder algorithm assesses the degree of pathological changes in the pro- and anti-mitotic signaling pathways and the ability of target anticancer drugs to compensate these changes. Bevacizumab is a target drug that belongs to the family of "mabs", i.e. therapeutic monoclonal antibodies. Bevacizumab binds to and inhibits the biological activity of human*vascular endothelial growth factor* (VEGF) protein, which is involved in many processes accompanying cancer development, including vascularization. Bevacizumab is routinely used for treatment of colorectal, kidney, non-small cell lung cancer, and certain brain tumors.We investigated the utility of OncoFinder algorithm in predicting the clinical efficiency of Bevacizumab for treatment of the patients with colon cancer. The gene expression profiles of the cancer tissue specimens taken from 26 patients that were either good or poor responders to the Bevacizumab treatment were processed with the OncoFinder platform and compared to the normal tissues. We show here that the OncoFinder-generated measures of potential drug utility termed "Drug Scores" differed greatly among the

© 2014 The Authors. FEBS Journal © 2014 FEBS

responder- and non-responder groups ($p < 0.003$). These results evidence that the OncoFinder platform if highly effective for prediction of the efficiency of colon cancer treatment with Bevacizumab.

Keywords: None.

TUE-191

Preferential binding of mutant p53 proteins to supercoiled DNA containing structural motifs in vitro and in cells

V. Tichy[1,2], L. Navratilova[1], M. Adamik[1], A. Polaskova[1], P. Bazantova[1], R. Helma[1], M. Brazdova[1]

[1]*Biophysical Chemistry and Molecular Oncology, Institute of Biophysics, Academy of Sciences of the Czech Republic,* [2]*Experimental Biology, Faculty of Science, Masaryk University, Bron, Czech Republic*

It was observed that the role of wild type p53 protein (wtp53) as a tumor suppressor depends on sequence specific interactions with promoters of target genes. This type of specific binding to DNA is performed by central DNA-binding domain (DBD) of p53 protein. Hot spot mutant p53 proteins (mutp53) are not able to bind to DNA sequence specifically because of mutations in their DBD domains. However, the binding of mutp53 proteins to DNA is assumed to be involved in mutp53-mediated repression or activation of several mutp53 target genes. The study of sequence specific binding of p53 protein revealed an importance of DNA topology in selective binding to responsive sequences. Structure specific binding of p53 protein is executed mainly by C-terminal DNA-binding domain (CTDBD), which is active also in mutp53 proteins.

In our work we investigated the importance of DNA topology on mutp53-DNA recognition *in vitro* and in cells by study of the interactions of seven hot spot mutp53 proteins with topologically different DNA substrates (supercoiled, linear and relaxed) containing and/or lacking mutp53 binding sites (mutp53BS). We used in this study a variety of techniques based on electrophoresis and immunoprecipitation. Our results show that all seven hot spot mutp53 proteins (R175H, G245S, R248W, R249S, R273C, R273H and R282W) retained the ability of wtp53 protein to preferentially bind supercoiled DNA, while linear or relaxed circular DNA was a poor substrate. The preference of mutp53 proteins for circular DNA at native negative superhelix density (supercoil-selective binding) was further supported by competition experiments with linear DNA or relaxed DNA *in vitro* and *ex vivo*. Similar results were obtained with DNA containing specific mutp53 binding site from promoter of *MSP/MST1* gene. Monoclonal antibodies specific for C-terminal or N-terminal epitopes of p53 protein were used for confirmation of important role of CTDBD domain in recognition of DNA topology. The preferential binding of mutp53 protein to supercoiled mutp53BS was explored also in cells by using chromatin immunoprecipitation. Moreover, an influence of DNA topology in p53 regulation of *BAX* and *MSP/MST1* promoters was detected by the luciferase reporter assay *in vivo*.

This contribution brings new information on mutp53 binding to topologically constrained DNA substrates and their biological consequences. Our work could be helpful for wider understanding of mutp53 protein functions in carcinogenesis.

Keywords: DNA topology, mutant p53 protein, protein – DNA interactions.

Preparation of fluorescent IgG monoclonal antibody conjugated PHB coated magnetic nonoparticles for imaging and cancer therapy

S. Yalcin[1], G. Unsoy[2], **N. Taghavi Pourianazar**[2], U. Gunduz[2]

[1]*Food Engineering, Ahi Evran University, Kırsehir,* [2]*Biotechnology, Metu, Ankara, Turkey*

Conjugation of monoclonal antibodies to magnetic nanoparticles is an effective method for cancer diagnosis and treatment. In this study the fluorescent IgG monoclonal antibody was conjugated to Polyhydroxybutyrate coated magnetic nanoparticles (PHB-MNPs). The conjugation process was carried out with the surface activation method of EDC (ethyl (dimethylaminopropyl) carbodiimide) and NHS (N-Hydroxysuccinimide). Fluorescent IgG monoclonal antibody conjugated PHB-MNPs were formed and incubated with MCF-7 cells prior to imaging. After washing the cells with PBS, they were observed by confocal laser scanning microscope. As a results, this method may be a useful method for detection of tumor cells, especially by MRI techniques.

Prognostic relevance of cholinergic signalling changes in head and neck squamous cell carcinomas

A. C. Castillo-González[1], S. Nieto-Ceron[1], J. P. Pelegrín-Hernández[1], C. J. Vidal[2], J. A. Noguera[1], M. F. Lopez-Moreno[1], J. N. Rodríguez-López[2], D. Hellin-Meseguer[3], J. Cabezas-Herrera[1]

[1]*Clinical Analisis Service, University Hospital Virgen Arrixaca-IMIB,* [2]*Department of Biochemistry and Molecular Biology A, University of Murcia,* [3]*Otorhinolaryngology Surgical Service, University Hospital Reina Sofia, Murcia, Spain*

The traditional view of acetylcholine (ACh) acting solely as neurotransmitter has changed based on the findings demonstrating that non-neuronal cholinergic system is vital for various types of cells such as epithelial, endothelial and immune cells. Changes in the expression of ACh-linked genes were causally related with cell proliferation. So, excess of ACh is expected to exacerbate cholinergic inputs and by this means accelerate tumour growth. This research was addressed to explore a possible link of cholinergic signalling changes with head and neck cancer. For this, paired pieces of head and neck squamous cell carcinoma (HNSCC) and adjacent non-cancerous tissue (ANCT) were compared for their mRNA levels for ACh-related proteins and ACh-hydrolyzing activity. The measurement in ANCT of acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) activities (5.416 ± 0.501 mU/mg protein and 6.442 ± 0.595 mU/mg protein) demonstrated that upper respiratory tract is capable of controlling the availability of ACh. In HNSCC, AChE and BChE activities dropped to 3.584 ± 0.633 mU/mg ($p = 0.002$) and 4.002 ± 0.418 mU/mg ($p = 0.001$). Moreover, tumours with AChE activity above 1.801 mU/mg (50th percentile) and BChE activity below 3.061 mU/mg were associated with increased patient overall survival. ANCT and HNSCC differed in mRNA levels for AChE-T and AChE-H, $\alpha7$ and $\alpha5$ of nAChR, and M3 and M2 mAChR. Our results suggest that the low AChE activity in HNSCC was associated with poor overall survival. So, the ChE activity level of head and neck carcinoma can be used as a reliable prognostic marker.

Keywords: cancer, cholinergic signaling, head and neck carcinoma.

Prognostic value of caspase activity in breast cancer tumor progression

U. Bagina[1], P. I. Kovchur[2], T. Volkova[3]
[1]Laboratory of Molecular Genetics of Innate Immunity, [2]Department of Radial Diagnostics and Radial Therapy, Oncology, Urology and Phthisiology, [3]Department of Molecular Biology, Biological and Organic Chemistry, Petrozavodsk State University, Petrozavodsk, Russian Federation

Caspases are the main components of apoptosis (programmed cell death) and are generally divided into regulatory caspases 8, 9, and effector caspases, such as caspase 3, 6, and 7. The universal mechanism of activation of caspases involves their aggregation and self-cleavage that ultimately results in cell death. It is generally accepted that apoptosis avoidance is one of the strategies of successful tumor progression. Accordingly, lower activity of caspases inhibits apoptotic processes and is usually associated with predisposal to several tumors including breast cancer. The aim of this study was to evaluate association of protease activity of the regulatory and effector caspases with breast cancer and to further investigate its possible correlation between grade of an oncopathology and caspase activity. We used breast cancer tissues derived from patients with various grades of breast cancer progression ranging from the first to the third grade. There were total 43 samples of breast carcinoma diagnosed in patients at Oncology Clinic of Republic of Karelia (Russia) between 2011 and 2013, and 30 normal breast tissue controls. Caspases -3, -6, -8, -9 activity assessment in a tumor tissue and peripheral blood lymphocytes was carried out at the different stage of breast carcinogenesis for determination of caspases activity. Caspase activity was measured using fluorogenic substrate while cellular apoptosis was assessed by means of cytofluorometric assay. For tissue caspases, there was statistically significant correlation between downregulation of caspases activity and degree of tumor progression. This difference held true for caspases 3, 6, 8, and 9. In contrast, we saw no decrease in activity for caspases 6 and 9 from peripheral lymphocytes. Furthermore, caspases 3 and 8 showed increase in activity in peripheral lymphocytes. Specifically, there was statistically significant difference between stages 1-3 of tumor progression for caspases 3 and 8. Overall, these data show that the activity of caspases in tissue can be used as prognostic parameter for breast cancer tumors.

Protease Nexin-1 enhances migration and invasion of C6 glioma cells through up-regulation of urokinase plasminogen activator and matrix metalloproteinase-9/2

V. Pagliara[1], A. Adornetto[2], M. Mammì[1], M. Masullo[3], D. Sarnataro[4], C. Pietropaolo[5], **R. Arcone**[3]
[1]Department of Health Sciences, University Magna Graecia, Catanzaro, [2]Department of Farmacy and Nutrition and Health Sciences, University of Calabria, Cosenza, [3]Department of Motory Sciences and Wellness, University Parthenope, [4]CEINGE, Advanced Biotecnologies S.C. a R.L., [5]Department of Molecular Medicine and Medical Biotecnologies, University Federico II, Napoli, Italy

Protease Nexin-1 (PN-1) or Serpine2 is a physiological regulator of extracellular proteases as thrombin and urokinase (uPA) in the brain. Recently, several experimental reports indicated that PN-1 is also implicated in some human cancers and further identifed as a substrate for matrix metalloproteinase (MMP)-9, a key enzyme in tumor invasiveness. In our study, we investigated the role of PN-1 in migration and invasive potential of glioma cells, using the rat C6 glioma cell line as stable clones transfected with pAVU+27 vector espressing PN-1 short-hairpin RNA. We find that PN-1 knockdown enhanced *in vitro* migration and invasiveness of C6 cells which also showed a strong gelatinolytic activity by *in situ* zymography. PN-1 silencing did not alter as prothrombin whereas increased uPA, MMP-9 and MMP-2 expression levels and gelatinolytic activity in conditioned medium from stable C6 cells. Selective inhibitors for MMP-9 (Inhibitor I) or MMP-2 (Inhibitor III) abolished the migration and invasive ability of PN-1 silenced cells in migration and matrigel invasion assays. Moreover, exogenous recombinant PN-1 added to the culture medium of silenced cells suppressed MMP-9 and MMP-2 gelatinolytic activity thus validating the specificity of PN-1 silencing strategy. Phosphorylation levels of extracellular signal-related kinases (Erk1/2 and p38 MAPK) involved in MMP-9 and MMP-2 signaling were increased in PN-1 silenced cells. Our findings suggest that PN-1 affects glioma cell migration and invasiveness through regulation of uPA and MMP-9/2 protein levels which contribute to the degradation of extracellular matrix during tumor invasion.

Proteome and metabolome analysis of ovarian cancer ascites as cell-cell communication medium

V. Shender[1], M. Pavlukov[1], G. P. Arapidi[1], S. Kovalchuk[1], N. Anikanov[1], I. Altukhov[2], D. Alexeev[2], R. Ziganshin[1], V. Govorun[1,2]
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, [2]Scientific Research Institute of Physical-Chemical Medicine, Moscow, Russian Federation

Ovarian cancer ascites is a native medium for cancer cells that allows investigation of the secretome of cancer cells in their natural environment. On the one hand, this medium is of interest as a promising source of potential biomarkers, on the other hand, as a medium for intercellular communication. Studies of the ascites with the use of omics technologies can help to understand the peculiarities of cancer cell activity in the organism and elaborate new therapeutic approaches. The aim of this study was to elucidate specific features of malignant ascites proteome and metabolome. Comparison of malignant ascites with those of cirrhosis allowed the revealing of the components specific for malignant ascites and omitting those that belong to systemic response to the ascites formation.

A novel combined approach to protein fractionation prior to mass spectrometry analysis allowed the identification of 1632 and 1139 proteins in ovarian cancer and cirrhosis ascites, respectively, 663 proteins were specific for malignant ascites. Importantly, this value was several times higher than the earlier published data. Interesting results were obtained by the functional analysis of proteomic data. We demonstrated that the major differences between cirrhosis and malignant ascites were observed for the cluster of spliceosomal proteins as well as large number of RNA-binding proteins was found in the malignant ascites.

In our GC/MS-based metabolomic analysis of the ovarian cancer and cirrhosis ascites, 129 compounds were found, and 89 of these compounds were identified as known metabolites. Forty-one compounds were considered to be statistically different

© 2014 The Authors. FEBS Journal © 2014 FEBS

according to the nonparametric Wilcoxon–Mann–Whitney test ($p < 0.05$) with Benjamini and Hochberg adjustment for p-values. Over one third of these compounds were identified only in the malignant ascites. The major significant differences between the malignant and control ascites were observed for fatty acids and their derivatives, which are known to be among the key components of intercellular signaling.

In summary this study extended our knowledge of the protein and metabolomic composition of the ovarian cancer ascites and revealed its specific features which were associated with the function of the ascitic fluid as a medium of interaction between the malignant cells and their environment.

Proteomic and protein glycosylation changes associated with TGFBR2 deficiency in MSI colorectal cancer

J. Kopitz
Applied Tumor Biology, University of Heidelberg, Heidelberg, Germany

Members of the transforming growth factor (TGF)-signaling pathway are common targets for mutation in colon cancers. Deregulation of this pathway appears to play an important role in colon carcinogenesis by affecting TGF-mediated growth inhibition, apoptosis, and differentiation as well as other TGF-regulated processes. In particular, inactivating mutations of the TGF-ß-receptor type II (TGFBR2) occur in more than 90% of microsatellite unstable (MSI) colon cancers. In order to systematically analyze TGFBR2-deficiency-associated changes of the biochemical phenotype of MSI colon carcinoma cells we used the TGFBR2-deficient MSI colon carcinoma cell line HCT116 as a model system. Stable clones conferring doxycycline (dox)-inducible expression of a single copy wild type *TGFBR2* transgene were generated by recombinase-mediated cassette exchange (RCME). By applying a click-chemistry approach with azido-derivatized amino-acids or monosaccharides we specifically labeled newly synthesized proteins or post-translational glycan modifications after dox-induction as well as in uninduced cells and clicked a biotin residue to the metabolically labeled proteins or oligosaccharide chains. Finally we extracted the labeled proteins by streptavidine-coupled magnetic beads. Identification of the bound proteins was achieved by nano-HPLC-coupled Orbitrap mass spectrometry. A total of 76 proteins was found to be expressed in a TGFBR2-dependent manner: 40 individual proteins were only expressed in TGFBR2-deficient cells and 36 individual proteins were exclusively found in TGFBR2-proficient cells. For 19 proteins altered sialylation and for 21 proteins altered fucosylation was found.

Altogether this study, based on a combination of three technologies, i.e. RCME, click-chemistry and mass spectrometry, provides a versatile platform to analyze proteomic as well as posttranslational modifications caused by MSI-relevant target genes like TGFBR2. On the one hand this approach can help to systematically puzzle out the consequences of tumor-specific mutations in a major signalling pathway as exemplified by the TFGBR2 tumor suppressor, on the other hand this approach facilitates the identification of tumor markers that could be used for diagnostic and therapeutic applications.

Keywords: colon cancer, microsatellite instability, TGF-beta signalling.

TUE-201
Quantitative expression analysis of the apoptotic gene BCL2L12 in breast cancer: association with clinical and molecular prognostic parameters

A. Kladi-Skandali[1], K. Michaelidou[1], A. Ardavanis[2], **A. Scorilas**[1]
[1]Department of Biochemistry and Molecular Biology, University of Athens, [2]First Department of Medical Oncology, Anticancer Hospital "Saint Savvas", Athens, Greece

Introduction: Apoptosis is a highly orchestrated, genetically regulated form of cell death, the impairment of which is crucial in breast cancer (BC) development and progression. *BCL2L12*, a member of the *BCL2* family of apoptosis-related genes, has been studied in various malignancies, revealing its potential role as a tumor biomarker. It has been recently found that *BCL2L12* is subjected to alternative splicing, resulting in the generation of 13 alternatively spliced variants. The aim of this study was the quantification of *BCL2L12* splice variants 1 and 2 (v.1 and v.2) expression at the mRNA level and the assessment of their biomarker potential in BC.

Methods: Total RNA was extracted from 40 pairs of BC and normal tissues. Thereafter, RNA was reverse transcribed into first-strand cDNA, which in turn was used as template in a SYBR Green based Real-Time PCR assay. Relative quantification analysis was conducted using the comparative C_T (2^{-ddC_T}) method, and the associations of *BCL2L12* variants expression with various clinopathological parameters, were evaluated by statistical analysis.

Results: *BCL2L12* v.1 mRNA levels were found to be significantly ($p = 0.003$) higher in malignant compared to their matched non-cancerous breast tissues. Moreover, *BCL2L12* v.1 demonstrated increased expression in premenopausal women ($p = 0.026$) as well as in those with early TNM stage tumors ($p = 0.039$). Interestingly, significant *BCL2L12* v.1 upregulation ($p = 0.044$) was observed in triple negative BC. Regarding *BCL2L12* v.2, a negative correlation with patients' age was found (($r_s = -0.376$; $p = 0.017$), whereas increased *BCL2L12* v.2 expression levels were associated with advanced tumor grade ($p = 0.022$) and ER-negativity ($p = 0.01$).

Conclusion: Our preliminary results indicate a possible involvement of *BCL2L12* v.1 and v.2 in BC progression and suggest their potential as biomarker in this malignancy.

Redox role of STAT3 in cellular survival during oxidative stress

C. Palmer[1], P. Shaw[1], L. Li[1], A. Larner[2]
[1]School of Life Sciences, The University of Nottingham, Nottingham, UK, [2]Department Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA

Signal Transducer and Activator of Transcription 3 (STAT3) is a transcription factor that is essential for embryogenesis and is involved in the development and maintenance of several tissues,

© 2014 The Authors. FEBS Journal © 2014 FEBS

including the heart. In the heart, STAT3 is vital for ischaemic preconditioning, an adaptive process in response to transient hypoxia that prevents cardiomyocyte apoptosis, a contributory factor in the progression of ischaemic heart disease.

Recently, a small pool of STAT3 was found to reside in the mitochondria and thought to modulate mitochondrial output by way of the electron transport chain (ETC). Deletion of STAT3 from the heart causes a reduction in the activity of complexes I and II of the ETC. In cells derived from mouse embryos we observed modest decreases in complex I and II stimulated respiration as well as complex I activity upon STAT3 deletion. The mitochondria are responsible for the majority of ROS generated in most cells, which is caused by electron leakage from primarily complexes I and III of the ETC. The mitochondria therefore contribute largely to the intracellular redox potential (IRP).

In the stressed heart, decreased oxygen tensions alter the IRP and can cause a concomitant increase in the production of reactive oxygen species (ROS). We have shown that STAT3 is directly sensitive to ROS. Oxidation of conserved cysteines by peroxide decreased STAT3 binding to consensus serum-inducible elements (SIE) in vitro and in vivo. A version of STAT3 that cannot be oxidized has been created (RI-STAT3) as have MEFs expressing RI-STAT3 and wild type STAT3 (WT STAT3) on a STAT3 null background. MEFs expressing RI-STAT3 have a reduced growth rate and appear not to sense oxidative stress as readily as wild-type STAT3 (WT-STAT3).

Our aim is to understand the role of STAT3 in ischaemic preconditioning. We seek to fathom if oxidation of conserved cysteines within STAT3 alter STAT3 mediated gene expression and indeed if the later is coupled to STAT3's ability to maintain mitochondrial integrity and ATP production in the face of oxidative stress.

TUE-204
Redox-mediated P-gp and MRP1 transport activity in human CD19+ lymphocytes

A. Tamashevski
Laboratory of Medical Biophysics, Institute of Biophysics and Cell Engineering of National Academy of Sciences of Belarus, Minsk, Belarus

In the last decade, there are a lot of experimental data about close relationship between tumor progression and cellular redox state. It is known that the alteration of the redox balance plays a key role in cell response to the antitumor agents action and is an important regulator of the expression of protein-transporters associated with multidrug resistance (MDR). However, the question about the influence of redox disbalance on the P-gp and MRP1 functional activity in various human subsets of immunocompetent cells still hasn't been studied in detail. So, necessity for such investigations is important for explaining a possible failure of the conventional chemotherapy and modifying its approaches taking into account the nature of the MDR transporters functioning under redox state changing and for development an adequate treatment strategy under B- or T-cell leukemia.

In current work the influence of the substrates of membrane transport proteins P-gp and MRP1 are using under the treatment of B-chronic lymphocytic leukemia (analogs fludarabine and cladribine, doxorubicin and vincristine) on the reactive oxygen species (ROS) accumulation in the donor's total lymphocyte population, $CD19^+$ (B-cells) and $CD19^-$ (T- and NK-cells) subpopulations is investigated, as well as the P-gp and MRP1 transport activity in these cells is estimated. So these enable to describe P-gp and MRP1 functioning under the redox-balance changing that is mediated by the anticancer drugs metabolism.

It is shown that P-gp transport activity is reduced in donor's B-lymphocytes as compared with the T-and NK-cells, moreover redox balance is shifted toward oxidants in this conditions. In intact donor's $CD19^+$ and $CD19^-$ lymphocytes the P-gp functionality depends on the redox balance. ROS level alteration relative to the physiological range (under the drugs influence) simultaneously determines the P-gp transport function in donors B-lymphocytes.

In turn, MRP1 functional activity in donor's $CD19^+$ and $CD19^-$ lymphocytes is almost equally as after drugs action as in intact cells. The accumulation of ROS lead to the activation, but ROS level decrease – to the inhibition of the MRP1 transport activity in the $CD19^+$ and $CD19^-$ intact cells. Shift the redox balance (relative to physiological range) towards oxidants results in decrease MRP1 transport activity in both subpopulations and towards antioxidants – increase only in B-lymphocytes.

Thus, the membrane transporters P-gp and MRP1 are involved in maintaining the physiological redox state in donor's intact lymphocytes. But there is a change in the functioning of these proteins in the $CD19^+$ cells under overrunning of this state.

TUE-205
Resveratrol enhances oxidative stress-induced apoptosis in mouse neuroblastoma Neuro 2a cells

J. Gerszon, A. Rodacka, M. Puchaa
Department of Molecular Biophysics, Univeristy of Lodz, Lodz, Poland

Resveratrol, (3,4′,5-trihydroxy-trans-stilbene) is a natural polyphenolic compound, produced naturally by some plants in response to several harmful factors such as attack by pathogens, UV radiation or increased oxidative stress. It is considered to be one of the strongest exogenous antioxidant with numerous properties. Many extensive investigations proved that this extraordinary polyphenol might slow progression or even prevent chronic diseases – cardiovascular, ischemic, neurodegenerative, diabetes. As the latest data show it also might improve chemotherapy.

The aim of our research was to evaluate the effects of resveratrol on nitric oxide- and hydrogen peroxide-induced oxidative stress in neuroblastoma cells (Neuro-2a). Resveratrol was added to the cells culture medium 3 and 12 hours before H_2O_2 or NOC-18 treatment. After 24 hours of incubation of Neuro-2a cells alone with H_2O_2 or NOC-18 respectively we observed reduced cell viability in dose-dependent manner. Concentration of the oxidants which caused 50% reduction in cell viability (IC_{50} value) was 0.037 mM and 0.27 mM for H_2O_2 and NOC-18, respectively. Resveratrol combined with oxidizing factors reduces cell viability substantially. Our data indicate that resveratrol in combination with H_2O_2 and NO increases the percent of apoptotic cells. Resveratrol more effective intensifies apoptosis in Neuro-2a cells in combination with nitric oxide-releasing compound than with hydrogen peroxide. We proved that resveratrol increases apoptosis via changes in mitochondrial membrane potential. Results demonstrate that impact of resveratrol on neuroblastoma cells depends both on concentration and time of incubation.

In conclusion, resveratrol in oxidative stress conditions, similar as are in tumor environment, intensifies apoptosis in Neuro-2a. This natural polyphenol might be applied in chemotherapy but still more evidences and further investigations of resveratrol action and its molecular targets are needed to use is as a drug.

Keywords: neuroblastoma, oxidative stress, resveratrol.

RGD-modified streptavidin selectively binds to and inhibits growth of cancer cells

M. A. Rubtsov[1], M. S. Syrkina[1,2], V. P. Veiko[2]
[1]Department of Molecular Biology, Moscow State University, [2]A.N.Bakh Institute of Biochemistry RAS, Moscow, Russian Federation

Nowadays the important role of cell adhesion molecules in invasion of metastatic tumor in surrounding tissues as well as in the growth of tumor blood vessels is well known. In particular the increased invasiveness and metastasizing that is typical for vertically growing melanoma is known to be mediated by specific integrins. So, integrin αvβ3 which is overexpressed in melanoma cells with high metastatic potential as well as in endothelial cells of tumor blood vessels and exhibits low expression level in normal melanocytes used to be an attractive target for melanoma diagnostics and therapy. Integrin αvβ3 is known to recognize the RGD peptide sequence which has been found in a wide variety of its natural ligands.

A number of expression vectors analogous to constructs described in [1, 2] has been constructed. These vectors provide the production of the streptavidin fused with RGD-bearing peptides (SR10, SR13, SR15) in *E.coli.* These proteins were demonstrated to bind selectively to murine (B16F10) and human (MeWo) melanoma cells as well as to endothelial cells (HUVEC).

In order to estimate kinetics of binding of each protein with receptors on the MeWo and HUVEC cell surface we've analyzed fluorescence intensity of cell population after incubation with FITC-labeled proteins SR10, SR13, SR15. We noted a characteristic feature – sharp decline in fluorescence intensity after 45 minutes of incubation. Probably this effect is due to the internalization of integrin receptors bound with SR10, SR13 or SR15. Internalization was confirmed by confocal fluorescent imaging of fixed MeWo and HUVEC cells. Luminous spots were detected on the membrane and in the compartment which is typical for endosome location. Moreover, it was noted that increase in incubation time leads to increase in fluorescence intensity both on the cell surface and in cytoplasm. Internalization observed might be caused by activation of the integrin receptors after binding with ligand. It's known that activated receptors undergo endocytosis with the following recycling [3].

An influence of different concentrations of SR proteins on cell viability was estimated by XTT-test. It was demonstrated that incubation of HUVEC in the presence of 1.5 μM SR15 leads to two-fold decrease in cell proliferation rate. The maximum decrease in MeWo proliferation rate (up to 18%) was achieved by exposition of cells to SR13 in 0.075 μM concentration.

This work was partially supported by: RFBR grant 13-04-01875.

RHOC-gtpase promotes colon cancer cell invasion in matrix metalloproteinase dependent manner

D. Keles[1], M. Sipahi[1], S. Inanc[2], G. Oktay[1]
[1]Medical Biochemistry, [2]Dokuz Eylul University, Izmir, Turkey

Introduction: RhoC GTPase is a member of the Ras superfamily of small GTPases which are involved in a wide range of cellular processes including polarization, migration, adhesion, vesicular trafficking, transcriptional regulation and, cell cycle. There are numerous studies which show that RhoC was overexpressed in many tumor cells especially during epithelial mesenchymal transition as well as in tumor invasion and metastasis. However the exact mechanism has not yet been identified how RhoC promotes invasion and metastasis. Matrix metalloproteinases (MMPs) are secreted and membrane bound endopeptidases which enhance the invasive and migratory potency of cells by removing extracellular barriers and releasing pro-metastatic molecules. In addition, MMPs are inhibited by endogenous tissue inhibitors of metalloproteinases (TIMPs) which are the major regulators of these proteases.

Purpose: The aim of this study is to investigate the effects of RhoC on invasive capacity of human primary (HCT-116) and metastatic (SW620) colon cancer cells via MMP expression and secretion levels.

Methods: RhoC gene was silenced by siRNA transfection in HCT116 and SW620 colon cancer cells. The depletion of RhoC mRNA and protein expression levels was confirmed with Real Time PCR and Western blot techniques, respectively. After siRNA mediated RhoC silencing; i) MMP-2, MMP-7, MMP-9, MMP-14, TIMP-1, TIMP-2 mRNA expression levels were detected with Real Time PCR ii) MMP-2, MMP-7, MMP-9 and TIMP-2 protein expression levels were investigated with Western Blot. iii) The activity levels of secreted MMP-2 and MMP-9 were determined with Gelatin Zymography. iv) The invasive capacity of HCT-116 and SW620 colon cancer cells was assessed by cell invasion assay kit.

Results: The knockdown of RhoC by siRNA strongly reduced MMP-7 protein expression levels in HCT-116 and also suppressed the secretion of proMMP-2 and proMMP-9 levels in both HCT116 and SW620 cells. Furthermore, the inactivation of RhoC resulted in upregulation of TIMP-1 mRNA expression levels in SW620 cells. Consistent with these results, cell invasion also decreased in both RhoC downregulated HCT-116 and SW620 cells.

Discussion: We predict that RhoC promotes invasion by both activating MMP-2, -7, and -9 and decreasing TIMP-1 levels in colon cancer cells. Therefore development of the new therapies that block RhoC activity may be effective to prevent the invasion of colon cancer cells.

RNase A caused rearrangement of intracellular pathways in tumor cells providing restoration of normal cell proliferation and differentiation

N. Mironova, O. Patutina, E. Brenner, A. Kurilshikov, M. Zenkova, V. Vlassov
Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

Recently, we have shown that the pancreatic RNase A is capable of inhibiting tumor and metastasis growth and one of the mechanisms is associated with the change of miRNA profiles in the

© 2014 The Authors. FEBS Journal © 2014 FEBS

blood and tumor cells (Mironova et al, 2013). Here, in order to find intracellular targets of RNase A, we performed an analysis of whole transcriptome of Lewis lung carcinoma tissue after treatment of tumor-bearing mice with RNase A by high-throughput sequencing using SOLiD 5.5 platform.

Analysis of sequencing data revealed that inhibition of tumor and metastasis growth by RNase A is accompanied by up-regulation of 320 genes and down-regulation of 645 genes in tumor cells. Top 20 of the mostly down-regulated genes includes snoRNA class (both C/D and H/ACA boxes) elevated in tumor cells; genes encoding proteins with cell-growth promoting and transforming activity (*PARK7*), genes encoding proteins functioned as negatively regulators of MAP kinase superfamily and tumor suppressor (*DUSP6*), which is associated with cellular proliferation and differentiation, anti-apoptotic genes (*LCN2*). Among top 20 of the mostly up-regulated genes are negative regulators (*FAM89B*) of TGF-beta signaling known to exert metastasis-promoting activity associated with epithelial-to-mesenchymal transition, modulation of cancer microenvironment and extracellular matrix components, inflammation and immune suppression at the later stage of tumor progression. Also we observed the increase in expression of genes encoding phosphatidylserine receptors (*JMJD6*) involved in phagocytosis of apoptotic cells, p53-inducible proteins (*STEAP3*), regulators of p53/TP53 stability (*USP10*).

Obtained data give the evidence that RNase A caused in tumor cells rearrangement of intracellular pathways associated with malignant transformation and tumor escape from immunological surveillance towards normalization.

ROCK specific inhibitor fasudil suppresses head and neck squamous carcinoma growth by stimulating gene expression and protein secretion of the chemokine CXCL14/BRAK

C. Miyamoto, S. Ozawa, T. Ikoma, S. Wada-Takahashi, S.-S. Takahashi, A. Yoshida, F. Yoshino, R.-I. Hata, M. C.-I. Lee, Y. Maehata
Kanagawa Dental University, Kanagawa, Japan

Ras-homologous small GTPase (RhoA) and Rho-associated coiled-coil-containing protein kinase (ROCK) are key regulators of the endocytic and exocytic trafficking of molecules in cells. Activation of this pathway promotes tumor invasion and metastasis. Fasudil is a specific inhibitor of ROCK, which has been approved for the treatment of cerebral vasospasm. We previously reported that fasudil has anti-tumor activity by stimulating Chemokine CXCL14/BRAK(BRAK) secretion in fibrosarcoma cells. But effect of Head and Neck Squamous Carcinoma cells (HNSCC) are not clear. We investigated the effects of Fasudil on BRAK secretion and gene expression in HNSCC cells.

We examined the effect of Fasudil on tumor growth. HSC-3 cells were inoculated subcutaneously into both sides of the dorsolateral regions of female mice (5 weeks old). These mice were daily-administered Fasudil, i.p. (50 mg/kg/day). Fasudil suppressed the growth of HSC-3 in vivo (n = 6). Next, we examined the effects of fasudil on the secretion of BRAK protein by using ELISA in HSC-3 cells. The secretion of BRAK protein was significantly increased by treatment with fasudil in HSC-3 cells. In order to determine the effects of Fasudil on the gene expression of BRAK by using qPCR in HSC-3 cells. The gene expression of BRAK was significantly increased by treatment with Fasudil (25 μM) in HSC-3 cells.

These results suggest that Fasudil inhibits tumor growth by stimulating secretion of BRAK protein and gene expression of BRAK in the HNSCC cells. These results suggest that HNSCC therapy using fasudil may have clinical efficacy.

TUE-210
Role of C3G in tumorigenesis: cross-talk with p38alfa MAPK pathway

N. Priego[1], M. Arechederra[1], C. Sequera[1], A. Vázquez[1], S. Ortiz-Rivero[2], C. Guerrero[2], A. Porras[1]
[1]*Biochemestry and Molecular Biology II, Faculty of Pharmacy Complutense University of Madrid, Madrid,* [2]*Centro De Investigación Del Cáncer (USAL-CSIC), Salamanca, Spain*

C3G is a guanine nucleotide exchange factor (GEF) for Rap1 and R-Ras, but it also plays functions independent of its GEF activity. It is essential for embryonic development due to its role in integrin-mediated adhesion and migration. The function of C3G in human cancer is controversial. It suppresses malignant transformation induced by several oncogenes in NIH3T3 cells, but it can also mediate it, as it occurs in papillary thyroid carcinoma. In addition, C3G inhibits migration of highly invasive breast carcinoma cells.

p38 MAPKs are activated by several stimuli leading to the regulation of different cellular functions, including migration and invasion. p38a MAPK is the most abundant isoform and essential for embryonic development. It can act as a tumour suppressor, but it can also promote migration, invasion and survival of tumour cells in some cases.

We have identified a functional interaction between C3G and p38a MAPK in the regulation of cell death and adhesion in mouse embryonic fibroblasts (MEFs) and in chronic myeloid leukemia cells. In these systems, C3G acts through the inhibition of p38a MAPK in order to either activate or inhibit apoptosis, depending on the stimulus. Thus, we have also evaluated by *in vitro* assays whether this C3G/p38a cascade regulates migration and invasion of MEFs and HCT116 colon carcinoma cells. We found that C3G knock-down promotes migration and invasion through the enhancement of p38a activation via a Rap-1 independent pathway. MMPs might be important mediators. These results indicate that C3G is an inhibitor of migration and invasion, while p38a will mediate these processes. So, C3G would impair the development of metastasis acting as a tumour suppressor. However, we have also found that C3G promotes tumour growth of HCT116 cells, both *in vitro* and *in vivo,* regardless of the presence of p38a. Moreover, in this model, p38a also favours tumour growth. Thus, C3G or p38a Knock-down, as well as p38a chemical inhibition, highly decrease anchorage independent growth and tumour growth in xenograft assays. We are currently evaluating the potential mediators of C3G and p38a actions and the mechanisms involved.

Role of GS28 on sodium nitroprusside-induced cell death in human cervical carcinoma cells

S.-W. Jeong[1], H. J. Yoo[1], H.-M. Kim[1], O.-J. Kwon[2]
[1]*Biochemistry,* [2]*Catholic University of Korea, Seoul, Korea*

We observed the decreased expression of GS28 (golgi SNAP receptor complex 1) in ischemic hippocampus of rat brain. GS28 is involved in ER-golgi transport of proteins synthesized in ER, but almost unknown in another role. In this study, we examined the role of GS28 and its molecular mechanisms on sodium nitro-

prusside (SNP)-induced cell death in human cervical carcinoma cells (Hela). GS28 siRNA-transfected (K/D) cells showed significant inhibition of cytotoxicity in the cells treated with SNP, compared with that of control cells. Pretreatment of GS28 K/D cells with p38 and JNK MAPK inhibitors reduced the inhibition of cytotoxicity in SNP–treated cells. And phosphorylation of p38 and JNK MAPKs decreased in control cells treated with SNP, but didn't decrease in that of GS28 K/D cells in immunoblot analysis. Pretreatment with ROS scavenger or iron chelator inhibited the cytotoxicity both of the control and GS28 K/D cells treated with SNP. Pretreatment of the GS28 K/D cells with pancaspase inhibitor had no effect on cytotoxicity both of the control and GS28 K/D cells treated with SNP, but autophagy inhibitors (bafilomycin and concanamycin A) reduced the cytoxicity of control cells. Taken together, GS28 has an inductive role on SNP-induced cell death via modulation of p38 and JNK activity in human cervical carcinoma cells.

Keywords: gs28, mapk, nitroprusside.

Role of p53 homologues p63 and p73 in CXCR5 gene regulation in human breast carcinoma cells under genotoxic stress

N. A. Mitkin[1], A. M. Muratova[1], A. M. Schwartz[1], D. V. Kuprash[1,2]

[1]Laboratory of Intracellular Signaling in Health and Disease, Engelhardt Institute of Molecular Biology RAS, [2]Department of Immunology, Lomonosov Moscow State University, Moscow, Russian Federation

Tumor cells often demonstrate overexpression of various chemokine receptors which is associated with their increased survival and migration potential. Recently, CXCR5-CXCL13 co-expression was identified as a negative prognostic factor in breast cancer patients with lymph node metastases. We set out to investigate CXCR5 attenuation as a possible therapeutic strategy for advanced metastatic breast cancer. We have previously shown that p53 could repress CXCR5 expression, CXCR5 promoter activity and cell migration in a breast cancer cell line. In the current study we examined the possible role of two other p53 family members, p63 and p73, in this process. p53 expression in MCF-7 breast cancer cells was suppressed by lentiviral transduction of an shRNA vector. CXCR5, p53, p63 and p73 expression was measured by QRT-PCR and by Western blotting. In order to activate p53-dependent protective and apoptotic mechanisms, we used DNA-damage agent methyl methanesulfonate (MMS).

P53 suppression in MCF-7 cells led to elevated expression of both p53 homologues, especially the p73. MMS exposure for 24 hours caused dose-dependent decrease in CXCR5 expression despite the low level of wild-type p53, indicating alternative activation of p53-dependent pathways, probably through p63 or p73. Our results led us to suggestion that genotoxic stress in p53-deficient cells causes reactivation of p53 pathway through p63 and p73 systems. To understand individual roles of p63 and p73 in CXCR5 regulation, we are generating derivatives of MCF-7 cells with different combinations of p53, p63 and p73 inactivation using the CRISPR-Cas9 system. For enhanced genome editing specificity and for minimized off-target activity, the single nicking D10A Cas9 mutant is being employed.

TUE-214

Smad proteins differentially regulate the activity of murine protein serine-threonine kinase 38 (MPK38)

H. Ha, H.-A. Seong, R. Manoharan

Biochemistry, Chungbuk National University, Cheongju, Korea

We have demonstrated previously that murine protein serine-threonine kinase 38 (MPK38/MELK), a member of AMP-activated protein kinase (AMPK) family, stimulates TGF-beta signaling in a kinase-dependent manner via Smad(s) phosphorylation. Based on this finding, we speculated that MPK38 activity is subjected to Smad regulation in which Smad proteins positively or negatively regulate the activity of MPK38. In this study, we demonstrate that Smad2/3/4 have a positive role, whereas Smad7 has a negative role, in the regulation of MPK38 activity and function. Wild-type Smad2/3/4 markedly increased the stability of MPK38 compared to control expressing empty vector, whereas Smad7 decreased the MPK38 stability. However, MPK38-mediated phosphorylation-defective Smad mutants (Ser^{245} of Smad2, Ser^{204} of Smad3, Ser^{343} of Smad4, and Thr^{96} of Smad7) had no such effect. We further analyzed the effects of Smad proteins on the complex formation between MPK38 and Trx, a destabilizer of MPK38, using RNA interference. Results showed that Smad2/3/4 decreased the complex formation, whereas the complex formation was increased in the presence of Smad7, indicating a differential role of Smad proteins for regulating the stability of MPK38. Consistently, ectopic expression of wild-type Smads (Smad, 2, 3, 4, and7), but not the MPK38-mediated phosphorylation-defective Smad mutants, differentially regulate MPK38-dependent ASK1, TGF-beta, and p53 signaling in a dose-dependent fashion by stabilizing or destabilizing the MPK38 protein, suggesting Smad proteins as potential regulators of MPK38 in cells.

Keywords: Smad proteins, ASK1, TGF-beta, and p53 signaling, MPK38/MELK.

TUE-215

Sox9 is required for basal cell carcinoma tumorigenesis

K. Zoidl, C. Adolphe, B. Wainwright

Institute for Molecular Bioscience, Brisbane, Qld, Australia

The epidermis comprises a variety of stem/progenitor cell populations within different epidermal compartments, which in the last years have been intensively studied for their potential in initiating basal cell carcinoma (BCC). The key molecular event driving the formation of BCCs is constitutive Hedgehog signaling. Independent of the histologic subtype, all BCCs express the transcription factor Sox9, which is thought to be a direct downstream target of Hedgehog signaling. Sox9 is required not only for the formation of the multipotent epidermal stem cell population, but also for maintaining the stem cell pool for each recurring adult hair follicle cycle. Here we addressed the hypothesis that Sox9 is the key Hedgehog target required for BCC initiation and/or maintenance.

Loss of Ptch1 leads to upregulation of Hedgehog signaling and formation of BCCs. Here, through the combination of a Ptch1 conditional allele ablated under the control of Keratin5 cre followed by grafting to immunodeficient mice, we verified that BCCs result.

Preliminary evidence indicates that concomitant ablation of both Ptch1 and Sox9 results in hair follicle-deficiency as previously reported in epidermal Sox9 knockout studies but more importantly, prevents development of BCC. These data reveal

© 2014 The Authors. FEBS Journal © 2014 FEBS

that Sox9 is a critical player in BCC pathogenesis. However, we cannot exclude the possibility that the blockage of BCC tumorigenesis might be the effect of loss of the cellular origin as Sox9 ablation also results in the loss of the multipotent stem cell population.

This study significantly contributes to the understanding of molecular cues underlying BCC carcinogenesis and has revealed a potential new therapeutic target.

Keywords: basal cell carcinoma, Sox9, transcription factor.

TUE-216
Standardization of collagen zymography method for determining matrix metalloproteinases -1, -8 and -13 activities

S. Inanc, D. Keles, G. Oktay
Medical Biochemistry, Health Sciences, Izmir, Turkey

Introduction: Matrix metalloproteinases (MMPs) are a large family of Zn^{+} and Ca^{2+}-dependent endopeptidases which are subdivided into collagenases, gelatinases, stromelysins, matrilysins and membrane-type according to their substrate specificity, primary structure and cellular location. MMPs are responsible for degradation of several extracellular matrix (ECM) components and cleavage of non-ECM molecules such as growth factors, integrins, and receptors. Therefore they involved in both physiological and pathological processes. MMP-1, -8 and-13, known as collagenases, are capable of degrading collagen type I, II, III, VII, VIII, X, XI, and processing some cytokines. Collagen zymography is an electrophoretic technique based on SDS-PAGE principle. It provides the detection of pro and active forms of collagenases in the same gel.

Objective: The goal of this study was to standardize collagen zymography method and determine the sensitivity of collagen zymography for each collagenases.

Method: Commercially obtained type I and type II collagen were used as substrate for comparing which substrate is the most sensitive to detect collagenases. Also, type I collagen was purified from rat tail tendons. The SDS-PAGE gels containing different substrate concentrations (0.15, 0.3 and 0.6 mg/ml) were prepared and recombinant human collagenases (rhMMP-1, -8 and -13) were loaded different concentrations (1-100 ng), and finally electrophoresed with molecular weight marker to identify band sizes for pro and active forms of each MMPs. Following electrophoresis and renaturation steps, the gels were incubated in developing buffer for 24 h and 48 h. Each experiment was repeated six times. Densitometric analysis of the lytic bands were quantified and standard curves were plotted as activity unit versus amount of rhMMP-1, -8 and -13. After standardization of the method, human thyroid cancer (8505C) and normal thyroid (Nthy-ori 3-1) cell lines were examined by using collagen zymography method.

Results: The purified type I collagen was determined as the best suitable substrate than commercial type I and type II collagen. The best clear lytic bands were obtained with 0.3 mg/ml type I collagen substrate concentration after 48 h incubation. We found that the lowest collagenase activity can be detected in these conditions was 1 ng. The quantifications of rhMMP-1, -8 and -13 bands showed linear standard curves ranged from 1 to 10 ng concentrations. According to collagen zymography results, proMMP-1 was found in thyroid cancer cell line.

Conclusion: In this study, we improved collagen zymography method by using type I collagen that purified from rat tail tendons. We also generated the standard graphs of each collagenases to quantify the activities of collagenases in unknown samples.

TUE-217
Sterically stabilized cationic liposomes for efficient glycotargeted gene delivery to hepatocytes

K. Naicker, M. Ariatti, M. Singh
Biochemistry, University of KwaZulu-Natal (Westville), Durban, South Africa

This study focused on the assembly, characterization, and *in vitro* evaluation of lectinized gene delivery lipoplexes for improved transfection efficiency via asialoglycoprotein receptor (ASGP-R) mediated endocytosis, with the design capacity for hepatocytic corrective gene therapy. Cationic liposomes based on two cholesteryl cytofectins, 3β-[*N*-(*N'*, *N'*-dimethylaminopropane)-carbamoyl] cholesterol (Chol-T) and *N*, *N*-dimethylaminopropyl-aminylsuccinylcholesterylformylhydrazide (MS09), and the neutral lipid dioleoylphosphatidylethanolamine (DOPE), were prepared. Stealth liposomes were prepared by steric stabilization using 1,2-distearoyl-*sn*-glycero-3-phosphoethanolamine-*N*-[methoxy(polyethylene glycol)-2000] ($DSPE\text{-}PEG_{2000}$) grafting while hepatocyte ASGP-R targeting was achieved using the cholesteryl-β- -galactopyranoside (Chol-β-Gal) functionality.

Cryo-TEM and DLS studies revealed that PEGylation generated smaller and denser aggregated lipoplexes than their non-PEGylated counterparts. All formulations were in the range 138 – 250 nm with narrow particle size distributions (polydispersity indices were <0.4). An increase in PEGylation was accompanied by decreased particle size and ζ-potential ($P < 0.001$). Liposomes bound and efficiently compacted pCMV-*luc* DNA as evidenced in band shift and ethidium bromide intercalation assays respectively, while nuclease digestion assays demonstrated that the degradative effect of serum on lipoplex-associated DNA was minimal. MTT [3-(4, 5-dimethyl-2-thiazolyl)-2, 5-diphenyl-2H-tetrazolium bromide] and AlamarBlue (AB) reduction studies, showed that the lipoplexes elicited a dose-dependent cytotoxic effect in both HEK293 and HepG2, with cell viability remaining above 70% (MTT) and 50% (AB). The *Ricinus communis* (RCA_{120}) agglutination test demonstrated that the galactosyl residues on the targeted lipoplexes were well exposed and accessible as shown by the selective and time-dependent agglutination and inhibition by the competitive binder, -galactose. Targeted lipoplexes were able to deliver pCMV-*luc* DNA up to 300% more effectively ($P < 0.001$) compared to their untargeted equivalents. An increase in PEGylation of the Chol-β-Gal liposomes was accompanied by an increase in luciferase activity. MS09 Chol-β-Gal 2% PEG and MS09 Chol-β-Gal 5% PEG complexes were able to achieve on average, 9% (N/P 2.3) and 20% (N/P 3.5) greater transfection levels in HepG2 cells than the commercial transfection reagent TurboFect (TF), respectively. Competitive inhibition studies produced a decline ($P < 0.001$) in luciferase activity of >83%, confirming targeting specificity and ligand-directed ASGP-R-mediated uptake of the targeted lipoplexes in HepG2 cells.

In vitro studies strongly suggest that PEGylated ASGP-R directed lipoplexes should be developed further for application *in vivo*.

Strict targeting of receptors by strereospecific monoclonal antibodies

M. Tomita, C. Miyamae, Y. Isozaki, Y. Yamasaki, K. Tsumoto
Division of Chemistry for Materials, Graduate School of Engineering, Mie University, Tsu, Mie, Japan

Until now, various kinds of monoclonal antibodies (mAbs) directed against target antigens have been established and widely utilized for many purposes. Lately, mAbs have also attracted

© 2014 The Authors. FEBS Journal © 2014 FEBS

attention as potent therapeutic medicines because of their strict specificity for particular antigens. The global market for therapeutic mAbs is expanding and is likely to be worth more than US $70 000 million in 2016. However, there is one big problem. Most established mAbs recognize the primary structures of antigens. If membrane receptors are the target antigens, stereospecificity of mAbs is of critical importance. However, practical protocols for generating stereospecific monoclonal antibodies (ssmAbs) have yet to be established. To address this question, we developed a new hybridoma technology termed the "stereospecific targeting (SST)" technique, which features two pivotal steps. One is employment of DNA immunization. The target antigens must be expressed in the mouse body retaining their original conformational structures and then be recognized by the immune system to sensitize B lymphocytes so that they mature to generate conformation-specific antibodies. Another point is the usage of antigen-expressing myeloma cells. If DNA-immunized B lymphocytes are selected by myeloma cells based on B cell receptors (BCRs), the selected B lymphocytes could produce stereospecific antibodies, since antigens expressed on the surface of myeloma cells keep their structures intact. Finally, myeloma cell-B cell complexes are selectively fused by electrical pulses to generate hybridoma cells secreting ssmAbs. The advantage using electric fusion is that only attached cells are preferentially fused. As a test, we selected EphA2 as an antigen, which is overexpressed by multiple types of epithelial tumors. As a result, the formation of myeloma cell-B cell complexes could be identified based on immunofluorescence analysis after targeting sensitized B lymphocytes with intact antigens expressed on myeloma cells Moreover, the desired mAb was successfully obtained, reacting with EphA2-expressing MDA-MB-231 cancer cells, but lacking cross-reactivity with recombinant EphA2. There is one more important point for this new technology. The SST technique may also be applicable for selective production of "human" ssmAbs by using transgenic mice producing human antibodies. Since the SST technique is very simple, ready generation of human ssmAbs is very feasible.

Keywords: monoclonal antibodies, receptors, stereospecificity.

Synergistic and antagonistic effect of heat shock-induced HSF1 on expression of NF-κB-dependent genes

P. Janus[1,2], T. Stokowy[3], R. Jaksik[1], L. Handschuh[4], K. Szoltysek[2], M. Kimmel[1], P. Widlak[2]
[1]*Faculty of Automatic Control, Electronics and Computer Sciences, Institute of Automatic Control, Silesian University of Technology,* [2]*Center for Translation Research and Molecular Biology of Cancer, Maria Sklodowska-Curie Memorial Center and Institute of Oncology, Gliwice, Poland,* [3]*Department of Clinical Science, University of Bergen, Bergen, Norway,* [4]*Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznan, Poland*

As the result of stress conditions, different signal transduction pathways are activated in cell that determine the mechanisms responsible for adaptation and survival. Among them are two major pathways, regulated and executed by NFκB and HSF1 transcription factors, which are critical for growth, development and response to the treatment of cancer and other human diseases. Both signaling pathways can interfere with each other, but mechanism of this regulation is not clear yet. Here we aimed to identify NFκB-regulated genes, which expression is affected by HSF1, in positive or negative way.

Expression of NFκB-dependent genes was analyzed in U2OS human osteosarcoma. These cells, either control and preconditioned with hyperthermia (HS) to activate endogenous HSF1, were stimulated with TNFα cytokine and the expression of TNFα-induced genes was analyzed by the expression microarrays. Actual sites of HSF1 binding to chromatin were detected in cells subjected to HS by chromatin immunoprecipitation assay coupled with DNA sequencing (ChIP-Seq approach). Bioinformatics analysis was also made for prediction of hypothetical κB and HSE motifs in promoter regions of analyzed genes.

We observed, that 324 genes changed their expression upon stimulation with TNFα; 191 genes were up-regulated while 133 genes were down-regulated compared to untreated control. Hypothetical κB motifs were found in proximal promoters of 114 of these genes (this group putatively represents set of genes regulated by NFκB). We found, that expression of 187 of TNFα-modulated genes was affected by the hyperthermia pre-treatment. Two modes of co-effects were observed: synergistic/additive (strengthen of TNFα effect) and antagonistic (reduction of TNFα effect). In general, among genes co-affected by TNFα and HS, the κB motif was present in proximal promoters of 74 genes, while the HSE motif and/or actual HSF1 binding was observed in regulatory regions of 52 genes. We identified 27 co-affected genes with binding sites (either hypothetical or actual) for both transcription factors. Among them there were 10 genes, for which observed effect of HS on their TNFα-induced expression was synergistic/additive (eg *EGR1, FOSB, RRAD*) and 17 genes with antagonistic effect (eg *CCL2, CCL20, CD83, IL8, TNF*).

This work was supported by Polish National Science Center, Grant 2013/08/M/NZ1/00935 (KS, PW) and DEC-2012/04/A/ST7/00353 (PJ, RJ, MK).

System Architecture of membrane-anchored Ras - big insight on the nanoscale

D. Abankwa
Turku Centre for Biotechnology, ÅBO Akademi University, Turku, Finland

The small GTPase Ras is highly mutated in human cancers and thus a major driver of cell transformation and tumorigenesis. In

© 2014 The Authors. FEBS Journal © 2014 FEBS

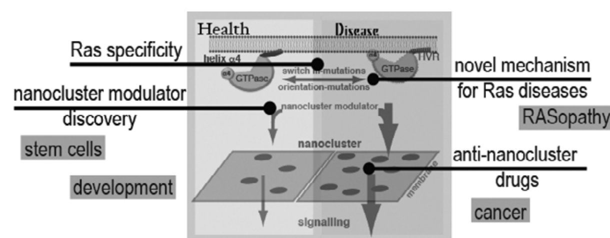

Fig. 1.

the plasma membrane approximately 40% of Ras proteins are organized into nanoscopic signaling platforms, called nanocluster. Ras nanocluster are dynamic proteo-lipid complexes that contain 6-8 Ras proteins and they are essential for Ras signaling. Lateral segregation of Ras paralogs to distinct nanocluster furthermore contributes to their specific activity. However, little is known about the composition, functioning and physiological relevance of Ras nanocluster.

Using biochemical, molecular cell biological, fluorescence superresolution microscopic and computational methods, we investigate how paralog-specific Ras nanoclusters are regulated. In addition, we exploit chemical screening to generate new tools to study Ras nanocluster and explore the potential to generate new lead compounds against Ras in cancer.

Our latest results revealed an unprecedented mechanism of Ras over-activation in cancer. Certain tumor associated mutations increase Ras activity by uniquely augmenting its nanoclustering, as not other biochemical activities are significantly affected. These findings validate Ras nanocluster as drug-targets. We therefore use customized nanoclustering-FRET biosensors to identify compounds that specifically affect the membrane organization of Ras and thus its signaling. This recently lead us to the discovery of cancer stem cell active drugs, which specifically affect K-ras signaling.

Our work aims at the complete description of the Ras signalling architecture on the membrane. We expect that improved understanding of Ras nanoclustering has special potential to yield innovative cancer-drug targets, –biomarkers and -drugs. Based on our evidence for nanoclustering of other classes of membrane anchored signalling proteins, we propose a broad implication of this mechanism in biology.

TUE-222
Systematic characterization of drug-induced adaptive responses in melanoma

M. Fallahi-Sichani[1], N. Moerke[1], M. Niepel[1], T. Zhang[2], N. Gray[2], P. Sorger[1]
[1]Systems Biology, [2]Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Boston, MA, USA

Activation of BRAF via a V600E mutation is the most prevalent genetic change in human melanoma, found in at least 50% of tumors. The $BRAF^{V600E}$ oncoprotein induces constitutive activation of pro-mitogenic RAF/MEK/ERK signaling. Therapy with RAF inhibitors such as vemurafenib leads to rapid tumor regression in most patients, but the duration of responses is highly variable with frequent relapse to lethal drug-resistant disease. It is increasingly clear that innate resistance of melanoma cells to RAF inhibitors involves adaptive responses that reactivate ERK or induce pro-growth pathways such as the PI3K/AKT cascade. Thus, understanding and ultimately preventing adaptive responses is a key to durable therapy. Systematic data comparing $BRAF^{V600E}$ tumor cells is generally lacking and is not known whether adaptation to different MEK and RAF inhibitors is fundamentally similar. It is also unclear whether the key difference between sensitive and resistant cells involves drug potency (difference in IC_{50}) or the fraction of cells that are responsive (E_{max}).

We develop a systematic approach to profiling drug adaptation that combines high density time- and dose-dependent multiplex biochemical measurement with single cell assays and statistical modeling, with the overall goal of (i) characterizing variability in adaptation with time, dose and genotype, (ii) discovering new or poorly characterized adaptive mechanisms, and (iii) demonstrating the effectiveness of a high-throughput approach involving multiplex measurement and computational modeling. Our analysis indicates that responses to RAF inhibitors are remarkably diverse and involve multiple cell signaling kinases that can be up or down-regulated over time, often in different directions in different cell lines, and extend well beyond the RAS/MEK/ERK and PI3K/AKT known to influence responses to RAF inhibitors in melanoma cells. We characterize the role of JNK/c-Jun in adaptation and show that RAF and JNK inhibitors induce synergistic cell killing. Single-cell studies show that JNK inhibition prevents a subset of vemurafenib–treated cells from becoming quiescent, thereby promoting apoptosis and increasing E_{max}. These findings have potential therapeutic significance and reveal the value of studying drug adaptation using systematic biochemical, single-cell and modeling methods.

Keywords: Adaptive response in melanoma, BRAF inhibitor therapy, Data-driven modeling.

TUE-223
Tamoxifen mediates premature senescence in human breast cancer and colon cancer cells through CK2 inhibition

Y.-S. Bae, L. Young-Hoon
[1]School of Life Sciences and Biotechnology, Kyungpook National Unisersity, Daegu, Korea

Cellular senescence is an important tumor suppression process in vivo. Tamoxifen is a well-known anti-breast cancer drug; however, its molecular function is poorly understood. Here, we examined whether tamoxifen promotes senescence in breast cancer and colon cancer cells for the first time. Human breast cancer MCF-7, T47D, and MDA-MB-435 and colorectal cancer HCT116 cells were treated with tamoxifen. Senescence was measured by SA-β-gal staining and based on the protein expression of p53 and $p21^{Cip1/WAF1}$. The production of reactive oxygen species (ROS) was determined by staining with CM-H_2DCFDA and dihydroethidium (DHE). As results, tamoxifen promoted senescence phenotype and ROS generation in MCF-7 and HCT116 cells. The ROS scavenger, N-acetyl-L-cysteine (NAC), and the NADPH oxidase inhibitor, apocynin, almost completely abolished this event. Tamoxifen inhibited the catalytic activity of CK2. Overexpression of CK2α antagonized senescence mediated by tamoxifen, indicating that tamoxifen induced senescence via a CK2-dependent pathway. A well-known CK2 inhibitor, DRB, also stimulated ROS production and senescence in MCF-7 cells. Finally, experiments using T47D (wild-type p53) and MDA-MB-435 (mutant p53) cell lines suggested that tamoxifen induces p53-independent ROS production as well as p53-dependent senescence in breast cancer cells. Taken together, these results demonstrate that tamoxifen promotes senescence through a ROS-p53-$p21^{Cip1/WAF1}$ dependent pathway by inhibiting CK2 activity in breast cancer and colon cancer cells.

Keywords: protein kinase CK2, senescence, tamoxifen.

TUE-225
The antiproliferative effect of nucleus-directed maspin on breast cancer cells

M. Machowska[1], K. Wachowicz[1], K. Piekarowicz[1], M. Sopel[2], R. Rzepecki[1]
[1]Biotechnology, University of Wroclaw, [2]Biology and Botanical Pharmacy, Medical University, Wroclaw, Poland

Background: Mammary Serine Protease Inhibitor (Maspin) belongs to the serpin family and is classified as a class II tumor suppressor protein. Maspin demonstrates antiapoptotic, antimetastatic and antiangiogenic properties. However, maspin expression is downregulated in malignant breast cancer and in most breast cancer cell lines. Many reports suggest that the nuclear fraction of maspin is responsible for anticancer effect rather than cytoplasmic maspin. It may be connected with influence of nuclear maspin on transcription factors activity or on nuclear enzymes, for example histone deacetylase (HDAC).

Observations: The aim of our research was to study an effect of maspin localization and level of expression on breast cancer cells. Maspin localization and Ki-67 protein expression was evaluated in samples from patients with breast cancer. Moreover, three breast cancer cell lines – MCF-7, MDA-MB-231, SKBR-3, and normal epithelial cell line from breast - MCF10A were transfected with plasmid encoding maspin-EGFP (fusion protein locates in cytoplasm) and maspin-NLS-EGFP (fusion protein with nuclear localization signal locates in nucleus) and Ki-67 protein expression was evaluated. We observed the inhibitory effect on cell proliferation of maspin located in nucleus both in tissue samples from patients with breast cancer and in breast cancer cell lines. A statistically significant negative correlation was observed between nuclear maspin and Ki-67 expression in patients with breast cancer. Furthermore, a correlation was found between nuclear maspin and loss of Ki-67 protein in breast cancer cell lines. In normal epithelial cells from breast, there was no effect on cell proliferation. The anti-proliferative effect of nuclear maspin on breast cancer cells was statistically significant in comparison to cytoplasmic maspin. Because of low transfection efficiency and lethal effect of high level of nuclear-localized maspin, we decided to use lentiviral system, which ensures higher efficiency of gene delivery and allows to manipulate the level of protein. This approach will provide homogeneous material for further analysis and will allow to investigate differences in cell cycle and in both enzymes and signaling pathways activity depending on maspin localization.

Conclusions: Understanding the molecular mechanisms of maspin activity depending on its subcellular localization may broaden our knowledge about functions of this protein and its role in cancer progression. Moreover, evaluation of the maspin localization may be use as a prognostic factor in breast cancer.

Keywords: breast cancer, maspin.

The *C. elegans* EGF homolog LIN-3 acts as guidance cue for anchor cell invasion

L. Mueller, A. Hajnal
Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland

During development, the epidermal growth factor (EGF) acts in multiple tissues as stimulator of cell proliferation, growth, differentiation and survival. Cancer cells take advantage of EGF signalling by expressing increased levels of EGF receptors (Mendelsohn and Baselga, 2000). Furthermore, EGF receptor signalling is implicated in controlling the invasiveness of metastatic cancer cells (Stock et al.; Yang et al.). The development of the C. elegans vulva is an excellent in vivo model to study cell invasion as a normal developmental process. During the third larval stage, a specialized uterine cell, the anchor cell (AC), invades through two basal laminae into the vulval tissue in order to connect the uterus with the developing vulva. AC invasion is a robust process, which is secured by a number of redundant signaling events that have not all been elucidated yet. Using tissue specific RNAi experiments and mutant analysis, we show that the EGF homolog LIN-3 produced by the vulval cells guides the AC during its invasion into the vulval epithelium LIN-3 EGF acts in parallel with a ventral Netrin signal to polarize the AC towards the ventral midline. Thus, the combined action of multiple guidance signals enable the AC to breach the basal laminae and invade the vulval cells at a precise location.

The coordinated action of BIK, p53 and ROS in DNA damage-induced cell death

O. Kutuk
Molecular Biology and Genetics, Inonu University, Malatya, Turkey

Cancer continues to be a leading cause of death along with cardiovascular diseases as a major health problem for the affected individuals and a socioeconomic burden for the society. Despite increased success with the help of fast sequencing of tumor genomes, smart targeted-therapies and increased screening and prevention efforts, de novo or acquired resistance to therapy remains to be a major factor negatively affecting prognosis and survival in cancer patients. In addition to surgery, conventional chemotherapy and radiotherapy constitutes the two main axes of cancer therapy strategies. These therapies trigger the elimination of cancer cells by inducing mitochondrial programmed cell death pathway. Mitochondrial cell death is regulated by BCL-2 protein family members and the release of cytochrome *c* into cytosol is the point of no return for commitment to cell death. Many chemotherapeutics and radiotherapy target DNA and cells respond to DNA damage with cell cycle arrest, senescence, DNA repair or cell death. DNA damage can also activate oncogenes and induce tumorigenesis. As a proapoptotic BH3-only protein, BIK binds to antiapoptotic BCL-2 proteins and neutralizes them to promote cell death. The expression of BIK can be regulated via p53-dependent or p53-independent mechanisms. In addition, reactive oxygen species (ROS) dictates cell death or survival in response to DNA damage, either by damaging cellular structures or by regulating gene expression. Our studies delineated how BIK is regulated in different p53 backgrounds in colon cancer cells and how this phenomenon is regulated by ROS formation in response to DNA damage.

Keywords: Cell death, DNA damage, ROS.

The cytotoxic analysis of free doxorubicin and doxorubicin loaded PHB-MNPs on sensitive and doxorubicin resistant MCF-7 cell lines

S. Yalcin[1], G. Unsoy[2], P. Mutlu[3], R. Khodadust[2], **N. Taghavi Pourianazar**[2], M. Parsian[2], U. Gunduz[2]
[1]Food Engineering, Ahi Evran University, Kırsehir, [2]Biotechnology, [3]Central Laboratory Molecular Biology and Biotechnology R&D, Metu, Ankara, Turkey

Doxorubicin is an antracycline antibiotic. It is a commonly used anticancer agent in many cancer types and its most serious side effect is damaging the heart cells. Therefore targeting of this chemotherapeutic agent with a suitable nano carrier mediated drug delivery system is important. Aim of this study, the cytotoxic effect of free Doxorubicin and Doxorubicin coated MNPs were compared on sensitive and Doxorubicin resistant breast cancer MCF-7 cells. In this study, Polyhydroxybutyrate (PHB) coated magnetic nanoparticles (PHB-MNPs) were synthesized by in situ coating method. Doxorubicin was loaded onto the PHB-MNPs. Cytotoxicity analysis of Doxorubicin loaded PHB-MNPs were performed on Doxorubicin resistant MCF-7 breast cancer cells. The cytotoxicity levels of free Doxorubicin and Doxorubicin loaded MNPs on both of the cell lines were tested by XTT cell proliferation assay. Doxorubicin loaded PHB-MNPs were about 2.5 fold more cytotoxic as compared to free drug on resistant MCF-7 cell line (1 μM Doxorubicin) *in vitro*. Therefore Doxorubicin loaded PHB-MNPs lead to overcome the drug resistance.

Keywords: Doxorubicin, drug resistance, breast cancer, cytotoxicity.

The effect of a phospholipase C gamma inhibitor on the proliferation and phenotype of Du145 prostate cancer cells

N. Režić Mužinić[1], A. Mastelić[1], A. Markotić[1], V. Čikeš Čulić[1], A. Ross[2], M. Vuica-Ross[3], D. Barker[4], J. Reynisson[4]
[1]Department of Medical Chemistry and Biochemistry, University of Split School of Medicine, Split, Croatia, [2]Department of Urology, [3]Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD, USA, [4]School of Chemical Sciences, The University of Auckland, Auckland, New Zealand

Introduction: Prostate cancer remains the second most common cause of cancer related death among men, highlighting the need for new therapies. Many cancer cellular functions have been discovered to be regulated by phospholipase C (PLC) gamma activation, suggesting that it represents an important therapeutic target for development of anticancer drugs. Here, we investigate the influence of a newly developed, small molecule PLC gamma inhibitor, with or without taxane therapy, on the growth and survival of sub-populations of a prostate cancer cell line.

Materials and Methods: Cells were incubated 48 h with Paclitaxel (5 nM) and PLC gamma inhibitor (1 microM) alone or in their combination.The viable cells were determined by the MTT assay. Flow cytometric analysis of cells positive to anti-CD44, anti-CD54, and propidium iodide staining was performed to characterise apoptotic Du145 sub-populations 48 h after inhibitor treatment.

Results: Treatment of the DU145 prostate cancer cell line with the PLC gamma inhibitor resulted in cell cycle arrest with minimal increase in apoptosis. Sub-populations of prostate cancer cell lines have unique phenotypes (with CD44 + cells being more proliferative and CD54 + cells serving as better CD8 + T cell targets). We examined the effects of the PLC gamma inhibitor on these subpopulations and found that exposure decreased the percentage of both CD44+ (p = 0.00007) and CD54+ (p = 0.009) sub-populations. In contrast, treatment with Paclitaxel only effected CD44+ cells (p = 0.0002). Combination treatment of the PLC gamma inhibitor and Paclitaxel however had synergistic effects on both CD44+ and CD54+ DU145 cells (p = 0.005 and p = 0.0002, respectively).

Conclusions: These results suggest that a combination of PLC gamma inhibitor and Paclitaxel could be a novel strategy for the treatment of prostate cancer.

Keywords: prostate cancer, phospholipase C inhibitor.

The effects of calcitriol on N-MYC downstream regulated gene-2 and sodium-iodide symporter gene expressions in undifferantiated human anaplastic thyroid cancer cell line

M. Sipahi[1], **D. Keles**[1], M. Calan[2], F. Bayraktar[2], G. Oktay[1]
[1]School of Medicine Department of Medical Biochemistry, [2]Department of Endocrinology and Metabolic Diseases, Dokuz Eylul University, Izmir, Turkey

Introduction: Anaplastic thyroid cancer is one of the most aggressive human cancers. The loss of expressions in sodium-iodide symporter (NIS) and thyroid-stimulating hormone receptor causes to the failure of conventional therapies. Thus, it is important to develop differentiation-inducing agents which can be used together with low cytotoxicity chemotherapeutics. Calcitriol (1,25-dihydroxyvitamin D_3) is the most active form of vitamin D and affects both directly and indirectly some gene and protein expressions. It has significant roles in apoptosis, angiogenesis and inflammation. N-Myc Downstream Regulated Gene-2 (NDRG2) is a differentiation marker which has tumor suppressor functions such as reduction of tumor growth, invasion and metastasis as well as induction of differentiation. Sodium-iodide symporter (NIS) is a membrane bound glycoprotein which is known to be a hallmark of differentiation of thyroid cancer. Thus, the loss of differentiation is correlated with decrease in NIS expression and function.

Objective: The aim of this study is to compare differences of the basal gene expression levels of NDRG2 and NIS in anaplastic thyroid cancer (8505C) and normal thyroid cancer (Nthy-ori-3-1) cell lines and to investigate whether calcitriol has effects on NDRG2 and NIS gene expression levels in 8505C cells.

Material and Methods: The basal gene expression levels of NDRG2 and NIS were detected with Real Time PCR in both cell lines. The IC 50 value of calcitriol was evaluated with WST-1 test. Then, 8505C cells were treated with calcitriol for 24, 48 and 72 hours and the differences in NDRG2 and NIS gene expressions were analyzed with Real-Time PCR. All experiments were performed in triplicate.

Results: Basal NDRG2 and NIS gene expressions were found significantly increased in Nthy-ori-3-1 cells compared with 8505C cells (p = 0.002 and p = 0.008, respectively). According to WST-1 test results, the IC 50 value of calcitriol was 60 μM which resulted in 62%, 63% and 56% reduction in cell viability at 24, 48 and 72 hours, respectively. Therefore, 8505C cells were incubated with 60 μM calcitriol by 24, 48 and 72 hours and no significant differences were found in NDRG2 and NIS gene expressions between control and calcitriol treated groups.

Conclusion: Basal NDRG2 and NIS gene expressions were found significantly lower in 8505C cells. However, calcitriol treatment did not show any significant difference in NDRG2 and NIS gene expressions in 8505C cells. This could be partially explained

by vitamin D receptor (VDR) polymorphism which affects negatively the translocation of VDR into the nucleus.
Keywords: Anaplastic thyroid cancer, calcitriol, N-myc Downstream Regulated Gene-2.

TUE-232
The effects of ceranib-2 on cancer and non-cancer cell ultrastructure

D. Vejselova[1], G. Kus[1], H. M. Kutlu[1], M. Cengiz[1], S. Kabadere[2]
[1]*Biology, Anadolu University,* [2]*Physiology, Eskisehir Osmangazi Universty, Eskisehir, Turkey*

Ceramide induce cell death on high levels on the contrary of sphingosine-1-phosphate high levels that lead to cell proliferation. Therefore, ceramide/sphingosine-1-phosphate ratio is critical for cell viability. Ceramidases are regulatory enzymes of this ratio. Ceranib-2, an inhibitor of human ceramidase, was used in this study to detect the effects of a ceramidase inhibitor on cell ultrastructure in cancer and non- cancer cell lines. The effects of ceranib-2 on H-Ras 5RP7 and 3T3 cells were determined using a transmission electron (TEM-FEI Tecnai Bio-TWIN) microscopic assay. 5RP7 and 3T3 cells tretaed with IC_{50} concentrations of ceranib-2 for 24 hours were fixed with 2,5% glutaraldehyde in 0.1 M phosphate buffer at pH 7.4 and left in buffer overnight at +4°C. After being embedded in agar and post fixation in %2 osmium tetroxide, cells were dehydrated in graded ethanol: 70, 90, 96 and 100%. Then cells were embedded in EPON 812 epoxy and sectioned on ultramicrotome (LEICA UC6), stained with uranyl acecate and lead citrate and observed on TEM.

It has been showed cell death caused by ceranib-2 inducing apoptosis on 5RP7 cells with 3 μM and 5 μM on 3T3 cells. As apoptotic sparks were detected condensed nucleus, blebbs on cell membrabe and apoptotic bodies. Ceranib-2, may be succesful in drug desingning for cancer treatment.

TUE-233
The Hedgehog receptor Patched functions in multidrug transport and chemotherapy resistance

I. Mus-Veteau[1], L. Sauvard[1], L. Fiorini[1], O. Thomas[2]
[1]*Institut de Pharmacologie Moléculaire et Cellulaire, Sophia Antipolis, CNRS UMR 7275, Valbonne - Sophia Antipolis,* [2]*Institut de Chimie de Nice, UMR7272 CNRS, Nice, France*

The Hedgehog (Hh) signaling pathway controls cell differentiation and proliferation. It plays a crucial role during embryonic development, but is also involved in cancer development, progression, and metastasis. The Hh receptor Patched is an Hh target gene that is over-expressed in many aggressive cancers. We recently demonstrated that Patched is involved in the efflux of drugs such as doxorubicin, a chemotherapeutic agent used for clinical management of recurrent cancers, suggesting that Patched could contribute to chemotherapy resistance of cancer cells (Bidet et al. 2012, patent WO2012-080630). We proposed Patched as a new target for cancer treatment, and we developed a screening based on the ability of molecules 1/ to inhibit growth of yeast over-expressing human Patched in medium containing doxorubicin, 2/ to increase doxorubicin cytotoxic effect on cancer cell lines over-expressing Patched. We showed that some molecules extracted from Mediterranean sponges are able to increase doxorubicin cytotoxic effect on human metastatic melanoma cell lines by inhibiting drug efflux activity of Patched.

TUE-234
The highly flexible and heterogeneous nature of E1A from human Adenovirus (HAdV) characterized at atomic resolution through NMR

I. C. Felli, T. Hošek, E. Calcada, T. Pagani, M. Nogueira, M. Salvi, R. Pierattelli
CERM, University of Florence, Sesto Fiorentino, Italy

The small DNA tumor viruses encode some of the most versatile hub proteins like the E1A protein from human Adenovirus (HAdV). The E1A protein is essential for productive viral infection in human cells and a vast amount of data are available on its interactions with host proteins. Up to now no high-resolution information on the full-length E1A protein is available despite its important biological role.

Here we present the NMR characterization of the entire 243 residue long 12S isoform of the E1A protein from HAdV (E1A-12S). The protein results very heterogeneous in terms of structural and dynamic properties with highly flexible modules. This study opens the way to characterize the many interactions in which this protein is involved.
Keywords: None.

The human cathelicidin peptide LL-37 increases intracellular calcium in cancer cells by activating the BKCa channel

A. Gambade[1], S. Zreika[2], M. Guéguinou[1], M. Potier-Cartereau[1], S. Chevalier[1], S. Roger[1], C. Vandier[1], C. Goupille[1], G. Weber[1]
[1]*Inserm UMR1069 Nutrition, Croissance et Cancer, Université François Rabelais de Tours, Tours, France,* [2]*Department of Medical Lab Technology, Jinan University, Tripoli, Lebanon*

Human cathelicidin hCAP18 and its C-terminal peptide LL-37, initially characterized by its antimicrobial properties, is a multifunctional protein affecting both nonmalignant and malignant cells. Among other activities, it increases cellular mobility, involved both in wound healing and dissemination of tumor cells, by a mechanism still to be discovered.

Since calcium signaling contributes to cell migration we investigated the impact of LL-37 on the calcium concentration in the MDA-MB 435s cancer cell line. We found that LL-37 dramatically increased intracellular calcium. This may be explained by direct activation of calcium-channels. Alternatively the activation of potassium channels may induce a membrane hyperpolarisation by K + -exportation and increase the driving force for calcium entry. Patch clamp analysis demonstrated that LL-37 induced an outward current that was blocked by iberiotoxin, a specific inhibitor of the mechanosensitive BKCa potassium channel. Likewise, iberiotoxin inhibited the induction of calcium influx and cell mobility by LL-37, demonstrating the indirect mechanism by the activation of BKCa.

The all-D enantiomer of LL-37 showed identical activities as the natural L-peptide, which basically excludes an interaction with a specific protein receptor. In agreement with previous findings from others, we propose that LL-37 exerts its function

© 2014 The Authors. FEBS Journal © 2014 FEBS

through its association with the cellular membrane, and alteration of the membrane structure.

To identify which calcium-channels were involved, we performed a candidate approach using pharmacological inhibitors and RNA interference. Surprisingly, the ionotropic ATP-gated P2X7 receptor, previously shown as being activated by LL-37, did not contribute. Instead, LL-37 induced calcium influx using members of the TRP family and the Orai1 channel.

LL-37 is highly expressed in a variety of cancer forms. Our findings may contribute to explain how this peptide may contribute to malignancy.

Keywords: calcium channels, LL-37, malignant transformation.

TUE-236
The influence of GSTP1 gene expression level in tumor on clinical outcome in childhood neuroblastoma patients

N. Svergun[1], N. Khranovska[1], G. Klymnyuk[2], O. Skachkova[1], M. Inomistova[1], S. Pavlyk[2], E. Shaida[2]
[1]*Experimental Oncology,* [2]*Paediatric Oncology, National Cancer Institute MPH of Ukraine, Kyiv, Ukraine*

Neuroblastoma (NB) is the most frequent childhood malignancy characterized by high clinical heterogeneity ranging from spontaneous remission to rapid tumor progression and death. Glutathione S-transferase P1 (GSTP1) enzyme is involved in phase II metabolism of many carcinogens and anticancer agents as well as in the regulation of c-Jun NH2-terminal kinase-mediated cell signaling. In tumor cells high GSTP1 expression level could enhance detoxification of chemotherapeutic agents and associate with drug resistance, failure of cancer chemotherapy along with poor survival of patients. The aim of our study was to estimate the influence of GSTP1 gene expression level in tumor on clinical outcome in childhood NB patients.

The case group comprised 75 patients with histologically confirmed NB aged 1.5-175 months (I-II stages: 13; III-IV stages: 62; MYCN gene amplified: 26.6%). Patients were treated according to risk groups under the international standard protocols. Response to chemotherapy was assessed according to INRC. Primary tumor tissue obtained from patients at diagnosis was used for molecular-genetic analysis. The GSTP1 gene expression level was analyzed by TaqMan real time RT-PCR and normalized to the expression level of house-keeping gene GAPDH. MYCN gene amplification was detected by FISH method.

We observed that GSTP1 expression level increases proportionally to the stage of disease ($p = 0.12$) with maximum value in stage IV. Also GSTP1 expression level was higher in MYCN-amplified tumors than in those without MYCN amplification ($p = 0.09$). We did not notice an association between demographic characteristics of the NB patients (age at diagnosis and sex) and GSTP1 expression level. Primary resistant tumors had significantly higher levels of GSTP1 gene expression compared to chemotherapy sensitive tumors ($p = 0.01$), regardless MYCN status. ROC analysis revealed that GSTP1 expression level in tumor is an important marker which is associated with clinical outcome of primary childhood NB patients (Se = 75.8 %; Sp = 62.5 %; AUC = 0.71; $p = 0.002$). Tumors were categorized into two groups (high or low GSTP1 expression) based on cutoff point - optimal criterion, that was determined by ROC analysis. High GSTP1 expression was associated with reduced event-free survival (EFS) in NB patients. The 2-year EFS rate for NB patients with high GSTP1 expression was 38 % compared to 71 % for low GSTP1 expression ($p = 0.042$).

Our results suggest the possibility that GSTP1 is involved to the clinical behavior of NB, which is consistent with its known roles in drug resistance development, cell cycle and cell death regulation. Target inhibition of GSTP1 could be very promising strategy for NB treatment.

Keywords: Glutathione S-transferase P1, neuroblastoma.

TUE-237
The influence of p73 isoforms on cell viability and proliferation

A. Dalina[1], D. Kochetkov[1], P. Chumakov[1,2,3]
[1]*Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow,* [2]*Novosibirsk State University, Novosibirsk, Russian Federation,* [3]*Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, USA*

The p53 family includes three proteins: the tumour suppressor p53 and its two siblings, p73 and p63, which play an important role in carcinogenesis and also in embryogenesis. All proteins of the family are expressed as multiple isoforms due to existence of two promoters and alternative splicing of N-terminal and C-terminal region. All proteins of the family have similar domain architecture. Half of the isoforms have N-terminal transactivation domain necessary for transcriptional activation of target genes. Central DNA-binding domain is highly conservative among family members, so transcriptionally active p63 and p73 isoforms with the full-length N-terminal domain (TA-isoforms) can transcriptionally activate many p53 targets including proapoptotic and cytostatic genes and so act as tumour suppressors. The isoforms lacking full-length N-terminal domain because of transcription from an alternative promoter or alternative splicing mostly act as oncogenes because of competition with TA-isoforms for responsive elements in promoter regions of target genes and also because of similarity between their oligomerization domains that allows them to form inactive heterooligomers with TA-isoforms (dominant-negative inactivation). The balance of different isoforms can impact in tumour development. The C-terminus of the p53 family protein is responsible for protein – protein interactions. Some isoforms of p63 and p73 have also additional C-terminal domain called sterile α motif which is present in many proteins involved in embryogenesis. The length of C-terminus also affects the level of transcriptional activity of TA-isoforms, for example the activity of full-length TAp73α is much less than of shorter TAp73β and TAp73γ isoforms. Nowadays there are many works devoted to the properties and functions of particular isoforms, and there few studies comparing the impact of p73 isoforms with different C-terminal domains on cell viability and cell cycle. To find it out we stably overexpressed TA- and ΔN-p73 isoforms with different C-termini (full-length α isoform and shorter β and γ isoforms) in HCT116 human colon carcinoma cells and tested their influence on the level of apoptosis and cell cycle. TAp73 isoforms induced apoptosis at similar levels, while overexpression of ΔNp73 isoforms decreased the number of apoptotic cells compared to control. Interestingly, overexpression of all p73 isoforms including ΔN-isoforms caused the decrease of amount of cells in G1-phase and accumulation of cells in G2/M-phase. This may provide additional information on the role of p73 in cell signalling pathways.

Keywords: apoptosis, Cell cycle, p53 family.

TUE-238
The mitochondrial protein VDAC1 and apoptosis modulators as signature biomarkers for cancer diagnosis, prognosis and treatment efficacy

L. Admoni, V. Shoshan-Barmatz
Department of Life Sciences, National Institute for Biotechnology in the Negev, Beer Sheva, Israel

Human tumors are riddled with genomic alterations that include not only mutations that disrupt a wide spectrum of genes yet also those that affect protein expression levels. Hence, such alterations can be identified at the mRNA level but most significantly at the protein expression level. A key challenge is identifying such alterations for use as biomarkers enabling early diagnosis of cancer, as well as for forecasting cancer development, treatment efficacy and to potentially guide personalized medicine. Given that in many cancers, cells undergo re-programming of metabolism and develop survival strategies involving anti-apoptosis defense mechanisms, we analyzed the expression of metabolism- and apoptosis-related proteins in several cancers. We found that a mitochondrial key player in cell metabolism and regulation of mitochondria-mediated apoptosis, voltage-dependent ion channel isoform 1 (VDAC1). is highly expressed in different cancers, such as CLL, cervix, lung, liver, thyroid cancer, glioblastoma. The expression profiles of other proteins involved in the re-programming of cancer cell metabolism and capability to evade apoptosis were also analyzed. These included the glycolysis enzyme hexokinase, the mitochondrial anti-viral-signaling (MAVS) protein and Bcl2, proteins that are all over-expressed in both solid and non-solid tumors. Unexpectedly, cancerous cells also over-express the mitochondrial pro-apoptotic proteins SMAC/DIABLO (second mitochondria-derived activator of caspases) and AIF (apoptosis-inducing factor). Moreover, we were able to predict the probability of disease based on the expression levels of VDAC1, Bcl2, SMAC/Diablo, MAVS or a combination of AIF and HK-I, by using binary logistic regression analysis. Furthermore, based on the levels of these biomarkers, we could predicate which of the CLL patients considered in this study would need drug treatment. The expression profiles of these apoptosis modulator proteins reflect the adoption of a cancer survival strategy involving anti-apoptotic defense mechanisms and thus, low susceptibility to apoptosis-mediated cell-killing compounds. When one considers VDAC1 function in cell metabolism and apoptosis, as well as its interaction with apoptosis-modulating proteins, then its over-expression in cancers is not surprising. Hence, the expression profiles of VDAC1 and selected apoptosis modulators can serve as biomarkers to forecast cancer development, treatment efficacy and potentially enable early diagnosis.

Keywords: Biomarkers, VDAC1.

TUE-240
The role of 8p deletions in breast cancer development and progression

Y. Cai, J. Crowther, A. Sablina
VIB Center for the Biology of Disease, CME, VIB, KU Leuven, Leuven, Belgium

In a typical cancer sample, 25% of the genome is affected by arm-level loss-of heterozygosity (LOH). A large size of the chromosomal deletions suggests a "two-hit" mechanism, when co-deletion of genes, miRNA clusters, and/or regulatory regions can synergistically promote tumor growth. In our study we focused on the short arm of chromosome 8 (8p), which is deleted in more than 50% of primary breast tumors. Although various potential tumor suppressive genes have been identified across the 8p region, none fulfils the Knudson criteria. The frequent loss of 8p could not be also explained by the presence of common fragile sites.

To assess the contribution of 8p deletion to tumorigenic transformation, I combined novel genetic engineering technologies and the experimental models of cell transformation derived from non-malignant human cells. As a first step, I optimized a semi-automatic workflow for the generation of human mammary cells with targeted chromosomal deletions. Using the TALEN approach, I succeeded to introduce deletions of the predetermined genomic DNA segments in the range of 4 Mb to 33 Mb at frequencies of 10^{-4} to 10^{-5}. I then generated a set of MCF10A cell lines harboring serial LOHs of 8p chromosome. Using a high-density SNP analysis, we also confirmed the integrity of the rest of the genome of the isolated clones. Currently, we are elucidating the contribution of 8p loss to several cancer-associated phenotypes. We anticipate that experimental models of human cell transformation that mimic cancer-associated chromosomal abnormalities will provide essential reagents for maximizing the efficiency of large-scale functional genomics efforts and accelerate the functional annotation of the human cancer genome.

Keywords: chromosomal deletions, human models of cell transformation, tumorigenesis.

TUE-242
The Role of DJ1, a PTEN inhibitor, and Sodium 4- Phenyl Butyrate in cancer cell motility and migration

M. El-Sibai
Natural Science, Lebanese American University, Beirut, Lebanon

DJ-1 is a 20-KDa protein that was first identified as an oncogene product responsible for a subset of familial Parkinson's disease; hence its name PARK 7. Previous studies showed that DJ-1 negatively regulated the tumor suppressor gene PTEN expression; thus promoting the phosphorylation of the PI3K/Akt signaling pathway, and activating cell proliferation and transformation. Therefore, DJ1 can be used as an indication of cancer metastasis and can be a potential therapeutic target. However, the detailed mechanism and the role of DJ-1 in cellular motility are still not fully understood. PBA or phenylbutyrate is a low molecular weight fatty acid that was shown to increase expression of many genes including anti-apoptotic genes, and it does so by binding to the Sp1 binding sites in the genes promoter. Knowing that DJ-1 has the Sp1 binding site, studies showed that phenylbutyrate can increase DJ-1 gene expression and cause growth arrest of malignant tumors as well. However, the effect of PBA on cellular motility is not fully understood. Therefore this study showed that DJ-1 increased cellular motility and migration in lung, brain, breast, and skin cancer cells by activating the PI3K pathway. We showed that this activation leads to the phosphorylation of Akt and thus activation of RhoGTPases (RhoA, cdc42 and rac) which are known to increase cellular motility. Moreover, this study also showed that PBA increase DJ-1 gene expression and leads to the decrease in cancer cells motility and migration.

Keywords: DJ1, invasion, PBA.

TUE-243
The role of LNX2 protein in regulation of Frizzled-7 receptor signalling

I. Bombik[1], N. Hotchin[2], T. Chris[1], F. Berditchevski[1]
[1]School of Cancer Studies, [2]School of Biosciences, University of Birmingham, Birmingham, UK

Frizzled receptors are a group of seven-pass transmembrane receptors that play a key role in the transduction of signals from secreted ligands known as Wnts. Wnt signaling plays a central role in development, regulating proliferation, stem cell maintenance and cell fate decisions. Deregulated Wnt signaling is also a major contributing factor to epithelial carcinogenesis, including breast and colon cancer. Activation of Wnt signaling, as evidenced by nuclear localisation of β-catenin, has been repeatedly described in human breast cancer. There is increasing evidence that endocytosis of Frizzled plays a key role in regulation of Wnt signaling. Endocytosis of Frizzled seems to depend on interaction with Dishevelled (Dsh), which in turn recruits components of the endocytic machinery. Upon internalization, the Fz-Dsh complex appears to dissociate indicating that post-endocytic trafficking of Frizzled receptors (and their subsequent degradation) is dependent on other proteins.

Frizzled 7 interacts with PDZ domain-containing proteins via the C-terminal binding motif. PDZ-containing proteins are abundant in cells and have the ability to form PDZ-based multiprotein complexes at the cell membrane. They are important for regulation of receptor trafficking and signal transduction. Among these proteins is LNX2, a member of RING finger-type E3 ubiquitin ligase family. It regulates Notch signalling pathway and plays an important role in tumorigenesis. We have found that LNX2 is a novel PDZ-protein interacting with Fz7. It is involved in post-endocytic trafficking of Frizzled-7 and regulates Wnt signalling in breast cancer cells.

Keywords: breast cancer, ubiquitination, WNT signalling.

TUE-244
The role of transmembrane residues in regulation of pore dilation of the P2X7 receptor channel

M. Jindrichova[1], A. Bhattacharya[1], T. Obsil[2], H. Zemkova[1]
[1]Institute of Physiology, Academy of Sciences of the Czech Republic, [2]Faculty of Science, Charles University, Prague, Czech Republic

P2X receptors are membrane cation-permeable channels that open in response to the binding of extracellular adenosine 5′-triphosphate (ATP). In mammals, seven P2X subunits (P2X1-P2X7) have been identified which form functional trimeric homomers or heteromers. The P2X7 subtype is the most specific in the P2X family and widely differs from other P2X subtypes. Functionally the P2X7 receptor attracts considerable interest in relation to human health and disease mainly due to the fact that the P2X7 gene is highly polymorphic and the receptor properties are changed in cancer cells. The most striking kinetic feature of P2X7 is that during sustained agonist application the receptor does not desensitize as other P2X subtypes, but its pore dilates reaching the permeability for organic cations. Formation of a pore in the plasma membrane is associated with uncontrolled influx of Ca^{2+} which can induce cell death.

The aim of our work was to investigate the role of selected amino acids of both transmembrane domains (TM1 and TM2) in the kinetics of the P2X7 receptor. We selected amino acids that have been previously shown to significantly influence kinetics of the P2X4 receptor - the most closely related receptor to P2X7 in the P2X family. Using single-point mutagenesis the selected residues were substituted to alanine, single-point mutants expressed in human embryonic kidney cells (HEK293), and agonist-induced currents were measured by whole cell patch clamp recording technique.

We found that alanine substitution of Y40 or F43 residue abolishes the ability of the P2X7 to dilate the pore. Moreover the Y40A mutant displays desensitization profile. In TM2 domain alanine substitution of G338 significantly increased sensitivity to various agonists and strongly prolonged deactivation time. Mutants L341A and G345A retain ability to dilate, but the ability was reduced. In summary, our experiments, supplemented with structural analysis, indicate that the P2X7 dilation is critically dependent on the aromatic residues in TM1 and that the G338, L341 and G345 residues of the TM2 domain are located in the signal transduction pathway that regulate pore dilation and the associated sensitization of the P2X7R.

Keywords: ion channel, P2X7 receptor, pore dilation.

Cellular stress responses are an integral part of normal physiology to either ensure cell survival or to eliminate damaged or unwanted cells. Aberrant cellular stress responses are tightly linked to many common diseases including cancer. Evasion of cell death can promote tumor initiation, progression, and resistance to cytotoxic therapies. Thus, a better understanding of the underlying mechanisms of cellular stress responses will help to identify key targets to interfere with these processes. Our current work suggests that Sall2, a member of the SPAL/SALL family of transcription factors, is a stress-inducible molecule involved in the cellular response to stress. Sall2 is deregulated in various cancers suggesting a role in the disease. We previously identified Sall2 as an interacting protein of neurotrophin receptors and demonstrated it is involved in neuronal differentiation. Recently we identify Sall2 as a direct target of p53 tumor suppressor. We demonstrated that p53 directly binds to the Sall2 promoter and regulates Sall2 expression under genotoxic stress. To further investigate Sall2 role in cellular stress, we use primary MEFs from Sall2-deficient mice and exposed them to metabolic (serum or glucose deprivation) or genotoxic (chemotherapeutic agents) stress conditions. We investigated for changes on Sall2 expression levels in wild type MEFs, and compare cellular stress response between Sall2-deficient and wild type MEFs. Our data suggest that Sall2 is a stress-inducible molecule and its role in cell survival depends on the cellular context. Under genotoxic stress Sall2 acts as a pro-apoptotic factor, while under metabolic stress Sall2 acts as a pro-survival factor. Further comprehension of Sall2 regulation and its direct targets under stress conditions is essential to fully understand its role in normal and disease states.

Keywords: cell survival, cellular stress, Sall2.

TUE-246
The scaffolder 14-3-3 sigma as a new modulator of TGF-beta signaling for growth inhibition

B.-C. Kim
Biochemistry, Kangwon National University, Chuncheon, Korea

Transforming growth factor-β (TGF-β) has a potent antiproliferative effect on a wide variety of cells, and insensitivity to this growth-inhibitory effect is closely associated with progression of tumors. To identify new target genes regulated by TGF-β, we performed cDNA microarray analysis using mRNA from normal Eph4 mammary epithelial cells and TGF-β-resistant Eph4-Ras cells treated with/without TGF-β and isolated 14-3-3 sigma as a new candidate gene induced by TGF-β. Our data show that TGF-β-mediated upregulation of 14-3-3 sigma is dependent on Smad3 not p53. 14-3-3 sigma functional study demonstrate that upon TGF-β stimulation, 14-3-3 sigma serves as an adaptor to bridge the E3 ligase anaphase promoting complex/ cyclosome (APC/C) to Cdc25A, which results in Cdc25A polyubiquitination and subsequent degradation. Our results uncover a previously unrecognized role for 14-3-3 sigma in the regulation of anti-proliferative TGF-β signaling and provide molecular insight into the mechanisms by which 14-3-3 sigma-APC/C target Cdc25A for degradation.

Keywords: 14-3-3 sigma, APC/C, TGF-beta.

TUE-247
The SH3 domain protein is a novel regulator of PKC/MAPK signaling in fission yeast

Y. Kanda, A. Doi, A. Kita, H. Naruse, R. Sugiura
Laboratory of Molecular Pharmacogenomics, School of Pharmaceutical sciences, Kinki University, Higashiosaka, Japan

Protein kinase C (PKC) is a calcium-dependent enzyme that phosphorylates serine and threonine amino acid residues on its substrate proteins, and is highly conserved in all eukaryotic organisms from yeast to man (Nishizuka *et al*, 1977). Numerous studies have clarified that PKC is involved in a wide range of physiological functions, and serves as a molecular target for anti-cancer drugs since it has been identified as the receptor for phorbol ester tumor promoters.

In our laboratory, we have been studying the signal transduction system using *Schizosaccharomyces pombe* (*S. pombe*) which is an excellent model to study the mechanisms of cellular proliferation and cancer in humans. Through molecular genetic screening using FK506, which is an immunosuppressive drug that inhibits calcineurin, we showed that Pck2, a protein kinase C homologue in *S. pombe*, acts upstream of Pmk1 MAPK (ERK homologue).

In this study, we identified that Skb5, a Src homology 3 (SH3) domain protein, as a regulator of Pck2 signaling by utilizing the cytotoxicity induced by Pck2 overproduction. Since Skb5 has been reported to bind to Mkh1, which is the MAPKKK found in Pmk1 MAPK signaling or Ptc1, which is the MAPK phosphatase for Sty1 or Pmk1, we assumed that Skb5 negatively controls the Pck2/MAPK signaling pathway by physically interacting with these proteins. However, the exact mechanisms of the physical/ functional interactions between Skb5 and these signaling molecules are poorly understood. Therefore, we attempt to uncover the physiological significance of Skb5 binding to both the MAPK activator Mkh1, and the MAPK suppressor Ptc1. In addition, Skb5 has proven to be implicated in the regulation of the stress-activated MAPK Sty1/Spc1 pathway, thus posing Skb5 as a key adaptor molecule in the PKC/MAPK signaling in yeast.

The TRPM4 channel regulates the Epithelial-Mesenchymal transition in prostate cancer cells

A. Sagredo[1,2], E. Sagredo[1,2], E. Salamanca[2], C. Luco[2], R. Andaur[1,2], L. Michea[1,3], F. Simón[4], J. Tapia[1,5], K. Marcelain[1,6], R. Armisén[1,2]
[1]Instituto de Ciencias Biomédicas, [2]Departamento Fisiopatología, [3]Departamento Fisiología y Biofísica, Universidad de Chile, [4]Departamento de Ciencias Biológicas, Universidad Andres Bello, [5]Departamento Biología Celular y Molecular, [6]Departamento Genética Humana, Universidad de Chile, Santiago, Chile

The Transient Receptor Potential Melastatin 4 (TRPM4) is a Ca^{2+} activated and voltage-dependent monovalent cation channel, which depolarizes the plasma membrane, thereby modulating Ca^{2+} influx through Ca^{2+}-permeable pathways. TRPM4 overexpression has been described in a number of cancers, including prostate cancer and it has been suggested that TRPM4 promotes cancer progression in these cells. Nevertheless, whether TRPM4 is involved in prostate cancer progression and the underlying molecular mechanisms remain unknown. In this work we analyzed the consequences of TRPM4 knockdown in the expression of epithelial-mesenchymal transition (EMT) markers (E-Cadherin, N-Cadherin, Vimentin, β-Catenin, Fibronectin1, ZEB1, SNAIL1 and SLUG) and related biological processes such as cellular migration and invasion. TRPM4 knockdown in PC3 and LnCaP prostate cancer cells resulted in a significant change in the expression pattern of EMT marker genes. These changes are compatible with a reversal of the EMT process in these cells. Also, TRPM4 knockdown produced a diminution in cell invasion and migration in PC3 cell line. To explore the underlying mechanism, we evaluated the activity of the β-Catenin and GSK3-β signaling pathway in these cells. TRPM4 knockdown cells have decreased total β-Catenin protein levels, and an increase in S33, S37 and T41 β-catenin phosphorylation as well as an increase in S9 GSK3-β inhibitory phosphorylation, suggesting that a down-regulation of components of the canonical WNT signaling pathway could explain the relationship between TRPM4, EMT and cell invasion.

Supported by Fondecyt 1120286 and Domeyko II “U-Cáncer” Universidad de Chile.

TUE-249
The Wilms Tumor protein 1 represses the expression of its pro-apoptotic co-factor, ZNF224, in leukemic cells

G. Sodaro, G. Montano, D. Sicuranza, V. Marturano, E. Cesaro, P. Costanzo
Molecular Medicine and Medical Biotechnologies, Federico II University, Naples, Italy

ZNF224 is a pro-apoptotic zinc-finger protein in Chronic Myelogenous Leukemia (CML), which is able to bind the Wilms Tumor protein 1, WT1, acting as a co-activator on pro-apoptotic WT1 target genes while suppressing WT1 mediated transactivation of anti-apoptotic genes.[1] Recently, we reported ZNF224 as negatively regulated by Bcr/Abl fusion protein kinase. Indeed, we demonstrated that Bcr/Abl forced expression in Acute Myelogenous Leukemia cell line KG1 (Bcr/Abl negative), lead to a decreased ZNF224 expression. Moreover, an increased ZNF224 expression was shown in Bcr/Abl positive CML cell line, K562, treated with Bcr/Abl inhibitor (Imatinib) or with PI3K inhibitor

© 2014 The Authors. FEBS Journal © 2014 FEBS

(Wortmanin), thus indicating ZNF224 as negatively regulated by Bcr/Abl through the downstream activated PI3K pathway. In addition, literature data reported a positive regulation by Bcr/Abl kinase and PI3K pathway on the transcription factor WT1, which results highly expressed in Bcr/Abl positive CML cell line K562.[2] This data lead us to consider WT1 as a putative transcription factor downstream Bcr/Abl and PI3K pathway, regulating ZNF224 transcription. At first, to confirm this hypothesis, we conducted bioinformatics analysis on a 1000 bp region of the ZNF224 promoter, thus reporting three putative WT1 binding sites. Then, we performed Chromatin Immunoprecipitation assays in K562 cells. The chromatin was immunoprecipitated with WT1 antibody and WT1 binding on ZNF224 promoter was confirmed. Finally, to investigate the role of WT1 on ZNF224 promoter activity, we performed a luciferase assay in K562 cells. The obtained results showed a decreased ZNF224 promoter activity when WT1 was overexpressed and an increased promoter activity in K562 cells treated with Imatinib. In addition, K562 cells treated with Imatinib and overexpressing WT1 showed no significant increase in ZNF224 promoter activity, thus corroborating WT1 as a putative transcription factor downstream Bcr/Abl and PI3K pathway, regulating ZNF224 transcription.

Tissue mechanics modulate glioma cell aggression

Y. A. Miroshnikova[1], J. Phillips[2], T. McKnight[3], V. Weaver
[1]Bioengineering & Surgery, [2]Neurological Surgery & Pathology, [3]Radiology & Biomedical Imaging, [4]Surgery & Anatomy, UCSF, San Francisco, CA, USA

Gliomas are the most common primary intracranial tumors in adults, accounting for more than 50% of all primary adult brain cancers. The most aggressive of these tumors are glioblastoma multiforme (GBM) with mean patient survival of 14.6 months. Diffuse invasion of glioma cells into healthy brain tissue prevents complete surgical resection of the tumors and contributes to a high rate of tumor recurrence and invariable lethality. Interestingly, upon clinical presentation, primary brain tumors typically exhibit high intracranial pressure and MRI elastography and vibrometry indicate that brain tumors might be quite stiff. In this respect, many solid state tumors exhibit elevated extracellular matrix (ECM) stiffness and display increased interstitial pressure. Elevation of ECM force is a known driver of malignancy and its inhibition reduces tumor aggression in many cancer types. Yet, the significance of such altered physical force to brain pathophysiology remains unclear. Using primary human tissues and various mouse models of GBMs, we tested whether the microenvironment of GBMs is mechanically different from that of non-malignant human brain tissue and whether ECM stiffness and mechanotransduction increases with glioma grade. Furthermore, we examined whether ECM stiffness per se modulates gene and protein expression that is associated with increased cell aggression, fostered invasion, and improved survival of primary GBM cells. Our nano-mechanical mapping of transgenic and orthotopic mouse models of human GBMs showed that brain tumors are stiffer than normal brain tissue and that the ECM of orthotopic mouse models with the most aggressive human GBM cells are stiffer than those injected with the less aggressive cells. Furthermore, nano-mechanical analysis of freshly-excised patient samples (6-10 cases per subtype) of different grades (0 – 4) revealed an increase in ECM stiffness with glioma grade. Consistently, we observed an increase in mechano-signaling with grade, as indicated by marked increase in pFAK^{397}, pMLC, and YAP. Furthermore we found that increase in ECM stiffness enhanced the expression of genes and proteins that are associated with increased glioma cell aggression, such as CD44, fibronectin, hyaluronic acid, mushashi-1, and CTGF. These findings argue that GBM aggression may be an adaptive response to a high force microenvironment which favors the growth and survival of highly-aggressive cells. Our work is the first to definitively report and present the consequences of altered biophysical force in gliomas.

Keywords: glioma, mechanotransduction.

TP53 codon 72 and 240 polymorphism and P53 expression: an association with oral squamous cell carcinoma

S. Saleem
The Karachi Institute of Biotechnology and Genetic Engineering (KIBGE), University of Karachi, Karachi, Pakistan

Oral squamous cell carcinoma (OSCC) is the leading cause of death in the developing countries like Pakistan. This problem aggravates because of the excessive use of available chewing products. In spite of widespread information on their use and purported legislations against their use, the Pakistani markets are classical examples of selling chewable carcinogenic mutagens. Reported studies indicated that these products are rich in reactive oxygen species (ROS) and polyphenols. TP53 gene is involved in the suppression of tumor. It has been reported that somatic mutations caused by TP53 gene are the foundation of the cancer. This study aims to find the loss of TP53 functions due to mutation/polymorphism caused by genomic alteration and interaction with tobacco and its related ingredients. Total 260 tissue and blood specimens were collected from OSCC patients and compared with age and sex matched controls. Mutations in exons 2-11 of TP53 were examined by PCR-SSCP. Samples showing mobility shift were directly sequenced. Two mutations were found in exon 4 at nucleotide position 108 and 215 and one in exon 7 at nucleotide position 719 of the coding sequence in patient's tumor samples. These result in substitution of proline with arginine at codon 72 and serine with threonine at codon 240 of p53 protein. These polymorphic changes, found in tumor samples of OSCC, could be involved in loss of heterozygocity and apoptotic activity in the binding domain of *TP53*. The interpretations could be helpful in establishing the pathways responsible for tumor formation in OSCC patients.

Transarterial chemoembolization for liver cancer patient: good or bad?

H. T. Kwan, R. Pang, R. Poon
Department of Surgery, The University of Hong Kong, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is one of the most common and lethal cancers worldwide. It has high mortality rate as most patients were diagnosed at an advanced stage in which only lim-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ited choices of treatment are available. At early stages, several effective treatments include tumor resection, liver transplantation, and radiofrequency ablation. However, only 20-30% of patients are eligible for such curative treatments. Therefore, transarterial chemoembolization has become the standard non-curative treatment for HCC patients who are not suitable for receiving curative treatments.

Transarterial chemoembolization (TACE) is a surgical procedure consisting of the injection of cytotoxic drugs (Chemotherapy) and the obstruction of blood supply of the tumor via transarterial embolization (TAE). Since the blood supply for liver tumors is mainly through the hepatic arteries whereas the liver parenchyma is supplied by portal veins, the emobolization of the hepatic artery will block nutrient supply and localize the cytotoxic drug to the tumor, thereby reducing the tumor growth. Although TACE can enhance the survival rate of HCC patients, its long term effect is unsatisfactory. Therefore, we are aimed to elucidate the possible mechanisms responsible for such failure.

Growing evidence suggests that HCC is originated from cancer stem cells (CSCs) that are a subpopulation of cancer cells with stem cell properties. They can self-renew, differentiate into multiple lineages and adapt to extreme micro-environments. In addition, CSCs are resistant to chemotherapies and extreme environments, leading to tumor maintenance and recurrence. Therefore, we are sought to find out the role of CSCs in the treatment of HCC after TACE.

Among Chemotherapy, TAE and TACE, TACE is the most effective method to inhibit the tumor growth of HCC. However, none of them can completely eradicate the tumor. Among all the well-known CSCs markers, we found that $CD44^{+}Epcam^{+}$ HCC cells were enriched in mice with HCC tumors after the treatments of either chemotherapy, TAE or TACE. Highest enrichment of $CD44^{+}Epcam^{+}$ HCC cells was observed in TACE treated mice, suggesting that chemotherapy and TAE synergistically enriched such cell population. By genome-wide sequencing we identified IGFBP1 as a potential candidate responsible for the enrichment of cancer stem cells after TACE treatment. Indeed, IGFBP1 was found to be up-regulated in HCC tumors after TACE *in vitro* and *in vivo*. Ectopic expression of IGFBP1 increased the proliferation rate and the sphere forming potential of HCC cells, suggesting that deregulated expression of IGFBP1 may enhance the tumorigenicity and the stemness of CSCs in HCC tumors. This study provides mechanistic explanation for the adverse outcomes of TACE treatment and reveals possible therapeutic approaches for improving the TACE.

Keywords: cancer stem cell, HCC, TACE.

TUE-254
Transcriptional and epigenetic regulation of osteopontin (SPP1) expression in glioma cells

M. Kloss, M. Kijewska, M. Dabrowski, I. Ciechomska, B. Kaza, B. Kaminska
Neurobiology Center, Laboratory of Molecular Neurobiology, Nencki Institute of Experimental Biology, Warszawa, Poland

Clinical and experimental studies show accumulation of microglia/macrophages in gliomas and their contribution to tumor progression. Re-programmed brain macrophages support tumor growth, invasion, induce immunosuppression and modulate response to cancer treatment. We identified osteopontin (known as secreted phosphoprotein 1 - SPP1) as one of the factors released by glioma cells which induces pro-invasive activation of microglia and creates the immunosuppressive tumor milieu. Osteopontin is overexpressed in many cancers including high grade gliomas and its expression inversely correlates with patient's survival. To investigate molecular mechanisms underlying regulation of osteopontin expression in glioma cells, we performed a computational analysis of the human *SPP1* gene promoter that revealed potential binding sites of transcription factor GLI1 (glioma-associated oncogene homolog 1), a Hedgehog signaling effector implicated in tumorigenesis. Using chromatin immunoprecipitation (ChIP) we confirmed binding of GLI1 to the *SPP1* gene promoter in U87MG, LN18 and primary glioblastoma WG4 cell, but not in nontransformed human astrocytes. Knockdown of *GLI1* expression in U87MG astrocytoma cells decreased the osteopontin expression at the mRNA and protein level. Previous studies on mouse embryos demonstrated binding of Oct4 (octamer-binding transcription factor 4), involved in maintaining stem cell pluripotency, in the first intron of *Spp1* gene. Using ChIP we showed that OCT4 binds to the first intron of the *SPP1* gene promoter in U87MG, LN18 and WG4 glioblastoma cells but not in normal human astrocytes. This finding implicates OCT4 in regulation of SPP1 expression in glioma cells. Accordingly, we found the increased level of osteopontin in populations enriched in glioma stem-like cells isolated by flow cytometry as side population or grown as cancer spheres. To investigate involvement of epigenetic mechanisms in regulation of osteopontin expression, we treated glioma cells with inhibitors of histone modifying enzymes (trichostatin A, 3-Deazaneplanocin A). Inhibition of histone deacetylases (HDACs) led to increase of the osteopontin expression in LN18 glioblastoma cells at the mRNA and protein level. Conclusions: Our results demonstrate re-establishment of the stem cell-type, transcriptional regulation of osteopontin expression in glioblastoma cells, in particular in glioma stem-like cells.

Supported by 2012/04/A/NZ3/00630 grant from the National Science Center.
Keywords: glioblastoma, osteopontin, transcriptional regulation.

TUE-255
Transcriptional factors p53 and p63 regulate expression of orphan nuclear receptors NR4A

O. Fedorova[1,2], A. A. Daks[2], A. Petukhov[2], O. Shuvalov[1], N. Barlev[2]
[1]*Institute of Cytology RAS,* [2]*St. Petersburg State Technological Institute (Technical University), Saint Petersburg, Russian Federation*

The p53 protein and its two homologues p63 and p73 are transcriptional factors regulating expression of many genes. The TP63 gene encodes two main isoforms: TAp63 and ΔNp63 which are expressed from alternative promoter. The p63 protein is known to act in the development of limb and skin both in mice and humans. In addition, p63 was shown to play role in tumorigenesis, but the relative impact of p63 in tumorigenesis remains unclear and needs further investigation. Search for new transcriptional targets of TAp63 and ΔNp63 can provide more clear understanding of the p63 role in tumorigenesis. Microarray gene expression analysis of cell lines with different status of p63 identified a number of potential target genes. One of these genes is the NR4A3 gene encoding a member of the steroid-thyroid hormone-retinoid receptor superfamily. NR4A receptors are early immediate-response genes that control a variety of cellular functions, such as inflammation, proliferation, apoptosis, cell cycle regulation, cancer genesis. The main purpose of our work was to determine the influence of p53 and p63 on transcription of NR4A. Two isoforms of p63 TAp63 and ΔNp63 were expressed in Saos2-Tet-On cell lines. Western blot analysis showed elevated levels of NR4A3 protein in ΔNp63-expressing cells but not in TAp63-expressing cells. Quantitative RT-PCR showed an accumulation of NR4A3 mRNA in ΔNp63-expressing cells suggesting that the expression of NR4A3 is specifically regulated by ΔNp63.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Since p63 is a member of the p53 transcriptional factors family, we hypothesized that p53 also affects expression of NR4A. To test this hypothesis we measured the expression levels of NR4A1, NR4A2 and NR4A3 in four cell lines U2OSp53 + and U2OSp53KD, HCT116 p53 + /+ and HCT116 p53-/- that differ by the status of p53. Quantitative RT-PCR shows up-regulation of NR4A1, NR4A2 and NR4A3 mRNA in p53-positive cells upon treatment with doxorubicin. The level of p21 mRNA, which is a well-known p53 transcriptional target, was used as a positive control. Western Blot analysis also showed increased expression of NR4A1, NR4A2 and NR4A3 in parallel with elevation of the p53 levels. Collectively, these data demonstrate that p53 and the ΔNp63 isoform regulates expression of NR4A1, NR4A2 and NR4A3 genes.

TUE-256
TSC2 is a negative regulator of mTORC1 in response to amino acid starvation

C. Demetriades, N. Doumpas, A. Teleman
German Cancer Research Center (DKFZ), Heidelberg, Germany

mTOR Complex 1 (mTORC1) is a potent anabolic regulator of cellular growth and metabolism. When cells have sufficient amino acids, mTORC1 is active due to its lysosomal localization mediated via the Rag GTPases. Upon amino acid removal, the Rag GTPases release mTORC1, causing it to become cytoplasmic and inactive.

We show here that upon amino acid removal, the Rag GTPases also recruit TSC2 to the lysosome, where it can act on Rheb. Only when both the Rag GTPases and Rheb are inactive is mTORC1 released from the lysosome. Upon amino acid withdrawal, cells lacking TSC2 fail to release mTORC1 from the lysosome, fail to completely inactivate mTORC1, and fail to adjust physiologically to amino acid starvation.

These data suggest that regulation of TSC2 subcellular localization may be a general mechanism to control its activity, and places TSC2 in the amino acid sensing pathway to mTORC1.

Keywords: cell growth, mTORC1, TSC2.

UCN-01 as a new tool to block drug export in melanoma

M. P. Fernández Pérez[1], M. F. Montenegro[1], M. Saez-Ayala[1], L. Sánchez-del-Campo[2], A. Piñero-Madrona[3], J. Cabezas-Herrera[4], J. N. Rodríguez-López[1]
[1]Biochemistry and Molecular Biology, University of Murcia, Murcia, Spain, [2]Nuffield Department of Clinical Medicine, Ludwig Institute for Cancer Research, Oxford, UK, [3]Department of Surgery, [4]Translational Cancer Research Group, University Hospital Virgen de la Arrixaca, Murcia, Spain

Melanoma is the most aggressive form of skin cancer and it is highly resistant to all current modalities of cancer therapy, including a wide variety of citotoxic drugs like methotrexate. In the last years, it has been discovered a new melanoma mechanism of resistance to methotrexate (MTX) by which this drug is sequestered into melanosomes and exported out of melanoma cells, driving to a reduced accumulation of this drug in the cytosolic compartment which is just able to induce growth arrest but

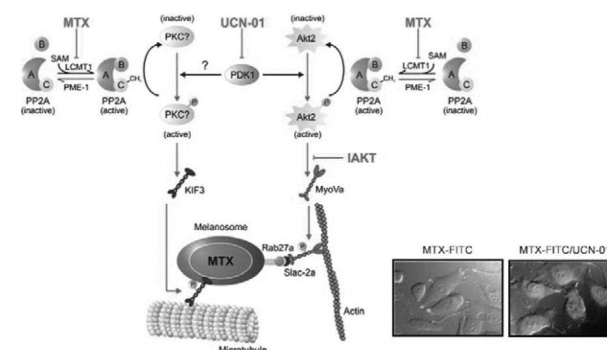

Fig. 1.

not cell death. Particularly, we found that melanoma treatment with methorexate altered melanogenesis and accelerated the exportation of melanosomas, but the cellular and molecular processes by which MTX is trapped into melanosomas and exported out of cells have not been elucidated. In this study, we identify a new methotrexate-activated molecular pathway involved in the export of melanosomas, in which the motor protein MyosinVa (MyoVa) plays a key role. The results demonstrated that melanoma treatment with MTX leads to Akt2-dependent MyoVa phosphorylation, which enhances its ability to interact with melanosomes and accelerates their exportation. Due to these findings, we designed a MTX combination therapy to increase the susceptibility of melanoma to this drug by blocking this MyoVa/Akt2 pathway. Because7-hydroxystaurosporine (UCN-01) has been shown to potently inhibit PDK1, which activates Akt by phosphorylation, we hypothesized that the inhibition of Akt2 phosphorylation by UCN-01 may result in the disruption of MTX stimulated melanosome transport. By avoiding MTX export, we observed that the E2F1 apoptotic pathway is functional in melanoma, and its induction activates p73 and Apaf1 following a p53-autonomous pro-apoptotic signalling event. *In vivo* studies in mice also indicated that low doses of UCN-01, when combined with MTX, produced a marked reduction for not only tumour growth but also melanoma metastasis. In summary, we observed that the combination of MTX and UCN-01 may represent a therapeutic option for the treatment of this evasive disease.

Upregulation of p16 by small interfering RNA for Galpha12 inhibits cellular proliferation of HepG2 human hepatoma cells

H. Lee[1], E. Lee[1], M. Seo[2]
[1]Brain Korea 21 Plus Project for Medical Science, and Endocrinology, College of Medicine, Yonsei University, [2]Severance Hospital Integrative Research Institute for Cerebral & Cardiovascular Diseases, seoul, Korea

Heterotrimeric GTP-binding proteins (G proteins) are known as signal transducers, which convert receptor-bound signals into intracellular signals to regulate cellular responses including proliferation, differentiation and apoptosis. Galpha12 (G12), one of G protein alpha subunits, is reported to be involved in tumor cell invasion and progression. However, the precise mechanisms by which G12 regulates proliferation of cancer cells are poorly understood. Thus, we aimed to investigate the effect of G12 on

© 2014 The Authors. FEBS Journal © 2014 FEBS

cellular proliferation and its underlying mechanism in HepG2 human hepatoma cells. To knock down G12 expression, HepG2 cells were transfected with G12 siRNA, which showed that G12 significantly inhibited the proliferation of HepG2 cells and the anchorage-independent colony formation. Moreover, G12 siRNA restored the expression of $p16^{Ink4}$ (p16) known to be silenced in many cancer cells and arrested the cell cycle progression of HepG2 cells. In conclusion, G12 siRNA inhibits the proliferation of HepG2 cells by upregulating p16 expression, suggesting that the abnormal proliferation of HepG2 cells might be resulted from G12 signaling to suppress p16 expression of HepG2 human hepatoma cells.

Keywords: hepatocellular carcinoma, Galpha12, proliferation.

TUE-261
Visfatin exerts proliferative and anti-apoptotic effects on MCF-7 breast cancer cells

M. Nourbakhsh[1,2], N. Kheiripour[3], Z. Gholinejad[3], A. Golestani[3], M. Shabani[1], N. Einollahi[4], S. Khaghani[3]
[1]Biochemistry, School of Medicine, Iran University of Medical Sciences, [2]Metabolic Disorders Research Center, Endocrinology and Metabolism Research Institute, [3]Biochemistry, School of Medicine, Tehran University of Medical Sciences, [4]Clinical Laboratory Sciences, School of Allied Medical Sciences, Tehran University of Medical Sciences, Tehran, Iran

There is accumulating evidence that visceral adiposity increases the risk of breast cancer and exacerbates its prognosis. Visfatin is a novel adipokine which is predominantly secreted from visceral fat tissue and or macrophages and plays an important role in a variety of cellular functions. Its intracellular form is the rate-limiting enzyme in NAD biosynthesis. Visfatin expression is increased in breast cancer and its high expression is associated with more malignant cancer behavior. Therefore in the present study the effects of visfatin on MCF-7 breast cancer cell proliferation and apoptosis were evaluated.

Methods: MCF-7 breast cancer cells were used as a model. Cell viability was assessed by MTT. BrdU assay was performed to measure cell proliferation after treatment with 10-200 ng/ml concentrations of visfatin. Cell proliferation was also evaluated in the presence of phosphatidylinositol 3-kinase inhibitor (LY29400), ERK1/2 inhibitor (U0126), and the inhibitor of visfatin enzymatic activity (FK866). Western blotting was performed to detect Akt and ERK1/2 phosphorylation. In order to evaluate the anti-apoptotic effect of visfatin, cells were treated with TNF-α as well as visfatin. Apoptosis was assessed by flow cytometry after double staining with Annexin V-FITC and propidium iodide. Western blotting was used to detect poly-ADP ribose polymerase (PARP) cleavage and survivin protein levels.

Results: Visfatin significantly increased cellular proliferation. This effect was inhibited by LY29400, U0126 which suggests that the effect of visfatin is mediated by ERK1/2 and Akt signaling pathway. Visfatin also significantly induced phosphorylation of ERK1/2 and Akt 10 min and 60 min after treatment, respectively, indicating a direct mechanism. Cell viability was reduced with FK866 whereas it returned back to normal by visfatin co-treatment. Visfatin treatment counteracted the apoptotic effects of TNF-α on MCF-7 cells and significantly reduced PARP cleavage. The levels of Survivin, a protein with anti-apoptotic properties, were increased by visfatin.

Conclusion: The present study shows that visfatin plays a critical role in development and progression of breast cancer by increasing proliferation of cancer cells, activation of Akt and ERK1/2, and prevention of apoptosis.

Keywords: breast cancer, visfatin.

WMJ-S-001, a novel aliphatic hydroxamate derivative, induces HCT116 colorectal cancer cell death through AMPK-p53-survivin signaling

Y.-H. Huang[1], W.-J. Huang[2], M.-J. Hsu[1]
[1]Graduate Institute of Medical Sciences, [2]Graduate Institute of Pharmacognosy, Taipei Medical University, Taipei, Taiwan

Hydroxamate derivatives have been widely studied and many lines of evidence demonstrated that they exhibit broad pharmacological activities. Recent studies reported their potential use in the treatment of cancer. However, the mechanisms by which this suppresses colorectal cancer progression remain to be elucidated. In this study, we explored the anti-tumor mechanisms of a novel aliphatic hydroxamate derivative, WMJ-S-001, in HCT116 colorectal cancer cells. WMJ-S-001 inhibited cell proliferation and induced cell apoptosis in a concentration-dependent manner. These results are associated with the modulation of $p21^{cip/Waf1}$, cyclin D1, survivin and Bax. WMJ-S-001 activated AMP-activated protein kinase (AMPK) and p38 mitogen-activated protein kinase (p38MAPK), whereas AMPK or p38MAPK signaling blockade abrogated WMJ-S-001's effects of modulating $p21^{cip/Waf1}$, cyclin D1, survivin and Bax. In addition, WMJ-S-001 time-dependently caused increases in p53 phosphorylation and acetylation. WMJ-S-001's actions on p38MAPK and p53 phosphorylation, $p21^{cip/Waf1}$, cyclin D1, survivin and Bax were reduced in cells transfected with AMPK dominant mutant (DN). Results from chromatin immunoprecipitation analysis showed that Sp1 binding to the survivin promoter region decreased while p53 binding to the promoter region increased after WMJ-S-001 exposure. Furthermore, WMJ-S-001 also suppressed tumor growth in HCT116 colorectal tumor xenograft model. In conclusion, we demonstrated in this study that WMJ-S-001 activates the AMPK-p38MAPK-p53-survivin cascade to cause HCT116 colorectal cancer cell death. The present study delineates, in part, the underlying mechanisms of WMJ-S-001 in decreasing survivin and subsequent colorectal cancer cell apoptosis.

Keywords: colorectal cancer, hydroxamate, p53.

TUE-264
A biomechanical feedback regulates cycles of Myosin II phosphorylation to shape tissue morphogenesis

A. Munjal, T. Lecuit
Institut de Biologie du Développement de Marseille, Marseille, France

Myosin II motors generate forces that power cell shape changes during tissue morphogenesis. Such actomyosin networks function like a mechanical ratchet where phases of pulsed contraction associated with cell deformation alternate with phases of shape stabilization. The mechanisms for differential regulation of these networks remain unknown. Cell intercalation driven *Drosophila* ectoderm extension exemplifies the role of the dynamic regulation of Myosin II. During this process, pulsed contractions of actomyosin mesh flow towards junctions aligned in dorso-ventral axis leading to their shrinkage. A planar polarized pool of Myosin II enriched at these junctions stabilizes the deformation making the process irreversible. We investigated the role of phosphorylation of Myosin II regulatory light chain (RLC) by the Rho1-ROCK pathway. Using phospho-mimetic Myosin II RLC that bypasses upstream regulation we found that phosphorylation is necessary and is alone sufficient to stabilize Myosin II at the junctions. Spatial control over phospho-cycles through ROCK and Myosin II Phosphatase mediates planar polarized enrichment through regulation of dissociation and hence turnover of the motor. We also show that phospho-cycles generate proper pulsatility of Myosin II to drive cell deformation, whereby phosphorylation determines pulse amplitude and phosphatase mediated dephosphorylation regulates pulse frequency. Interestingly, the regulators of Myosin II themselves, namely Rho1, ROCK and Myosin II Phosphatase, incorporate in pulsatile networks suggesting that they constitute an upstream biochemical pacemaker of pulsatility. However, our experiments indicate that Myosin II pulsatility is not a simple outcome of a biochemical pacemaker but an emergent behavior of a feedback between Myosin II contractility and the regulators of its contractility.

Keywords: actomyosin contractility, cellular signalling, planar cell polarity.

TUE-265
A generic methodological framework for studying single cell motility in high-throughput time-lapse screening data

A. Schoenauer Sebag[1,2,3,4,5,], C. Tomkiewicz-Raulet[3], R. Barouki[3], J.-P. Vert[1,4,5], T. Walter[1,4,5]
[1]*CBIO, Mines ParisTech,* [2]*Agro ParisTech,* [3]*UMR-S 1124, INSERM-Univ Paris V,* [4]*U900, INSERM,* [5]*Institut Curie, Paris, France*

Cell motility plays a key role in many physiological processes such as embryonic development or immune response, and is also involved in tumor invasion and metastasis.

To better understand the regulation of this biological process and detect its potential chemical disruptors, tools are needed which allow a systematic study of cell migration in a high-throughput setup.

Many assays have been specifically designed to study cell migration mechanisms. They are typically based on a method for targeting selected genes or proteins, and a measure of cellular motility. Examples include analysis of cell traces on coated layers while overexpressing genes of interest [1], wound healing assays for the investigation of gene silencing effect on cell population migratory behaviour [2], or cell tracking in low-throughput time-lapse experiments while inhibiting key enzymes [3]. However, no study evaluating single cell migration was ever realized on a large scale: published high-throughput (HT) migration screens are all based on a measure of cell motility at the population level (e.g. [2] and [4]).

Here, we propose a generic methodological framework to quantitatively study cell migration at single cell resolution in HT data. It consists of cell tracking, cell trajectory mapping to an original feature space, identification of migratory patterns using unsupervised clustering, and discriminant characterization of each experimental condition in terms of migratory behaviours (cf figure).

We apply this workflow to an existing genome-wide RNAi screen (RNA interference screen), the Mitocheck dataset. It is composed of 200 000 HeLa cell time-lapse experiments, each of them resulting from a single gene knockdown [5]. Our workflow allowed us to identify potential migration suppressors, some of which are known to be involved in cell migration.

Furthermore, we show that the application of our framework to newly generated Environmental Toxicology data allows us to study in a quantitative and fully automated way the perturbation of cell motility following TCDD (2,3,7,8-tetrachlorodibenzodioxin) exposure. This opens up the possibility to systematically screen environmental chemicals with respect to their effect on cellular migration.

TUE-266
A new role for CaMKIIβ in the regulation of neuronal migration

O. Nicole[1], **E. Pacary**[2]
[1]*CNRS, UMR5293, Institut des Maladies Neurodégénératives, Université Bordeaux,,* [2]*INSERM U862 – Neurocentre Magendie, Bordeaux, France*

The calcium/calmodulin-dependent protein kinases (CaMKs) represent a critical link between the external environment and cellular responses in neurons. CaMKII, one of the major CaMKs in the brain, exists as a holoenzyme composed of multiple subunits, which form a complex through their association domains. Brain CaMKII predominantly consists of the α and β isoforms, which form heteromeric or homomeric complexes. Although the functions of CaMKIIα have been extensively studied, the isoform-specific functions of CaMKIIβ remain underexplored, especially in the embryonic brain where the α isoform is not expressed.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Here we show that CaMKIIβ is expressed from E14.5 in the cortical plate (CP) of the embryonic cerebral cortex. By using in utero electroporation, we demonstrate that CaMKIIβ knock-down accelerates the radial migration of projection neurons in the CP whereas its overexpression leads to migration defects. Interestingly, these defects are not observed when the F-actin binding domain (ΔFABD) of CaMKIIβ or its association domain necessary for the multimerization (ΔAsso) are deleted, indicating that CAMKIIβ regulates neuronal migration through its actin-bundling activity. In addition the binding of CAMIIβ to the actin cytoskeleton is regulated by Ca^{2+} fluctuations. Indeed, in cultured cells, an increase of Ca^{2+} entry induces the dissociation of CaMKIIβ from actin filaments and this is reversed when Ca^{2+} decreases. These data thus suggest that CAMKIIβ may mediate the effects of Ca^{2+} fluctuations on the saltatory movement of migrating neurons in the CP.

Altogether these data, by showing that CaMKIIβ is critical for neuronal migration during cortical development, reveal a novel function for CaMKIIβ in the mammalian brain

Keywords: Actin, CaMKIIβ, neuronal migration.

TUE-267

A theoretical study towards understanding the structural mechanism of Human Gamma-adducin and its isoforms

J. Muthukumaran[1], S. Gonçalves[2,3,4], C. Antignac[3,4,5], T. Santos-Silva[1]

[1]UCIBIO@REQUIMTE, FCT-UNL, 2829-516 Caparica, [2]Nephrology Department, University Hospital Santa Maria, CHLN, Lisbon, Portugal, [3]Université Paris Descartes, Sorbonne Paris Cité, [4]Inserm U1163, Institut Imagine, Paris, France, [5]AP-HP, Genetics Department, Necker-Enfants Malades Hospital, Paris, France

Adducin is a membrane-skeletal protein which is a candidate to promote assembly of a spectrin-actin network in erythrocytes [1]. Three types of adducin proteins (alpha, beta and gamma) are encoded by three different genes, namely *ADD1*, *ADD2* and *ADD3*. All three adducin proteins contain an N-terminal protease resistant globular head domain, a neck domain and a C-terminal protease-sensitive tail domain [2]. Adducin has been suggested to be involved in kidney disease, cardiac morphogenesis and synaptic plasticity but so far no structural studies are available for these proteins. In the present work, the three-dimensional (3D) structure of gamma-adducin has been predicted by theoretical approach and its structural stability was analyzed through molecular dynamics simulation (MDS). Also, two isoforms produced by alternative splicing have also been characterized, where isoform 1 corresponds to the short protein (in which residues 576-607 are missing), and isoform 2 corresponds to the long protein (chosen as the canonical sequence). Furthermore, we also characterized the structural impact, on both adducin gamma isoforms, of a mutation found in affected individuals from a consanguineous family, presenting steroid resistant nephrotic syndrome, myocardiopathy, intellectual deficit and cataracts. Initially, the sequence of gamma-adducin was retrieved from UniProt database (ID: Q9UEY8). Due to the very low sequence similarity and low query coverage of gamma-adducin with its related structural neighbours, the homology modeling approach alone could not be used to attain the final 3D models. Hence, we used Robetta full-length protein structure server for predictions. This server parses protein chains into putative domains with the Ginzu protocol, and models those domains either by homology modeling or by ab initio modeling. Subsequently, the predicted models were subjected to MDS studies for understanding their structural stability using various parameters, such as RMSD, RMSF, etc. Four final models could be obtained for this protein which will further be compared with experimental data. This type of comparative structural analysis will be an effective tool to understand the role of new mutations found in various genetic disorders.

Accumulation of actin-binding protein zyxin in different types of adherens junctions of nontransformed and transformed epithelial cells

D. Ayollo, N. Gloushankova

Research Institute of Carcinogenesis, Blokhin Russian Cancer Research Center, Moscow, Russian Federation

The main course of our investigation is to study two distinct types of adherens junctions (AJs). Stable tangential AJs are typical of normal epithelial cells, while dynamic radial AJs are common to transformed epithelial cell and fibroblasts. Earlier we have reported of dissimilarities in regulation of tangential and radial AJ mediated by E-cadherin. Radial AJs require ROCK activity and actomyosin contractility for its formation, while tangential AJs require activity of Rac and mDia1. Our next goal was to examine distinctions in accumulation of actin-binding protein zyxin within adhesion plaques of tangential and radial AJs. To address this goal we used pairs of cell lines of same histological origin. IAR2 cells originate from rat liver explants and have normal epithelial phenotype while IAR6-1 cells derived from NDMA-treated IAR cells are moderately transformed. Along with IAR cell lines we used cells originated from human pancreatic carcinomas. Highly differentiated Capan-2 cells have virtually nontransformed morphology and form tangential AJs just as IAR2 cells do. Likewise PANC-1 cells underwent moderate degree of morphological transformation and form radial AJs similar to those of IAR6-1 cells. Cells of all four lines express E-cadherin. We examined accumulation of zyxin in mature AJs formed in cellular monolayers. It turned out that tangential AJs in IAR2 and Capan-2 cells lacked zyxin while AJs of IAR6-1 and PANC-1 accumulated it. We further tested zyxin accumulation in newly formed AJs. Specimens of narrow wound showed well-defined zyxin staining in radial AJs of IAR6-1 and PANC-1 cells whereas in case of IAR2 and Capan-2 cells there was a somewhat controversial picture of zyxin accumulation. In newly formed tangential AJs zyxin was stained either all along the contact, or in discrete patches, or in peripheral regions of contact. To clarify the way zyxin incorporates in different AJ types we examined the dynamics of its accumulation in IAR2 and IAR6-1 cells which simultaneously expressed GFP-E-cadherin and mCherry-zyxin. It became apparent that zyxin starts to accumulate in AJs along with E-cadherin in course of formation of both tangential and radial AJs. Radial AJs contained zyxin all along the period of observation while tangential AJs gradually lost it in the middle part of contact along with its elongation. Peripheral parts of tangential AJs preserved zyxin up to wound closure. On the basis of these observations we suggest that zyxin plays crucial role in linking radial AJs to dynamic actin cytoskeleton. This distinction apparently contributes to the ability of transformed epithelial cells to migrate relative to each other and normal cells.

Keywords: adherens junctions, epithelial cells, zyxin.

TUE-269

An intercellular polyamine transfer via gap junctions in epithelial cells: implications for the control of cell proliferation and the response to stress

D. Bénédicte, H. Loic, **P. David**
Institut National de la Santé et de la Recherche Médicale (INSERM), UMR829, Université Evry-Val d'Essonne, Evry 91025, France

Gap junctions are the only intercellular junctions in the animal kingdom that allow the direct exchange of small molecules (<1 KDa) such as ions, small metabolites and second messengers from cell to cell. Gap junctions are known to play a key role in various cellular processes like mechanotransduction, calcium signaling, and control cell proliferation. By the past, many studies have been focused on the gating of some gap channels by polyamines, especially spermine in vitro. Here we rather explore whether polyamines can be directly exchanged between adjacent cells via gap junction communications to participate in the growth control (Desforges et al, 2013). For instance, the transfer of polyamines from cell to cell can be important when quiescent epithelial cells resume cycling as a result of various stimuli including wound healing or oxidative stress. Indeed, under such conditions, quiescent cells need to increase their polyamine levels in order to resume cycling. To do so, quiescent cells can either resume polyamine synthesis or increase their active transport to resume proliferation. However, using our model, another alternative pathway can be put forward: an exchange of polyamines from cycling cells to quiescent cells through gap junctions. This hypothesis makes sense if we consider the scarce presence of free polyamines in plasma compared to the large intracellular pool. In addition, due to their small size, and to their hydrophilic nature, polyamines, especially putrescine, satisfy all the requirements to be transported from cell to cell via gap junctions. We will also discuss the potential application of the polyamine-mediated intercellular interactions during wound healing and the collective response to oxidative stress.

Assessment of zinc-substituted trisulphonated phthalocyanine effect on COLO 829 cell proliferation through real-time electrical impedance-based technique

M. Tampa[1,2], C. Matei[1,2], R.-M. Ion[3], C. Constantin[2], M. Neagu[2]
[1]*Dermatology, "Carol Davila" University of Medicine and Pharmacy,* [2]*Immunology, "Victor Babes" National Institute of Pathology,* [3]*Chemistry, ICECHIM Institute, Bucharest, Romania*

Photodynamic therapy (PDT) is a modern approach directed to killing tumor cells mainly by apoptosis induction and reactive oxygen species production. PDT employs a photosensitiser and the use of light of an appropriate wavelength, adequate for its activation. Zinc-substituted trisulphonated phthalocyanine (ZnS3Pc) is a novel chemical compound with good photosensitiser proprieties that recommend it for use in PDT. To date, there are no studies concerning the effect of ZnS3Pc on skin fibroblast proliferation. The objective of the present study was to assess, through real-time label-free monitoring using impedance analysis, the effect of various concentrations of ZnS3Pc on the proliferation capacity of skin fibroblasts. Human skin fibroblasts from COLO 829 standardised cell line established from a patient with metastatic melanoma were seeded in two different cellular densities (5000 and 10000 cells/well) and left to adhere for 2 hours (37°C, 5% CO_2) in specially designed well plates, supplied at the bottom with sensor electrodes able of read the fluctuations in electrical impedance. ZnS3Pc was added to the wells after 4 hours in different concentrations (0.1, 2 and 4 microM). We have monitored cell proliferation using xCELLigence platform, a simple, yet powerful method that provides results in real-time, standing as a significant advantage over other traditional methods that rely on end-point analysis. The data was acquired over a 72 hours interval as a function of changes in impedance on the surface of electrodes at the bottom of the wells. Experiments were performed in triplicate. In the experimental model of fibroblasts seeded at 5000 cells/well, we have registered an activation of the cellular proliferation almost immediately after ZnS3Pc was added; this activation was best observed after 48 h of cultivation. The activation potential had a clear inverse dose-effect pattern, as the lowest concentration used (0.1 microM) activated cell proliferation more intense that the higher ones (2 and 4 microM, respectively). As for the other cellular density used (10000 cells/well) the case was opposite, namely the degree in which ZnS3Pc inhibited cell proliferation paralleled the compound concentration. Through this method we have shown a clear dependency between cell versus compound concentration in the system, thus the future medical applications of the photosensitizers must be tailored to the actual number of cell-targets. To the best of our knowledge, this is the first study that investigates the cytotoxicity of ZnS3Pc on COLO 829 cells via real-time monitoring.

Keywords: cell proliferation, Photodynamic Therapy, Phthalocyanines.

Bazooka (Par-3) and atypical protein kinase C regulate dynamic actomyosin networks during *Drosophila* amnioserosa apical constriction

D. J. David[1,2], T. J. C. Harris[1]
[1]*Cell & Systems Biology, University of Toronto, Toronto, ON, Canada,* [2]*Cell Biology and Infection, Institut Pasteur, Paris, France*

Cell shape changes drive tissue remodeling. Polarized activity of actin and myosin drive apical constriction, as seen for example in *Drosophila* embryonic amnioserosa cells during dorsal closure (DC). First, we characterized interactions between apical actomyosin networks and the cell polarity regulators Bazooka (Baz, the *Drosophila* Par-3), Par-6, and atypical Protein Kinase C (aPKC) (the PAR complex) during *Drosophila* DC. We found that both actomyosin networks and the PAR complex are enriched at the apical surfaces of amnioserosa cells and that actomyosin contractility is driven by cyclical assembly and disassembly of actomyosin networks. The pulsatile actomyosin networks translocate across persistent apical surface PAR complex puncta. To assess whether the PAR complex interacts with actomyosin, we characterized myosin dynamics with PAR loss- and gain-of-function perturbations. Baz enhances, whereas Par6/aPKC inhibits actomyosin. Our studies suggest that PAR proteins regulate pulsatile apical actomyosin networks mediating constriction of amnioserosa cells (David *et al*., 2010). Next, we characterized actomyosin networks during a shift in their dynamics. Amnioserosa constriction transitions from pulsatile to persistent from early to late DC. Since oscillatory networks result from delayed negative feedback, we examined whether such regulation exists in these actomyosin

© 2014 The Authors. FEBS Journal © 2014 FEBS

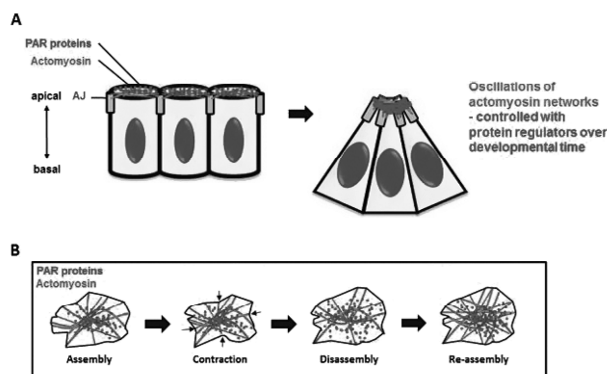

Fig. 1. (A) Apical constriction driven by apical actomyosin networks. (B) Oscillatory apical actomyosin and apical PAR surface puncta.

networks. The actomyosin inhibitor aPKC is recruited to the apical surface by actomyosin and, in turn, aPKC recruits Baz. To examine the significance of Baz – aPKC dynamic interactions, we ectopically stabilized their interactions. This inhibited the antagonism of actomyosin networks by aPKC, suggesting that Baz can act as a competitive inhibitor of aPKC. We found that interactions between Par-6 and Baz increase during DC, suggesting an increase in aPKC inhibition during DC progression. To examine whether decreased inhibition can tune oscillatory actomyosin networks, we collaborated with Qiming Wang and Dr. James Feng (University of British Columbia) to test this oscillation *in silico*. Computer modeling suggests that decreasing delayed negative feedback can transition actomyosin oscillations towards stabilized constriction. Together, these results demonstrate the requirement of Baz – aPKC interactions for their localization and for dynamic regulation of aPKC by a competitive inhibitor (David *et al.,* 2013). Finally, our research reveals a regulatory circuit to tune actomyosin behaviour during development.

TUE-272
Biophysical analysis of cellular targets for designing novel antitumour metallopharmaceuticals

E. Suleymanoglu
Pharmaceutical Chemistry, Faculty of Pharmacy, Gazi University, Ankara, Turkey

Metals are essential evolutionarily selected by nature cellular components designed to function in several indispensable molecular processes for living organisms. Metals are engaged in unique characteristics that include reaction kinetic activity, variable coordination modes, and reactivity towards a wide variety of substrates. Despite their well-established roles in numerous cellular events, such as regulation of cell macromolecular assemblies of membranes, proteins and nucleic acid topologies, in gene transcription and expression, in translation and intracellular trafficking, as well as in macromolecular crowding, their further cellular functions still remain to be elucidated. Due to their reactivity, metals are tightly regulated under normal conditions and non-physiological metal ion concentrations are associated with various pathological disorders, including cancer, autoimmune and neurodegenerative diseases. The work presented herein is devoted to characterization of selected metals that have gained considerable interest in both the development and the treatment of cancer. The characterization of yet unclear cellular targets of Boron, Gallium, Germanium, Rhodium and Gold, is emphasized as the major goal of this preliminary work. Such a characterization of major cellular macromolecular targets would pave the way of designing novel inorganic therapeutic strategies to target molecular pathways as anticancer agents. A novel hypothesis concerning the possible mechanisms of action of these inorganic drugs at the molecular level is proposed. This hypothesis is based on our newly developed theoretical model considering cell membrane phospholipids, serum and intracellular proteins and cellular nucleic acids as targets of these metal ions. Thus, the hypothesis addresses two major questions with basic cellular and therapeutic emphasis, respectively. Elucidating the molecular mechanisms of metal ion-cell biomolecule interactions would give important clues for molecular mechanisms of functioning of cellular machinery in important events such as cellular differentiation, regulation, apoptosis and evolution, besides deciphering their roles in regulation of gene expression and genome function. On the other hand, characterizing such molecular recognitions between inorganic ions and cellular biomolecules would serve as a motivation for starting research on designing novel therapeutic strategies towards biomacromolecule directed drug design with further therapeutic implications in cellular oncology research.

Bubbly vertex dynamics: a dynamical and geometrical model for epithelial tissues with curved cell shapes

Y. Ishimoto, Y. Morishita
RIKEN CDB, Kobe, Japan

In order to describe two-dimensionally packed cells in epithelial tissues both mathematically and physically, there have been developed several sorts of geometrical models, such as the vertex model, the finite element model, the cell-centered model, the cellular Potts model. So far, in any case, pressures have not neatly been dealt with and the curvatures of the cell boundaries have been even omitted through their approximations. We focus on these quantities and formulate them in the vertex model. Thus, a model with the curvatures is constructed, and its algorithm for simulation is provided. The possible extensions and applications of this model will also be discussed.

Keywords: computer simulation, epithelial cells, Tissue mechanics.

TUE-274
CaMKII/Androgen receptor signaling pathway stimulates MEF2 transcription factor to induce cardiomyocyte hypertrophy by testosterone

J. Duran, M. Estrada
Physiology and Biophysic, Faculty of Medicine, University of Chile, Santiago, Chile

Both Ca^{2+}/Calmodulin-dependent protein kinase (CaMKII) and androgen receptor have been involved in cardiac hypertrophy by using different action mechanisms. CaMKII regulates myocyte-enhancer factor 2 (MEF2) transcription factor, which is a key regulator of cardiac hypertrophy. However whether CaMKII/MEF2C signaling is involved on testosterone-induced cardiomyocyte hypertrophy is unknown. The aim of this study was to investigate whether testosterone activates CaMKII-MEF2C during hypertrophic process. The results show that in primary cultures of cardiomyocytes testosterone (100 nM) increased the phosphorylation of both CaMKII (Thr286) and its substrate phospholamban (Thr17). The hormone induced MEF2C nuclear retention and increase MEF2-lux activity. These effects were prevented by the use of siRNA-CaMKIId, a peptide inhibitor of CaMKII (AIP) and bicalutamide (an androgen receptor inhibitor). Cardiomyocytes transfected with a constitutively active form of CaMKII (CaMKII-T286D) increased *per se* MEF2-lux activity and posterior testosterone stimulation enhanced even more the effect of CaMKII-T286D on MEF2, this last increase was prevented by androgen receptor inhibition. These results suggest that the increase in MEF2 activity induced by testosterone in cardiomyocytes is under the control of multiple pathways such as mechanisms dependent of androgen receptor as well as calcium dependent as CaMKII activation. Cardiomyocyte hypertrophy was assessed by increases in β-myosin heavy chain and skeletal a-actin proteins, aminoacid incorporation and cell size. All these effects were increased by testosterone, but were prevented by AIP, siRNA-CaMKIId and by siRNA-MEF2C. Collectively, these are the first evidences suggesting that testosterone activate CaMKII/MEF2C to induce cardiomyocyte hypertrophy.

Keywords: CaMKII, Cardiomyocyte hypertrophy, MEF2.

Cell motility and molecular analysis of fibroblast spheroid

S. Kunii[1], Y. Horiuchi[2], S. Kishigami[1], Y. Hiraoka[3], **K. Morimoto**[1]
[1]Biology-Oriented Science and Technology, Kindai University, Kinokawa, [2]Life Science Institute, Kindai University, Osakasayama, [3]Nitta-gelatin Inc., Yao, Japan

Background: Fibroblasts exist in the connective tissue and are generally separated by collagen bundles. Some of functions in fibroblast are synthesis, secretion, and degradation of extracellular matrix (ECM) components such as collagens or proteoglycans. The ECM proteins have a great influence on not only mechanical strength but also proliferation and differentiation. As the results, the connective tissue is kept with normal, healthy conditions. In addition, fibroblasts play a critical role in wound healing. In particular, myofibroblasts interact with ECM proteins to contract the wound. Therefore, the function of fibroblasts cultured on the ECM proteins has energetically been investigated. However, the molecular mechanism of wound repair still remains to be clarified. We found that fibroblast cultured on enzyme-treated collagen spontaneously form an aggregated sphere body (spheroid). In this study, we report the cell motility and the protein expression patterns in fibroblast spheroid.

Methods: Pig type I collagen was treated with an enzyme X, and we obtained collagen preparation (N-Col) (Patent pending). Culture dish (ϕ35 mm) was coated with N-Col solution. Subsequently, mouse NIH/3T3 cells, mouse primary embryonic fibroblasts (MEF), or normal human dermal fibroblasts (NHDF) were cultured on N-Col coated dish. After 24 hrs, we observed cell morphology by using a phase-contrast microscope. To investigate the cell dynamics, we stained filamentous actin (F-actin) with DyLight 555-labeled phalloidin. To further demonstrate the relationship between spheroid and epithelial mesenchymal transition (EMT), we observed EMT protein markers stained by DyLight 555-labeled polyclonal antibodies. Finally, cell motility was monitored for a period of 24 hrs and analyzed by a time-lapse observation.

Results and Conclusion: Each of NIH/3T3, MEF and NHDF cells formed the spheroid morphology by culturing on the coated dish with N-Col. F-actin of each cell in spheroid was highly expressed as compared with that in a single cell. Besides, we confirmed that there are no apoptosis cells in spheroid. Interestingly, cell motility drastically changed by formation of spheroid. In conclusion, we demonstrated that N-Col has ability to grow sphere body of fibroblasts.

Funding: This work was supported by the Adaptable and Seamless Technology Transfer Program through target-driven R&D, Japan Science and Technology Agency [AS2414037P to K.M.].

icity. Additionally, silica-based fluorescent nanoparticles (Si-FNPs) are used as imaging and analytical standard probes to study the molecular dynamics and the property of cellular micro-environment because of high solubility, brightness and photostability. Many previous reports are only focused on understanding how cells uptake NPs, trafficking process and potential toxicity of NPs. NPs uptake into the cell by endocytosis and arrived at cytoplasm and then it is met with a variety of molecular environment like as proteins, protein complexes, vesicles, and organelles. Previous reports have showed that various NPs, including SNPs, quantum dots, and gold nanoparticles, could be uptaken and localized into the cells by endocytosis process or by artificial methods such as electroporation and microinjection. However, the intracellular dynamics and interaction with the cellular constituents were not fully understood.

In this study, complementary methodologies of fluorescence correlation spectroscopy (FCS), confocal microscopy (CLSM), and electron microscopy (TEM) was used, to describe the detailed time course of uptake process, diffusion dynamics, and localization of SNP and Si-FNPs with diameter of 50 nm. Moreover, difference of the cellular process between endocytosis and electroporation methods in the living cells was quantitatively compared.

TUE-277

Changes in the activity of antioxidant barrier after treatment of K562 cell line with doxorubicin - transferrin conjugate

M. Szwed[1], K. D. Kania[2], Z. Jozwiak[1]

[1]Department of Thermobiology, University of Lodz, [2]Laboratory of Transcriptional Regulation, Lodz, Poland

Doxorubicin (DOX), one of the oldest member of the anthracycline antibiotics, has been administered for over 50 years to patients with leukemias and solid tumors. However, the high unspecified DOX toxicity, related with reactive oxygen species (ROS), affects its limitation in clinical application. Therefore we proposed the usage of human transferrin as a doxorubicin carrier in order to improve the quality of doxorubicin application in conventional chemotherapy. In this study we are concentrating on the influence of doxorubicin – transferrin (DOX-TRF) conjugate on the antioxidative system in chronic erythromyeloblastoid leukemia cell line (K562). We carried out neutral red cytotoxicity assay, reduced glutathione (GSH) content and alterations in the activities of catalase and enzymes responsible for maintaining glutathione in reduced form. Exposure of leukemia cells to the investigated anticancer agents caused a time-dependent depletion of intracellular GSH, accompanied by an increase of catalase activity. Moreover, analysis of GSH-related enzymes showed a significant increase in the activities of thioredoxin reductase and glutathione peroxidase after DOX-TRF application. In contrast, glutathione reductase activity was reduced by conjugate treatment to 50%. Significant differences between the pro-oxidative actions of the investigated anticancer compounds were observed in RT-PCR experiments, which confirmed that changes in the activity of catalase and GSH-related enzymes are strictly correlated with their gene transcription changes.

Keywords: anticancer drug conjugates, reactive oxygen species, transferrin.

TUE-278

Citrullination of collagen II decreases integrin-mediated cell adhesion by receptor specific manner

K. Sipilä[1], S. Haag[2], K. Denessiouk[3], J. Käpylä[4], E. C. Peters[5], A. Denesyuk[3], U. Hansen[6], Y. Konttinen[7], M. S. Johnson[3], R. Holmdahl[2], J. Heino[4]

[1]Departmen of Biochemistry, University of Turku, Turku, Finland, [2]Karolinska Institutet, Stockholm, Sweden, [3]Åbo Akademi University, [4]University of Turku, Turku, Finland, [5]Genomics Institute of the Novartis Research Foundation, San Diego, USA, [6]Muenster University Hospital, Muenster, Germany, [7]Institute of Clinical Medicine, Helsinki, Finland

Citrullination is a posttranslational modification of arginine residues catalyzed by enzymes peptidyl arginine deiminases (PAD). Some extracellular matrix (ECM) proteins, including collagen II and fibronectin, are citrullinated in human rheumatoid arthritis *in vivo*. Interestingly, some of the anticitrullinated protein autoantibodies, a well-studied rheumatoid arthritis markers, recognize citrullinated CII and can mediate arthritis in mouse. In this study, we are interested the functional effects of citrullination on ECM proteins. Furthermore, we are searching for new *in vivo* targets of PADs by the mass spectrometric analysis of synovial fluids collected from arthritis patients.

The presence of citrullinated of collagen II in arthritis joint *in vivo* was previously reported. We demonstrate by mass spectrometric and chemical analysis that PAD2 and PAD4, rheumatoid arhtritis relevant PAD isoforms, can citrullinate GFOGER, the critical binding motif of integrins, in collagen II. Citrullination of collagen decreased the adhesion of several cell types including primary synovial fibroblasts. Interestingly, the effect of citrullination varied notably between different cell types. For further investigation, we studied how the citrullination of GFOGER affects the ligand recognition of collagen receptor integrins. The data show that citrullination of GFOGER decreases significantly the alpha10beta1 and alpha11beta1 integrin mediated cell adhesion but has only a minor effect or no effect at all in the case of integrin alpha1beta1 and alpha2beta1. The receptor specific effect of citrullination can be explained by molecular modeling based on the crystal structure of integrin alpha I domain - GFOGER complex.

Given the fact that integrins regulate numerous cellular functions like apoptosis, cell survival, and proliferation, our study suggests that the citrullination of collagen II may have a role in the pathological destruction of joints by disturbing integrin-mediated cell-matrix interactions.

Keywords: citrullination, integrin, rheumatoid arthritis.

TUE-279

Cooperation between the actin nucleators mDia1 and Arp2/3 complex controls membrane ruffling

T. Isogai[1], R. van der Kammen[1], D. Leyton Puig[2], K. M. Kedziora[2], K. Jalink[2], M. Innocenti[1]

[1]Molecular Genetics, [2]Cell Biology I, The Netherlands Cancer Institute, Amsterdam, Netherlands

Polymerization of branched actin filaments mediates the formation of lamellipodia and ruffles, protrusions of the plasma membrane involved in cell migration, phagocytosis and macropinocytosis. Biochemical evidence indicates that actin-related protein 2 and 3 (Arp2/3) complex nucleates branched actin filaments upon activation by Wiskott-Aldrich syndrome protein (WASP)-family verprolin-homologous protein (WAVE)

© 2014 The Authors. FEBS Journal © 2014 FEBS

complex. Genetic studies demonstrate that both complexes are required for the formation of lamellipodia and ruffles. However, whether and how other actin nucleators participate in this process is still unknown. Here we show that the actin nucleator mDia1 acts in concert with the Arp2/3 complex to promote the efficient formation of ruffles. Knockdown and rescue experiments revealed that EGF-induced membrane ruffling requires mDia1 and its actin-nucleation abilities. Although activated full-length mDia1 and Arp2/3 complex were poor actin nucleators, their combination triggered explosive polymerization of branched actin arrays *in vitro*. These results suggested that mDia1 polymerizes linear actin filaments igniting autocatalytic Arp2/3-complex-dependent nucleation of branched actin filaments and ruffling. Consistently, super-resolution microscopy localized WAVE and mDia1 within EGF-induced ruffles. Hyperactivation of the Arp2/3 complex in mDia1 knockdown cells and overexpression of mDia1 in WAVE-complex knockdown cells restored EGF-induced ruffling, thus showing that mDia1 and the Arp2/3 complex cooperate in the making of ruffles. Given that the expression levels and the activity of mDia1 and the Arp2/3 complex dictate the contribution of either nucleator to membrane ruffling, it appears that cell-intrinsic and cell-extrinsic factors sculpt the lamellipodium/ruffle-making machinery.

Keywords: actin reorganisation, Arp2/3, mDia1.

Curcumin and neurite outgrowth: investigations for spinal muscular atrophy

G. Bora Tatar, H. Erdem-Yurter

Medical Biology, Faculty of Medicine, Hacettepe University, Ankara, Turkey

Spinal Muscular Atrophy (SMA) is a neurodegenerative disease, which is caused by deletions or mutations of the Survival of Motor Neuron 1 (*SMN1*) gene. SMN is ubiquitously expressed protein that plays a role in actin dynamics, axonal transport, and neurite outgrowth in neurons. Low levels of SMN protein leads to neurite outgrowth defects in neuronal cells and rescue of the defect is thought to be a reasonable therapeutic strategy for SMA. Neuroprotective compounds, like polyphenols and histone deacetylase (HDAC) inhibitors, may be good candidates for restoring of the defect. In the present study, it was investigated whether neurite outgrowth defects could be rescued by curcumin, which is SMN-inducing polyphenol, having HDAC inhibition activity. Curcumin was applied to wild type and SMN knockdown PC12 cell lines and neurite lengths were measured. According to our results, curcumin significantly increased the neurite lengths of the wild type but not SMN knockdown cells at 3 days of differentiation. To investigate whether neurite promotion in wild type cells was caused by increasing the SMN protein, total and nuclear SMN protein levels were analyzed in response to curcumin using Western blot and immunofluorescence staining of nuclear bodies, respectively. It was found that both total SMN level and nuclear body numbers remained unchanged. According to our results, even though curcumin failed to rescue the outgrowth defect, it lost its neurite promoting ability when the SMN level was decreased. Taken together, our results indicated that the neurite promoting effect of curcumin dependent on the SMN protein. Further studies using primary neurons and induced pluripotent stem cell-derived patient motor neurons will be valuable to understand the function of SMN protein at outgrowth mechanism.

Keywords: Curcumin, Neurite outgrowth, Spinal muscular atrophy.

TUE-281

Cx43 mutant expressing fibroblasts from oculodentodigital dysplasia patients exhibit diverse properties that predict variability in wound healing

J. J. Kelly[1], Q. Shao[1], E. W. Jabs[2], J. Sampson[3], M. Auranen[4], D. Bai[5], D. W. Laird[1]

[1]Anatomy and Cell Biology, Western University, London, Canada, [2]Genetics and Genomic Sciences, Mount Sinai Medical Center, [3]Neurology, Columbia University Medical Center, New York City, NY, USA, [4]Neurology, Helsinki University Central Hospital, Helsinki, Finland, [5]Physiology and Pharmacology, Western University, London, Canada

Connexins (Cx) are a large gene family with Cx43 being the most commonly found connexin in human tissues. Cx43 oligomerizes into hemichannels that traffic to the cell surface and form intercellular gap junction channels with neighbouring cells. To date, over 70 *Cx43* (*GJA1*) gene mutations have been discovered that cause the developmental disorder known as oculodentodigital dysplasia (ODDD). In the present study, we characterized three dermal fibroblast cell lines obtained from ODDD patients with autosomal dominant Cx43 missense mutations (L7V, G138R, G143S), and further described properties of two others (D3N and V216L). Immunofluorescent labelling revealed that the L7V, G138R and G143S Cx43 mutants trafficked to the cell surface and formed gap junction-like plaques. Dual whole cell patch clamp recordings revealed functional gap junctional conductance between cells expressing both the G138R and G143S mutations. However, the L7V mutant had no detectable conductance suggesting it was a potent dominant-negative to co-expressed wild-type Cx43. Since Cx43 is important in wound healing, we further found that mutant expressing fibroblasts had significantly reduced proliferative and migratory properties as well as an inability to correctly polarize the Golgi apparatus in an *in vitro* scratch wounding assay. All cells treated with the wound healing cytokines PDGF and TGF-β initiated a robust increase in Cx43 expression, but mutant-expressing cells failed to increase the P2 phosphorylation state, which is indicative of enhanced gap junction assembly. In response to TGF-β all fibroblasts elicited an increase in α-smooth muscle actin (α-SMA) expression suggesting that the cells retained variable ability to differentiate into myofibroblasts. However, when seeded in 3D collagen gels, the D3N and V216L expressing fibroblasts were less efficient at contracting the gels after TGF-β treatment. In parallel, a dermal punch biopsy wound healing assay was performed on a $Cx43^{I130T/+}$ mouse model of ODDD. As predicted from the collagen contraction studies with the G138R and G143S mutant expressing cells (same domain as the I130T mutant), no significant difference in wound healing was observed. In summary, in dermal fibroblasts, ODDD-linked Cx43 mutants may exert little effect on co-expressed Cx43 or be potent dominant-negatives. Thus, some ODDD patients are predicted to have delayed wound healing, an outcome that is dependent on the specific mutation they harbor.

Supported by the Canadian Institutes of Health Research to DWL.

TUE-282
Determination of the inhibitory effect of water samples on the light emission of Vibrio fischeri

M. C. C. Maior[1], R. Carpa[1,2], R. Fetke[2], V. Muntean[2]
[1]*Institute of Technology,* [2]*Department of Molecular Biology and Biotechnology, Babes-Bolyai University, Cluj-Napoca, Romania*

Inhibition of light emitted by a bioluminiscent bacterium, *Vibrio fischeri,* is the basis for several toxicity bioassays. This study is focused on *Vibrio fischeri* bioluminiscence inhibition assay, which is often chosen as the first test in a test battery based on speed and cost considerations. Water samples from Secu and Văliug dam reservoirs, Caras-Severin county (Romania) were analysed in order to determine the toxicity level. These reservoirs represents the main source of tap water for Resita city. Standard 5, 15 minutes test were compared with a 30 minutes assay using the same organism and the same test parameter. For that purpose concentration-response relationships were determined for a set of selected substances, reflecting different modes and mechanisms of action. The values of the effective concentrations which reduce the intensity of light emission by 20% (EC_{20}) and 50% (EC_{50}) were calculated. For comparison with our samples, $ZnSO_4$ x $7H_2O$ and $K_2Cr_2O_7$ were used as reference. Based on EC_{20} and EC_{50} values, we concluded that water from Secu dam reservoir is more toxic for *Vibrio fischeri.* Our results were confirmed by reported enzymological and bacteriological results.

Keywords: bioluminescence, toxicity, Vibrio fischeri.

TUE-283
Development of II-D cell blot method

K. Nagashima[1], S. M. B. Muhamad Yusop[1], Y. Mukai[2], T. Terasaki[2]
[1]*Dept. Electr., Grad. Sch. Sci & Tech.,* [2]*Dept. Electr. & Bioinfo., Sch. Sci & Tech., Meiji University, Kawasaki, Japan*

The development of new methods that enable high-throughput analysis of protein functions comprehensively is of utmost importance. Hayman *et al.* have developed the SDS-PAGE cell blot method for the analysis of cell-adhesive proteins [1]. In their study, the proteins separated by SDS-PAGE were transferred to a membrane, where cells were then cultured. Unknown cell binding proteins were then found by observing the spots where cells were attached. However, this method is not prevalent because SDS is known as a detergent which denatures many kinds of proteins. Moreover, this method requires two blotting sheets, one for protein staining and one for cell staining. By comparing these two membranes, the protein hotspots in which cell morphology has changed are determined. When trying this method two-dimensionally, merging these two membranes and defining the hotspots could pose difficulties. In a previous paper, Manabe and Jin reported a non-denaturing II-DE method that enables the separation of proteins which preserve biological structures and functions [2].

In this study, a new method that enables comprehensive analysis of proteins functions has been developed by combining the SDS-PAGE cell blot and the non-denaturing II-DE method, and a protein that induces apoptosis in *Pieris rapae* was analyzed using the Two-Dimensional Cell Blot method. The proteins in body fluid of *Pieris rapae* were separated using non-denaturing II-DE method and were transferred to a PVDF membrane. HeLa cells were plated over the protein-transferred membrane evenly, and both the proteins and the cells stained by CBB were then observed on the membrane. From these experiments, nuclear condensation, membrane bleb and cytosol overflow were found in the cells on the hotspot. These phenomena show that the protein on the hotspot had apoptosis activity. The isoelectric point of this protein was six and was almost equal to that of "Pierisin" known as the apoptosis protein in body fluids of *Pieris rapae*. The hot spot was consistent with the area where "Pierisin" protein was expected to exist. This method using II-D Cell Blot could be useful for the comprehensive analysis of proteins that induce cell morphological changes by combining with MALDI-TOF-MS. This method is also advantageous in that it requires only a small amount of proteins, about 20 μg.

TUE-284
Differential effect of Antioxidants in Cell Death-Related Oxidative Stress in wild-type MEFs

K. Pegan[1], N. Kavcic[1], P. Vandenabeele[2], B. Turk[1]
[1]*Department for Biochemistry, Molecular Biology and Structural Biology, Jozef Stefan Institute, Ljubljana, Slovenia,* [2]*Department for Molecular Biomedical Research, Molecular Signalling and Cell Death Unit, Ghent University, Ghent, Belgium*

Reactive oxygen species (ROS) that can cause cellular stress are generated in the mitochondria. Physiologically ROS function as cellular signals in different molecular pathways. However, higher concentrations of ROS are toxic to cells and can trigger apoptotic or necrotic cell death. Superoxide dismutase (SOD), glutathione (GHS) and other vitamins, such as tocopherols, are considered the primary cellular defence against oxidants. In daily life, vegetables and fruits represent the main sources of antioxidants in the humans' diet. Generally, the intake of antioxidants is believed to decelerate cell aging and loss. However, recent studies report conflicting results.

The aim of our study was to evaluate the effect of different antioxidants, including N-acetyl cysteine (NAC) that replenish intracellular GHS, the lipophilic vitamin α-tocoferol, and two SOD mimetics, MnTBAP and tempol, in scavenging ROS in MEFs in three different models of cell death, including MD-induced necrosis and STS and TNFα-induced apoptosis. Apart from MnTBAP, all other antioxidants are used as drugs or dietary supplements. The antioxidant's efficiency was measured as the capacity to decrease intracellular ROS production and to prevent cell death. The antioxidants were the most efficient in scavenging MD-induced ROS, followed by STS-induced ROS, whereas they were the least efficient in scavenging TNFα -induced ROS. However, major differences were observed when using tempol. The most striking result was that tempol increased ROS production *per se* and was unable to decrease oxidative stress following MD and STS treatments. Tempol's antioxidant potential was shown only upon TNFα treatment using concentrations up to 5 mM. At concentrations above 5 mM, tempol lost its antioxidant properties also in TNFα model. However, all the antioxidants were much less efficient in enhancing cell viability as in ROS scavenging. Thereby we have shown not only that different antioxidants have different capacity to scavenge ROS, but also that ROS contribute to different extent to cell death, depending on the pathway. Clarifying the role of antioxidants in ROS production and the correlation with cell death will improve our knowledge of how oxidation modulates molecular signalling and cell faith. Moreover, due to the wide use of antioxidants in

© 2014 The Authors. FEBS Journal © 2014 FEBS

therapies for diseases from the common influenza to cancer, a complete understanding of how different antioxidants work at the molecular level might be used to improve therapeutic approaches based on antioxidants.

Keywords: Antioxidants, Cell death, Oxidative stress.

TUE-285
Effect of auranofin, N-acetyl cysteine and buthionine sulfoximine on the glutathione status in Taenia crassiceps cysticerci

J. D. J. Martínez-González, A. Guevara-Flores, J. L. Rendón, I. P. del Arenal
Departamento de Bioquímica, Facultad de Medicina, Universidad Nacional Autónoma de México, Ciudad de México, Mexico

In the parasite lineage of Platyhelminthes the redox homeostasis is dependent on thioredoxin-glutathione reductase (TGR), a mixed-function selenoenzyme that acts transfering electrons from NADPH to the oxidized states of both GSSG and thioredoxin. TGR has been proposed as a pharmacological target because in these organisms is the only enzyme involved in the reduction of both GSSG and oxidized Trx. Previously, we studied the effect of TGR inhibition by auranofin (an anti-rheumatic gold compound) on the viability of *Taenia crassiceps* cysticerci. It was demonstrated that micromolar concentrations of auranofin in the culture medium were high enough to fully inhibit TGR and kill the parasites (Parasitol Res. 2010. 107:227-31). In this work we have analyzed the dynamic of changes in the glutathione pool following the addition of auranofin, as well as the effect of N-acetyl cysteine (NAC) and buthionine sulfoximine (BSO).

The results obtained showed that, as result of the presence of the gold compound, the total concentration of glutathione (GSH + GSSG) decrease, concomitant with a diminution in the GSH/GSSG ratio. Such changes were simultaneous with the formation of GSH-protein complexes as well as with the export of GSSG from cysticerci. The incubation of cysticerci in the presence of both auranofin and NAC, a promotor of GSH biosynthesis, prevents all the above changes, mantaining the viability of the parasites. By contrast, the simultaneous addition of auranofin and BSO, an inhibitor of GSH biosynthesis, results in an encourage in the effects of the gold compound.

These results suggests the lethal effect on *T. crassiceps* cysticerci due to auranofin can be explained, at least partially, as a consequence of major changes in the glutathione status resulting in an irreversible damage, probably by an increase in the oxidative stress.

This work was supported by Research Grants IN220710-3 and IN219414-25 from Dirección General de Asuntos del Personal Académico (DGAPA), and a Doctoral Scholarship from Consejo Nacional de Ciencia y Tecnología (CONACyT), México, to J.J. Martínez-González.

Keywords: glutathione distribution, redox homeostasis, thioredoxin-glutathione reductase.

TUE-286
Effects of soft argon-plasma jet on the cytoskeleton of fibroblasts: implications to plasma medicine

J.-H. Han[1], M.-K. Nam[1], Y.-H. Kim[2], J.-Y. Jang[1], J. Yi[1], J. E. Yun[1], E. H. Choi[2], H. Rhim[1]
[1]Department of Medical Life Sciences, The Catholic University of Korea, [2]Plasma Bioscience Research Center, Kwangwoon University of Korea, Seoul, Korea

Argon-plasma jet is generated by ionizing argon gas, and the resulting argon-plasma jet consists of a mixture of neutral particles, positive and negative electrons, and various reactive species, especially hydroxyl radical. Although argon-plasma jet has been used in various biomedical applications, little is known about the biological effects on cells located near the plasma-exposed region. Here, we investigated the effects of soft argon-plasma jet on actin cytoskeleton of mouse embryonic fibroblasts (MEFs) in response to exposure to argon-plasma jet. This argon-plasma jet was generated at 500 ml/min of flow rate and 100 V electric power with our device. Because actin cytoskeleton is the key cellular machinery involved in cellular movement and is implicated in regulation of cancer metastasis, it seems to be a highly desirable target for cancer therapy. In this study, we examined the actin filament architectures in the argon-plasma jet treated MEFs by staining with a fluorescent actin-specific phalloidin. Interestingly, the argon-plasma jet treatment causes destabilization of actin filament architectures in the regions indirectly exposed to argon-plasma jet, but no changes in MEFs treated with argon gas alone and untreated cell control. The result indicates that this phenomenon is a specific cellular response against argon-plasma jet in the live cells that are indirectly exposed to argon-plasma jet. Collectively, our study provides scientific information that argon-plasma jet may have potential as anti-cancer drug effect through direct destabilization of the actin cytoskeleton. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIP) (NRF-2010-0027963).

Keywords: anti-cancer, destabilization of actin filament, Soft Argon-Plasma Jet.

TUE-287
Epinephrine inhibits the activity of the Na+/K+ atpase in colonic cancer cells via PGE2 and NO

S. Kreydiyyeh, L. El Moussawi
Biology, American University of Beirut, Beirut, Lebanon

Stress and stress hormones have been shown to promote tumor growth and angiogenesis. On the other hand a change in the activity of the Na+/K+ ATPase was found to accompany cancer. Whether a cause effect relationship exists between the hormones and the pump is still unclear. This work was undertaken to study the effect of epinephrine on colonic Na+/K+ ATPase using Caco-2 cells, a colorectal cancer cell line, as a model. The activity of the pump was assayed by measuring the amount of inorganic phosphate liberated in presence of ouabain, a specific inhibitor of the ATPase. Epinephrine, added for 20 min, exerted a significant inhibitory effect on the pump. This effect disappeared in presence of yohimbine, a blocker of alpha 2 receptors but persisted in presence of prazocin, propranolol and butoxamine. RpcAMP, an inhibitor of PKA, imitated the effect of epinephrine and confirmed the involvement of alpha 2 receptors which are known to be coupled to Gi proteins. The effect of epinephrine disappeared when cells were pre-treated with indomethacin, PTIO, and calphostin, respective inhibitors of COX-2, NOS, and PKC, indicating the involvement of these mediators in the signaling pathway. Treating the cells with exogenous PGE2, the nitric oxide donor SNAP, and the PKC activator phorbol myristate acetate (PMA), led, similar to epinephrine, to a decrease in the activity of the ATPase, confirming further their involvement. The inhibitory effect of PGE2 disappeared however, when NOS or PKC were inhibited, revealing their presence downstream of PGE2. The data indicate the involvement of alpha 2 receptors in the effect of epinephrine on the pump. This effect is mediated via PGE2 which in turn acts by activating PKC and by generating NO.

Keywords: Epinephrine, Na+/K+ ATPase, PGE2.

The aim of this study was to assay the anti cancer effects of *Cetraria islandica* on HUVEC and human breast cancer cell lines, MCF-7 and MDA-MB-231. In the experiment, xCELLigence cell index (CI) impedance measurements were performed according to the instructions of the supplier. The cells were resuspended in medium and subsequently adjusted to 50 000 cells/ml. After seeding 200 μl of the cell suspensions into the wells of the E-plate 96, cells were allowed to attached to the bottom of the plate. After 30 min, the cells were exposed to 0, 0 (DMSO), 1, 5, 25 and 125 μg/ml *C. islandica* extracts and monitored every 15 min by the xCELLigence system during 72 h exposure. Half maximum effect concentrations (EC50) were determined based on the dose–response curves derived by xCELLigence measurements. In addition, the effects of *C. islandica* extracts on the proliferation and viability of MCF7 cells were aslo determined by using MTT test. DNA fragmentation and apoptosis by Annexin V/PI double staining assay using FACS were evaluate in MCF-7 cells exposed with *C. islandica* extract during 24 and 48 hour. Following real-time analysis during 72 hour, EC50 values of *C. islandica* on MCF-7 and MDA-MB-231 cells were found to be 9.2047 E^{-5} g/ml and 1.933 E^{4} g/ml, respectively. The MTT test results of MCF-7 cells exposed with *C. islandica* extracts were showed that there was no effect on cell viability and proliferation in MCF-7 cells exposed to 1 and 5 μg/ml *C. islandica* extract. On the other hand, 25 and 125 μg/ml *C. islandica* extract were found to cause a reduction in the survival and proliferation of MCF-7 cells and these results was in accordance with xCELLigence measurements. After 24 hour exposure, there was no stained MCF-7 cells with Annexin V and few cells stained with PI. 2% of MCF-7 cells were found to be in the early or late apoptosis, and 15% of the cells in necrosis. On the other hand, both the apoptotic and necrotic MCF-7 cells decreased in number after 48 hour-exposure.

TUE-289

Evaluation of cellular dynamics of optogenetically modified cells by electro-optical methods

L. Stanica, M. Gheorghiu

[1]*Biosensing Department, International Centre of Biodynamics, Bucharest, Romania*

A multi-parametric bioanalytical platform is able to reveal dynamic changes in cellular properties like adherence, mobility and morphology (1) in response to extracellular stressors thus responding to basic and applied questions within biomedical and bioevaluation fields. The toolbox introduced by optogenetics (2), a combination of optics, genetics and bioengineering to control different cellular functions within different cell types could be applied for the development of biosensing platforms. To this end, we propose a novel cellular platform integrating electro-optical assessment of optogenetically modified cells via light-sensitive microbial membrane proteins (opsins) (3).

We will present our results regarding dynamic evaluation of cellular processes like spreading, cell-substrate adherence and cell-cell junctions upon light stimulation and application of noxious pharmacological agents on Human Embryonic Kidney (HEK) cells expressing channelrhodopsin-2 (ChR2) in conjunction with voltage dependent calcium channel, $Ca_v1.2$ and inward rectifying ATP dependent potassium channel, ROMK1. Cellular responses at the level of monolayer adherence, mobility, morphology and electrical cell parameters were revealed using sensitive interfacial analytic techniques such as Total Internal Reflection Fluorescence Microscopy (TIRFM) and Electrical Impedance Spectroscopy (EIS) whereas cell membrane parameters were determined based on patch clamp measurements.

The advantages of this bioanalytical platform for real time label-free noninvasive quantitation of the effects of stressor compounds at cellular level will be highlighted.

Fractional killing in response to TRAIL and therapeutic antibody agonists arises from cell-to-cell variability in overcoming a caspase-8 activity threshold

J. Roux[1], M. Hafner[2], S. Bandara[2], J. J. Sims[2], P. K. Sorger[2]

[1]*Institute for Research on Cancer and Aging, Nice, Université de Nice-Sophia Antipolis, Nice, France,* [2]*Harvard Medical School, Boston, MA, USA*

Ligands of death receptor (DR) -4 and -5, such as TRAIL and agonistic antibodies, trigger apoptosis in tumor cells. Although promising, drugs targeting this pathway have stalled in Phase II/III of clinical trials because of variable efficacy. Many mechanisms of resistance have been proposed to explain patient-to-patient variability but no quantitative model has been built to evaluate and compare these different hypotheses. In this study, we aim to understand which features of death-inducing signaling complex (DISC) control fate when cells are exposed to DR agonists, and how resistance can be overcome with drug combinations. For this task, we used a quantitative model of DISC dynamics to extract parameters predictive of cell fate.

Using live cell imaging and HeLa cells engineered with a FRET reporter of Bid cleavage, we monitored caspase-8 activity at the single cell level after exposure to DR ligands. For each cell, we derived parameters that characterize DISC dynamics. We find that a simple three parameter model involving the rate and duration of caspase-8 activation by the DISC is sufficient to discriminate between surviving and dying cells across a range of DR4/5 agonist concentrations. In cells in which random variations in these parameters exceeds a threshold value, cells die; otherwise they survive, showing that cell death decisions rely on an activity sensor for caspase-8.

Using this framework, we also explains the role of c-FLIP and Bcl-2 overexpression in promoting TRAIL resistance and the proteasome inhibitor bortezomib in promoting sensitivity. Finally, our findings help explain why therapeutic antibodies such as Apomab are such poor DR agonists and how new therapeutic molecules should be tested to ensure their potency.

Keywords: apoptosis, drug resistance, single-cell heterogeneity.

Functional specificity of the tail-anchored proteins Mff and Fis1 on peroxisomal and mitochondrial dynamics

A. M. S. Gouveia[1], S. Gomes[1], S. Guimarães[1,2], M. G. Lázaro[3], P. Sampaio[4], M. Schrader[1,2], D. Ribeiro[1]
[1]Centre for Cell Biology & Department of Biology, University of Aveiro, Aveiro, Portugal, [2]Department of Biosciences, University of Exeter, Exeter, UK, [3]INEB – Instituto de Engenharia Biomédica, [4]IBMC – Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal

Peroxisomes and mitochondria are ubiquitous, highly dynamic and essential subcellular organelles whose protein composition, morphology and abundance are tightly regulated upon external stimuli in order to maintain cellular homeostasis. Morphology and dynamics of these organelles have been shown to play an important role in cell physiology. Mitochondrial morphology has been shown to influence neurodegeneration, calcium signalling, lifespan, cell death and even the immune response. Similarly, deregulation of peroxisome dynamics has been linked to several disease conditions such as peroxisome biogenesis disorders, carcinogenesis, liver cirrhosis and viral infections.

These organelles exhibit a close interrelationship with metabolic cooperations and cross-talk, as well as an overlap in key components of their division machinery. Final scission depends on the recruitment of the dynamin-like GTPase DLP1 (in mammals, also named Dmn1 in *S.cerevisiae* and Drp1 in *Caenorhabditis elegans*) that forms ring-like structures around constricted membranes to mediate scission through GTP hydrolysis. The search for the adaptor proteins for DLP1 at organelle′s membrane have been subject to many controversial studies. In yeast, the tail-anchored Fis1 has shown to play an essential role in the recruitment of Dnm1 to mitochondrial fission foci through the adaptor proteins Mdv1p and Caf4p, whose mammalian homologues have not yet been identified. There is also evidence that Fis1 is involved in DLP1 recruitment to the peroxisomal and mitochondrial membranes in mammals, however, its absolute requirement remains controversial. Recent reports show that Fis1 may be a bifunctional protein that is also involved on the regulation of apoptosis. More recently, some studies have shown that the novel tail-anchored protein Mff plays a major role in the recruitment of DLP1 to both peroxisomes and mitochondria. Moreover, recent results show that, in peroxisomes, Mff interacts and regulates interaction between DLP1 and Pex11β, which mediates peroxisomal elongation prior to fission.

In order to finally unravel which of the two proteins, Fis1 or Mff, plays the most important role as DLP-adaptor during peroxisomal and mitochondrial division, we have performed a detailed comparison study on the localization and function of these two proteins in the two organelles. Our results surprisingly show that these organelles make use of different DLP-anchors: Mff is the preferential DLP-adaptor at the peroxisomal membrane, whether Fis1 is the protein that assumes this role at the mitochondrial membrane.

TUE-292
Galectin-3 as new regulator of spindle pole stability

J. Magescas[1], L. Sengmanivong[2], F. Poirier[1], D. Delacour[1]
[1]Institut Jacques Monod, [2]Nikon Imaging Center, Institut Curie, Paris, France

Mitosis is a highly regulated cellular process, where many internal rearrangements of the microtubule cytoskeleton occur. Through cell division, microtubules are rearranged from a centrosome-centered array to two antiparallel arrays, namely mitotic spindles. Spindle and astral microtubules connect cell poles to kinetochores and to the cell cortex, respectively. Motor proteins and microtubule organizer proteins regulate the assembly of microtubules at spindle poles. This newly formed microtubule network helps control of cell division positioning and orientation, and ensures the correct segregation of sister chromatids in both daughter cells. Any defects in microtubule *organization and dynamics* during mitosis will lead to chromosomal instability and generate aneuploidy.

Recently a new kind of post-translational modification, the *O-linked N-acetylglucosamine* addition, was reported to regulate spindle pole assembly. However no potential molecular mechanism has as yet been described at that level.

One particular protein is interesting in this regard, Galectin-3, a lectin mainly expressed in epithelial cells. Its expression has been frequently correlated with cancer progression. At the cellular level, it is described as a multifunctional intra- and extracellular protein. Most recently, our group described Galectin-3 as a new key player in centrosome biology. We reported during ciliogenesis that Galectin-3 transiently associates with basal bodies in kidney cells as well as in multiciliated tracheal cells; there, Galectin-3 has been shown to be important for the recruitment of g-tubulin and thus the anchorage of microtubules to the basal body MicroTubule Organizing Center.

Here, we investigated the potential participation of Galectin-3 in mitosis and spindle dynamics *in vitro* in different human epithelial cell lines. We show that Galectin-3 is required for correct cell division. Its depletion generates a large panel of mitotic defects (multipolar mitosis, supernumerary centrosomes,...). During mitosis, Galectin-3 is located at the minus-end of spindle microtubules. We demonstrate that this localization is dependent on its interaction with NuMA, a well-known microtubule array organizer. Moreover, this association is glycosylation –dependent. Abrogation of Galectin-3 binding induces defects in NuMA dynamics and in spindle pole structure. This suggests that Galectin-3 strengthens NuMA complexes, helping cohesion of the spindle microtubule array. Altogether, our data demonstrate that Galectin-3 may behave as a stabilization factor for NuMA, and actively take part in the cohesion of spindle microtubule arrays.

TUE-293
Grb2 is required for regulation of integrin-mediated podosomal stability in osteoclasts by protein tyrosine phosphatase epsilon

E. Levy-Apter, A. Elson
Molecular Genetics, Weizmann Institute of Science, Rechovot, Israel

Protein tyrosine phosphatase epsilon (PTPe) is involved in osteoclast (OCL) adhesion signaling and podosomal stability as it participates in Src kinase activation by dephosphorylating it on its inhibitory tyrosine 527, downstream of integrins. Phosphorylation of tyrosine 638 at the C terminus of PTPe is crucial for the

© 2014 The Authors. FEBS Journal © 2014 FEBS

ability of PTPe to efficiently activate Src. The adaptor protein Grb2 binds pY638 of PTPe through its SH2 domain; however, the physiological significance for this binding is unknown. We show that Grb2 knockdown (KD) in OCLs results in decreased phosphorylation of Src and Pyk2, as well as decreased Y638 Phosphorylation of PTPe, while Grb2 overexpression increases these parameters. Podosomal stability is also impaired in Grb2 KD OCL; this can be rescued by re-introducing Grb2 into the cells. OCLs from PTPe-knockout (EKO) mice or in which Grb2 was knocked down exhibit similar abnormalities in podosomal organization and Src phosphorylation. Expression of PTPe in EKO OCLs rescues these phenotypes when Grb2 is present, but not in Grb2 KD OCLs; this indicates Grb2 functions downstream of PTPe. Integrin activation induces increase in PTPe phosphorylation at Y638 and Grb2 binding to PTPe, and Grb2 forms a complex with PTPe, Src and Pyk2 in non-stimulated OCLs. We conclude that Grb2 recruits Src to PTPe downstream of activated integrins in OCLs. Upon integrin activation, partially activated Src phosphorylates PTPe at Y638; the Grb2-Src complex binds PTPe at pY638, allowing PTPe to dephosphorylate and fully activate Src. Lack of PTPe, of its Y638 phosphorylation site or of Grb2 disrupts integrin signaling and podosomal organization in these cells.

Keywords: Grb2, Osteoclasts adhesion, Protein Tyrosine Phosphatase Epsilon.

TUE-295

Importance of tissue transglutaminase nitrosylation in fibroblasts migration and MMP regulation

I. Kurt[1], A. N. Kiliç[1], M. Griffin[2], D. Telci[1]

[1]Genetics and Bioengineering, Yeditepe University, Istanbul, Turkey, [2]Life and Health Sciences, Aston University, Birmingham, UK

As an extracellular second messenger, nitric oxide (NO) mediates the modification of proteins through nitrosylation of cysteine and tyrosine residues. Tissue Transglutaminase (TG2) is a Ca^{2+} activated, sulfhydryl rich protein with 18 free cysteine residues, which catalyzes ε-(γ glutamyl) lysine crosslink between extracellular and intracellular proteins. NO can nitrosylate up to 15 of the cysteine residues in TG2, leading to the irreversible inactivation of the enzyme activity. The interplay between these two agents was revealed for the first time by our study showing that NO inhibited the TG2-induced transcriptional activation of TGFβ1 and extracellular matrix (ECM) protein synthesis by nitrosylating TG2 in an inactive confirmation with inert catalytic activity. However, nitrosylated TG2 was still able to serve as a novel cell adhesion protein. In the light of our previous findings, in this study we aim to elucidate the NO modified function of TG2 in cell migration using an *in vitro* model mimicking the tissue matrix remodeling phases of wound healing.

Using transfected fibroblasts expressing TG2 under the control of the tetracycline-off promoter, we demonstrate that upregulation of TG2 expression and activity inhibited the cell migration through the activation of TGFβ1. Increased TG2 activity led to a rise in the biosynthesis and activity of the gelatinases, MMP-2 and MMP-9, while decreasing the biosynthesis and activity of the collagenases MMP-1a and MMP-13. NO donor S-Nitroso-N-acetylpenicillamine (SNAP) treatment relieved the TG2 obstructed-cell migration by blocking the TG2 enzyme activity. In addition, decrease in TG2 activity due to nitrosylation led to an inhibition of TGFβ1, which in turn affected the pattern of MMP activation.

Recent evidence suggests that, once in complex with fibronectin in the ECM, TG2 can interact with syndecan-4 or integrinβ-1 and regulate the cell adhesion. In the other part of this study, the possible role of nitrosylated TG2 on the regulation of cell migration during wound healing was investigated with respect to its interactions with integrin β1 (ITGB1) and syndecan-4 (SDC4). Treatment with TG2 inhibitor Z-DON resulted in a 50% decrease in the TG2 interaction with ITGB1 and SDC4, while increasing concentrations of SNAP firstly led to a substantial decrease and then completely abolished the TG2/ITGB1 and TG2/SDC4 complex formation on the cell surface. Taken together, data obtained from this study suggests that nitrosylation of TG2 leads to a change not only in the binding partners of TG2 on cell surface but also in TGFβ1-dependent MMP activation, which give rise to an increase in the migration potential of fibroblasts.

Keywords: nitric oxide, tissue transglutaminase, matrix metalloproteinases.

TUE-296

In cellulo demonstration of E-cadherin oligomerization and its functional implication on epithelial cell-cell contact formation and maturation

P.-O. Strale[1], L. Duchesne[2], G. Peyret[1], L. Montel[3], S. Hénon[3], B. Ladoux[1,4], R. M. Mège[1]

[1]Institut Jacques Monod, CNRS, Paris, [2]Institut de génétique et développement, CNRS, Rennes, [3]Matière et systèmes complexes, CNRS, Paris, France, [4]MBI, NUS, Singapore, Singapore

Oligomerization of Cell Adhesion Molecules could provide the necessary stability and strength to ensure cell and tissue cohesion. Cadherin mediate homophilic cell-cell adhesion by forming adhesive bonds between molecules presented by adjacent cell membranes. These trans interactions are involved in the growth of cadherin clusters which are further stabilized by anchoring of cadherin cytoplasmic tails to actin. Recent structural, biochemical and modeling data suggest that cadherin also interact in cis by bonds formed between EC1 and EC2 domains of an adjacent cadherins. These bonds of weak energy are predicted to stabilize cell-cell junctions by shifting cadherin clusters from a fluid to an ordered (oligomeric) phase. However, no evidence has been provided so far for the existence of such ordered cadherin clusters *in vivo* and for the impact of cadherin oligomerization on cell-cell contact stability. We developed a monovalent nanogold labelling allowing the visualization of single cadherins within cell membrane at a nanometric resolution. Then, we studied the consequences of the disruption of the cis-oligomerization interface on cadherin complexes dynamics, adherens junction formation, cell-cell contact stability and collective cell behavior. E-cadherin molecules arrange in ordered lattices of a few to tens of molecules spaced by less than 10 nm, providing the first demonstration of the existence *in cellulo* of the predicted nanometric arrays of oligomeric E-cadherin at cell-cell contacts. In contrats E-cadherins mutated for the two amino-acids responsible for cis dimerization display a random distribution. We further provided evidence that cadherin cis-oligomerization requires initial trans-adhesive interactions. Cell aggregation, bead-cell adhesion assay and electron microscopy analysis indicated that ci-dimerization was not essential for cell aggregation and adherens junction formation. Analysis of protein dynamics by FRAP revealed that impairment of cis-dimerization slightly increases the mobility of junctional E-cadherin but also α-catenin. This moderate destabilization had a strong effect on E-cadherin anchoring to F-actin, on cell-cell contact dynamics and finally on collective cell migration as evaluated by magnetic tweezers manipulation and wound closure, respectively. Altogether, these data demonstrate that cadherin oligomerization occurs in a cellular context. Unexpectedly, the

© 2014 The Authors. FEBS Journal © 2014 FEBS

formation of ordered clusters of cadherins at cell-cell junction primarily controls the anchoring of the adhesion complexes to the actin cytoskeleton and finally the fluidity of cell-cell contacts.
Keywords: cadherin, cell-cell contact dynamics, cytoskeleton.

TUE-298
Influence of Snail-1 protein on integrines profile in HMEC-1 cells

M. Wiktorska[1], I. Sacewicz-Hofman[1], K. Sobierajska[1], K. Wieczorek[1,2], P. Kusmierczyk[1], J. Niewiarowska[1]

Pol-Nor/202952/5/2013, HARC FP7-REG-POT-2012-2013-1.

Integrins, which are prevalent cell membrane receptors, actively participate in various cell processes such as adhesion, migration and cell signaling.

It is also known, that EndMT process in endothelial cells is regulated by numerous factors including Snail-1 or Slug transcription factors.

In our experiments we used human microvascular endothelial cells (HMEC-1), transiently transfected with pcDNA3.1 vector containing cDNA for Snail (pcDNA3.1-Snail). The impact of Snail-1 overexpression on integrin receptors has been evaluated by flow cytometry technique. It was found that among investigated proteins, the integrin β1 and α4 subunits expression have significantly decreased. This decrease has been observed also using Western Blotting technique. We have successfully confirmed the impact of Snail-1 protein on different integrin subunits expression regulation.
Keywords: endothelial cell, integrins, Snail-1.

TUE-299
Investigating cell competition between wild-type and scribble mutant cells in tissue culture

L. Wagstaff, M. Goschorska, I. Kucinski, E. Piddini
Gurdon Institute, Cambridge, UK

Cell competition is a process whereby defective or less fit cells are selectively recognised and eliminated by their fitter wild-type neighbours. This is thought to act as a cellular quality control mechanism and has additionally been linked to cancer development.

We are investigating the mechanisms involved in competitive interactions using an established *in vitro* cell culture system of cell competition. In this system MDCK cells silenced for the tumour suppressor gene *scribble* are eliminated by their wild-type neighbours (Norman et al., 2012). Our results show that cell contact is required for cell competition and that *scribble*^{KD} cells are compacted in the presence of wild-type cells, before they are outcompeted. We are currently investigating whether this is required for competition. In parallel, in order to home in on potential molecular players and markers of competitive interactions we are using transcriptional profiling to identify genes differentially expressed in *scribble*^{KD} cells. The results from both these approaches will be presented.

Is MVI important for myoblast differentiation?

J. Karolczak, L. Majewski, M. J. Rędowicz
Nencki Institute, Warsaw, Poland

Myosin VI (MVI) is the only known myosin walking towards a minus end of actin filament. It acts as a motor transporting a cargo (various particles and vesicles) and/or an anchor positioning various cellular structures within the actin cytoskeleton. MVI seems to play a very important role in striated muscle functioning as mutation in human MYO6 leads to hypertrophic cardiomyopathy. However its function in striated muscles remains poorly understood Our previous studies showed that in skeletal muscles MVI could be involved in postsynaptic trafficking within the muscle fiber, maintenance of and/or transport within the sarcoplasmic reticulum as well as in gene expression. Recently, we have found that MVI could be important for myoblast differentiation. We observed that MVI knockdown leads to aberrations in actin cytoskeleton organization of C2C12 myoblasts, which led to inhibition of their migration and adhesive structure formation. Moreover, we observed impairment of MVI-deficient myoblast differentiation into myotubes. We also found that MVI was engaged in organization of endoplasmic reticulum and Golgi apparatus, and possibly in gene transcription.

Our data indicate that MVI by involvement in myoblast migration and adhesion, key processes during myoblast differentiation could play important role in myogenesis.
Keywords: cell migration, myogenesis, myosin VI.

TUE-301
Lamellipodia and membrane blebs drive electrotactic migration of Walker WC 256 carcinosarcoma cells

J. Sroka, I. Krecioch, E. Zimolag, S. Lasota, M. Rak, P. Borowicz, M. Gajek, Z. Madeja
Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Kraków, Poland

Endogenous electric fields (EF) may provide and important signal for directional cell migration during wound healing, embryonic development and cancer metastasis but the mechanism of cell electrotaxis is poorly understood. Additionally, there is no research addressing the question on the difference in electrotactic motility of cells representing various strategies of cell movement - specifically blebbing vs lamellipodial migration. There is a fundamental difference between bleb formation and mechanisms of lamellipodia expansion. In contrast to bleb formation which is driven by hydrostatic pressure a central role in lamellipodium expansion plays actin polymerization which drives the protrusion of the cell membrane. In the current study we arranged an unique experimental model which allows investigation of the electrotactic movement of cells of the same origin but representing different modes of cell migration. By epigenetic selection we obtained two adherent sublines of Walker carcinosarcoma cells representing different modes of cell migration: weakly adherent, spontaneously blebbing WC256 cells (BC) and lamelliopodia forming WC256 cells (LC). Visualization of-actin in living cells a revealed that in blebbing (BC) WC256 cells, expanded blebs were devoided of actin and the cell membrane detached from the cortex. In contrast, in lamellipodia forming (LC) WC256 cells the protrusion was seen as wide band of fluorescent labeled F-actin. Here, we report that both BC and LC sublines show robust cathodal migration in a physiological EF (1-3 V/cm). The directionality of cell movement was completely reversible upon reversing the field polarity. However, the observed reaction was much faster in the case of BC (5 minutes) than LC cells (30 minutes) after the change of dcEF polarity. We also investigated distinct requirements for: Rac, Cdc42 and Rho pathways and extracellular Ca^{2+} ions in guidance by electric fields of WC256 sublines forming different types of cell protrusions. Significant differences in the reaction were observed after Rac, Cdc42 and ROCK inhibition. It was found that Rac GTPase is required for directional movement of LC but not for BC cells. In contrast Cdc42 and

© 2014 The Authors. FEBS Journal © 2014 FEBS

ROCK activity was necessary for electrotaxis of BC but not LC cells. The obtained results also showed that Ca^{2+} ions are essential only for the electrotactic reaction of BC cells.

In conclusion, our results reveal that both lamellipodia and membrane blebs can efficiently drive electrotactic migration of WC 256 carcinosarcoma cells but mediated by different signalling pathways.

Keywords: electrotaxis, blebbing and lamellipodial migration.

TUE-302

Late endosomal cholesterol regulates Syntaxin 6 localization and function in cell migration

T. Grewal[1], M. Reverter[2], C. Rentero[2], M. Hoque[1], C. Enrich[2]
[1]*Faculty of Pharmacy, University of Sydney, Sydney, NSW, Australia,* [2]*Departament de Biologia Cellular, Immunologia i Neurociences, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain*

Cell migration in wound healing and cancer cell metastasis depends on the cell surface delivery of integrins and the secretion of extracellular matrix (ECM). Both exocytic processes are driven by SNARE proteins, a family of small, membrane-associated proteins that regulate intracellular membrane and cargo trafficking. Cholesterol is an essential membrane component that determines SNARE localization and function and is indispensible for cell migration. This concept is predominantly based on artificial manipulation of cellular cholesterol levels. However, the cellular cholesterol pools that determine SNARE localization and function in cell migration are still unknown. Most cells acquire cholesterol by endocytosis of Low Density Lipoproteins (LDL). In late endosomes (LE)/lysosomes, Niemann Pick Type C 1/2 (NPC1/2) delivers LDL-cholesterol to other cellular sites. We previously implicated LDL-cholesterol from LE to regulate the localization and function of caveolin and t-SNAREs Syntaxin 4 (Stx4) and SNAP23 in the secretory pathway (Cubells et al., Traffic 8, 1568-89, 2007; Reverter et al., Mol Biol Cell 22, 4108-23, 2011). Here, using Chinese Hamster Ovary (CHO) NPC1 mutant cells and human NPC1 mutant fibroblasts, which accumulate LDL-cholesterol in LE, we demonstrate that LDL-cholesterol determines the localization and function of another t-SNARE, Syntaxin 6 (Stx6), in integrin-dependent cell migration. Stx6 is predominantly found in the trans-Golgi-network (TGN) to interact with the v-SNARE VAMP4, and shuttles between the TGN and recycling endosomes (RE). Loss of NPC1 causes diminution of cholesterol at the plasma membrane and TGN, while cholesterol in RE fractions is elevated. This triggers the accumulation of Stx6 into VAMP3, transferrin and Rab11-positive RE to increase Stx6/VAMP3 interaction. Enhanced Stx6/VAMP3 complex formation interferes with Stx6-dependent recycling of $\alpha V\beta 3$ and $\alpha 5\beta 1$ integrins, and is associated with strongly reduced cell migration. Most interestingly, in NPC mutant cell lines, restoration of cholesterol levels in the TGN, but not VAMP3 inhibition or VAMP4 overexpression, restores the steady state localization of Stx6 in the TGN. In contrast, elevation of cholesterol in RE is associated with Stx6 translocation to this compartment. Hence, the fine-tuning of cholesterol levels at the TGN-RE boundaries modulates the localization of a subset of cholesterol-sensitive SNARE proteins to play a novel regulatory role in cell migration and invasion (Reverter et al., Cell Reports 2014, in press).

Keywords: LDL-cholesterol, migration, syntaxin-6.

Lipid droplets as a novel cargo of tunneling nanotubes

K. Astanina[1], M. Koch[2], C. Jüngst[3], A. Zumbusch[3], A. K. Kiemer[1]
[1]*Pharmaceutical Biology, Saarland University,* [2]*Leibniz Institute for New Materials, Saarbrücken,* [3]*Department of Chemistry, Konstanz University, Konstanz, Germany*

Intercellular communication is one of the fundamental processes in the development and functioning of multicellular organisms. Known mechanisms of cell-to-cell interaction include exocytosis or direct transfer of small cytoplasmic components *via* gap junctions. Recently, an essentially new type of intercellular communication, based on thin membrane channels between mammalian cells, has been reported. These structures, called intercellular or tunneling nanotubes (TNTs) permit direct exchange of various components or signals (ions, proteins, organelles) between non-adjacent cells at distances over 100 μm.

The functional role of this type of intercellular communication between endothelial cells has as yet not been investigated. Therefore, aim of this study was to characterize endothelial TNT morphology, cytoskeletal organization, and cargo.

Our studies show the presence of tunneling nanotubes in microvascular endothelial cells (HMEC-1). The TNTs were studied with live cell imaging, environmental scanning electron microscopy (ESEM), and Coherent anti-Stokes Raman scattering spectroscopy (CARS). Tunneling nanotubes showed distinct persistence: the TNTs could connect cells over long distances (up to 150 μm) for several hours. Even during mitosis dividing cells were connected to other cells by long TNTs. Plasma membrane staining revealed that the whole nanotube always belongs to one "host" cell. We observed at least three types of TNTs: either actin- or tubulin-containing TNTs or nanotubes with both actin filaments and microtubules. Several cellular organelles were present in TNTs, for example lysosomes and mitochondria. Moreover, we could identify lipid droplets as a novel type of cargo in TNTs. Under angiogenic conditions (VEGF treatment) the number of lipid droplets increased significantly. Arachidonic acid application resulted not only in the increased number of lipid droplets, but also in TNT formation.

Taken together, our current study shows for the first time lipid droplets as a cargo of TNTs and thereby opens a new field in intercellular communication research.

Keywords: endothelial cells, lipid droplets, tunneling nanotubes (TNTs).

TUE-304

Lysosomal GTPase Arl8b governs HOPS mediated late endosome-lysosome fusion in mammals

D. Khatter, D. Dwivedi, A. Sindhwani, S. Bahl, M. Sharma
[1]*Biological Sciences, Indian Institute of Science Education and Research, Mohali, India*

Eukaryotic cells have an elaborate endo-membrane system consisting of morphologically and functionally distinct compartments that are in constant communication with each other through vesicular carriers. The vesicle fusion machinery has been extensively studied, but what determines the specificity of fusion, is still a question. Our research focuses on deciphering the answer in the context of late endosome-lysosome fusion. Fusion at the lysosome relies on a complex interplay of small GTPases, tethering factors and SNARE proteins. The tethering factors are generally recruited by small GTPases to specific organelles, where they

© 2014 The Authors. FEBS Journal © 2014 FEBS

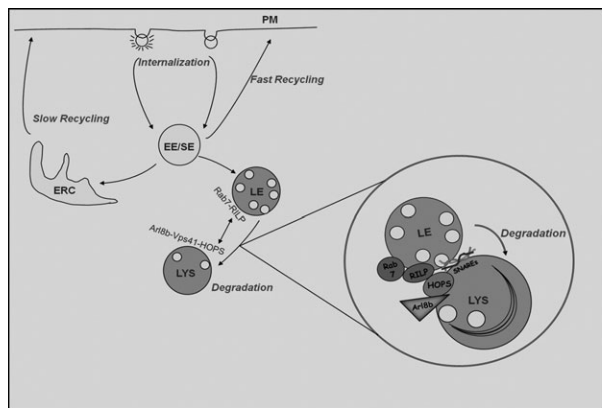

Fig. 1. Late endsome-lysosome fusion orchestrated by small GTPases Rab7 and Arl8b and their effectord. Fusion at the mammalian lysosome is regulated by small GTPase, tethering factors and SNARE proteins. The late endosomal small GTPase Rab7 recruits its effector RILP, which in turn interacts dircetly with HOPS complex, thereby recruiting it to late endosomes. The lysosomal small GTPase Ar18b interacts with HOPS complex, that determines the assembly of HOPS complex on lysosomal membranes. Following its recruitment to lysosomes, HOPS complex tethers the two compartments and mediates SNARE-department fusion of late endosomen with lysosomes.

aid to tether apposing membranes, and in conjunction with SNARE proteins bring about vesicle fusion. One such late endosomal/lysosomal tethering factor is HOmotypic Fusion and vacuole Protein Sorting (HOPS) complex, a six subunit protein complex that is conserved from yeast to humans. Much is known about mechanisms governing HOPS function in yeast, but a similar understanding of the mammalian system is still underway. Here, we present evidence that the recently characterized lysosomal small GTPase Arl8b interacts with Vps41 subunit of mammalian HOPS complex, and promotes its recruitment to lysosomes. Moreover, hVps41 interacts with only the GTP-bound form of Arl8b, suggesting that it is indeed an effector of Arl8b. Small interference RNA (siRNA)-mediated knockdown of Arl8b results in loss of membrane association of hVps41, an effect that can be rescued by expression of siRNA-resistant Arl8b. Using yeast-two-hybrid analysis and immunofluorescence studies we have identified how interaction between subunits of the HOPS complex drives their assembly to lysosomal membranes in an Arl8b-dependent manner. To understand if Vps41 interaction with Arl8b is critical for its function in regulating endocytic traffic to lysosomes, we performed EGF-receptor trafficking assay in Vps41 knockdown cells. Knockdown of Vps41 delays EGF-receptor trafficking to lysosomes that can be rescued by overexpressing Vps41 along with Arl8b in these cells. Together, our data suggests that Arl8b promotes assembly of mammalian HOPS complex on lysosomes, being facilitated by direct interaction of Arl8b with Vps41 subunit of the complex, which in turn directs traffic towards lysosomes.

Keywords: HOPS complex, Lysosomes, Vesicle fusion.

TUE-306
Molecular mechanisms of the CtBP1-S/BARS-dependent membrane fission processes

L. L. Giordano, C. Valente, A. Pagliuso, A. Luini, D. Corda
IBP-Cnr, Naples, Italy

Membrane curvature and the membrane fission that follows are essential events in the regulation of intracellular membrane trafficking. They are required for the formation of membranous transport carriers and are controlled by a cooperative contribution of both lipids and proteins. Membrane fission appears to rely on multiple mechanisms, the best-characterised fission process is driven by dynamin, which triggers fission mechanically by GTP-dependent conformational changes. Fission can also be induced by shallow insertion of hydrophobic proteins containing amphipathic alpha-helices, to generate membrane curvature and promote fission (e.g., epsin, amphiphysin, endophilin, Arf1, Sar1). Further, others fission mechanisms have been proposed, although their physiological significance remains unclear; e.g., actin-based fission, or fission induced by phase separation of lipids to create 'line energy' at interfaces, to induce fission, which can be facilitated by actin dynamics. Other fission events are mediated by CtBP1-S/BARS (C-terminal binding protein 1-short form/ brefeldin A ADP-ribosylation substrate; BARS), a dual-function protein, as a transcriptional co-repressor in the nucleus, and a fission-inducer in the cytoplasm. BARS controls fission of post-Golgi and endocytic fluid-phase carriers and COP1-coated vesicles, with roles in mitotic Golgi partitioning and macropinocytosis. We have previously reported that the fission-inducing property of CtBP1-S/BARS is dependent on a lysophosphatidic acid acyltransferase activity, which is responsible for the generation of phosphatidic acid (PA) from lysophosphatidic acid (LPA) and acylCoenzyme A (acylCoA). Lysophosphatidic acid has been proposed to facilitate tubulation when present in the cytosolic leaflet of membranes, through its wedge-like shape; conversely, through its conical shape, PA has been proposed to destabilise tubules, which induces membrane fission. Here we report that BARS specifically binds LPAAT4, a Golgi-resident lipid metabolic enzyme that we have characterized as an LPAAT enzyme able to incorporate AcylCoA into LPA to form PA onto Golgi membranes. The LPAAT4 activity is required during post-Golgi carriers (PGCs) formation, specifically at the fission step as shown by inhibition of this enzyme, which results in long tubular carrier precursor unable to detach from the *trans*-Golgi network. We provide evidence that BARS activates this enzyme to generate a local membrane increase of PA that in turn, induces the fission of post-Golgi tubular carriers.

Keywords: Golgi, Membrane fission, membrane trafficking.

TUE-307
Molecular pathogenesis of low-oxygen enhanced invasion by GBM cells

H. M. Fathallah-Shaykh
Neurology, University of Alabama at Birmingham, Birmingham, USA

Malignant gliomas remain associated with poor prognosis and high morbidity because of their ability to invade the brain; furthermore, human gliomas exhibit a phenotype of accelerated brain invasion in response to anti-angiogenic drugs. Here, we study 8 human glioblastoma cell lines; U251, U87, D54 and LN229 show accelerated motility in low ambient oxygen. Src inhibition by Dasatinib abrogates this phenotype. Molecular discovery and validation studies evaluate 46 molecules related to motility or the src pathway in U251 cells. Demanding that the molecular changes induced by low ambient oxygen are reversed by Dasatinib in U251 cells, identifies neural Wiskott-Aldrich syndrome protein (NWASP), Focal adhesion Kinase (FAK), -Catenin, and Cofilin. However, only Src-mediated NWASP phosphorylation distinguishes the four cell lines that exhibit enhanced motility in low ambient oxygen. Downregulating c-Src or NWASP by RNA interference abrogates the low-oxygen-induced enhancement in motility by *in vitro* assays and in organotypic brain slice cultures. The findings support the idea that c-Src and NWASP play key roles in

Myocardin-related transcription factor B is involved in EndMT in HMEC-1cells as a Snail expression regulator

K. Sobierajska[1], M. Wiktorska[1], M. Karakula[1], K. Pestka[1], K. Wieczorek[1,2], I. Sacewicz-Hofman[1], J. Niewiarowska[1]
[1]Department of Cell Molecular Mechanisms, [2]Department of Endocrinology and Molecular Diseases, Medical University of Lodz, Lodz, Poland

Myocardin-related transcription factor A (MRTF-A) and myocardin-related transcription factor B (MRTF-B) are the two members of myocardin family. In contrast to myocardin, which is only restrictedly expressed in smooth and cardiac muscles, MRTFs are broadly distributed in human embryonic and adult tissues but their role in non-muscle cells is largely unclear, except from the regulation of mammary myoepithelial differentiation. Recent data suggested participation of MRTFs in regulation of TGFβ-induced EMT in cancer cells. In our studies we would like to identify the nature of interaction between Snail and MRTFs pathways during EndMT and its effect on HMEC-1 cytoskeleton reorganisation. In our analysis we confirmed the presence of both MRTFs in HMEC-1 on the protein and transcription level. We observed that in endothelial cell line HMEC-1 induced by TGF-β1 the nuclear translocation of MRTF-B appeared. Our analysis based on EMSA and ChIP assays revealed that MRTF-B has the ability to control Snail expression. We also presented that overexpression of MRTF-B provoked changes in cell morphology manifested by more mesenchymal character and increased expression of mesenchymal markers. In conclusion, obtained results suggest that MRTF-B seems to be a mediator of TGFβ by regulation of Snail expression in endothelial HMEC-1 cells.

TUE-309
Naturally occurring wound electric fields as proposed determinant of bone marrow cells attraction to the site of injury

E. Zimolag, J. Borowczyk, E. Karnas, E. Zuba-Surma, J. Sroka, S. Lasota, J. Drukala, Z. Madeja
Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Direct current electric fields (DC EFs) were found to occur in living organisms and take part in some physiological processes like embryonic development, wound healing or cancer metastasis. After wounding they are created as a result of the transepithelilal potential (TEP) disruption, when the conductive extracellular pathway is created and ion flux generate electric field with the negative pole located in the site of the wound. These naturally-occurring EFs last during healing and may guide cell migration by process known as an electrotaxis. To date, there was shown that many cell types respond to physiological levels of EFs with accelerated, directed migration mostly toward the cathode. Mounting of evidence suggests that bone marrow derived cells may be involved in optimum healing of cutaneous wound, contributing to skin cells or releasing regulatory cytokines.

In our study, application of DC EF of physiological level (100-300 mV/mm) to the adherent fraction of mouse bone marrow cells results in their accelerated migration parallel to the EF lines. Further analysis lead us to discrimination of two cell subpopulations migrating to the opposite poles. These populations exhibit significantly different morphological and migratory features. The anodal cells are relatively small, elongated and they form a narrow lamellipodium at the anode-facing site of the cell setting their long axis square with the EF lines. At the same time, the cathodal cells are larger, more flattened and they tend to elongate perpendicular to the field lines. Both populations show most directed migration in 300 mV/mm with the directional cosinus γ values of 0.84 ± 0.04 for cathodal, and -0.90 ± 0.02 for anodal cells. Moreover, these two cell types utilize different cellular pathways in their response to DC EF. Phosphatydyloinositol-3 kinase/Akt kinase seem to be more essential for efficient migration of cathodal cells under EF, whereas small GTPases Cdc42 and Rac1 are more involved in electrotactic response of anodal cells. Whether it is cell-type or reaction-type specific has to be established. Interestingly, cell markers analysis lead us to conclusion, that cells migrating toward the anode are of hematopoietic origin, mostly they comprise bone-marrow macrophages, while the cathodal cells contain the fraction of mesenchymal stem cells.

Taken together, our results suggest that response to physiological DC EF may be one of the factors that discriminate bone marrow mesenchymal stem cells attraction to the site of wounding simultaneously excluding other cell types like macrophages from the wound bed.

TUE-310
Nuclear actin isoforms in the human colon adenocarcinoma LS180 cells and their selected sublines with different metastatic potential

M. Migocka-Patrzalek[1,2], M. Malicka-Blaszkiewicz[2]
[1]Faculty of Biological Sciences, [2]Faculty of Biotechnology, University of Wroclaw, Wroclaw, Poland

Actin is a multifunctional protein existing in all eukaryotic cells. Six actin isoforms exist in vertebrates: two of them are present in striated muscle (alpha-skeletal actin and alpha-cardiac actin), two isoforms are characteristic for smooth muscles (alpha-smooth and gamma-smooth muscle actin) and two non-muscle isoforms beta and gamma are typically cytoplasmic [Vandekerckhove J and Weber K, 1978 J Biol Chem].

Actin is present in the cytoplasm and in the nucleus. Compared to cytoplasmic actin the organization and functions of nuclear actin are not well recognized. It has been reported that actin in the cell nucleus participates in transcription, chromatin remodeling, nuclear structure organization and signal transduction. However, there is still lack of information about actin isoforms presence in the nucleus, especially about their potential role in cancer metastasis [de Lanerolle P, 2012 J Cell Sci; Migocka-Patrzalek M and Malicka-Blaszkiewicz M, 2009 Postepy Biochem].

The goal of presented research was to identify and analyze the nuclear actin isoforms level in cancer cells with different metastatic potential.

Experiments were performed on human colon adenocarcinoma LS180 cells and their selected sublines exhibiting an increased motility and metastatic potential (EB3, 3LNLN and 5W).

Our studies revealed that actin was shown in the nucleus of investigated cells, using the immunocytochemistry and monoclonal antibodies, directed against total actin and beta and gamma isoforms. We demonstrated that beta- and gamma-actin is present in the nucleus.

Quantitative analysis showed, that the nucleoplasm/cytosol total actin ratio for sublines with different metastatic potential is

© 2014 The Authors. FEBS Journal © 2014 FEBS

similar when compare to parental line LS180. However the nucleoplasm/cytosol ratio calculated for beta-actin is significantly higher in EB3 and 3LNLN sublines. To highlight the differences in nuclear actin isoforms level in human colon adenocarcinoma sublines we compare the obtained values within each subline. This interpretation let us to conclude, that in the nucleoplasm obtained from EB3 subline the beta- is on the higher level than gamma- actin. In 3LNLN both isoforms are on similar level, whereas in the nucleoplasm from 5W sublines the gamma izoform dominates over beta.

Our study of actin and its beta and gamma isoforms in the nucleoplasm of human colon adenocarcinoma LS180 and its sublines with different metastatic potential shows diverse level of actin isoforms, in spite of the unchanged quantity of total actin. Further investigations focused on nuclear actin isoforms level and its correlation with cancer cells motility and metastatic potential would give more details.

Keywords: nuclear actin cancer.

Occurrence of protein disulfide bonds in different domains of life: a comparison of proteins from the protein data bank

A. Bielen[1], V. Bojović[2], T. Šegvić-Bubić[3], I. Bošnjak[1]

[1]Department for Biochemical Engineering, Faculty for Food Technology and Biotechnology, [2]NMR Centre, Ruđer Bošković Institute, Zagreb, [3]Laboratory for Aquaculture, Institute of Oceanography and Fisheries, Split, Croatia

Disulfide bonds (SS bonds) are important post-translational modifications of proteins. They stabilize a three-dimensional structure (structural SS bonds) and also have the catalytic or regulatory functions (redox-active SS bonds). Although SS bonds are present in all groups of organisms, no comparative analyses of their frequency in proteins from different domains of life have been made to date. Using the Protein Data Bank, the number and subcellular locations of SS bonds in Archaea, Bacteria and Eukarya have been compared. Approximately three times higher frequency of proteins with SS bonds in eukaryotic secretory organelles (e.g. endoplasmic reticulum) than in bacterial periplasmic/secretory pathways was calculated. Protein length also affects the SS bond frequency: the average number of SS bonds is positively correlated with the length for longer proteins (>200 amino acids), while for the shorter and less stable proteins (<200 amino acids) this correlation is negative. Medium-sized proteins (250–350 amino acids) indicated a high number of SS bonds only in Archaea which could be explained by the need for additional protein stabilization in hyperthermophiles. The results emphasize higher capacity for the SS bond formation and isomerization in Eukarya when compared with Archaea and Bacteria.

TUE-312

Oxysterols-induced cytoskeleton disruption via modifications of lipid raft-associated proteins and cell death receptor activation

E. Olivier[1], M. Dutot[1,2], P. Rat[1]

[1]CNRS UMR 8638, C-TAC, PARIS, [2]Yslab, QUIMPER, France

Aims of the Work: Oxysterols (oxidized derivatives of cholesterol) are known to induce important toxic effects and are implicated in some aging-associated diseases. They can be formed de novo by oxidation of cholesterol, but they also come from alimentation (meat, oily fishes...). Molecular mechanisms of oxysterols toxic effects are poorly understood. The purpose of our study was to characterize the effects of two different oxysterols on skin cells.

Methods: The effects of 7-ketocholesterol (7-KC) and 25-hydroxycholesterol (25-OH) were studied on keratinocytes (human HaCaT cell line) and on macrophages (human U937 differentiated cell line). Cytoskeleton disruptions and modifications of lipid raft-associated proteins (P2X7 receptor, caveolin-1 and CD44 receptor) were evaluated using confocal microscopy and in-cell Western technique. P2X7 cell death receptor activation was quantified using microplate cytometry (YOPRO-1/7-AAD assay). Inflammation was studied by quantification of IL-1β and TNFα in cell supernatants using ELISA.

Key Results: After a 48 h-incubation with 7-KC or 25-OH disruptions in actin cytoskeleton were observed particularly at 25 μM (7-KC) and 40 μM (25-OH). Modifications in the expression of some key lipid raft-associated proteins were highlighted on keratinocytes. Activation of P2X7 cell death receptor was observed on keratinocytes and macrophages. IL-1β and TNFα were increased in macrophages supernatants.

Conclusion: Our work shows that toxic effects of oxysterols are associated with cytoskeleton disruption, lipid raft-associated proteins modifications and P2X7 cell death receptor activation on keratinocytes. On macrophages, P2X7 cell death receptor activation is coupled with inflammation. These cellular effects could be considered as interesting targets to prevent some aging-associated diseases.

Keywords: Oxysterol, cytoskeleton, P2X7 receptor.

Phosphorylation-dependent disulphide cross-linking of protein phosphatase-2A and heat shock protein 27: interrelated regulation of activity and localization

A. E. Kabakov, V. Kudryavtsev, A. Demidkina

Department of Radiation Biochemistry, Medical Radiological Research Center, Obninsk, Russian Federation

In stressed mammalian cells, the 27-kD heat shock protein (Hsp27) is phosphorylated in the p38 MAP kinase/Hsp27 pathway so that its phosphate-modified (low-size-oligomer) species are involved in cytoprotection. In its turn, protein phosphatase PP2A dephosphorylates a pool of phosphorylated Hsp27 when stressful stimuli disappear. On the other hand, PP2A is known to be extremely sensitive to oxidative stress, while the phosphorylated species of Hsp27 protect oxidatively stressed cells from depletion of reduced glutathione and apoptosis. Taking this into consideration, we hypothesized that, upon oxidative stress conditions, PP2A and Hsp27 interact with each other to regulate their functional activities and intracellular distribution. Using reciprocal immunoprecipitation, native electrophoresis and immunoblotting we found that, in mammalian cells (human endothelium or rat cardiomyoblasts) treated with (pro) oxidants or undergoing oxidative stress in a model of ischemia/reperfusion, a large pool of inactivated PP2A is in complexes with di- or tetramers of phosphorylated Hsp27. These complexes are resistant to a high ionic strength and SDS but dissociate in the presence of mercaptoethanol or dithiothreitol, or other thiol group-containing reagents that implies intermolecular S-S cross-linking. By means of immunofluorescence staining, we revealed analogous S-S-linked PP2A-Hsp27 complexes associated with F-actin bundles which were not extractable with non-ionic detergents; thiol group-containing reagents allowed to extract PP2A from actin filaments and to restore its phosphatase activity that was accompanied by dephosphorylation of Hsp27 and its dissociation from F-actin. Inhibition of the Hsp27 phosphorylation with SB203580 suppressed the S-S-linked PP2A-Hsp27 complex formation in

© 2014 The Authors. FEBS Journal © 2014 FEBS

oxidatively stressed cells. Non-phosphorylatable mutant forms of Hsp27, being overexpressed in the transfected cells, were never detected in such PP2A-Hsp27 complexes, whereas the pseudo-phosphorylated mutant forms are found in them. We suggest that the PP2A-Hsp27 coupling causally occurs as a response to the oxidative stress-induced Hsp27 phosphorylation and depletion of reduced glutathione and serves for transient inactivation of PP2A: while PP2A remains inactive, phosphorylated Hsp27 stabilizes the actin cytoskeleton and ensures restoration of a pool of reduced glutathione in the cell recovering from oxidative stress. Later, a glutathione circuit-mediated mechanism causes a reduction of the S-S bonds between PP2A and Hsp27 that leads to the PP2A reactivation and subsequent Hsp27 dephosphorylation on the spot. Also, the S-S-linked PP2A-Hsp27 complexes may be a biomarker of some oxidative stress-associated pathological states.

Plakophilin3 expression results in an increase in the level of desmosomal components and the formation of calcium independent desmosomes

M. C. Gurjar, K. Raychaudhuri, S. Mahadik, A. Atak, L. Sehgal, M. Karkhanis, P. Gosavi, S. N. Dalal
Sorab Lab, KS-215, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Navi Mumbai, India

Desmosomes are calcium dependent adherens like junctions found in almost all epithelial tissues and in cardiac muscles, that aide in cell-cell adhesion. Our lab has previously reported that loss of the armadillo family member plakophilin 3 (PKP3) results in increased tumour formation and metastasis in vivo. This is characterised by a decrease in desmosome size and cell-cell adhesion and an increase in cell migration and anchorage independent growth. The reduction in desmosome size maybe due to the fact that other desmosomal proteins such as desmoplakin, desmocollins 2/3 and desmoglein 2 fail to localize to the border in the absence of PKP3.

In contrast, our current study shows that, over expression of PKP3 in HCT116 cells results in increased cell-cell adhesion and the formation of calcium independent desmosomes. This was accompanied by the increased localization of other desmosomal proteins such as desmocollins 2/3, desmoglein 2, plakoglobin and desmoplakin to the cell border in the presence and absence of calcium and increased expression of these proteins at the protein level and increase of desmocollin 2 at mRNA level. These results show that PKP3 might regulate the expression of other desmosomal proteins, thereby driving desmosome formation.

These results, taken together with the previously published data about the phenotypes of PKP3 loss, show that PKP3 can play an important role in cancer metastasis by regulating desmosome function.

Keywords: adhesion, desmosome, plakophilin.

TUE-316
Profiling sulfation/epimerization pattern of full length Heparan Sulfate by NMR spectroscopy following 13C-glucose metabolic labeling of cell culture

M. Pegeot[1], R. Sadir[2], J.-P. Simorre[3], P. Gans[2], H. Lortat-Jacob[3]
[1]*Grenoble-Alpes University,* [2]*CEA,* [3]*CNRS, Grenoble, France*

Heparan sulfate (HS) is a complex cell surface polysaccharide. Through its ability to bind a large array of proteins, it regulates key functions at the cell-tissue interface, including cell proliferation, migration and development, inflammation and immune response, angiogenesis, matrix assembly, or viral attachment. To do so, HS can either or both provide scaffolds to ensure that proteins mediating specific functions will be presented at the correct site and time, and directly contribute to biological activities or signaling processes.

Consistently with its multiple binding activities, HS features extended structural variability. It consists of glucuronic acid (GlcA)-N-acetyl-glucosamine (GlcNAc) repeats which sulfation and epimerization generate up to 48 different disaccharides, the combination of which creates an extremely high density of information.Therefore, changes in HS structure, which appeared to be cell and development stage specific and is dynamically regulated during physiologic processes or disease states, can alter its protein binding capacity, resulting in change or loss of function.

Here we use NMR spectroscopy to reveal both the sulfation and epimerization pattern of native HS, directly isolated from cell culture so that any modifications induced by stimuli or growth conditions can be determined. For that purpose we took advantage of the presence of 11 C-H bonds in a HS disaccharide unit and thus used ^{13}C-glucose as a precursor of both GlcN and GlcA to metabolically label HS produced by growing cells. To set up the experimental details and demonstrate that quantitative analysis is possible, we first extracted HS from epithelial Hela cells that were maintained in 13C-glucose containing medium. NMR signals assignment of the HS chains enabled to determine the mains characteristics of the polysaccharide, i.e. the percentage of *N*-, 2-*O*- and 6-*O*- sulfation and the IdoA/GlcA ratio.

To support the interest of this approach, we showed that this method permit to follow HS regulatory processes, using human Caco-2 colon carcinoma cells which undergo spontaneous differentiation when maintained in culture post-confluency and WT and KO fibroblasts, the latter being silenced for NDST1 expression, one of the HS biosynthetic enzymes.

In conclusion, these results showed that the main HS characteristics can be profiled using NMR based non destructive analysis, directly from cell culture extracted material. This method should fine ample applications, as it has been well known that HS modifications have a pivotal role in development, physiology and pathology.

Protein/nanoparticules interaction: a case of adsorption

G. L. Klein[1,2], S. Devineau[1], J.-C. Aude[2], Y. Boulard[2], J. Labarre[2], S. Pin[1], J.-P. Renault[1]
[1]*DSM/IRAMIS/Groupe PCR,* [2]*DSV/IBITEC-S/SBIGeM, CEA SACLAY, Gif sur Yvette, France*

The understanding of the mechanisms involved in the interaction of proteins with inorganic surfaces is of major interest in both fundamental research and applications such as nanotechnology. Given that nano-sized objects tend to be more toxic than their large scale form it would be unwise to allow the unnecessary build up of nanoparticles within the body until the toxicological effects of that nanoparticle are known.

There are several ways that nanoparticles can enter the body. These include inhalation, ingestion, absorption through the skin and direct injection for medicinal purposes. Once the particles are in the body they undergo surface changes, in particular via coating by a protein corona, which is of primary importance for the biodistribution and the fate of the nanoparticle in the body. Moreover, depending on the composition of the corona, for

© 2014 The Authors. FEBS Journal © 2014 FEBS

example the blood brain barrier can be crossed by certain nanoparticles, a very interesting property that can be used for future medical applications.

However, despite intense research, the mechanisms and the structural determinants of protein/surface interactions are still unclear. We developed proteomic strategies consisting in identifying, in a mixture of hundreds of soluble proteins, those proteins that are edsorbed on the surface and those that are not and in studying the effect of adsorption on the structure/function of stress proteins. This study was lead with silica nanoparticles on demonstrated that various biological functions can be impaired by nanoparticles.

Keywords: adsorption, Nanopatricle, protein aggregation, misfolding.

TUE-318
Proteomic analyses uncover a new role of mDia2 in p53 regulation

M. Innocenti[1], T. Isogai[1], R. van der Kammen[1], M. Altelaar[2], S. Goerdayal[2], A. Heck[2]
[1]The Netherlands Cancer Institute, Amsterdam, [2]University of Utrecht, Utrecht, Netherlands

mDia2 is an auto-inhibited Formin influencing actin dynamics upon conversion to the active conformation. mDia2 regulates actin-based protrusions and cell invasion, cell differentiation, vesicle trafficking and cytokinesis. However, whether mDia2 has additional functions and how its action is functionally specified remain unknown. Here, we draw the interactome of auto-inhibited and constitutively active mDia2 to address these issues. We embed mDia2 in protein networks accounting for its attributed functions and unexpectedly link it to the Ubiquitin Proteasome System. Taking SCFFBXO3 as a test case, we show that mDia2 binds FBXO3 and p53, and regulates p53 transcriptional activity in an actin-nucleation-independent and conformation-insensitive manner. Increased mDia2 and FBXO3 levels elevate p53 activity and expression leading to p53-dependent apoptosis, whereas their decrease produces opposite effects. Thus, we discover a new role of mDia2 in p53 regulation suggesting that the closed conformation is biologically active and an FBXO3-based mechanism to functionally specify mDia2's activity.

Keywords: Formins, mDia2, p53.

TUE-319
Real-time analysis of human breast cancer cell line (MDA-MB-435) proliferation potential

S. Bozkurt[1], B. Öztürk[1], E. N. Korucu[1], H. Vatansev[1], A. Ünlü[1], E. Karaöz[2]
[1]Biochemistry, Selcuk, Konya, [2]Stem Cell and Gene Therapies Research, Kocaeli, Kocaeli, Turkey

Purpose: Aim of this study was by continuous monitoring to assay the proliferative capacity of human breast cancer (MDA-MB-435) cell line using the xCELLigence system. These systems utilize an electronic readout called impedance to quantify adherent cell proliferation and viability in real-time.

Methods: The proliferation of human breast cancer (MDA-MB-435) cell line was investigated by a real-time cell analyzer (xCELLigence, ACEA Biosciences, Inc, CA, USA). xCELLigence cell index (CI) impedance measurements were performed according to the instructions of the supplier. MDA-MB-435s were resuspended in DMEM F-12 and subsequently adjusted to 5000, 10 000, 20 000, and 40 000 cells/well. After seeding 100 μL of the cell suspensions into the wells (8 well per each group) of the E-plate 16, MDA-MB-435s were monitored every 15 min for a period of up to 192 h by the xCELLigence system. MDA-MB-435s on the E-plate 16, which has 16 wells, were treated every other day with DMEM F-12 containing 10% FBS. The values of the electrode impedance were represented as the 'cell index'.

Results: To assess dynamic cell proliferation, human breast cancer (MDA-MB-435), were seeded at 5000, 10 000, 20 000 and 40 000 cells per well in 16 E-Plates. The cells were

monitored every 15 minutes for the indicated period of time. Changes in cell status such as cell number, viability, morphology and adherence were monitored and quantified by detecting sensor electrical impedance. Statistical analysis demonstrated that the impedance CI of 5000, 10 000, 20 000, and 40 000 cells/well increased proportionally to cell number.The CI of each cell concentration sharply increased after seeding up to reach its maximum from 15 to 20 h. The CI initial of 5000, 10 000, 20 000 and 40 000 cells/well respectively were determined 0.5, 1, 1.5, 2.5.Thereafter the CI of 5000 and 10 000 cells/well increased to reach a minimum at 15 h to increase again to a maximum at 100 h. The CI of 20 000 cells/well showed a minimum

at 20 h and reached its second maximum at 100 h. In contrast, the CI of 40,000 cells/well made a sharp increase during the first 5 h to reach a plateau value after 50 h, where it remained thereafter. In all, we conclude that the response seen in the 5000–10.000 cells/well experiments reflects cell cycle effects, while the concentration of 20.000-40.000 cells/well were not suited for further experimentation, possibly because of a too high cell density and the resulting contact inhibition.

Conclusion: Our data suggests that the xCELLigence live cell analysis system offers dynamic live cell monitoring and combines high data acquisition rates with ease of handling. Therefore the xCELLigence system can be used as a rapid monitoring tool for cellular proliferation.

Keywords: xCELLigence, MDA-MB-435, Cell Culture.

Relationship between adipocytokines, angiogenesis-related factors and ADP-induced platelet aggregation in patients with preeclampsia

Ö. Balcı Ekmekçi[1], H. Ekmekçi[1], Z. Gungor Ozturk[1], A. Tüten[2], M. Toprak[1], M. S. Korkmaz[1], M. Öncül[2], G. Ayaz[3], O. Çalışkan[1], M. Kucur[1], O. Donma[1], R. Madazlı[2], T. Ulutin[3], H. Sönmez[1]
[1]Biochemistry, [2]Obstetrics and Gynecology, [3]Medical Biology, Cerrahpaşa Medical Faculty, İstanbul University, İstanbul, Turkey

Preeclampsia and pregnancy loss are considered to result from under perfusion of placenta due to structural and occlusive changes including thrombosis in the placental vessels. The effects of adipocytokines on endothelial function, inflammation and adipocyte metabolism makes them key players in the pathogenesis of metabolic syndrome, a cluster of clinical symptoms including obesity, insulin resistance, hypertension-related diseases. In addition, the anti-angiogenic state in preeclampsia may partially affect of platelet function via changed levels of nitric oxide and prostacyclin. In this study, some of the adipocytokines, angiogenesis-related factors and platelet aggregation levels were determined and correlated in patients with preeclampsia and control pregnant womens.

52 preeclamptic and 27 control pregnant women were included into the scope of this study. Ghrelin, leptin, adiponectin, transforming growth factor β1 (TGFβ1), von willebrand factor (vWF), vascular endothelial growth factor (VEGF), endoglin, placental growth factor (PlGF) and P-selectin levels were determined by ELISA. Colorimetric method was used to determine

© 2014 The Authors. FEBS Journal © 2014 FEBS

the nitric oxide levels. Platelet aggregation tests with adenosine diphosphate (ADP) were analyzed by using aggregometer.

In patients with preeclampsia, blood leptin, vWF and endoglin levels were found to be significantly higher than controls ($p < 0.001$) Contraversely, blood PIGF levels was lower in pre-eclamptic patients than controls ($p < 0.001$). In addition; we could not found any significant difference for ghrelin, adiponectin, TGF β1, VEGF, nitric oxide, P-selectin and ADP-induced platelet aggregation levels between preeclamptic and control pregnant womens. According to pearson correlation test, there was positive correlations between endoglin and vWF, endoglin and leptin [$r_p = 0.322$, p = 0.005; $r_p = 0.420$, p = 0.000, respectively], and negative correlations between PlGF and vWF, PlGF and Endoglin, PlGF and leptin [$r_p = -0.507$, p = 0.000; $r_p = -0.388$, p = 0.000; $r_p = -0.381$, p = 0.000, respectively]

This study demonstrated that altered blood levels of the angiogenesis-related factors were not related with platelet aggregation in preeclamptic patients. Although insignificant positive correlations, increased leptin and vWF levels may still contribute to platelet activation/aggregation in patients with severe preeclampsia.

Keywords: adipocytokines, angiogenesis-related factors, platelet aggregation.

TUE-322
Retromer complex controls JAK/STAT signaling at the endosome.

D. Chmiest[1], N. Sharma[2], C. Viaris de Lesegno[1], L. Johannes[1], G. Schreiber[2], C. Lamaze[1]
[1]TRANSPOL Chemical Biology of Membranes and Therapeutic Delivery Unit U1143 INSERM - UMR 3666 CNRS, INSTITUT CURIE, Paris, France, [2]Department of Biological Chemistry, Weizmann Institute of Science, Rehovot, Israel

The JAK/STAT pathway is a major intracellular signaling pathway activated by several cytokines including interferons (IFNs) that have strong antiviral and antiproliferative activities. A pioneering approach taken by team in the past proved endocytic trafficking of the IFN receptor (IFN-R) to be a key for the IFN type I induced JAK/STAT activation. Here we propose the endosomal retromer complex – VPS26/29/35 (vesicular sorting protein 26/29/35) to form a direct link between the IFN-R trafficking and the JAK/STAT activation. For the first time we report the interaction between IFN-R and VPS26 or VPS35 (combination of biochemistry and cell imaging approaches). Trafficking assays of the IFN-R in cells depleted from the VPS26 and VPS35 subunits revealed strong block of the IFN-R2 recycling to the plasma membrane (i.e. abnormally prolonged presence in the early endosomes). Study of the IFN type I induced STAT1 phosphorylation and the expression of 96 IFN-stimulated genes revealed prolonged JAK/STAT pathway activation in VPS35 depleted cells when compared to control cells. Therefore VPS26/29/35 trimer may be a good candidate for the spatiotemporal control of the IFN-R sorting at the early endosome and the IFN-R2 endosome-to-plasma membrane trafficking which in turn could regulate proper JAK/STAT activation. In addition, another set of the endosomal proteins - sorting nexins (SNXes) - was identified as the potential IFN-R interacting partner. Whether it contributes to the retromer-dependent IFN-R sorting and possibly JAK/STAT signaling is currently under investigation.

Keywords: Endocytosis, Interferon alpha receptor, JAK/STAT signaling.

TUE-323
Single-cell analysis of heterogeneous cell population in suppression of PC12 neuronal differentiation by direct microinjection of a differentiation inhibitor

J. Chung[1], N. Miura[1], A. Ito[2], M. Sawada[2], S. Nishikawa[3], K. Kuroda[1], M. Ueda[1]
[1]Graduate School of Agriculture, Kyoto University, Kyoto, [2]Fujitsu Ltd., Atsugi, [3]Waken B Tech Co., Ltd., Kusatsu, Japan

Recent developments in technologies regarding single-cell isolation and small-scale analysis have demonstrated that there exists a large degree of heterogeneity among individual cells growing under the same condition. Especially, genomic and phenotypic diversities of cells going through a seemingly identical differentiation process have been hindering accurate analysis and efficient application of obtained information for clinical purposes. In order to solve the problems regarding efficiency and safety of cell differentiation regulation technologies, it is necessary to investigate the minor changes and characteristics of individual single cells which might in fact be critical.

In our study, to investigate the single-cell changes in PC12 neuronal differentiation which occur when inhibited by U0126, an inhibitor of mitogen-activated protein kinase kinase (MEK), we directly injected the chemical in individual target cells and analyzed the outcomes (neurite outgrowth) at the single-cell level. Direct microinjection of the differentiation inhibiting factor enabled accurate control of the quantity being introduced into each target cell, which was not possible by the common methods of simple addition to culture medium or genetic engineering of target cells. As a result, we were able to elucidate the quantitative relationship between the amount of U0126 in each target cell and the inhibitive effect on neuronal differentiation, in comparison with addition of the inhibitor to the culture medium at certain concentrations. Furthermore, time-course analysis of neurite outgrowth at the single-cell level using fluorescence staining method showed that the changes in neurite length of differentiating PC12 cells were not homogeneous, but were largely variable across individual target cells. Based on these results, heterogeneity in cellular differentiation process and the importance of single-cell analysis on these phenomena will be discussed.

all, Rac1 and its upstream activators facilitate engulfment of apoptotic cells[2], whereas RhoA and its downstream effector Rho kinase has an inhibitory role[3,4]. However, the coordinate actions of Rac1 and RhoA at the individual phagocytic cup would sophisticatedly regulate phagocytic process, which are not fully addressed before. Using FRET biosensors to visualize the spatiotemporal dynamics of Rho family GTPases, here we showed that Rac1 and RhoA coordinately regulate critical points of phagocytic process through turning on/off their activities at precise timing and site. RhoA, a negative regulator, known to be down-regulated during phagocytosis, was unexpectedly up-regulated in broad area upon challenge of apoptotic cells but transiently down-regulated at the phagocytic cup right before the ingestion. Rac1 was up-regulated around phagocytic cup during engulfment then immediately down-regulated ensuing actin disassembly prior to phagosome maturation. Demolition of these dynamic activities of RhoA and Rac1 leaded to uncontrolled engulfment and delayed phagosome maturation, respectively. Our results revealed distinct regulatory roles of Rho family GTPases, RhoA as an engulfment keeper and Rac1 as a maturation keeper during phagocytosis. We believe our findings provide insight how the phagocytes determine when and where to eat apoptotic cells as well as to digest. Furthermore, understanding of regulatory mechanism of phagocytosis could be applied to therapeutic approaches based on phagocytosis of immune cells.

Structural characterization of human Varp: Rab32 complex involved in melanin production

I. Pérez Dorado[1], I. Schäfer[2], A. McCoy[3], P. Evans[4], D. Owen[3]
[1]Department of Life Sciences, Imperial College London, London, UK, [2]Department of Structural Cell Biology, Max Planck Institute of Biochemistry, Martinsried, Germany, [3]Cambridge Institute for Medical Research, University of Cambridge, [4]Laboratory of Molecular Biology, Medical Research Council, Cambridge, UK

VARP (Vps9-domain Ankyrin Repeat Protein) is a Rab32/38 effector and a Rab21 GEF, also able to bind the endosomal R-SNARE VAMP7. VARP expression, as well as its ability to bind Rab32/38 and VAMP7, is required for proper melanosome biogenesis and, more concretely, for the transport of enzymes involved in the synthesis of melanin. The transport of melanogenic enzymes to the melanosome is crucial for synthesis of this pigment and, therefore, for the proper protection of the skin against ultraviolet radiation. Interaction of Rab32/38 with VARP takes place *via* the ankyrin-repeat domain 1 (ANKR1) of the effector, which is the first ankyrin-repeat domain reported to have Rab-effector activity. Here we report the structure of human VARP-ANKR1 domain in complex with human Rab32: GTP, which mechanistically defines a new mode of Rab:Rab-effector binding. Our structural and biochemical studies have allowed us to characterize this novel Rab-effector and its interaction with Rab32/38 GTPases, which also sheds light on the process of melanosome biogenesis.

Keywords: Ankyrin repeat protein, melanosome biogenesis, Rab-effector.

Structural study of whirlin, a crucial PDZ containing protein involved in the mechanotransduction of auditory hair cells

F. Delhommel[1], A. Chaffotte[1], E. Pepermans[2], B. Baron[3], A. El Bahloul[2], P. England[3], C. Petit[2], M. Delepierre[1], N. Wolff[1]
[1]Unité de RMN des Biomolécules UMR3128 CNRS, [2]Génétique et physiologie de l'audition, [3]Biophysique moléculaire, Institut Pasteur, Paris, France

Mammals perceive sound thanks to mechanosensory hair cells. The sound-induced vibration displaces cilia that are bound together by a network of cadherins and scaffolding proteins. The stretching of the network is directly responsible for the opening of an ion channel that translates the vibration into an electric signal transmissible to the brain. Nearly all proteins involved in the cilia-associated network contain a PDZ binding motif (PBM). PBM are short C-terminal motifs recognized by PDZ domains. PDZ are the most common protein-interaction domains that maintain scaffolding complexes by binding PBM to their target proteins. Only two proteins of the cilia-associated network contain PDZ: Harmonin and Whirlin. They are central for the link between membrane proteins and the cytoskeleton. We study Whirlin, a protein composed of three PDZ domains. The N-terminal part of the protein encompasses two PDZ domains and two HHD domains (Harmonin Homology Domain). HHD is known to interact with the PDZ domain in a highly homologous protein, modulating the PDZ affinity and specificity. Using sequence alignment, we recently identified the second domain HHD downstream to Whirlin second PDZ domain, creating a symmetric organization: HHD_1-PDZ_1-PDZ_2-HHD_2. We show that PDZ_2 and HHD_2 domains are in cis-interaction, likely to modulate the binding of the PDZ domain. We cloned, expressed and purified constructions of each four domains, along with the three tandem constructions to decipher Whirlin interactome and the function of Whirlin modular organization.

Keywords: Auditory mechano-electrical transduction, PDZ domains, protein network.

TUE-327
Targeting of tail-anchored proteins to peroxisomes and mitochondria in mammalian cells

F. Camoes[1], M. Islinger[2], J. Costello[3], S. Gomes[1], N. Bonekamp[1], M. Almeida[1], I. Castro[3], D. Ribeiro[1], M. Schrader[1,3]
[1]University of Aveiro, Aveiro, Portugal, [2]University of Heidelberg, Heidelberg, Germany, [3]University of Exeter, Exeter, UK

Tail-anchored (TA) proteins are characterised by a single membrane-spanning helix at the C-terminus which anchors them to the membranes of peroxisomes, mitochondria and the endoplasmic reticulum (ER). They are a diverse group of proteins fulfilling a variety of different cellular processes for which insertion into the membrane of the correct organelle is critical. The position of the membrane-spanning domain at the C-terminus dictates that membrane insertion is post-translational and must involve the action of specific chaperones or systems to guide the TA protein to the correct organelle. The systems involved in targeting TA proteins to the ER are relatively well-understood and involve the GET-protein pathway whereas the mechanisms for mitochondria and peroxisomes are less clear. Further complexity has recently emerged with evidence that there are examples of TA proteins targeted to both peroxisomes and mitochondria in mammalian cells, such as Mff, Fis1 or GDAP1 which are involved in organelle division.

© 2014 The Authors. FEBS Journal © 2014 FEBS

To assess how extensive sharing of TA proteins between organelles is, we tested a number of mitochondrial TA proteins for peroxisomal association. This revealed a number of candidates which were both peroxisomal and mitochondrial. Additionally, several exclusively peroxisomal proteins were identified which, in the absence of peroxisomes, were targeted to the mitochondria. One of these, ACBD5, was analysed further to dissect the properties which contribute to organelle targeting. ACBD5 targeting to peroxisomes is dependent upon a highly charged region following the membrane-spanning helix. Successive mutations in this region, which replace positively charged residues with hydrophobic residues, led to mis-targeting, initially to the mitochondria, and finally to the ER if sufficient positive residues are replaced. As with GDAP1 targeting to peroxisomes appears to be dependent upon Pex19. In cells lacking Pex19, which do not contain peroxisomes, peroxisomal TA proteins are targeted to mitochondria suggesting a potentially overlapping binding site which is competed for by different shuttling receptors. Subtle changes in this binding site which add or remove polarity may increase affinity for the different receptors resulting in differential targeting. In summary, our findings indicate that the sharing of membrane components between peroxisomes and mitochondria is more prevalent than previously thought and that targeting of TA proteins to either organelle is achieved by subtle changes in the C-terminal tail.

Keywords: mitochondria, Peroxisomes, Tail-anchored proteins.

Protocadherin-15 (Pcdh15) is a component of the tip-links, the extracellular filaments that gate hair cell mechano-electrical transduction channels in the inner ear. There are three Pcdh15 splice isoforms (CD1, CD2, CD3), which only differ by their cytoplasmic domains; they are thought to function redundantly in mechano-electrical transduction during hair-bundle development, but whether any of these isoforms composes the tip-link in mature hair cells remains unknown. By immunolabeling and both morphological and electrophysiological analyses of postnatal hair cell-specific conditional knockout mice ($Pcdh15^{ex38-fl/ex38-fl}$ $Myo15\text{-}cre^{+/-}$) that lose only this isoform after normal hair-bundle development, we show that Pcdh15-CD2 is an essential component of tip-links in mature auditory hair cells. The finding, in the homozygous or compound heterozygous state, of a *PCDH15* frame-shift mutation (p.P1515Tfs*4) that affects only Pcdh15-CD2, in profoundly deaf children from two unrelated families, extends this conclusion to humans. These results provide key information for identification of new components of the mature auditory mechano-electrical transduction machinery. This will also serve as a basis for the development of gene therapy for deafness caused by *PCDH15* defects.

Keywords: Auditory mechano-electrical transduction, Deafness, Protocadherin-15.

TUE-330
The mechanism of aquaporin translocation

M. Salman, M. Conner
Biomedical Sciences, Sheffield Hallam Uniersity, Sheffield, UK

Water is the principal constituent of cells and tissues in the animal kingdoms, and water exchange is essential for life. Water can pass through cell membranes by diffusion, but the rapid control of water flow into and out of cells in continually changing osmotic environments is mediated by a family of membrane proteins called aquaporins (AQPs), which are required to ensure appropriate membrane permeability to water molecules. At least 13 members of this family (named from AQP0 to AQP12) occur in mammals and are subdivided according to their permeability characteristics into three major functional groups: 1) water-channels, 2) aquaglyceroporins, and 3) AQPs of unknown specificity. The wide distribution of AQPs throughout the body and their involvement in many physiologies and pathologies makes them a valuable and important target for drug therapies.

Water homeostasis in the brain is crucial for maintaining the normal function of the central nervous system (CNS), which is considered to be very sensitive to any raise in intra-cranial pressure. Because of the rigid brain encasement, brain oedema could rapidly turn into a serious, life-threatening condition. It has been suggested that AQPs play a key role in maintaining brain homeostasis. At least six AQPs have been identified and characterized in the rodent brain: 1, 3, 4, 5, 8, and 9; 1, 4 and 9 are the best-studied examples.

This project aimed to identify and study the molecular tools that could manipulate the translocation of brain AQPs as promising drug targets. Plasmid DNA encoding AQP4-, AQP1-, or AQP9-GFP fusion protein-was transfected into an immortalised HEK293 cell line and secondly into a more physiologically relevant cell line of U373 MG astrocytes. The responses of these AQPs were visualised following hypotonicity/hypertonicity-mediated translocation using confocal microscopy. The transfection protocol and reagents were optimised for each AQP in the different cell lines.

Western blotting analysis and MALDI were used to determine the membrane localization of AQP4 and AQP1 in astrocytes. In addition, immunostaining was employed to recognize endogenous AQPs in the astrocytes and also to confirm the phenotype of the examined cells.

In order to investigate the effects of mannitol (a proven therapy in the treatment of brain oedema which has been investigated as a model to validate an effective assay for other different molecules) on astrocytes, this project examined the effects of three different mannitol incubation periods on the cross-sectional diameter of U373 MG astrocytes as a function of their response following hypotonic stress through an osmotic swelling assay.

The role of [Cl-]i-sensitive kinases on CFTR anion selectivity

Y. Kim, I. Jun, J. Jung, H. W. Park, M. G. Lee
Department of Pharmacology, Yonsei University, College of Medicine, Seoul 120-752, Korea

Human pancreas secretes pancreatic juice which contains as much as 140 mM bicarbonate (HCO_3^-). Recently, we have shown that $[Cl^-]_i$-sensitive activation of WNK1-OSR1/SPAK pathway plays a critical role in pancreatic HCO_3^- secretion by increasing the bicarbonate permeability (P_{HCO3}/P_{Cl}) of CFTR. However, how $[Cl^-]_i$-sensitive kinases modulate P_{HCO3}/P_{Cl} of CFTR remains elusive. In the present study, we investigated molecular mechanisms that underlie the WNK1-OSR1/SPAK-induced regulation of CFTR anion selectivity. Overexpression and knockdown of each kinase in HEK 293 and epithelial cells revealed that WNK1 is the key molecule that governs overall effect of $[Cl^-]_i$-sensitive kinases on the CFTR bicarbonate permeability. Furthermore, experiments with truncated WNK1 indicated that N-terminal parts of WNK1 are required to regulate P_{HCO3}/P_{Cl} of CFTR. Interestingly, WNK1 affects permeability of other anions as well as bicarbonate in patch clamp recordings. Especially, the interval of relative permeabilities (P_x/P_{Cl}) between each anion was greatly narrowed by WNK1. Consequently, WNK1 increased the dielectric constant of the hypothetical selectivity filter of CFTR. These findings suggest that WNK1 increases the bicarbonate permeability of CFTR by modulating the polarizability of anion selectivity filter and provide insight into the fundamental question of how ion selectivity of anion channels can be regulated by cytosolic signaling at the molecular level.

Keywords: CFTR, WNK1, anion selectivity.

TUE-332
The role of Galectin-7 in collective cell migration

T. Advedissian[1], T. Dang[1], E. Pichard[1], F. Poirier[1], M. Viguier[1], F. Deshayes[1]
[1]*Cell biology, CNRS, Paris cedex13, France*

Galectins are a family of lectins characterized by a conserved carbohydrate recognition domain and a high affinity for b-galactosides. These proteins are involved in multiple biological processes and exhibit unique expression patterns. Galectin-7 is expressed in stratified epithelia such as the epidermis. We have previously shown that galectin-7 null mice present healing retardation and defective migration properties of the keratinocytes at the wound edge. Moreover, electron microscopy analysis of epidermis from galectin-7 null mice revealed altered cell to cell junctions. In order to decipher the role of galectin-7 in cell-cell contacts during cell migration, we set up an *in vitro* model of collective cell migration using immortalized human keratinocytes (HaCaT). Removal of a Plexiglas insert generates a free edge that initiate collective cell migration and mimics gap closure during wound healing. Preliminary results show defects in cell migration in keratinocytes with reduced galectin-7 expression (HaCaT cells expressing a Galectin-7 specific shRNA) compared to control HaCaT cells. Consistently, proteomic analysis suggested that galectin-7 directly or indirectly interacts with components of epithelial cell junctions. Our model is that galectin-7 is involved in the establishment and/or the maintenance of cell-cell contacts in the epidermis and thus, the absence of Galectin-7 leads to altered cell-cell junctions that impairs collective cell migration. By relying on the proteomic results, our aim is to further characterize the role of galectin-7 at the molecular level in the keratinocytes intercellular contacts during cell migration.

Keywords: Cell migration, Galectins, Keratinocytes.

TUE-333
The search of nucleic ACID-binders and cell membrane – directed molecules as antineoplastic drugs: the use of boron clusters as reagents to measure and manipulate cell functions

E. Suleymanoglu
Department of Pharmaceutical Chemistry, Faculty of Pharmacy, Gazi University, Ankara, Turkey

Boron-containing agents have been studied for the purpose of both boron neutron capture therapy of brain tumours and as anticancer agents not involving boron neutron capture. These efforts led to searches for synthesis of novel isostructural boron compounds with remarkable antineoplastic and cytotoxic effects. Having considered their yet unknown cellular targets, our study focuses on their nucleic acid and biomembrane lipid binding mechanisms in terms of exerting cellular therapeutic effects. Basic physicochemical issues related to preparation and use of organometallic self-assemblies formed between boron agents and cell membrane phospholipids, and nucleic acids with various conformation and size are presented. The boron agents interact with DNA as seen by shifts of T_m value from microcalorimetric measurements and UV melting curve analysis, as well as by the lack of hyperchromic shift in the UV absorption from 220 to 340 nm. This suggests that possibly the agents intercalate between the polynucleotide base pairs, as supported by Circular Dichroism spectroscopic measurements. The model is based on the mechanisms of DNA strand scission and reduced DNA viscosity. Subsequently, the resulting DNA fragmentation is deduced from agarose gel electrophoresis. Data is interpreted in terms of previous models suggesting that the major target of the boron agents appeared to be the purine synthetic pathway and nucleoside enzymes along with considerable DNA fragmentation and cytotoxic effects on nucleic acid methabolism, including inhibition of DNA topoisomerase activities. Alternatively, the surface recognition and interfacial behaviour of such complexes with lipids modeling biomembranes are studied by Langmuir-Blodgett lipid monolayers and lipid vesicles, coupled to Transmission Electron Microscopy. Size analysis and morphology of these complexes are determined by z-potential measurements and by Dynamic Light Scattering. Isothermal Titration Calorimetric measurements of boron-biomolecule structures are used to build the thermodynamic and kinetic models of their structural transitions. Such biophysical approaches are used to follow their secondary structural changes upon recognition with the organometallic compounds. This work forms the base for our further efforts directed towards studying promising metal-based nucleic acid and cell membrane pharmaceuticals.

Acknowledgements: The staffs of The Central Laboratory of Middle East Technical University and Bilkent University-UNAM (Ankara) are greatly acknowledged.

Keywords: boron agents, boron-lipid vesicles' associations, DNA binding.

TUE-334

The temperature dependence of cell division is shifted between *C. elegans* N2 and the high temperature tolerant *C. briggsae* AF16

M. Begasse[1,2], M. Leaver[1], F. Vazquez[2,3], A. Hyman[1]
[1]*MPI of Molecular Cell Biology and Genetics,* [2]*MPI for the Physics of Complex Systems, Dresden, Germany,* [3]*Instituto de Física de Líquidos y Sistemas Biológicos, La Plata, Argentina*

Accurate timing of early embryogenesis is key for the development of an organism. Temperature fluctuations challenge the coordination of cell division and development in ectothermic organisms, where molecular rates depend on ambient temperature. We compared *C. elegans* N2 with the high temperature tolerant *C. briggsae* AF16 to address the following questions: How is cell division affected by changes in temperature and what sets the thermal limits of the viable range? We could show that the asymmetric first cell division of *Caenorhabditis* embryos is most sensitive to high temperature. In *C. elegans* N2, timing of the first embryonic cell division is exponentially proportional to temperature - it follows the Arrhenius law. However, it does so only within certain limits. Close to the upper temperature limit of reproduction, the cell cycle rates slow down, so that the temperature at which they reach the maximum rate of cell division coincides with the maximum temperature at which they are fertile. In *C. briggsae* AF16, the range over which the speed of cell division follows the Arrhenius equations is shifted upwards. The gain in fitness at high temperature comes at a loss of fitness at low temperatures. Interestingly, the maximum speed of cell division is the same for these two organisms. Our results indicate that timing of cell division is controlled by one universal mechanism that can respond to evolutionary pressure. We found that hatching success and fecundity of *C. briggsae* are also shifted to higher temperatures compared to *C. elegans*. Understanding the link between embryonic fitness and survival of an organism will help to recognize the adaptive potential of species to changing temperature, and thus how they cope with current and future climatic change.

Time dependent phosphorylation in eNOS linked signal transduction pathways reveals a complex feedback network in endothelial cells

C. A. Chrestensen[1], T. M. Nabors[1], K. A. Helms[1], J. L. McMurruy[1], M. L. Mickanen[1], V. M. Ngwa[1], J. L. Blake[1], A. D. Lathrop[1], E. V. Meana[2], J. C. Salerno[3]
[1]*Chemistry and Biochemistry, Kennesaw State University, Kennesaw, GA,* [2]*Physics, University of Georgia, Athens, GA,* [3]*Biology, Kennesaw State University, Kennesaw, GA, USA*

A complex network of signaling pathways regulates developmental and metabolic states in mammalian cells. Negative feedback systems are prone to oscillation, are inherently stable only for some parameter sets, and may be subject to bifurcation.

S600 in eNOS is phosphorylated by MAP kinases including ERK and p38. S600 phosphorylation inhibits NO synthesis through effects on the reductase conformational manifold that produce changes in FMN fluorescence. S1177 and S617 phosphorylation by kinases including Akt and PKA conformationally activate eNOS. Other covalent modifications also act via effects on protein-protein interactions with regulators such as calmodulin.

We examined the phosphorylation of eNOS and multiple signal transduction components of cultured endothelial cells in response to stimuli (e.g., EGF, bradykinin, insulin) as a function of time. After stimulation, rapid changes in phosphorylation of eNOS (e.g., S1177 and S600) and associated kinases (including Akt and ERK2) are observed; oscillatory behavior at several sites is obvious, establishing the presence of feedback loops that include delays (e.g., from diffusion, unobserved intermediates, complex formation/dissociation, etc.). Minimal models allowing simulation of the results with delay differential equations will be presented that reproduce the observed time courses, establishing the existence of several linked negative feedback loops incorporating specific kinases and phosphatases.

The experimentally observed oscillations can be simulated using the minimal feedback model shown below, or with models including extended cascades incorporating additional protein kinase components. Such cascades are described by analogous systems of differential equations, but at least some of the delay may be accounted for by additional intermediates.

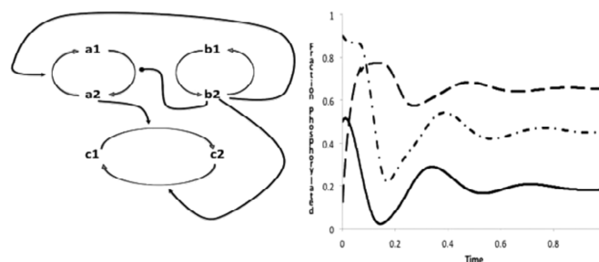

Fig. 1.

Figure: Feedback network model for oscillation of phosphorylation state in response to external signals. A represents kinase arm, B phosphatase arm, and C passive target; traces at left show a time course for phosphorylated states a2 (dash-dot), b2 (dashed), and c2 (solid) with oscillations induced by moderate delays.

Towards understanding the structure-function relationship of tubulin modifying enzymes

A. Sharma[1], J. Souphron[2], M. Steinmetz[1], C. Janke[2]
[1]*Laboratory of Biomolecular Research, PSI, PSI Villigen, Switzerland,* [2]*Institut Curie, CNRS UMR 3306, Orsay, France*

Microtubule filaments are dynamically assembled from tubulin subunits, and play fundamental roles in diverse cellular processes including cell division, cell migration and intracellular transport. Tubulin is posttranslationally modified by a range of different modifications, however two particularly modifications are polyglutamylation and polyglycylation that generate glutamate or glycine side chains on tubulin. Specific patterns of these two polymodifications were shown to be involved in the regulation of microtubule functions and behavior in vitro and in vivo, most likely by affecting the activity of microtubule-associated proteins and molecular motors. Tubulin Tyrosine Ligase-like (TTLL) proteins and Cytosolic Carboxypeptidases (CCP) belong to two families of enzymes that are implicated in the generation of polyglutamylation and polyglycylation.

Characterization of these enzymes has shown that they have a specific reaction and substrate preference, allowing them to generate differentially modified tubulin variants.

The aim of our study is to elucidate the molecular mechanisms by which TTLLs and CCPs assure the specificity of the modifications they catalyze. For that purpose, we are using recombinant protein technologies, biophysical methods and X-ray crystallography to analyze these enzymes alone or in complex with their substrates. In addition, we are developing biochemical assays for the

© 2014 The Authors. FEBS Journal © 2014 FEBS

quantitative measurement of the enzymatic and binding properties of TTLLs and CCPs towards both tubulin and microtubules. Together, this work will lead to a detailed description of mechanisms underlying these two key families of tubulin modifying enzymes. As alterations in the activity of TTLLs and CCPs have been suggested to be linked to human pathologies, including neurodegenerative diseases and cancer, our work should also be valuable to the development of TTLL and CCP inhibitors capable to block enzyme activities in the purpose to develop therapeutic interventions.

Keywords: Tubulin posttranslational modification.

TUE-338
Transfer of mitochondria through tunneling nanotubes rescue apoptosis-stressed cells

X. Wang
Institute of Biomedicine, University of Begen, Bergen, Norway

Tunnelling nanotubes (TNTs) are membrane tubes that form between cells in culture and tissue. They are reported to mediate intercellular communication ranging from electrical signalling to the transfer of organelles. Here, we studied the role of TNTs in the interaction between apoptotic and healthy cells. We found that PC12 cells treated with ultraviolet light (UV) were rescued when co-cultured with healthy PC12 cells. UV-treated cells formed a different type of TNT with healthy cells, which was characterised by continuous microtubule localized inside these TNTs. Observation of movement of end-binding protein 3 (EB3) and accumulation of detyrosinated tubulin in these TNTs indicate that they are highly regulated structures. In addition, these TNTs show different biophysical properties such as increased diameter allowing dye entry, prolonged lifetime and decreased membrane fluidity. Further study demonstrated that microtubule-containing TNTs were formed by stressed cells which had lost cytochrome C but did not enter into the execution phase of apoptosis characterised by caspase-3 activation. Moreover, mitochondria were found to be co-localized with microtubules and pass through TNTs from the healthy to the stressed cells. Importantly, cells lacking TNT-connections and cells with defective mitochondria were unable to rescue stressed cells in the co-culture. We conclude that the delivery of functional mitochondria via TNTs reverse stressed cells in the early stages of apoptosis. This provides new insights into the survival mechanisms of damaged cells.

Keywords: apoptosis, microtubule, tunneling nanotubes (TNTs).

Heavy metal induced physiological changes in oregano (*Origanum vulgare* L.)

E. Karalija[1], E. Muratovic[2], F. Pustahija[3], A. Parić[2]
[1]*Biology,* [2]*Faculty of Natural Sciences and Mathematics, University of Sarajevo,* [3]*Faculty of Forestry, University of Sarajevo, Sarajevo, Bosnia and Herzegovina*

Evaluation of heavy metal toxicity on oregano (*Origanum vulgare* L.) was done by application of Cobalt and Copper (50, 100 and 200 mg per kg of air dried soil) at duration of three months under 16 h photo regimes. Decreasing of germination rate was recorded when oregano was exposed to higher Co and Cu concentrations, and no seedling development on 200 mg of Co per kg of dried soil was detected, while for the same treatment with Cu number of seedlings was drastically lower comparing to control. Increasing of protein content was noticeable for every treatment in comparison to control. Peroxidase activity was statistically increased when plants were exposed to higher Co or Cu concentrations. Lower concentrations of Cu had some stimulating effect on chlorophyll *b* production, while production of carotenoids was inhibited. Reduction in chlorophyll content was obtained for oregano exposure to 100 mg of Co per kg of dried soil. This study showed that higher concentrations of Co, as well as Cu, induce both, reduction in carotenoids content and noticeable increase in protein content and peroxidase activity.

Keywords: heavy metal stress, Peroxidase activity, Protein content.

TUE-340
Unraveling the molecular basis of cardiotoxicity in immunoglobulin light chain amyloidosis

E. Imperlini[1], F. Lavatelli[2], D. Sarnataro[1], S. Orrù[1,3], P. Rognoni[2], G. Palladini[4], S. Perlini[4], F. Salvatore[1], G. Merlini[2]
[1]*CEINGE-Biotecnologie Avanzate Scarl, Naples,* [2]*Department of Molecular Medicine, University of Pavia, Amyloidosis Research and Treatment Center, University Hospital San Matteo, Pavia,* [3]*Department of Exercise and Wellness, University of Naples "Parthenope", Naples,* [4]*Department of Internal Medicine, University Hospital San Matteo and University of Pavia, Pavia, Italy*

Amyloidoses are a set of heterogeneous pathological conditions that range from cerebral forms such as Alzheimer's disease, to systemic disorders such as immunoglobulin light chain (AL) amyloidosis. Their common trait is the extracellular deposition of misfolded proteins as amyloid fibrils, whose presence is associated with cell and organ dysfunction. In AL amyloidosis, which is the most common systemic form, whose prognosis is dictated by cardiac involvement, fibrils originate from monoclonal immunoglobulin light chains (LC). A growing body of experimental evidence suggests that soluble amyloidogenic LC proteins are the principal mediators of cardiotoxicity. However, the mechanisms underlying AL cardiomyopathy remain obscure and no human cell models have yet been tested in this field, although studies conducted using animal cell cultures have shed light on human LC toxicity. Human cardiac fibroblasts (hCFs) are a promising cellular model since they play a critical role in the homeostasis of the extracellular matrix and are involved in cardiac tissue remodeling in response to several pathogenic stimuli. Therefore, using a differential proteomic approach, we evaluated the cellular and molecular effects induced by amyloidogenic cardiotoxic LC in hCF. We purified soluble LC, collected from the urine of a well characterized patient with cardiac AL amyloidosis. Non-cardiac AL amyloidosis LC, namely LC from a patient affected by multiple myeloma, served as control. First, our confocal microscopy study confirmed that all the analyzed LCs were internalized and directed to the endo-lysosomal compartment. Furthermore, conventional cell viability assays demonstrated increased apoptosis and impaired viability in hCF cultured in presence of cardiotoxic LC. We next investigated protein expression profiles of hCF exposed to cardiotoxic LC and control LC versus untreated hCF using proteomic 2D-DIGE technology. The quantitative step of this analysis showed statistically relevant protein spots related to species whose expression profiles differ significantly in the three conditions. In conclusion, the identification of proteins with altered expression by mass spectrometry may shed light on the molecular basis of cardiac damage in AL amyloidosis.

TUE-341
Visualizing cell state transition during myogenesis using Raman microscope

T. Ichimura[1], L.-D. Chiu[2], K. Fujita[2], S. Kawata[2], T. Watanabe[1], **H. Fujita**[1]
[1]QBiC, Riken, [2]Applied Physics, Osaka University, Osaka, Japan

Background: We have visualized the cell state transition during C2C12 differentiation using Raman microscope. C2C12 differentiation takes multiple steps where cells first become confluent and elongate, then fuse to form multi-nucleated myotube, and mature to form sarcomere structure with contractility. This process is well documented in biochemical methods, however, how each cell change their state is poorly understood due to the difficulty in analyzing the cell state at a single cell level. Because Raman spectrum arises from molecular vibration of the constituents, Raman spectrum from the cell contains information such as molecular species, their amount and location, it is expected to be capable of reporting the cell state.

Observations: Large differences were observed in Raman spectrum from C2C12 cell nucleus at various stages of differentiation. By calculating and comparing the size of the Raman peaks, we were able to distinguish the extent of C2C12 differentiation. Furthermore, using Raman microscope in combination with principal component analysis (PCA), we have visualized the cell state transition during C2C12 differentiation. Myoblasts which were in homogeneous cell state before induction of differentiation became heterogeneous when differentiation was induced. After forming myotubes, cells state became homogeneous again, being in different cell state compared with myoblasts. These results illustrate the disappearance and reappearance of attractor in the differentiation landscape during myogenesis.

Conclusions: Raman microscope is capable of distinguishing the cell state in non-invasive manner without the need of any labeling. Because Raman microscope can investigate the cell state at a single cell level, it is especially useful in analyzing the population dynamics of the cell state. Raman spectral imaging combined with PCA can be used to distinguish the cell state, where Raman spectrum can be used as a fingerprint of the cell state.

Zn(II)-binding diversity of human metallothioneins isoforms – insights into protein stability and cellular functions

A. Drozd, A. Krężel
Laboratory of Chemical Biology, The University of Wroclaw, Wroclaw, Poland

Human metallothioneins are encoded by 17 genes located on chromosome 16q13. They consist of 61–68 amino acid residues, with 25–30% of the cysteine content of the sequence. MTs are divided into four isoforms: MT1, MT2, MT3 and MT4, whereof the MT1 is present in seven sub-isoforms: MT1A,B,E,F,G,H,X. Differences between isoforms arise mainly from changes in the amino acid sequence, despite the sequence homology reaches about 90%. MT1 and MT2 are present in every type of tissue but MT3 and MT4 occur specifically in nervous system and squamous epithelium, respectively. Metallothioneins are involved in numerous cellular processes, they are important regulators of metal ion homeostasis and protectors against oxidative damage [1]. Their altered mRNA expression has been correlated with variety of cancers [2]. The understanding of metallothionein functions is not completed due to its high diversity. Our previous studies on MT2A showed that metallothionein differs in Zn(II) affinity (10^{-8}–10^{-12} M) and demonstrated high coordination dynamic of metal clusters [3]. So far, not all metallothionein isoforms were characterized in terms of metal ion binding and their thermodynamic stability. Here, we present the procedure of expression and purification of ten metallothionein isoforms MT1-MT4 with special attention on their apo- and holo-forms preparation. All purified apo-isoforms were characterized in terms of Zn(II) and Cd(II) binding using UV-Vis and CD spectroscopy. Zn(II)-reconstituted proteins were analyzed in details in terms of a number of metal ions bound per protein molecule using UV-Vis spectroscopy, fluorimetry and ICP-MS. We found that all metallothionein isoforms bind seven Zn(II) per molecule (Zn_7T) in a tetrathiolate coordination environment. Our studies uncovered that all metallothionein isoforms demonstrate similar to MT2A affinities for Zn(II) that vary from nanomolar to low picomolar range. This unusual properties of metallothioneins are responsible for free Zn(II) ions control under cellular conditions.

TUE-344
1H-NMR urinalysis of healthy subjects and patients with complications of Type 2 diabetes mellitus

L. I. Stefan[1], A. Nicolescu[2], G. Mustafa[3], S. A. Preda[4], M. Mota[5], C. Deleanu[6]
[1]Department of Biochemistry, Craiova County Clinical Emergency Hospital, Craiova, [2]Group of Biospectroscopy, Petru Poni Institute of Macromolecular Chemistry, Iasi, [3]Department of Diabetes and Metabolic Disease, County Clinical Emergency Hospital, [4]Department of General Medicine, [5]Department of Diabetes and Metabolic Diseases, University of Medicine and Pharmacy, Craiova, [6]Group of Biospectroscopy, National Laboratory of Nuclear Magnetic Resonance Spectroscopy, Institute of Organic Chemistry, Bucharest, Romania

In the first study, we obtained the global profiles of biochemical composition in urine samples from healthy individuals living in Romania and we evaluated the gender-related and age-related urinalysis differences by proton nuclear magnetic resonance spectroscopy method (^{1}H-NMR). The metabolic profiles were compared with ^{1}H-NMR urine profiles of Italian, Greek and Swedish healthy subjects.

In the second study, we compared the NMR urine profile between type 2 diabetes mellitus patients (T2DM) with hepatic steatosis and hepatic chirrosis and we investigated the potential relationship between diabetic retinopathy (DR), diabetic neuropathy (DN) and urinary T2DM metabolites concentrations trying to obtain a reliable expression of the progression of diabetic complications.

Serial urine samples of 159 healthy subjects and 173 T2DM patients with a history of type 2 diabetes mellitus less than 5 years were investigated by ^{1}H-NMR. The ^{1}H-NMR spectra have been recorded on a Bruker Avance DRX 400 MHz spectrometer. To 0.9 ml urine, 0.1 ml of a stock solution of 5 mM sodium 3-(trimethylsilyl)-[2, 2, 3, 3-d_4]-1-propionate (TSP) in D_2O has been added. The results are evaluated in mmol/mol of creatinine. $p < 0.05$ was taken as significant.

There are gender-related differences in the excretion of citrate, lactate, 3-hydroxyisovaleric acid, alanine, TMAO, glycine and hippurate between males and females in healthy Romanians. The healthy subjects above 35 years old tended to have higher urinary concentrations of TMAO, dimethylamine and 3-hydroxyisovaleric acid compared to subjects below 35 years old. There are significantly decreased differences in the excretion of citrate, hippurate, glycine in Romanian healthy subjects vs. Italian normal group. Romanian volunteers men excreted lower concentrations of TMAO than women, whereas the excretion of this metabolite in Greek men was higher.

A significant difference between the excretion of 3-hydroxyisovaleric acid, lactic acid and dimethylamine in the T2DM patients with hepatic steatosis and T2DM patients with chirrosis was found. The values for citrate, 3-hydroxyisolateric acid and gamma-aminobuthyrate increase in T2DM patients with retinopathy vs. without retinopathy. There was no correlation between DN and urinary metabolite picture in T2DM patients.

^{1}H-NMR spectroscopy could explore the metabolites and their concentrations in healthy subjects and T2DM patients for early detection of associated diseases and complications in diabetes.

The effects of ceranib-2 on cancer and non-cancer cell morphology

M. Kutlu[1], D. Vejselova[1], G. Kus[1], M. Cengiz[1], S. Kabadere[2]
[1]Biology, Anadolu University, [2]Physiolgy, ESOGU, Eskisehir, Turkey

Inhibitors of acid lysosomal ceramidase can induce apoptosis causing an increase in ceramide in the cell. Acid ceramidase inhibitors found to be effective on radiotherapy and chemotherapy causing cell death on *in vivo* and *in vitro* cancer models. A number of acid sphingomyelinase inhibitors are developed. Ceranib-1 and ceranib-2 are developed as inhibitors of human ceramidase activity. In our study we aimed to investigate the effects of ceranib-2 on 5RP7 cancer cells and 3T3 non cancer cells morphology via confocal microscopy. For this manner, 3T3 and 5RP7 cells threated with ceranib-2 (IC_{50} value for each cell line) were incubated for 24 hours.At the end of incubation period, growth medium was removed and cells were washed with PBS, fixed washed again with PBS and finally double-stained with acridine orange and Alexa fluor-488 phalloidine. Stained cells were imaged on confocal microscopy. On our results condenced nuclei, frangmented DNA and cytoskeleton and cell membrane disorders are showed. In conclusion, ceranib-2 was found to be effective in changing cell morphology in low concentrations and cause apopotosis in cancer cells. This may be an inspiration for developing new anti-cancer drugs.

TUE-346
A new type of nonribosomal peptide synthase is involved in the biosynthesis of marine toxins

T. Yamazaki, M. Tamura, H. Jenke-Kodama
Microbiology and Biochemistry of Secondary Metabolites Unit, Okinawa Institute of Science and Technology, Onna-son, Japan

Polyketide synthases (PKSs) and nonribosomal peptide synthases (NRPSs) are multienzyme complexes of bacterial and fungal secondary metabolism. They comprise various enzymatic activities and are often organised in so-called modules, each of which inserts one building block. The minimal NRPS module consists of an adenylation domain, which selects and activates the substrate, a condensation domain, which catalyses the formation of the new peptide bond, and a thiolation domain for binding intermediates. In the last decade, PKS and NRPS genes have been identified in various protists, including some dinoflagellate species. A strain of the dinoflagellate *Ostreopsis ovata* that was sampled in Okinawa, Japan, produces several ovatoxin variants. Ovatoxin belongs to the same structural family as the extremely poisonous compound palytoxin. Sequencing of the *O. ovata* transcriptome by means of RNA-Seq revealed a wide range of genes encoding PKSs and NRPSs. Most interestingly, *O. ovata* possesses a new type of NRPS, which is characterised by an unusual monofunctional architecture. These enzymes form a dinoflagellate-specific clade in phylogenetic reconstructions. Expression of those genes on the RNA level was confirmed by RT-PCR, and the sequences of the full-length transcripts could be obtained. Heterologous expression of identified adenylation domains in *Escherichia coli* followed by biochemical determination of sub-

© 2014 The Authors. FEBS Journal © 2014 FEBS

strate specificities showed that the new type of NRPS found in *O. ovata* is probably involved in the biosynthesis of ovatoxin and related compounds.

Disclosure of Interest: None Declared.

A pollutant mixture strengthens the metabolic shift in colon cancer cells

E. Saunier[1], C. Perrière[1], A. Lopes-Costa[1], P. Benit[2], P. Rustin[2], X. Coumoul[1], R. Barouki[1], C. Benelli[1], S. Bortoli[1]
[1]INSERM UMR-S 1124, Centre Universitaire des Saints-Pères, [2]Inserm UMR1141, PROTECT, Hôpital Robert Debré, Paris, France

During tumorigenesis, most cancer cells exhibit an altered metabolism that is characterized by an elevated uptake of glucose and an increased glycolytic rate (Warburg effect).This alteration of cellular metabolism is critical during cancer development and constitutes a major feature of aggressive tumors conferring selective advantage to cancer cells. Considering the recent observations on the impact of persistent organic pollutants (POPs) on cell metabolism, we hypothesized that POPs could exert their carcinogenic effects by promoting metabolic alterations that could converge to a metabolic shift favoring a tumoral phenotype.

Colon cancer cells were treated with dioxin and/or α-endosulfan, two environmental pollutants mainly produced by human activities and designated by the International Agency for Research on Cancer as probable or well-established carcinogens for humans. A significant decrease of glucose oxidation associated with an increase in lactate production was observed after a 48 hr-treatment with the two pollutants whereas each pollutant alone had no significant effect. The pollutant mixture induced a drop in respiration suggesting a deregulation of the mitochondrial respiratory chain. These changes were associated with a significant modulation of cell impedance, suggesting a modification of cell proliferation or an epithelial- mesenchymal transition. We have shown that calcium, a key regulator of mitochondrial metabolism, is a mediator of these changes since EGTA, a calcium chelator, completely abolished the POP-induced decrease in glucose oxidation. Moreover, the reduction of oxidative capacity by the POPs was totally abolished after the blockade of mitochondrial calcium uniport by ruthenium red.

Taken together, these results suggest that the POPs mixture strengthens the Warburg metabolic phenotype of colon cancer cells and deregulates mitochondria homeostasis. Further studies are in progress to elucidate the signalling pathways involved in these effects.

A role for peroxisomes in prostate cancer development

I. Valença[1], N. Pértega-Gomes[2], J. R. Vizcaino[3], F. Baltazar[2], D. Ribeiro[1]
[1]Centre for Cell Biology and Department of Biology, University of Aveiro, Aveiro, [2]Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Braga, [3]Department of Pathology, Centro Hospitalar do Porto, Porto, Portugal

Peroxisomes are highly versatile subcellular organelles whose composition, morphology and abundance are tightly regulated upon external stimuli in order to maintain cellular homeostasis. Defects on their morphology and dynamics lead to significant implications in health and disease. However, information on the role of peroxisomes in cancer is still limited. Prostate cancer (PCa) is the second most common malignancy in men, involving challenging diagnostics with at times insufficient sensitivity and specificity. Several proteins, among which monocarboxylate transporter 2 (MCT2), have been identified as PCa biomarkers. Although MCTs mainly localize at the plasma membrane, the localization MCT2 at peroxisomes has initially been shown in non-tumor liver fraction.

The main aim of this study was the evaluation of MCT2 localization at subcellular level in several prostate cell lines PNT1A (non-tumor), 22Rv1 (localized tumor) and PC3 (bone metastasis). Our results show that MCT2 localizes at peroxisomes in all the tested PCa tumor cell lines, whether in non-tumor prostate cells its localization is mainly cytoplasmic. We have also observed that MCT2 travels to peroxisomes through an interaction with Pex19, the protein that is responsible for the transport of peroxisomal membrane proteins to this organelle.

Our results suggest a possible role for peroxisomes in PCa that may further be exploited for the study of this organelle's dynamics as target for cancer therapy.

Keywords: MCT2, Peroxisomes, Prostate cancer.

TUE-349
A study of embryonic type of copper metabolism in rats and its switch to adult type

Y. Zatulovskaia[1], L. Puchkova[1,2]
[1]Biophysics, St Petersburg State Polytechnical University, [2]Molecular Genetics, Institute of Experimental Medicine, St Petersburg, Russian Federation

Copper in mammals is essential as a catalytic and structural cofactor for copper-requiring enzymes and it also acts as a second messenger. But free copper ions can initiate Fenton type reactions and catalyze formation of free radicals. So, in cuproenzymes copper is tightly bound in active centers and the safe cell traffic of copper is provided by dedicated cellular metabolic system. Copper level in circulation is controlled by liver – the central organ that distributes copper throughout the body. Absorbed copper enters hepatic cells. A portion of this copper is incorporated into cuproenzymes, such as ceruloplasmin (Cp), and secreted to bloodstream. Nowadays there appears an increasing amount of data indicating that copper secretion from liver is stimulated by organs requiring copper. Moreover, sparse data show that liver copper secretion is performed under the control of adrenal glands (AG). Nevertheless, current knowledge on the copper metabolism in AG is almost absent so far. The current study is focused on the ontogenetic changes of copper metabolism in liver and AG.

Rats with embryonic type of copper metabolism (ETCM, before 13th day postnatal) and adult type of copper metabolism (ATCM) were taken for this study. We used AAS to measure copper concentration, RT-PCR analysis to assess gene expression level and Western blot to evaluate content of immunoreactive polypeptides. Our results provide several significant insights into the turnover of copper and the profiles of expression of genes related to copper metabolism. We have shown the primary accumulation of copper in nuclei of hepatocytes in early ontogenesis and then relocation of copper to mitochondria. The second peculiarity of ECTM consists in the fact that copper import into hepatocytes of newborns does not involve CTR1 protein, but, supposedly, CTR2 plays an important role. Expression of CTR1 gene increases rapidly in liver after the ETCM to ATCM switch. We showed that SOD1-mRNA content and translation level do

© 2014 The Authors. FEBS Journal © 2014 FEBS

not change significantly in liver, but SOD1 activity rises in adult rats. The system of copper metabolism was studied in AG for the first time. We revealed that from two Cu(I)-ATPases (ATP7A and ATP7B) only ATP7A is expressed in AG cells during both ETCM and ATCM. The expression level differs for two genes encoding cuproenzymes. The PAM-mRNA content falls, but the concentration of mRNA of GPI-Cp rises. Besides, Cp gene is active in AG of newborn rats and its activity increases, but only splice isoform encoding GPI-Cp is synthesized.

Our results allows us to suppose the existence of inter-organ interaction between copper metabolic systems of liver and AG.

Keywords: adrenal glands, copper, liver.

TUE-350

Altered vasoactive peptide composition in the tissues of Cathepsin A deficient mice

Z. Timur, S. Akyildiz Demir, Y. Calhan, T. Korak, E. Ates, V. Seyrantepe

Molecular Biology and Genetics, Izmir Institute of Technology, İzmir, Turkey

Cathepsin A (lysosomal carboxypeptidase A), belonging to serine proteases family, has deamidase/esterase as well as carboxypeptidase activity. Besides its protease activity, it has a protective role in lysosomes. It forms a multienzyme complex with sialidase Neu1 and b-galactosidase enzyme in lysosome to protect them against proteolytic degradation. Since it is secreted to the blood plasma by platelets and lymphocytes, it has been suggested that Cathepsin A play an extra-lysosomal regulatory role for a variety of bioactive peptide hormones by hydrolyzing them. However, the physiological function of Cathepsin A outside the lysosome is not explored fully. Previously generated knock-in mouse model with inactive Cathepsin A had a significantly induced level of the vasoactive peptide Endothelin-I resulting increased arterial blood pressure (Seyrantepe *et al.*, 2008). The aim of our study is to analyze serum and brain of mouse model with Cathepsin A enzyme deficiency and understand whether Cathepsin A has hydrolyzing function on Endothelin-I, Angiotensin-I, Oxytocin, Substance P and Bradykinin in physiological states by immunohistochemistry and ELISA. In immunohistochemistry we showed that there is significantly increased level of Endothelin-I in deficient mice brain. We also confirmed the increase in level of the Endothelin-I in serum of deficient mice by ELISA but not in brain. In addition, increased concentration of Angiotensin-I in serum was determined in Cathepsin A deficient mice but not in brain. It has been shown in those mice 4 fold increased oxytocin in serum and 14 fold increased in brain indicating that Cathepsin A play important role on oxytocin cleavage. However, this difference has not been shown in immunohistochemistry analysis of brain tissues. Although the level of Substance P in serum is not increased significantly, 5 fold higher level of accumulated Substance P was detected in the brain of Cathepsin A deficient mice. Although the level of Bradykinin did not appear significant changed in the Cathepsin A deficient mice brain, there was 2 fold increase in serum. Our study suggests that Cathepsin A enzyme in vivo contributes hydrolysis of varies vasoactive peptides in serum and brain.

TUE-351

An enzymatic analysis of serum esterases of pesticide toxicological concern in the Mediterranean spur-thighed tortoise, Testudo graeca, from the Cappadocia Region (Turkey)

M. K. Sahin[1], S. Martinez[2], S. Martinez[2], D. Kolankaya[1], D. Kolankaya[1], J. C. Sanchez-Hernandez[3]

[1]*Biology Department, Hacettepe University, Ankara, Turkey,* [2]*Environmental Science, Universidad Castilla La Mancha,* [3]*Environmental Science, Universidad Castilla La Mancha, Toledo, Spain*

Free-ranging vertebrates inhabiting agricultural areas may be at risk from pesticide exposure. Nevertheless, there is a lack of field studies concerning pesticide toxicity on terrestrial tortoises. As the preliminary part of a broader project aimed to investigate blood biomarkers for monitoring pesticide exposure on the Mediterranean spur–thighed tortoise (*Testudo graeca*), serum esterases were enzymatically characterized and basal levels were determined in individuals sampled from an agricultural and a reference (uncontaminated) area. Blood samples were collected from adult tortoises caught from rangelands (n = 54 individuals) and agricultural (n = 34) sites in Cappadocia Region (Turkey) during their active period (April to October).

Cholinesterase (ChE, EC 3.1.1.7/8) and carboxylesterase (CbE, EC 3.1.1.1) activities were examined in vitro using multiple substrates, specific inhibitors and pesticides. Serum ChE activity cleaved the substrate acetyltiocholine at a higher rate (V_{max} = 1.70 ± 0.14 U/ml serum, mean ± SE) than butyryltiocholine (V_{max} = 0.32 ± 0.03 U/ml serum), but the hydrolysis of both substrates decreased dose-dependently with tetraisopropyl pyrophosphoramide (a specific inhibitor of butyrylcholinesterase activity). Carboxylesterase activity was significantly higher towards naphthyl- and nitrophenyl acetate (V_{max} = 10.5–15.8 U/ml serum) than when naphthyl- and nitrophenyl butyrate were used as substrates (V_{max} = 4.3–5.2 U/ml serum). In vitro inhibition of ChE activity by chlorpyrifos-oxon or carbaryl resulted in IC50 (i.e., median inhibitor concentrations) values in the range of 10^{-7} M, whereas the sensitivity of CbE activities to these pesticides was higher (IC50s = 10^{-8}–10^{-9} M). The occurrence of multiple esterase isozymes in the tortoise serum was corroborated by native polyacrylamide electrophoresis; a proteomic method that enabled to identify sensitive esterases to pesticides in an isozyme-specific basis.

No significant differences were found in the serum esterase activities between both field populations suggesting no pesticide exposure, at least, during the sampling campaigns. However, there was a significant seasonal variation for all esterase activities with a maximum enzyme activity in September-October.

These preliminary results indicated: (1) the occurrence of a ChE activity with hydrolytic properties close to mammalian-type butyrylcholinesterase activity, (2) a hihger sensibility of CbE activity to pesticide inhibition than ChE activity, and (3) a marked seasonal pattern of serum esterase activities in natural populations of tortoise.

TUE-352

Analysis of cytochrome *c* modifications induced by reactive aldehydes

A. P. Menezes, P. Di Mascio, **M. H. Medeiros**

Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brazil

Several lines of evidence associate pathological states and diseases, such as cancer, atherosclerosis, Alzheimer's, amyotrophic lateral

© 2014 The Authors. FEBS Journal © 2014 FEBS

sclerosis (ALS), and prion diseases to oxidative stress. Nucleophilic attacks to phospholipids by reactive oxygen species could lead to the breakdown of these molecules, producing reactive aldehydes. Unsaturated aldehydes have been shown to promote protein and DNA damage, to induce mutagenesis, and to be involved in cell signaling cascades. Proteins are major targets of reactive aldehydes by means of reactions, mainly with nucleophilic amino acids. A great deal of attention has focused on modifications promoted in cytochrome *c* by reactive aldehydes. This protein has a high content of lysine residues that make it a target to covalent modifications. It is important to note that mitochondria are major producers of reactive oxygen species, which makes their proteins targets of oxidative injuries. Here, the modification of cytochrome *c* promoted by 4-hydroxy-2-nonenal (HNE) and 4-hydroxy-2-hexenal (HHE) was investigated. Matrix-assisted laser desorption/ionization time offlight experiments indicated increases in the molecular weight of cytochrome *c* (2.5 mM), consistent with the formation of two Michael additions by HNE (2 mM) and six Michael additions by HHE (2 mM). *Nano LC-ESI-TOF*-MS analysis of tryptic digests indicated that His-33 was modified by HNE. Lys-13, Lys-22, Lys 53, Lys-79, Lys-87 and His-33 were modified by HHE. Today, it is generally accepted that cytochrome *c* release from mitochondria into cytosol is a determining event in apoptosis signaling through the activation of the caspase family proteins. The covalent modifications in cytochrome *c* could play a role in mitochondrial dysfunction associated with oxidative stress. Supported by FAPESP: 2011/10048-5, CAPES, INCT Redoxoma: 573530/2008-4, NAP Redoxoma: 2011.1.9352.1.8, CEPID Redoxoma: 2013/07937-8.

TUE-353
Analysis of thiopurine *S*-methyltransferase genotypes in children with acute lymphoblastic leukemia

D. M. N. E. Elkaffash[1], H. A. E. Hassab[2], A. A. Abou Zeid[1], **D. A. E. M. Elnily**[1], I. O. A. Shaaban[1]
[1]Clinical Pathology, [2]Pediatric, Faculty of Medicine, Alexandria, Egypt

Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer. The thiopurines, 6-mercaptopurine (6MP) and thioguanine (TG), are the backbone of current therapy for childhood ALL. Since their introduction to leukemia treatment in the 1950s, they have played an essential role in treatment protocols for ALL. Thiopurine S-methyltransferase (TPMT) polymorphism represents a determinant of 6-MP response and ALL outcome and is well characterized in most populations. Four common polymorphic alleles are associated with impaired activity of the enzyme. These are TPMT*2 (238G>C), TPMT*3A (460G>A, 719A>G), TPMT*3B (460G>A) and TPMT*3C (719A>G).

Objective: The aim of the present study was to determine the frequency of the functional TPMT polymorphisms and their association with the occurrence of adverse events, in pediatric patients with standard risk ALL who are subjected to 6-Mercatopurine therapy for consolidation.

Patients and methods: TPMT polymorphism was analyzed in 40 children diagnosed with acute lymphoblastic leukemia and 40 age and sex matched healthy controls. The frequency of TPMT genotypes was examined by PXG-TPMT StripAssay based on Polymerase Chain Reaction (PCR) and reverse hybridization using blood samples. Clinical follow up using complete blood picture and liver transaminases following 6-MP therapy for consolidation were then performed for patients in order to access drug toxicity.

Results: In the study sample, none had homozygous mutant TPMT genotypes (e.g. TPMT*3A/*3A, TPMT*2/*2, TPMT*3A/3C, etc.). Also neither the cases nor the controls in the study sample had TPMT*1/*2 and TPMT*1/*3B genotypes. In patients group, 39 (97.5%) were of the wild-type homozygous TPMT*1/*1 genotype, 1 (2.5%) patient only was of the heterozygous TPMT*1/*3A genotype and no patient had TPMT*1/*3C genotype. In the control group, we identified 36 subjects (90%) with wild-type homozygous TPMT*1/*1 genotype, 3 (7.5%) with heterozygous TPMT*1/*3A genotype and 1 (2.5%) heterozygous TPMT*1/*3C genotype. TPMT*3A was the most prevalent variant allele followed by TPMT*3C detected in the studied sample with an allelic frequency of 2.5% and 0.6%, respectively. The only patient with variant TPMT*1/*3A genotype did not show any evidence of thiopurine intolerance (hematotoxicity and hepatotoxicity).

Conclusions: Cases of myelosuppression in ALL pediatric patients treated with 6-MP cannot be all explained by the existence of TPMT alleles (*2, *3A, *3B and *3C). Other polymorphic alleles in TPMT gene, or factors other than TPMT polymorphisms may be responsible for the development of toxicity.

Keywords: pediatric ALL, thiopurine toxicity, TPMT polymorphism

TUE-354
Antioxidant activities of purine and pyrimidine bases

B. Kara Kisla, O. Sacan
Department of Chemistry, Faculty of Engineering, Istanbul University, 34320 Avcilar-Istanbul/Turkey

Antioxidants are compounds that inhibit or delay the oxidation of other molecules by inhibiting the initiation or propagation of oxidizing chain reactions. There are two basic categories of antioxidants, namely, synthetic and natural. In general, synthetic antioxidants are compounds with phenolic structures of variousdegrees of alkyl substitution, whereas natural antioxidants can be phenolic compounds (tocopherols, flavonoids, and phenolic acids), nitrogen compounds (alkaloids, chlorophyll derivates, amino acids, and amines), or carotenoids as well as ascorbic acid. The human body has a complex system of natural enzymatic and non-enzymatic antioxidant defenses which counteract the harmful effects of free radicals and other oxidants. Free radical are responsible for causing large number of diseases including cancer, cardiovascular disease, ulcerative colitis, aging and atherosclerosis. Protection against free radicals can be enhanced by ample intake of dietary antioxidants. Antioxidants may be of great benefit in improving the quality of life by preventing or postponing the onset of degenerative diseases. In the present study, the antioxidant properties of purin and pyrimidin bases were investigated by using different antioxidant assays such as 2,2-diphenyl-1-picrylhydrazyl free radical (DPPH•) scavenging, N,N-dimethyl-p-phenylenediamine (DMPD•+) scavenging, and reducing power. Trolox and ascorbic acid were used as the reference antioxidant compounds. Antioxidant activity was increased with increasing bases concentration. All purine and pyrimidine bases showed a potential antioxidant activity. According to these results purine and pyrimidine bases are important compounds in pharmaceutical industries due to their antioxidant activity.

[1]Biology, [2]Food Engineering, METU, Ankara, Turkey

In recent years, increased consumption of fruits and vegetables has been consistently recommended since many epidemiological studies have showed the relation between consumption of polyphenol-rich foods or beverages and the prevention of certain diseases such as cancers, cardiovascular diseases and aging. Phenolic compounds are abundant in all plant organs therefore they form an integral part of the human diet. Salvia species, commonly known as sage, have been used since ancient times for more than 60 different ailments ranging from aches to epilepsy. There are around 900 species of Salvia, 95 of which are represented in Turkey. Rosmarinic acid, reported to be a powerful antioxidant, is the main phenolic component in Salvia species. Other phenolics and flavonoids in Salvia species include catechin, caffeic acid, vanillic acid, ferulic acid, rutin, apigenin, quercetin, and luteolin. Glutathione S-transferases (GSTs) are multifunctional detoxification enzymes that protect the cell from the damage of electrophilic compounds. Overexpression of GSTs in cancer results in resistance to chemotherapeutic agents and inhibition of the over expressed GSTs has been suggested as an approach to combat GST-induced resistance.

In this study, rosmarinic acid content of water extract of *Salvia fruticosa* was determined by using RP- HPLC. DPPH● and ABTS● radicals scavenging activities, total phenolic and flavanoid contents as well as bovine liver cytosolic Glutathione S-transferases (GSTs) inhibitory potentials of the extract were investigated. Total phenolic content and the total flavanoid content of the plant extract were determined as 425, 1 mg GAE/g extract and 94 mg CE/g extract, respectively. IC_{50} value for DPPH radical scavenging percent inhibition was evaluated as 0.0348 mg/ml and TEAC value of the extract was evaluated as 1297 mmol TE/g extract. Rosmarinic acid content of the extract was determined as 59.3 mg/g extract. IC_{50} value for GST inhibiton activity was determined as 6.8 μg/ml.

Turkish endemic sage *Salvia fruticosa* is reported to be a potantial GST inhibitor and as a promising medicinal plant, it has the potential to be used as adjuvant with chemoterapeutic agents to overcome the drug resistance occuring during chemotherapy. Further investigations are ungoing to reveal its bioactive components and their beneficial activities in biological systems.

TUE-356
Antioxidant and anticholinesterase activity of extracted from wild beet (*Beta maritima* L. var. pilosa Del.)

H. Gursul, G. Cevahir Oz[1]
Biology, Istanbul University, Istanbul, Turkey

Chenopodiaceae family contains about 103 genera and 1400 species worldwide. In Turkey there are about 129 species from 33 genera. The members of the family are annual or perennial herbaceous plants that are spreaded out in many places all over the world but especially on dry regions, gravel soil, sea coasts, sides of the roads, sides and insides of fields and soils that are rich in nitrogen and potassium nitrate.

Beta genus belonging to Chenopodiaceae family, has 6 species in Turkey: *Beta trigyna*, *Beta lomatogona*, *Beta macrorhiza*, *Beta maritima* and *Beta trojana*. In this Ph. D. thesis *Beta maritima* L. var. *pilosa* Del., will be investigated. The spread zone of this variety in Turkey is the coastal and inner parts of Western and Northern Anatolia.

In this study, after the aerial parts and roots of "*Beta maritima* L. var. *pilosa* Del." were dried and ground. After exracting with petroleum ether, dichloromethane and ethanol the total phenolic and flavonoid contents and total phenolic and total flavonoid contents of the extracts from the aerial parts of Wild Beet (*Beta maritima* L. var. pilosa Del.) were determined as pyrocatechol and quercetin equivalents, respectively. The antioxidant activity was carried out by using DPPH free radical scavenging activity methods, Cuprac method and the anticholinesterase activity by the Ellman assay. In this study, anticholinesterase and antioxidant activity of the *Beta maritima* L. var. *pilosa* Del. will be carried out for the first time.

Keywords: anticholinesterase activity, antioxidant activity, *Beta maritima* L. var. pilosa Del.

TUE-357
Antioxidant efficiency of seabuckthorn extract in ehrlich ascites carcinoma of Balb/c mice Model

N. Cavak[1], M. K. Gumustas[1], A. Aras Perk[2], B. Yavuz[3]
[1]Department of Medical Biochemistry, Cerrahpasa Faculty of Medicine, Istanbul University,, [2]Department of Biology, Faculty of Science, Istanbul University,, [3]Duzen Laboratories Group, Istanbul, Turkey

Background: Seabuckthorn (SBT; *Hippophae rhamnoides* L.), a unique and valuable plant has recently gained worldwide attention, mainly for its medicinal and nutritional potential. The aim of the present study was to evaluate the antioxidant activity of SBT against Ehrlich Ascites Carsinoma (EAC) cells by measuring primer antioxidant enzyme superoxide dismutase (SOD) and lipid peroxidation products malondialdehyde (MDA).
Methods: Mice were divided into three groups. First group was control. Second group was injected EAC interperitoneally. Third group was received both EAC and SBT extract daily 10 U for 3 weeks. All groups received diet and water *ad-libitum*. Both control and experimental groups SOD activities, MDA levels and EAC cells protein contents were determined by the methods of Sun, Buege JA and Lowry, respectively.
Results: Both in ascetic fluid and EAC cells, EAC group MDA levels (93.27 ± 5.63, 220.31 ± 13.91 nmol/mg protein, respectively) were significantly high when compared with EAC treated with SBT group (26.61 ± 4.18, 121.59 ± 5.24 nmol/mg protein, respectively) ($p < 0.001$). Although, SOD activity was found decreased in ascetic fluid ($p < 0.001$), same enzyme activity was found increased in EAC cells ($p < 0.001$). When plasma EAC group compared with control, high levels of EAC plasma MDA levels were found ($p = 0.001$). But, SBT application on EAC showed that plasma oxidative stress were found decreased by MDA levels ($p < 0.001$).
Conclusions: According to these results, increased SOD activity by SBT implementation in EAC cells shows that radical metabolism is still active in EAC cells. SBT has antioxidant effect in ascetic fluid when significantly decreased SOD activity is considered. It is the case that plasma MDA levels significantly deplete and also SBT indicates antioxidant effect to whole body by circulation.

TUE-358
Antioxidant response to titanium dioxide nanoparticles by *Saccharomyces cerevisiae* grown in different carbon sources and heat-shock conditions

J. Capela-Pires, R. Ferreira, I. Alves-Pereira
ICAAM, Department Química, ECT, Universidade de Évora, Évora, Portugal

The physicochemical properties that make nanomaterials unique, also equip them with potential for affect environment adversely, causing oxidative injuries in the living beings. However, organisms also had to develop antioxidant defences to protect their cells from reactive oxygen species (ROS). Failure in the cell antioxidant defences, due to the contact with xenobiotic, results in stress causing oxidatives damages leading to loss of cell viability. Yeasts can contribute to understand the toxicity of titanium dioxide nanoparticles (TiO2-NP), because its cell structure and functional organization, share similarities with mammalians. Since the response of yeast to NPs can be influenced by temperature and available carbon source, the aim of this study was to evaluate the antioxidant response of *Saccharomyces cerevisiae*, grown in presence of glycerol with addition of 2% glucose and 5 µg/mlTiO_2-NP, in heat-shock conditions. TiO_2-NP (size <100 nm) stock suspensions were prepared by sonication. Bioassays were performed in YEPG medium (1% yeast extract, 2% peptone, 3% glycerol). Culture flasks were inoculated with wild-type *Saccharomyces cerevisiae* UE-ME_3 and shaken 150 rpm, at 28°C. At exponential phase was added glucose and TiO_2-NP stock solution (YEPGD-NP) to obtain a final concentration of 2% and 5 µg/ml. Yeasts grown 200 min at 28 or 40°C (heat-shock, HS). Flasks lacking glucose (YEPG) or NPs served as controls. Biomass was quantified by dry weight. Post-12000 *g* supernatants were used for determination of GSH, GSSG and ROS contents by fluorescence as well as glutathione reductase (GR), glutathione peroxidase (GPx), glucose-6-phosphate dehydrogenase (G6PD), catalase (CTT1) activity by spectrophotometry. Post-12000 *g* pellets were used for determination of catalase (CTA1) activity. Statistical analysis by ANOVA I and Duncan test. The results showed that biomass, ROS level and GR activity in the cells grown in YEPGD were higher than those detected in cells grown in YEPG. Furthermore, cells grown in YEPGD exhibited lower levels of GSH and MDA and CTT1activity comparatively with yeasts grown in YEPG. *S. cerevisiae* grown in YEPGD-NP in HS showed growth inhibition to levels near of cells which used glycerol as carbon source. Additionally, it was also detected a decrease in the GSH contents, GSH/GSSG ratio, GPx, CTT1 and CTA1 activities as well as an increase in ROS content and GR activity, relatively to the cells growing only in glycerol. It was also observed an increase in ROS level and GR activity in the yeast grown in YEPGD-NP, relatively to *S. cerevisiae* grown in YEPGD. TiO_2-NP in HS caused oxidative stress in yeast grown in presence of glycerol and glucose, decreasing GSH/GSSG ratio, increasing ROS content and GR activity.

Keywords: metal nanoparticles, stress oxidative, yeast

TUE-359
Assessment of urinary epidermal growth factor level in patients with chronic renal failure

Ç. Akkaya[1], S. Alagoz[2], M. Pekpak[2], Y. Dincer[1]
[1]Biochemistry, [2]Nephrology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Purpose: Epidermal growth factor (EGF) is a peptide expressed in various tissues. It has mitogenic effect on epithelial and mesothelial cells. EGF can be measured in all body fluids. It has been suggested by previous studies that a large part of the urinary EGF is originated from kidney, a small amount of EGF is derived from other organs. If urinary EGF has renal origin, EGF concentration in the urine may reflect the number of functional nephrons and it may be a good marker for assessment of renal function. In the present study, determination of the urinary EGF concentration was purposed in diabetic and non-diabetic patients with chronic renal failure.
Method: Urinary EGF levels were measured in 24-hour urine samples obtained from patients with chronic renal failure (n = 57) and age matched controls (n = 20). EGF measurements were performed with commercial ELISA kit and EGF concentration is calculated as ng/mg creatinine. Statistical analysis was performed with SPSS 10 software package.
Results: In the control group, urinary EGF level in women was higher than those in men. Urinary EGF level was found to be lower in the total patient group than those in the control group when gender differences were not taken into account (p = 0.010). Urinary EGF level was lower in the women of the total patient group as compared to women of the control group (p = 0.025), but there was no significant difference for men. No significant difference was found for urinary EGF concentration between diabetic and non-diabetic chronic renal failure groups with regard to gender. While urinary EGF level was lower in the non-diabetic women with chronic renal failure compared to women of the control group (p = 0.025), there was no significant difference between diabetic women with chronic renal failure and women of the control group.
Conclusion : It was concluded that the urinary EGF excretion may be a reliable marker for assessment of renal function in non-diabetic women with chronic renal failure.

Association between blood Pb and Fe levels in Turkish metallurgy workers and a polymorphism of DMT1 gene

M. (Odabaşı) Yaylagül[1], Z. Kayaalti[2], V. A. Türksoy[2], H. Yılmaz[3], I. Kurt[4], T. Soylemezoglu[5]
[1]Vocational High School of Health Services, Adiyaman University, Adiyaman, [2]Ankara University, [3]Occupational Diseases Hospital, [4]Department of Medical Biochemistry, Gulhane School of Medicine, [5]Forensic Sciences Institute, Ankara University, Ankara, Turkey

Lead is a heavy metal that used for years and still used for various industrial purposes. Lead exposure can cause many biological effects depending upon the level and duration. In adults, lead toxicity is most commonly caused by occupation in workplace. Especially after oral exposure, toxic metals are derived from gastrointestinal tract. In the duodenum Divalent Metal Transporter-1 (DMT-1) protein plays a crucial role for dietary Fe uptake but also recognizes nonessential metals such as Pb. Aim of this study

© 2014 The Authors. FEBS Journal © 2014 FEBS

was to determine whether DMT1 IVS4 + 44C/A single nucleotide polymorphism (SNP) has an effect on Pb, Fe and Erythrocyte protoporphyrin (EP) levels in blood and Aminolevulinic Acid (ALA) and total porfirin levels in urine of Turkish metallurgy workers. For this purpose blood samples were obtained from 82 male and studied by standard PCR-RFLP technique. Pb and Fe were measured Atomic Absorption Spectrometry. EP was measured with molecular fluorimeter, and ALA and Total Porphyrin were measured with spectrofotometer. Genotype frequencies of IVS4 + 44 C/A polymorphism were determined as; 42.68% homozygote typical, 45.12% heterozygote and 12.20% homozygote atypical. Consequently, Pb and Fe levels were measured as; 372.37 ± 145, 20 ppb; 463.91 ± 83.45 ppm. When Pb levels were evaluated with groups, Pb levels were determined as 317.02 ± 122.39 ppb, 399.22 ± 121.85 ppb and 466.79 ± 221.34 ppb in homozygote typical (CC), heterozygote (CA) and homozygote atypical (AA) genotypes, respectively. Statistically significant association ($p < 0.005$) was found between the IVS4 + 44 C/A and Pb, but statistically no association were found between the IVS4 + 44 C/A polymorphism and Fe, EP, ALA and Total Porfirin levels ($p > 0.05$).

TUE-361
Association of adiponectin with acute myocardial infarction

A. Sotoodeh Jahromi, M. shojaei
Jahrom University of Medical Sciences, Jahrom, Iran, Islamic

Backgrounds: Adiponectin is an adipose tissue-derived mediator with significant anti-atherogenic properties. A few studies were done in acute phase of myocardial infarction especially in non obese patients. We design a study to investigate the association between adiponectin concentration and acute phase of myocardial infarction in non obese patients.
Methods: This case-control study was done in Paymaneah Hospital (Jahrom, Iran) from Feb 2007 to May 2008. Plasma adiponectin levels were measured in 43 patients with acute myocardial infarction (mean age: 62.7 +/– 13.3 years, male: 67.4%) at the first 24 h of admission and 43 normal controls (mean age: 62.1 +/– 12.3 years, male: 55.8%) matched for age, sex and other coronary artery disease risk factors.
Results: Adiponectin levels in patients with acute myocardial infarction (3.36 μg/ml) were significantly lower than that of the control group (5.03 μg/ml) ($p < 0.0001$). Lower adiponectin were independently associated with higher risk of acute myocardial infarction (odds ratio= 8.97; 95% CIs: 2.3–34.5; $p = 0.001$). Adiponectin levels negatively correlated with triglyceride (r: -0.46, $p = 0.002$) and total cholesterol ($r = -0.32$, $p = 0.03$) in the case group and with body mass index in control subjects.
Conclusion: The present study showed that adiponectin was associated with acute myocardial infarction in non obese patients but it is not related to sex, age and other coronary artery disease risk factors.

Keywords: Adiponectin, infarction

TUE-363
Atrazine herbicide cause cell damages in *Saccharomyces cerevisiae*, probably due a slowdown of glutathione redox cycle

R. Nunes, R. Ferreira, I. Alves-Pereira
Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Departamento de Química, Universidade de Évora, Évora, Portugal

Atrazine (ATZ) has been used extensively as an herbicide, mainly due to its relatively low cost and ease of application. Previous studies have shown that many pollutants are redox active being able to enter microorganisms, causing a univalent reduction of dioxygen with reactive oxygen species (ROS) formation. These products can severely attack cell membranes causing lipid peroxidation. Many cells have developed antioxidative defence system, consisting of ROS-scavenging enzymes, e.g. glutathione peroxidase (GPx) or catalases (CTT1, CTA1), and antioxidants, e.g. glutathione (GSH). Catalases and GPx can catalyze H_2O_2 reduction to H_2O and GPx can also scavenge lipid hydroperoxides, converting them in correspondent alcohols. ROS can be produced in cells not only as by-products of normal cellular metabolism but also under stress situations as contact with xenobiotics. So far, the oxidative stress responses to several pollutants as atrazine have been examined in bacteria plants and animals, but few studies have shown the response of antioxidant enzymes in *S. cerevisiae* to herbicides stress. So, the purpose of the present work was to evaluate the antioxidant response by yeast to atrazine exposure. *Saccharomyces cerevisiae* UE-ME_3 a wild-type yeast deposited in the collection of laboratory of Enology, University of Évora, at mid-exponential phase were inoculated in YEPD medium, 2% (w/v) glucose, at 28°C, and shaken 150 rpm for 72 h in presence of 5 or 50 μM ATZ and compared with control (YEPD). Yeasts were harvested by centrifugation at 3000 *g* for 10 min and washed with ultra-pure sterile water. The obtained cells were suspended in 10 mM phosphate buffer pH 7.0, and disrupted by sonication. The post-12 000 *g* supernatants were used for ROS, malondialdheyde (MDA), glutathione (GSH) and glutathione disulfide (GSSG) determination by fluorescence as well as alkaline phosphatase (ALP), CTT1, CTA1, glutathione reductase (GR), GPx and glucose 6-phosphate dehydrogenase (G6PD) activities by molecular absorption spectrometry. The statistical analyses were performed by ANOVA I and Duncan test ($p < 0.01$), using SPSS for Windows, version 22. The results showed a decrease in biomass, GSH/GSSG ratio, GR and GPx activities in the cells grown in presence of 5 or 50 μM atrazine. Additionally, it was also detected an increase in ROS and MDA contents as well as in CTT1, G6PD and ALP activities of cells exposed to 50 μM atrazine. In conclusion, the exposure to 50 μM atrazine, a triazine herbicide, caused oxidative stress and cell damages in wild-type *S. cerevisiae* UE-ME_3, probably due a slowdown of glutathione redox cycle, despite a protection resulting from an increase of cytoplasmic activities catalase and ALP.

TUE-364
Beta-blocker timolol has important beneficial action on diabetes-induced kidney tissue damage by enhancing the activities of some antioxidant enzymes

H. Gokturk[1], N. N. Ulusu[2], **M. Gok**[3], E. Tuncay[4], B. Can[5], B. Turan[4]
[1]Department of Histology-Embryology, Yildirim Beyazit University, Faculty of Medicine, Ankara, [2]Department of Medical Biochemistry, Koc University, School of Medicine, Istanbul, [3]Department of Medical Biochemistry, Hacettepe University, Faculty of Medicine, [4]Department of Biophysics, [5]Department of Histology-Embryology, Ankara University, Faculty of Medicine, ANKARA, Turkey

Together with other risk factors, increasing diabetes-prevalence result in significant increases in chronic kidney disease, globally. Since hyperglycemia generates more reactive oxygen species and reduce the efficiency of antioxidative mechanisms, numerous studies demonstrated that, hyperglycemia-induced oxidative stress played a major role in extracellular matrix expansion. The eventual objective of the present study was to determine whether timolol treatment of streptozotocin-induced diabetic rats (timolol for 12-week with 5 mg/kg daily following diabetes-induction) has advantage to prevent hyperglycemia-induced renal damage by enhancing the depressed antioxidant defence in the kidney. Light microscopy data and their quantification demonstrated that timolol treatment prevented basically glomerular hypertrophy, mesangium expansion, thickening of glomerular basement membrane, fibrosis, and accumulation of glucogen in epithelial cells of tubules. Additionally, electron microscopy data demonstrated that timolol treatment also prevented hypertrophy of podocytes, disappearing of filtration gaps and slit-diaphragms, mesangium cell increase, and vacuolization in distal tubular cells. Biochemical analysis of kidney tissue, related with antioxidant defence system enzymes such as glutathione-S-transferase, glutathione reductase, and glucose-6-phosphate dehydrogenase, further supported that diabetes-induced damage in kidney is mostly dependent on increased oxidative stress and timolol, having an antioxidant-like action, can prevent kidney against hyperglycemia-induced damage though it does not alter high blood glucose levels of diabetic rats. Consequently, it can be suggested that, although β-blockers are widely used for the treatment of cardiovascular diseases, β-blocker therapy of diabetics seem to be a new therapeutic approach against hyperglycemia-induced organ damage.

TUE-365
Biochemical modifications induced in mouse liver post-exposure to micelle coated iron oxide nanoparticles

I.-M. Din (Popescu)[1], O. Cinteza[2], A. Hermenean[3,4], A. Dinischiotu[1]
[1]Department of Biochemistry and Molecular Biology, Faculty of Biology, University of Bucharest, [2]Department of Physical Chemistry, Faculty of Chemistry, University of Bucharest, Bucharest, [3]Department of Histology, Faculty of Medicine, Pharmacy and Dentistry, Vasile Goldis Western University of Arad, [4]Department of Experimental and Applied Biology, Institute of Life Sciences, Vasile Goldis Western University of Arad, Arad, Romania

Iron oxide nanoparticles have a great variety of biological and medical applications including MRI usage as contrast agents.

The aim of our study was to evaluate the biochemical effects induced by micelle coated iron oxide nanoparticles in male CD1 mice liver. The individuals were injected with the suspensions of nanoparticles in 0.7% sodium chloride in the tail vein in 3 animal groups of 10 individuals each: one control, and the other ones treated with solution of 5 mg Fe/Kg body weight, respectively 15 mg Fe/Kg body weight. The level of some biomarkers of oxidative stress such as: reduced glutathione (GSH), advanced oxidation protein products (AOPP), protein thiol groups (PTG), glutathione reductase (GR) activity as well as glutathione-S-transferase (GST) and glutathione peroxidase (GPX) ones were analyzed after one, two, three, seven and fourteen days after administration.

For both doses, the AOPP level slowly decreased towards 14 days, but it always stayed above the control, while the concentration of PTG and GSH always stayed below the control, decreasing from 24 h to 72 h and then increasing to 14 day exposure. The GR activity decreased until 72 h exposure below the control one and then settles above the control after 7 days, whereas GST activity gradually increased up to 14 days. On the other hand, the level of GPX gradually decreased in a time-depndent manner.

Taking into acount all these data it appears that, the CD1 mouse liver antioxidant defense system counteracts to a certain extent, the oxidative stress induced by the exposure to micelle coated iron oxide nanoparticles.

TUE-366
Biological activities of some Lamiaceae species

B. Atalay[1], M. E. Diken[2], S. Dogan[3]
[1]Biology, Balikesir Universty, [2]Biology, [3]Molecular Biology and Genetics, Balikesir University, Balikesir, Turkey

Daily dietary herbal teas are important part of the food industry. In addition, they have gained greater importance in treatment of some diseases because of their flavonoids, total phenolic contents and antioxidant capacity. In this study, some of the Lamiaceae species (*Salvia tomentosa* Miller, *Sideritis perfoliata* L. subsp. *athoa* (Papanikolaov & Kokkini), *Sideritis trojana* Bornm, *Stachys tmolea* Boiss, *Stachys cretica L. Smyrnaea* Rech fil) were obtained from Kazdagi (Ida mount). The antioxidant capacity, antimicrobial activity, total phenolic, flavonoid contents, total protein content and cytotoxic activity of these species were studied. Their antioxidant capacity, total phenolic and flavonoid contents were determined by 2,2-diphenyl-1-picrylhydrazyl radical scavenging capacity (DPPH) method, Folin-Ciocalteu method and by the method of Ramful et. al (2011), respectively. Moreover, by the disc diffusion method a gram-positive and a gram-negative bacteria (*Staphylococcus aureus* ATCC-6538, *Escherichia coli* ATCC-8739) were studied to determine antimicrobial activity of plant extracts. Cytotoxic activity is determined by the method of Smitha et. al. and the total protein content is determined by the DUMAS nitrogen analyser.

As a result, among all these samples the highest antioxidant capacity, total phenolic content and total flavonoid amount were observed in *Sideritis perfoliata* (94.7%), *Sideritis trojana* (30.8 mg/g) and *Salvia tomentosa* (0.1 m/g), respectively. In addition, highest cytotoxic activity and total protein amount were seen in *Sideritis trojana*. On the other hand, *Stachys cretica* showed lowest total phenolic content, flavonoid amount and antioxidant capacity (13.57 mg/g, 0.065 mg/g, 92.79%, respectively). As a result of antimicrobial analysis the highest activity was observed in *Sideritis athoa* (1.934 mm) with *E. Coli and Sideritis trojana* (1.972 mm) with *S. aureus*.

TUE-367
Biosynthesis of brassinosteroids, a plant hormones, in *Scenedesmus obliquus* cultures

A. Bajguz, A. Piotrowska-Niczyporuk
Institute of Biology, Department of Plant Biochemistry and Toxicology, University of Bialystok, Bialystok, Poland

Brassinosteroids (BRs) occur ubiquitously in angiosperms, gymnosperms and lower plants. The occurrence of BRs has been demonstrated in almost every part of higher plants, such as pollen, flower buds, fruits, seeds, vascular cambium, leaves, shoots and roots. In this study, BRs have been isolated in microalga *Scenedesumus obliquus (Turpin) Kützing (Chlorophyceae) (SAG Strain No.: 276-6)*. BRs, including teasterone, typhasterol, 6-deoxoteasterone, 6-deoxotyphasterol, 6-deoxocastasterone, castasterone and brassinolide, were identified by UPLC–MS/MS. All compounds belong to the BR biosynthetic pathway. The results suggest that early and late C6 oxidation pathways are operating in *Scenedesmus obliquus*. Elucidation of BR biosynthesis is fundamental to understanding how plants regulate the endogenous level of active BRs for their proper growth and development.

This project has been financed from the funds of the National Science Centre allocated on the basis of the decision number DEC-2012/05/B/NZ8/00958.
Keywords: biosynthesis, brassinosteroids, microalgae

TUE-368
Bisphosphogliceratemutase: a key player in cancer cells metabolic reprogramming

C. Mugnaioni, A. Santi, A. Caselli, P. Paoli, P. Cirri
Department of Biomedical Clinical and Experimental Science, University of Florence, Firenze, Italy

Many kind of cancer cells exploit glycolysis rather than oxidative phosphorylation for energy production even in the presence of oxygen. This kind of metabolism, although less efficient in terms of ATP production, generates high levels of glycolytic intermediates necessary to support the high biosynthetic flux of rapidly proliferating cells.This mechanism is further enhanced in cancer cells by the expression of a particular form of pyruvate kinase (PKM2) which promote a low efficiency glycolysis (in terms or ATP production) and consequently an increase in the formation of biosynthetic metabolites. In this work we investigate the role of Bisphosphogliceratemutase (BPGM) an enzyme involved in the metabolic reprogramming of highly proliferating cancer cells. BPGM acts both as a mutase, converting the glycolytic intermediate 1,3-bisphosphoglycerate (1,3-BPG) to 2,3-bisphosphoglycerate (2,3-BPG) and as a phosphatase, converting the 1,3-bisphosphoglycerate to 3-phosphoglycerate. BPGM is an erythrocyte-specific enzyme but our real time PCR and western blotting experiments show its expression in many cancer cell lines and in proliferating primary human fibroblasts. BPGM silencing lead to a strong decrease of cell proliferation rate.BPGM activity in cancer cell lead to the skipping of the first ATP production in the glycolytic pathway of glycolysis, causing an increase of glycolytic flux necessary to sustain the high rate of intermediates production needed for support cancer cells growth.

TUE-369
Carbonic anhydrase activity of isolated coupling factor CF_1 from spinach chloroplasts

A. V. Semenikhin, A. P. Khomochkin, **E. K. Zolotarova**
Membranology & Phytochemistry, M.G. Kholodny Botany Institute, Kyiv, Ukraine

ATPsynthase (EC 3.6.3.14) is a membrane enzymatic complex carried out synthesis and hydrolysis of ATP coupled with the transmembrane proton transfer in mitochondria, chloroplasts and bacteria. It consists of a hydrophobic portion – Fo functioning as a proton channel and hydrophilic part – coupling factor F_1 which contains several nucleotide binding sites and performs catalytic function. The catalyst portion of all ATPsynthases consists of five types of polypeptides in stoichiometric ratio $\alpha 3\beta 3\gamma\delta\varepsilon$. Unlike other F_1ATPases, ATPase activity of isolated chloroplast F_1 (CF_1) is latent and increases due to heating or the treatment with thiol compounds, trypsin, alcohols, oxyanions or detergents. Thylakoid membranes of chloroplasts were prepared from fresh spinach leaves. Soluble CF_1 was isolated from thylakoid membranes by 1 mM EDTA. The purity of the isolated CF_1 was tested by electrophoresis in native conditions, and its subunit composition was analysed by SDS electrophoresis. Latent isolated CF_1-ATPase was activated by heating at 60°C for 2 min or by trypsin treatment. A solution of trypsin in 1 mM HCI was used at a concentration of 100 μg/ml and added to 30–40 μg of purified enzyme. The action of trypsin was stopped by adding double amount of soybean trypsin inhibitor. Ca -dependent ATPase activity of the enzyme was assayed by the release of inorganic phosphate. Latent enzyme activity was 0.9 μmol $Pi \cdot min^{-1} \cdot mg^{-1}$ (protein).

Carbonic anhydrase activity was determined in PAAG using pH -dependent color reaction in the presence of a pH indicator (bromothymol blue) or in solution using an infrared gas analyzer (IFGA S151, Qubit Systems Inc. Canada). The rate of HCO_3^-dehydration was determined by an increase in CO_2 concentration in the gas phase of IFGA in response to the addition of 15 mM sodium bicarbonate.

Bromothymol blue analysis of the isolated CF_1 after separation in native gel showed that protein zones exhibiting ATPase activity accelerated also a conversion of carbon dioxide with bicarbonate and protons formation. Water-soluble carbonic anhydrase inhibitor acetazolamide inhibited also ATPase activity of isolated CF_1.

Thus, an isolated catalytic part of the ATPsynthase – multisubunit coupling factor CF_1 along with ATPase has also carbonic anhydrase activity. Ability of CF_1 to catalyze the interconversion carbonic acid forms may have functional significance for ensuring the efficient operation of ATPsynthase promoting a proton exchange associated with the ADP phosphorylation and ATP hydrolysis.

Cardiovascular risk assessment in obese children treated with Omega-3 fatty acids supplements

L. A. Popescu[1], B. Virgolici[1], O. Timnea[2], H. Virgolici[1], D. Oraseanu[1], L. Zagrean[1]
[1]*"Carol Davila" University of Medicine,* [2]*Ecologic University, Bucharest, Romania*

Childhood obesity is associated with increased risk of cardiovascular disease in young adulthood. It was demonstrated that during adulthood, Omega-3 fatty acids reduce the cardiovascular disease risk.

This study aimed to determine the effects of Omega-3 fatty acids supplements on the cardiovascular system, in obese children. The most important cardiovascular risk factors were assessed before and after the treatment.

Sixty obese children (9–16 years old) and thirty lean children were involved. Each day, for three months, obese children took Omega-3 fatty acids (DHA 130 mg and EPA 25 mg) and vitamins (A 200 μg, D 1.25 μg, E 2.5 mg and C 30 mg). The measured variables were: fasting lipid profile (total cholesterol, HDL-C, triglycerides, LDL-C), inflammatory markers as fibrinogen, CRP (C reactive protein), WBC (white blood cells), ESR (erythrocyte sedimentation ratio), adiponectin/leptin ratio, proteinuria, CIMT (carotid intimal media thickness), IVS (interventricular septum thickness) and HOMA-IR (homeostatic model assessment-insulin resistance). Spectrophotometric and ELISA methods were used for plasma variables and ultrasounds for IVS.

All the measured parameters were modified in obese children versus lean subjects. In the obese children, the treatment lowered the rise of CIMT ($p < 0.001$), IVS ($p < 0.001$), inflammatory markers ($p < 0.01$) with the exception of WBC, HOMA-IR ($p < 0.001$), proteinuria ($p < 0.001$), blood pressure values ($p < 0.001$), total cholesterol ($p < 0.001$), triglycerides ($p < 0.01$) and LDL-C ($p < 0.001$) and increased the adiponectin/leptin ratio ($p < 0.001$) and the level of HDL-C ($p < 0.001$). Proteinuria was positively correlated with HOMA-IR ($r = 0.34$, $p < 0.05$), IVS with CIMT ($r = 0.31$, $p < 0.05$) and CIMT with adiponectin/leptin ratio ($r = -0.30$, $p < 0.05$) and with CRP ($r = 0.29$, $p < 0.05$).

In conclusion, in childhood obesity, Omega-3 fatty acids supplements reduced the increased values of the interventricular septum, lowered the atherosclerotic risk and decreased inflammation and insulin resistance.

Change peroxidation cascade in blood of women with helminthiasis invasion

K. Z. Berikbay[1], D. Raushan[2], Y. Tanzira[2], T. Anar[2]
[1]*Department of Molecular Biology and Medical Genetics,*
[2]*Karaganda State Medical University, Karaganda, Kazakhstan*

Introduction: In recent years, there is an active study of pathogenesis in helminthiasis, it is known that during parasitism, especially during the migration of the larvae, the body receives a huge amount of metabolic products of helminths damaging hereditary apparatus of somatic cells of the host, causing parasite antigens intoxication and violation of free radical processes in helminthiasis.

Aim: To evaluate the condition of the products lipoperoxide cascade in the blood of women with helminthiasis invasion.

Materials and methods: To assess the performance oxidative metabolism was studied content of primary, secondary and final products of lipid peroxidation.

Determination of conjugated dienes (CD), ketodienes (KD), total of the primary product (TPP), total of secondary product (TSP). Shiff bases was performed by standardized methods of Ushkalova V.N. and Kadochnikova G.D. (1987). Determination of malonic dialdehyde (MDA) was performed according to the method of Korobeynikova Ye.N (1989).

Statistical analysis of the results was performed using the standard package of statistical program Microsoft Excel.

Results: The results showed that in blood of women with ascaridiasis invasion observed activation of lipid peroxidation. In blood of women with ascaridiasis invasion CD content exceeds 1.4 times as compared with control. MDA levels in blood of persons surveyed was significantly higher than control values – in 4.0 times ($p < 0.05$).

From the obtained results it is evident, aside from CD, MDA at different stages of peroxide cascade formed a number of other toxic metabolites LPO: ketodien, conjugated trienes, 4-hydroxy alkenes, alkenes, aldehydes therefore the content in blood not only individual, but also total of primary (TPP) and total of secondary (TSP) products the LPO was defined.

Mean levels of TPP and TSP in women with ascaridiasis invasion exceed the value of control in 2.0 times ($p < 0.05$).

Conclusion: In our view, the preferential growth of the TPP and the TSP is a testament to the whole spectrum of education toxic catabolites LPO, both at the stage of initiation and lipo peroxide cascade the propagation stage, as well as increasing the concentration of the contents of primary and secondary products can be attributed to the lipoperoxide cascade pronounced cytotoxicity of MDA, which contribute to the formation of other deep oxidation products of lipid aldehydes, ketones and acids.

TUE-372
Characterization of the squalene synthase from *Methylococcus capsulatus* that requires no detergent

T. Hoshino[1,2], K. Ohtake[2]
[1]*Applied Biological Chemistry,* [2]*Graduate School of Science and Technology, Niigata University, Niigata, Japan*

Owing to the dearth of information regarding squalene synthases (SQSs) from prokaryotes, we set out to characterize the SQS from *Methylococcus capsulatus* (mcSQS). We also studied its reaction mechanism by kinetic analysis and evaluated the structure of the substrate/inhibitor-binding sites by homology modeling. To this end, we transfected the gene for mcSQS to *Escherichia coli* for its expression and purification by Ni-NTA column chromatography. We also produced mcSQS mutants by site-directed mutagenesis directed at various amino acids and potential active-site residues in the two binding-site motifs $^{58}DXX^{61}E^{62}D$ (S1 site) and $^{213}DXX^{216}D^{217}D$ (S2 site), which have been thought to be involved in the binding of the substrate farnesyl diphosphate (FPP) through the Mg^{2+} ion. Very interestingly, mcSQS was water-soluble and did not require any detergent for its activity, unlike other SQSs hitherto studied; in fact, supplementation of any type of detergent inhibited the enzyme's activity. Under catalytic optimal conditions, the specific activity of the wild-type mcSQS was estimated to be 800 ± 36 nmol·min^{-1}·mg^{-1}. The kinetic constant values for the substrate FPP were as follows: $K_m = 13.6 \pm 0.92$ μM, $k_{cat} = 0.549 \pm 0.01$ s^{-1}, and $k_{cat}/K_m = 0.04$ μM^{-1}·s^{-1}. For NADPH, the parameters were as follows: $K_m = 75.4 \pm 1.02$ μM,

© 2014 The Authors. FEBS Journal © 2014 FEBS

k_{cat} = 0.33 ± 0.0015 s^{-1}, and k_{cat}/K_m = 0.004 $\mu M^{-1} \cdot s^{-1}$. The substrate analog farnesylmethylenediphosphate was a potent inhibitor of the enzyme, with a K_i^{FPP} value of 0.1 μM. From the site-directed mutagenesis studies, we first demonstrated the importance of the S1 site. In addition, two basic residues (R55 and K212) were revealed to be responsible for the binding of the substrate FPP.

Keywords: farnesyl diphosphate, *Methylococcus capsulatus*, squalene

TUE-373
Charge-tagging approach in corticosteroid detection

A. Dmitrochenko, A. Yantsevich
Institute of Bioorganic Chemistry, Minsk, Belarus

Corticosteroids belong to a group of steroid hormones that are produced by adrenal cortex of vertebrates and involved in a wide range of regulatory processes, including electrolyte homeostasis, carbohydrate metabolism, stress and immune response. Corticosteroid level detection is a valuable instrument for understanding mechanisms of physiological processes. Although corticosteroids are rather polar molecules, its detection limit by HPLC-MS in APESI ionization mode is too high to detect minor quantities in biological samples. To improve detection limit of oxysterol metabolites, charge-tagging derivatization was proposed and now it is widely used for oxysterol identification and quantitation in biological samples [1]. Up to date charge-tagging of corticosteroids for MS-analysis was not a subject of specific investigation, although the interest in this derivatization approach is growing [2, 3]. In our work we tested three variants of charge-tagging reagents, viz Girard reagent P and T, hydroxylamine to introduce a positive charge or to enhance proton binding capability of cortisol, corticosterone and aldosterone. Presence of two (or three in case of aldosterone) carboxyl group in molecules of tested steroids suppose few reaction products, but we show that mainly reaction occurs at the carbonyl group of C3. We obtain and interpret SID as well as CID fragmentation patterns for derivatization products, so this information may be very useful for identification of minor unknown metabolites of the stated hormones. Optimized technique was applied for comparative analysis of corticosteroid level in brain sections, obtained from intact and stressed rats.

CHO-MT58: a model system for functionality studies of *Plasmodium falciparum* CTP: phosphocholine cytidylyltransferase

L. Marton, G. N. Nagy, N. Kucsma, G. Szakács, B. Vertessy
Institute of Enzimology, Hungarian Academy of Sciences, Research Centre for Natural Sciences, Budapest, Hungary

Malaria – caused by the protozoan *Plasmodium falciparum* – is still one of the most threatening infectious diseases in the 21th century. In *Plasmodium falciparum* as in all eukaryotic cells phospholipid biosynthesis has a key role in synthesis of cell membrane and intracellular membrane elements. The most prevalent way of *de novo* biosynthesis is Kennedy-pathway, where the reaction catalyzed by CTP: phosphocholine cytidylyltransferase[1] (CCT) (CTP + choline-phosphate à CDP-choline) is rate-limiting. Because of the persistent need of Plasmodium for membrane synthesis during its life cycle, de novo phospholipid biosynthesis emerges as a target for new generation antimalarial drugs.[2]

CHO-MT58 cell line was proved to be an appropriate tool for investigating intracellular function of CCT harboring a point mutation in its endogenous CCT, causing thermo-sensitivity.[3] At non-permissive temperature (40°C) the endogenous CCT activity decreases dramatically, which blocks membrane synthesis and ultimately leads to apoptosis.[3] It was demonstrated that supply of external phosphatidylcholine or the heterologous expression of the rat CCT can successfully complement the mutant strain. Our aim was to develop a model system using this inducible CCT "knock out" cell line, where we can study the functionality of heterologously expressed *Pf*CCT constructs in cellular environment, excluding the effect of endogenous CCT.

In this study we transfected CHO-K1 and CHO-MT58 cells with CCT constructs and incubated them at permissive and non-permissive temperatures. To verify the rescue we performed FACS experiment with these and with cells transfected with catalytically inactive *Pf*CCT as control. Having obtained a higher ratio of active *Pf*CCT expressing cell population at non-perimissive 40°C than at permissive temperature 37°C, we have demonstrated for the first time that heterologously expressed Plasmodium CCT is able to complement the respective endogenous cytidylyltransferase activity in mammalian cells. Thus, a suitable test system has been established for the functional investigation of different protozoan-specific structural elements of *Pf*CCT. Furthermore, the possibility to assess the functionality of either endogeneous mammal CCT or Plasmodium CCT enables testing the selectivity of novel antimalarials acting on *de novo* phospholipid metabolic pathways.

Introduction: Non-alcoholic steatohepatitis (NASH) is assumed to be developed by two-hit process, the first hit is lipid accumulation in the liver cells and the second hit includes Oxidative stress,

© 2014 The Authors. FEBS Journal © 2014 FEBS

proinflamatory cytokines and adipokines. Regarding their metabolic and inflammatory activity, adipokines have been shown to play key role in the pathogenesis of NASH. C1q/TNF-related protein-1(CTRP-1) is a member of CTRP superfamily which has been demonstrated to play important roles in energy homeostasis, insulin resistance and inflammation. This study was conducted to measure the plasma concentrations of CTRP1 in four groups including NASH, type 2 diabetes mellitus (T2DM), NASH-T2DM and healthy controls.

Methods: A total of 86 subjects including 22 with NASH, 21 with T2DM, 22 with NASH-T2DM and 21 healthy controls were participated in this study. Plasma concentration of CTRP1 was measured with ELISA method. Anthropometric assessment, ultrasonographic and biochemical evaluation were performed for all study subjects. Liver stiffness scores were measured via transient elastography. The homeostasis model assessment (HOMA) was used as a surrogate model for assessmant of Insulin resistance (IR)

Results: Plasma concentration of CTRP1 in NASH, T2DM and NASH-T2DM was significantly elevated compared to healthy subjects ($P < 0.001$). Moreover, we observed the a significant correlation ($P < 0.001$) between plasma level of CTRP1 and conventional diabetes and fatty liver risk factors including the HOMA, fasting blood suger (FBS),liver stiffness scores,alanine aminotransferase (ALT) and aspartate amino transferase (AST) in the whole study population.

Conclusion: Our study, uncovered,for the first time, changes of CTRP1 levels as a possible tool for NASH and T2DM detection. Our data also suggest that serum CTRP1 level may be associated with more advanced form of NASH.

Citrulline counters hepatic lipid metabolism disorders in fructose-induced non-alcoholic fatty liver disease

P. Jegatheesan[1], D. S. Beutheu[1], G. Ventura[1], G. Sarfati[2], E. Nubret[1], N. Kapel[3], A. J. Waligora-Dupriet[3], L. Cynober[1,2], J.-P. De Bandt[1,2]

[1]Nutrition Biology Laboratory, EA4466, Faculty of Pharmacy, Paris Descartes University, Sorbonne Paris Cité, [2]Clinical Chemistry Department, Hôpitaux Universaires Paris Centre, APHP, [3]Microbiology, EA1065, Faculty of Pharmacy, Paris Descartes University, Sorbonne Paris Cité, Paris, France

Rationale: A high fructose (HF) intake has been shown to induce insulin-resistance, changes in liver metabolism and gut barrier function ultimately leading to non-alcoholic fatty liver disease (NAFLD). Citrulline (Cit), Glutamine (Gln) and Arginine (Arg) may improve insulin sensitivity and may have beneficial effects on gut trophicity. The aim of our study was to evaluate the effects of these amino acids (AA) on liver and gut functions in a rat model of fructose-induced NAFLD.

Methods: 58 male Sprague-Dawley rats (225–250 g) received for 4 weeks a fructose-enriched (60%) diet or standard chow either alone or supplemented with Cit (0.15 g/d) or an isomolar amount of Arg or Gln. All diets were made isonitrogenous by addition of a mixture of non-essential amino acids (NEAA). On week 4, nutritional and metabolic status (plasma glucose, insulin, cholesterol, triglycerides (TG) and AA, and net intestinal absorption) were determined. Steatosis (hepatic TG content (HTG), histological examination), hepatic function (plasma AST, ALT, ALP, and bilirubin) and hepatic inflammation (TLR4 mRNA and protein expression) were assessed. Gut barrier integrity (myeloperoxydase activity, portal endotoxemia, tight junction protein expression and localization) was evaluated. We also assessed the influence of the different diets on caecal microbiota by quantifying total bacteria and main bacterial groups of caecal microbiota.

Résultats: In our experimental conditions of HF isonitrogenous feeding, fructose led to significantly increased liver weight, HTG and plasma TG. However, there was no alterations in glucose homeostasis, liver function and gut permeability. Fructose diet tended to increase endotoxemia and decreased significantly Bifidobacterium and Lactobacillus intestinal contents. While Arg and Gln supplementations were ineffective, Cit supplementation prevents hypertriglyceridemia and attenuates liver fat accumulation.

Conclusion: While nitrogen supply by itself notably attenuate fructose-induced NAFLD, Cit seems to act directly at hepatic level on lipid metabolism partially preventing hypertriglyceridemia and steatosis. This occurs in the absence of noticeable changes in gut microbiota, intestinal barrier function, and insulin sensitivity suggesting a specific regulatory role of this AA on lipid metabolism.

Obesity is a major cause of increased risk of atherosclerosis and diabetes. Visceral adipose tissue (AT) development plays an important role in the occurrence of metabolic syndrome, observed with excessive weight gain. The metabolic dysregulations linked to obesity is the result at least in part of the unbalance between fatty acid (FA) storage in AT and their release determined by lipolysis, beta-oxidation and re-esterification. Our previous results showed that CIT exerted a direct effect on FA metabolism in explants of retroperitoneal (RET) AT from old rats, hence favoring FA output. We postulated that CIT could also directly affect FA metabolism in RET AT explants from young Sprague Dawley male rats (2 month-old) fed a high-fat diet (HFD) for 8 weeks compared to a standard diet (CD). HFD rats were overweight and RET AT mass doubled compared with their CD counterparts. We first evaluated the effects of a 24 h incubation with 2.5 mM CIT on RET CD (n = 5) and HFD (n = 5) AT explants on FA and glycerol release in the incubation medium. In the presence of CIT, no significant release of glycerol was detected, whereas FA output was significantly increased about twofold selectively in HFD explants. Concomitantly, CIT significantly up-regulated the level of phosphorylated hormone-sensitive lipase (HSL) in CD (60%) and HFD (100%) explants. The absence of glycerol release can be explained by the observed twofold increase in glycerol kinase gene expression in both CD and HFD explants. To start deciphering the mechanism by which FA output was augmented, we monitored beta-oxidation capacity, by measuring the production of $^{3}H_2O$ from (9,10-^{3}H) palmitate, and the glyceroneogenic flux, through the incorporation of [1-^{14}C]-pyruvate into lipids. We observed a threefold increase in oxidative capacity in both CD and HFD explants

© 2014 The Authors. FEBS Journal © 2014 FEBS

in agreement with a 68% (CD) and 42% (HFD) up-regulation of very long-chain acyl-CoA dehydrogenase. The glyceroneogenic flux was attenuated in CD explants (50%) but drastically decreased (80%) in HFD explants. This was the result of a significant down-regulation (40–48%) by CIT of the cytosolic phosphoenolpyruvate carboxykinase, the key enzyme of glyceroneogenesis. Therefore, CIT alters FA metabolism in RET AT from overweight rats predominantly by reducing glyceroneogenesis and FA reesterification.

TUE-378
Connective tissue metabolism markers for increase of ovarian cancer efficiency treatment

M. Knyazyeva[1], A. Prokopyuk[2], T. Pavlova[3]
[1]Biochemistry, Kharkov National University by V.N. Karazin, [2]Gynaecology, Kharkov Regional Clinical Oncology Centre, [3]Oncology, Public Organization "New thinking in medicine", Kharkov, Ukraine

As known glycosaminoglycans (GAG) are components of connective tissue (CT) and biochemical markers of its metabolism. We used total GAG and GAG-spectrum as part of a diagnostic complex evaluation of treatment efficiency in ovarian cancer (OC) stages III-IV. It is well known that 65–85% of patients having OC start the first course of treatment at the III-IV stages of tumor process. The above mentioned fact makes difficult the possibility of doing citoreductive operations at the first stage of treatment and it requires the use of neoadjuvant chemotherapy (NPChT), the optimal course number of which has not been determined yet. After the NPChT it becomes possible to make an operation to delete the original tumor in (OC) patients.Structural degradation of extracellular matrix (ECM) appears in the epithelial tissues of patients during the OC III-IV stages- development. It effects the GAG spectrum in blood serum and evidently precedes invasion and tumor metastasis.

GAG fractions and total GAG in blood serum of 82 patients having OC at III-IV stages before treatment and after NPChT were determined by M. Shtern et al. method. ELISA method were used to determine CA125 content-famous marker of OC.

It was found that the changes in level of total GAG in blood serum up to 75–70%, chondroitinsulphate up to 80–65%, II GAG- fraction (contained Ch-4-S and dermatansulfate) up to 75–65% of the original, I (contained mainly Ch-6-S) and III (contained heparansulfates, keratansulfates and heparin) fractions, ratios of total GAG and their fractions, to normal data, as well as the content of CA 125 to 9.6–3.6% of its initial value are markers of making operation possibility in patient having OC stages III-IV. These findings correlated with changes of clinical, ultrasound and morphological parameters and became the basis of diagnostic complex of treatment efficiency evaluation.

TUE-379
Covalent immobilization of benzoylformate decarboxylase on magnetic solid support and its carboligation reactivity

T. Tarhan[1], B. Tural[2], S. Tural[3]
[1]Vocational High School of Health Services, Mardin Artuklu Universty, Mardin, [2]Department of Chemistry, Faculty of Education, [3]Department of Chemistry, Faculty of Education, Dicle University, Diyarbakır, Turkey

In the present work, HIS-tagged benzoylformate decarboxylase (BFD E.C. 4.1.1.7) from *Pseudomonas putida* was covalently attached onto the magnetic epoxy support. In order to obtain an immobilized biocatalyst with high amount of enzyme loading and activity recovery, the effects on the immobilization efficiency of immobilization conditions including enzyme concentration, pH, ionic strength and coupling time were investigated. The maximal enzyme loading and enzyme activity were investigated under the optimal immobilization parameters. A three-step immobilization/stabilization procedure is applied. The enzyme is primarily covalently immobilized under appropriate experimental conditions (e.g. pH 7.0, no added $MgSO_4$ and 20°C). Secondly, the enzyme is immobilized under more drastic conditions (higher pH values, higher ionic strengths etc.) to facilitate an increase in effective concentration of the enzyme on the support near the epoxide reactive sites. Thirdly, the remaining epoxy groups are blocked to stop any additional interaction between the enzyme and the support. With more drastic conditions, the loading of enzyme can be increased from 1.25 to 6.70 mg enzyme per gram of support. The covalently bounded enzyme was characterized in terms of its activity and stability for the formation of (*S*)-2-hydroxypropiophenone (2-HPP). The activity of the immobilized BFD was determined to be 53.0% related to the activity of the free enzyme. The immobilized biocatalyst retained 95% of its original activity after five reaction cycles.

TUE-380
CTRP-5 levels and non-alcoholic steatohepatitis: is it through insulin resistance?

S. Emamgholipour[1], H. Poustchi[2], N. Moradi[1], H. Naeimi Khaledi[1], P. Shabani[1], M. Beigy[3], M. Doosti[1]
[1]Department of Biochemistry, [2]Liver and Pancreatobiliary Diseases Research Center, Digestive Diseases Research Center, [3]Students' Scientific Research Center (SSRC), Tehran University of Medical Sciences, Tehran, Iran

Introduction: A growing body of evidence indicates that type 2 diabetes, obesity and insulin resistance are major risk factors for non-alcoholic steatohepatitis (NASH). Recently, it has been suggested that C1q/TNF-related protein-5(CTRP-5), as a novel adipokine of adiponectin paralogs, may play an important role in lipid and glucose metabolism. The aim of present study was to investigate,for the first time, plasma levels of CTRP-5 in NASH patients with type 2 diabetes,NASH patients without type 2 diabetes and also patients with type 2 diabetes in comparison with healthy subjects and also examine the association between circulating CTRP-5 levels and clinical parameters of NASH and type 2 diabetes and liver stiffness scores in all participants.
Methods: A total of 86 subjects, all males were recruited for this study. The study participants were categorized into healthy subjects (n = 21), NASH with type 2 diabetes (n = 22), NASH without type 2 diabetes (n = 22) and type 2 diabetic patients (n = 21). All participants underwent extensive physical examination, anthropometric assessment, ultrasonographic and biochemical evaluation. Plasma CTRP-5 levels were analyzed by enzyme-linked immunosorbent assay. Liver stiffness scores were examined by transient elastography .Insulin resistance (IR) was determined by the homeostasis model assessment (HOMA).
Results: The plasma concentration of CTRP-5 was found to be significantly decreased in patients with type 2 diabetic NASH as compared with controls (122.52 ± 22.24 ng/ml and 164.96 ± 12.15 ng/ml, respectively). In addition, the plasma level of this adipokine were significantly lower in non-diabetic NASH patients (124.7 ± 19.55 ng/ml) and type 2 diabetic subjects (118.31 ± 19.27 ng/ml) as compared with healthy individuals .

Additionally,there was a significant correlation between the plasma levels of CTRP-5 with HOMA-IR (r = –0.496),fasting

© 2014 The Authors. FEBS Journal © 2014 FEBS

blood sugar (FBS)(r = −0.445) and insulin (r = −0.338) .The circulating CTRP-5 levels also showed an inverse and significant correlation with body mass index (BMI) (r = −0.337),alanine aminotransferase (ALT)(r = −0.243) and liver stiffness scores (r = −0.544).

Conclusion: It appears that the assessment of CTRP-5 with other biochemical and metabolic parameters could be partially useful to elucidate the pathways contributing to NASH and other diabetes –related diseases.

TUE-381
Cytotoxic effect of two endemic subspecies of *Tanacetum praeteritum* (Horw.) Hey-wood (Asteraceae) from Turkey on cervical carcinoma

Z. C. Arıtuluk[1], S. Karakurt[2], N. Ezer[1], O. Adalı[3], A. M. Gençler-Özkan[4]
[1]Department of Pharmaceutical Botany, Faculty of Pharmacy, Hacettepe University, Ankara, [2]Department of Biochemistry, Faculty of Science, Selcuk University, Konya, [3]Department of Biological Sciences, Joint Graduate Program in Biochemistry, Middle East Technical University, [4]Department of Pharmaceutical Botany, Faculty of Pharmacy, Ankara University, Ankara, Turkey

Background: Cervical cancer is the second most common form of cancer in women aged 15–44 years in developing countries. Approximately 530 000 new cases are diagnosed and 275 000 deaths occur each year. Up to 60% of the approved chemotherapeutic drugs are derived from natural compounds. *Tanacetum* is a genus which is composed of nearly 200 species in the aster family (Asteraceae). Several species of *Tanacetum* genus are traditionally used in a variety of health conditions including pain, fever, inflammation, arthritis, migraine, respiratory and gastrointestinal disorders. Sesquiterpenoids and sesquiterpene lactones as the typical constituents of these plants might be partially or wholly responsible for these effects. Additionally, earlier investigations showed that sesquiterpene lactones isolated from *Tanacetum praeteritum* ssp. *praeteritum* have cytotoxic activity against the human lung carcinoma cell line GLC_4 and the colorectal cancer cell line COLO 320. Therefore, in the present study we investigated the cytotoxic and anticancer activities of the methanol extracts of the aerial parts of *Tanacetum praeteritum* ssp. *praeteritum* and *T. praeteritum* ssp. *massicyticum* which are endemic subspecies from Turkey on human cervical carcinoma.

Methods: Plant materials collected in flowering time from Antalya/TURKEY have been extracted by the method described in the European Pharmacopoeia. Air-dried and powdered aerial parts of the plant materials (20 g) were extracted with methanol (3 × 500 ml) in a water-bath at 60°C, concentrated to dryness under reduced pressure and lyophilized in vacuo. Cervix cancer cell line, HeLa was grown in EMEM medium supplemented with 10% fetal bovine serum and 2 mM glutamine. Cytotoxicity of methanol extract of *T. praeteritum* ssp. *praeteritum* and *T. praeteritum* ssp. *massicyticum* on HeLa cell lines were determined with Alamar blue Assay and IC_{50} value was calculated.

Results: The yield of extract obtained from *T. praeteritum* ssp. *praeteritum* was 14.1% and obtained from *T. praeteritum* ssp. *massicyticum* was 12.6%. In this study, we found both *T. praeteritum* ssp. *praeteritum* and *T. praeteritum* ssp. *massicyticum* have the potential to inhibit the proliferation of HeLa cell line in a concentration-dependent manner with an IC_{50} of 0.25 mg/ml and 0.21 mg/ml, respectively.

Conclusions: The results showed that the methanol extracts of both *T. praeteritum* ssp. *praeteritum* and *T. praeteritum* ssp. *massicyticum* were found to be effective inhibitor against cervical carcinoma at low concentration, which indicates that these plants might have potential for cervix cancer treatment.

Cells are exposed to various chemical and physical influences *in vitro* environment of a heterotrophic culture, so the conditions more effective forming the low-temperature adaptation mechanisms in cells of a suspension culture and intact plants may differ. In this connection, the purpose of this study was to investigate the metabolic changes of cells in a plant suspension culture under the influence of low positive temperatures, namely their effects on fatty acid composition, stress proteins accumulation and changes of a respiratory metabolism. The work was carried out with 8 day old winter wheat suspension culture (*Triticum aestivum* L.), using the treatment with 4 and 8°C for 7 days. It has been shown that the exposure of the culture to 8°C led to decreasing of saturated fatty acids contents in cells: pentadecylic acid – by 35%, palmitic acid – by 19.9%, stearic acid – by 65.4%, and to increasing the content of unsaturated linolenic acid nearly in two times. The treatment of the culture with 4°C caused no significant changes in the cells fatty acid composition. Then the exposure of the culture to low positive temperatures also affected the dehydrins synthesis in the winter wheat cells: their content increased with the treatment with both studied temperatures, but during the action of temperature 8°C this process occurred more intensely. It is known that an important component of plant adaptation is change of a respiratory metabolism, in particular, the ratio of the alternative cyanide-resistant and the cytochrome cyanide-sensitive pathways contributions in respiration. Alternative oxidase (AOX) functioning in a plant cell is one of the mechanisms preventing the generation of reactive oxygen species. In our study an increase of the AOX contribution in the respiration is shown to occur only in the treatment of the culture with 8°C, while the effect of 4°C treatment resulted in a significant increase of the respiration rate, but almost no influenced on the AOX functioning. Thus, our results indicate that the treatment of the winter wheat suspension culture with 4°C had a stress impact to the cells, and adaptation mechanisms forming more effective occurred at the temperature of 8°C. This work was supported by RFBR grant (■ 14-04-32126).

TUE-383
Disruption of carbohydrate metabolism by xenobiotic mixtures

A. Leblanc, E. Blanc, A. Ambolet-Camoit, C. Benelli, S. Bortoli, M. Aggerbeck
INSERM, Paris, France

Epidemiological studies have shown that exposure to certain xenobiotics is associated with an increased prevalence of metabolic

© 2014 The Authors. FEBS Journal © 2014 FEBS

diseases. Since humans are exposed to mixtures of xenobiotics detoxified by the liver, we used two xenobiotics, both endocrine disruptors and persistent organic pollutants, which use different signaling pathways, to study hepatic energy metabolism: 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), which uses the AhR, and α-endosulfan, an organochlorine pesticide, which acts via the PXR and/or the estrogen receptor.

Differentiated HepaRG cells, which resemble human hepatocytes, were exposed for 30 h to 25 nM TCDD, 10 μM α-endosulfan, or the mixture. Gene expression was measured by transcriptomics and RT-qPCR. Oxidation of glucose to CO2 (radioactive incorporation) and production of lactate and glucose (colorimetry) were measured.

The expression of two genes of hepatic gluconeogenesis critical for hepatic energy metabolism, glucose transporter 2 (GLUT2) and glucose-6-phosphatase (G6Pc), were reduced 80% by the mixture (more than either xenobiotic alone). The expression of other glucose metabolism genes (pyruvate kinase, glycogen synthase, glycogen phosphorylase, pyruvate dehydrogenase 2) also was decreased suggesting that the mixture may markedly impact carbohydrate metabolism. Glucose production decreased 40% with the mixture under gluconeogenic conditions. Under glycolytic conditions, although the oxidation of glucose into CO_2 decreased 30% after 72 h exposure to the mixture, lactate production was not affected. Long-term treatment (8 days) with lower doses (0.2–5 nM TCDD, 3 μM α-endosulfan) similarly decreased G6Pc and Glut2 expression.

Thus, the mixture of TCDD and α-endosulfan decreases, *in vitro*, the expression of hepatic glucose metabolism genes even at low doses and decreases hepatic gluconeogenesis and glucose oxidation. Chronic exposure of individuals to low doses of xenobiotics might significantly affect hepatic carbohydrate metabolism and be a contributing factor in the development of the metabolic syndrome.

Donepezil analogs as acetylcholinesterase inhibitors

D. Desiderio[1], A. Lamberti[2], S. Roberta[3], P. Costanzo[4], M. Oliverio[4], F. Ortuso[4], A. Procopio[4], S. Alcaro[4], G. Raimo[1], R. Arcone[3], M. Masullo[3]
[1]*Dipartimento di Bioscienze e Territorio, Università del Molise, Isernia,* [2]*Dipartimento Scienze Motorie e del Benessere,* [3]*Dipartimento Scienze Motorie e del Benessere, Università di Napoli "Parthenope", Napoli,* [4]*Dipartimento di Scienza della Vita, Università di Catanzaro "Magna Graecia", Catanzaro, Italy*

To explore novel effective drugs for the treatment of Alzheimer's disease (AD), a series of acetylcholinesterase (AChE) inhibitors were designed based on a molecular docking strategy.

AD, a progressive neurodegenerative disorder, is characterized by cholinergic system deficits leading to deposition of beta amyloid in the form of neurofibrillary tangles and amyloid plaques, a process based on the modulation of the cholinergic system. Tacrine, donepezil, rivastigmine and galantamine are clinically employed for the treatment of AD as they enhance cholinergic transmission directly by inhibiting the activity of AChE. In addition, also butyrylcholinesterase (BuChE) activity play an important role in Ab-aggregation during the early stages of senile plaque formation.

In this study, two series of new Donepezil-like derivatives were developed, with chemical replacements on indanone or benzilpiperdine ring systems. Firstly, a double bond between these two moieties, leading to a more rigid structure, was inserted. On this scaffold a metoxilic 5-components series, characterized by the presence of metoxyl groups in different structural positions, was developed and synthesized (GP9, GP10, GP11, GP12, GP13). On the basis of molecular docking analysis these modifications should ensure a better interaction with the AChE catalytic site. Furthermore, with the aim at improving compound solubilisation, a different phenolic 4-components series was designed and synthesized (DEMG3, DEMG7, DEMG5, DEMG6).

The inhibitory effect of the new synthesized compounds was assessed on AChE from *Electrophorus electricus*, using Ellman assay with acetyl-thiocholine as substrate, and the results were compared to that of Donepezil. For all the compounds tested the IC_{50} of AChE activity was within micro-molar range except for GP9 (IC_{50} = 162.8 nM) which showed an inhibitory efficacy much close to that of Donepezil (IC_{50} = 30 nM). Dilution experiments showed that the inhibition is completely reversible for all the compounds tested and kinetic analysis highlighted a non-competitive mechanism of action. To assess the specificity of these compounds, their effect was also checked on BuChE from horse serum, using butyrylthiocholine as substrate, and the results indicated that all tested compounds exhibited a higher specificity towards AChE.

Experiments are in progress to evaluate the cytotoxicity of synthesized compounds on neuronal cell lines as well as in other cell lines.

TUE-385
Early laboratory diagnosis and bone marrow transplantation in MPS type I

K. El Moustafa[1], I. Lay[1,2], Ö. Ünal[3], S. Sivri[3], T. Coşkun[3]
[1]*Department of Medical Biochemistry,* [2]*Clinical Pathology Laboratories,* [3]*Children's Hospital Nutrition and Metabolism Unit, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Mucopolysaccharidosis (MPS) Type I is a rare lysosomal storage disorder in which heparan and dermatan sulphates accumulate in different tissues and organs due to a defect of IDUA gene which encode the α-L iduronidase. The purpose of presenting this case is to highlight the importance of the establishment of laboratory diagnostic tests and early laboratory diagnosis in the populations that have higher incidence of MPS. A 16-months-old girl was admitted with complaints of waist curvature and nasal obstruction realized at 6 months by her mother. On examination, her head circumference, weight and height were found in 95, 3–10 and 3–10 percentiles, respectively. She had coarse facial features, a depressed nasal bridge, large tongue, rough and though hair, thick eyebrows and hypertrichosis. Corneal clouding, kyphosis in the lumbar spine and minimal limitation in knee extension were observed. Radiologic X-ray images were compatible with dysostosis multiplex. Ultrasonography of abdomen showed minimal hepatomegaly, increased liver parenchymal echogenicity and coarsening. Recently, MPS urinary GAG analysis with electrophoresis and specific enzyme activities from leukocytes for all types of MPS were established in our laboratory. Increased dermatan and heparan sulphate bands in electrophoresis were found in urinary GAG analysis. Alpha-L-iduronidase specific activity measurement in leukocytes was found 0.008 μmol/gram protein/hour (reference range: 10–50). The marked deficiency of alpha-L-iduronidase suggested a diagnosis of MPS type I. Molecular analysis revealed that the patient was heterozygous for IVS11 + 5G>C and exon 14 1893 del C mutations of IDUA gene. Enzyme replacement therapy (ERT) was started at 20 months of age. Eight months after (28-months-old) bone marrow transplantation (BMT) was performed from a non-relative, tissue group 4/6 compatible donor. Chimerism in first month was

© 2014 The Authors. FEBS Journal © 2014 FEBS

found 85% and second, third and sixth months were found 100%. Rashes occured in the second month. She received treatment for graft-versus-host-disease (GVHD). At fifth month alpha-L-iduronidase specific activity was found normal. Meanwhile, she is 6 years of age and going to preschool, except little hearing loss life quality is fine and being followed up for the progress. If patients are to be diagnosed as early as possible they could be treated safely and effectively. Due to the high ratio of consanguineous marriages (21%) in Turkey, the incidence is expected to be more and it is important to establish the laboratory diagnostic tests in the populations that have higher incidence of MPS.

Keywords: bone marrow transplantation, early laboratory diagnosis of MPS, Mucopolysaccharidosis

TUE-386
Effect of co-administration of endosulfan and morin on biomarker enzyme activies in rat liver

C. Sapmaz[1], T. Firat[2], A. Kukner[2], A. Bozcaarmutlu[1]
[1]Department of Chemistry, [2]Department of Histology and Embryology, Abant Izzet Baysal University, Bolu, Turkey

Endosulfan is an organochlorine pesticide, used extensively in the agricultural areas against insects. It may exist in air, freshwater, sea water, soil samples and foods. Endosulfan causes damage in the immune system, central nervous system and reproductive system. Morin is one of the flavonoids obtained from plants. The role of morin in the treatment and prevention of toxic effects of chemicals have not been clarified yet. The aim of this study is to determine the effect of morin in the presence of endosulfan. For this purpose, twenty eight male Wistar rats (6–7 weeks old and weighing 170–245 g) were randomly selected and divided into four groups. The rats in control group were treated with corn oil three times in a week. Morin-treated groups (morin and endosulfan + morin) were gavaged with 25 mg/kg body weight morin three times in a week. Endosulfan treatment was started at the 12th day of the administration period at a dose of 5.0 mg/kg body weight endosulfan in endosulfan and endosulfan + morin groups. This treatment was continued through the administration period with the frequency of three times in a week. Rats were killed by cervical dislocation on the 54th day of the administration period. Microsomes and cytosols were prepared for each liver tissue by differential centrifugation. Cytochrome P4501A (CYP1A) associated 7-ethoxyresorufin O-deethylase (EROD) activities of control, endosulfan, morin, and endosulfan + morin groups were 71 ± 7, 121 ± 5, 112 ± 6, and 121 ± 9 pmol/min/mg protein, respectively. Glutathione S-transferase (GST) activities of control, endosulfan, morin, and endosulfan + morin groups were 365 ± 14, 365 ± 24, 430 ± 27, and 460 ± 10 nmol/min/mg protein, respectively. Catalase activities of control, endosulfan, morin, and endosulfan + morin groups were 618 ± 29, 540 ± 38, 569 ± 34, and 612 ± 48 nmol/min/mg protein, respectively. Glutathione reductase activities of control, endosulfan, morin, and endosulfan + morin groups were 46.7 ± 2.2, 46.3 ± 1.7, 49.7 ± 1.6, and 46.3 ± 1.2 nmol/min/mg protein, respectively. In conclusion, morin, endosulfan and endosulfan + morin administrations increased EROD activities in rats. EROD activities measured in treatment groups were significantly different from EROD activities measured in control group ($p < 0.05$). Catalase and glutathione reductase activities were not altered with co-administration of morin and endosulfan. GST activities increased in morin and endosulfan + morin groups. The results of this study indicate that co-administration of morin and endosulfan significantly increases CYP1A and GST activities.

TUE-387
Effect of high glucose and AGEs on lysosomal proteases of cultured kidney cells

G. B. Peres[1], M. A. Juliano[2], N. Schor[3], Y. M. Michelacci[1]
[1]Biochemistry, [2]Biophysics, [3]Medicine, Universidade Federal de São Paulo, São Paulo, Brazil

Diabetic nephropathy is one of the most prevalent consequences of diabetes mellitus (DM), and microalbuminuria is one of its early symptoms. It was previously reported that, while urinary excretion of albumin increased, excretion of sulfated polysaccharides decreased in DM rats. Exogenous dextran sulfate accumulated in liver and kidney, suggesting cell internalization, and higher amounts accumulated in DM. Recently, we have reported decreased lysosomal enzymes (proteases and glycosidases) in DM rat kidney. Excretion of less degraded or intact albumin explained observed albuminuria. Concerning sulfated polysaccharides, decreased activities of glycosidases led to intracellular deposition of partially digested macromolecules, and this could explain their decreased urinary excretion and tissue buildup. Concerning kidney morphology, the main changes observed were proximal convoluted tubules with thinner walls and thinner brush border, and immunohistochemistry revealed that most of cathepsin B was located in the brushborder of proximal tubular cells, highlighting the involvement of these cells in diabetic nephropathy. The aim of the present study was to investigate the possible mechanisms leading to these effects on lysosomal enzymes. As persistent hyperglycemia contribute to the formation of advanced glycation end products (AGEs), the first issues to be investigated were the effects of sustained high-glucose and of AGEs on lysosomal protease activities of immortalized lineages of kidney cells: human mesangial cells (IHMC), porcine proximal tubular cells (LLCPK) and canine distal tubular cells (MDCK) were used. These cells were cultured under normal (5.5 mM) or high (30 mM) glucose, for 15 days. They were also exposed to 0.5 mg/ml albumin (BSA) or ribose-derived albumin (AGE-BSA), and were cultured for either 48 or 72 h. Cell proliferation curves revealed that only mesangial cells behaved differently under high glucose, doubling 13% faster. Nevertheless, all cells were affected by AGE-BSA, proliferating less than controls, while BSA by itself did not affect them. Cysteine protease activities were measured in cell extracts with two different fluorimetric substrates, in presence or absence of inhibitors. The main cysteine protease was cathepsin B, and its activity was differently modulated by AGE-BSA depending on cell lineage: it increased in mesangial and distal tubular cells (IHMC: 1.2–1.5; MDCK: 2.0–2.5), while decreased in proximal tubular cells (0.6–0.75). These data show that different kidney cells are not affected in the same way by sustained high-glucose and AGEs, and is in agreement with our previous report on proximal tubules. Grants from FAPESP, CNPq and CAPES.

Effect of morin on cytochrome P450-dependent monooxygenase activities in 7,12-dimethylbenz[a]anthracene treated rats

C. Sapmaz[1], T. Firat[2], A. Kukner[2], A. Bozcaarmutlu[1]
[1]*Department of Chemistry,* [2]*Department of Histology and Embryology, Abant Izzet Baysal University, Bolu, Turkey*

7,12-Dimethylbenz[a]anthracene (DMBA) is a lipid soluble molecule, producing toxic and carcinogenic effects within the body. It is possible to expose to DMBA with smoking cigarette, breathing car exhaust and furnace gases in daily life. Morin is a dietary flavonoid having chemoprotective and antioxidant properties in living organisms. The effects of morin have not been well defined in the presence of toxic chemicals. Therefore, this study is aimed to determine the effect of morin on cytochrome P4501A2 (CYP1A2), cytochrome P4502B (CYP2B) and cytochrome P4503A (CYP3A) in DMBA-treated rats. For this purpose, twenty eight male Wistar rats (6–7 weeks old and weighing 170–255 g) were randomly selected and divided into four groups. The rats in control group were treated with corn oil three times in a week. 25 mg/kg body weight morin was given to morin and DMBA + morin groups three times in a week. DMBA-treated groups were gavaged with 30.0 mg/kg body weight DMBA at 12th, 19th and 26th days of the administration period. Rats were killed by cervical dislocation on the 54th day of the administration period. Microsomes were prepared for each liver tissue by differential centrifugation. CYP1A2 associated 7-methoxyresorufin O-demethylase (MROD) activities of control, morin, DMBA, and DMBA + morin groups were 34.0 ± 0.7, 41.4 ± 1.2, 52.1 ± 1.9 and 58.8 ± 4.1 pmol/min/mg protein, respectively. CYP2B associated 7-pentoxyresorufin O-depentylase (PROD) activities of control, morin, DMBA, and DMBA + morin groups were 18.0 ± 1.0, 17.6 ± 0.8, 16.9 ± 0.7 and 18.5 ± 1.0 pmol/min/mg protein, respectively. CYP3A associated erythromycin N-demethylase (ERND) activities of control, morin, DMBA, and DMBA + morin groups were 0.38 ± 0.01, 0.44 ± 0.03, 0.48 ± 0.03 and 0.44 ± 0.04 nmol/min/mg protein, respectively. In conclusion, DMBA exposure increased the activities of CYP1A2, CYP3A, but not CYP2B in rats. CYP3A related ERND activities decreased in DMBA + morin group compared to DMBA group. CYP1A2 related MROD activities increased in DMBA + morin group compared to DMBA group.

Valproic acid (VPA) has been used for more than 30 years for treating various medical disorders in adults and children, including migraine headaches, seizures and psychiatric disorders. In animal studies, it was effective in shrinking both lymph nodes and spleen in animals with conditions similar to autoimmune lymphoproliferative syndrome. Moreover in recent years VPA has been shown to be effective in various cancer types and Alzheimer disease. Chard (*Beta vulgaris* L. var. cicla) is a herbaceous biennial leafy vegetable cultivated in many parts of the world. It is a low cost plant and has a widespread use in many traditional dishes. It has been demonstrated that chard has antioxidant, anti-acetylcholinesterase, antidiabetic, antitumor and hepatoprotective effects. The aim of this study is to evaluate whether VPA and/or chard might interfere with oxidative metabolism in spleen. Female rats were divided into four groups as intact control animals, VPA (0.5 g/kg/day,i.p.), chard (100 mg/kg/day, oral) and VPA + chard (in same dose and time) given groups for seven days. Chard extract was given 1 h prior to the administration of VPA. On the 8th day the animals were sacrificed under anesthesia and spleen samples were homogenized in saline. Oxidant-antioxidant biochemical parameters were determined in homogenized spleen samples. Results were evaluated statistically and discussed.

Amiodarone which is used for the treatment of arrhythmias, causes many side effects in all organ systems. Cabbage (*Brassica oleracea* L. var. capitata) is one of the most important vegetables grown worldwide. It provides significant amounts of vitamins (A,C,E,K) and other photochemicals, such as glucosinates and other sulfur containing compounds which are beneficial for human health. Numerous studies report protective effects of cabbage against many chronic diseases, several cancer types, cardiovascular, cerebrovascular, ocular and many neurological diseases and peptic ulcers. It may protect from the side effects of amiodarone. In literature there is no study which focuses on the effects of amidorone and cabbage on aort. In this study, we aimed to investigate the effects of amiodarone and cabbage extract on rat aorta. Female Sprague-Dawley rats were randomly divided into four groups as follows; control group receiving corn oil; cabbage extract (500 mg/kg/day) given group; amiodarone (100 mg/kg/day) given group; amiadaron + cabbage extract (in same dose) given group. Cabbage extract and amiodarone were given by gavage to rats for 7 days. Amiodarone was given to the animals one hour after cabbage extract administration during the experimental period. All animals were fasted overnight and on the 8th day they were sacrificed under anesthesia. Aorta samples were taken from animals and homogenized in saline. Oxidant-antioxidant biochemical parameters were determined in homogenized aorta samples. Results were evaluated statistically and discussed.

Effects of Cr(VI) on the production of reactive oxygen species, and the ethylene response in *Arabidopsis thaliana* L. (Magnoliophyta: Brassicaceae)

M. Martinez-Trujillo, G. Rangel-Sanchez, J. López-Bucio, Y. Carreon-Abud
Biologia, Universidad Michoacana, Morelia, Mexico

Chromium in its hexavalent [Cr(IV)] form is a toxic element that has increased its concentration in the environment due to human activities, representing a danger to organisms, including plants (1). The responses of plants to Cr(VI) are similar to those induced by other heavy metals, so it is proposed that there are common physiological mediators that help plants adapt to stress conditions that generate these metals, mainly reactive oxygen species (ROS) and some signaling pathways of hormones like etileno (2). In this work, the production of ROS in *A. thaliana* seedlings exposed to various concentrations of Cr(VI) was evaluated. Plants with wild phenotype (Col0) were used, as well as a mutant of a key gene in the signaling pathway of ethylene (*ein2-1*), which were grown at concentrations of 20, 40, 60, 80, 100 μM Cr(VI). We found that at concentrations of 20 and 40 μM, the seedlings showed an increase in primary root length and in the number of lateral roots, both in the wild line as in the *ein2-1* mutant. However, from 60 μM, the root length decreased, with a maximum reduction at 100 μM Cr (VI), 87.6% and 28.04% for wild seedlings and *ein2-1*, respectively. Additionally, in the case of the wild line, this coincides with an increase in the number and length of root hairs near to the root apex region, and the formation of adventitious roots. Also, the mitotic activity of the root meristem was lost in the wild line, but not in *ein2-1,* at a concentration of 100 μM Cr(VI). To assess whether the effects of Cr(VI) on the modification of root architecture were associated with increased levels of reactive oxygen species (ROS), an analysis was performed to detect the levels of H_2O_2 using the Hyper reporter line (4) or using the fluorochrome (H2DCF-DA) for wild and mutant line *ein2-1*, respectively. H_2O_2 levels were increased significantly in the wild line in a concentration-dependent manner, peaking at 100 μM Cr(VI) (Figure 1A). In line *ein2-1*, H_2O_2 levels were increased at a lower rate relative to the wild (Figure 1B). Our results suggest that Cr(VI) modulates the interaction of ROS and root architecture possibly through an ethylene-dependent signaling pathway.

Key words: Chromium, ROS, Arabidopsis.

Effects of hormone replacement therapy on plasma and tissue fibrinolytic activity in a rat model of surgically induced menopause

A. Topcuoglu[1], M. Albayrak[2], H. Erman[3], H. Balci[4], M. Karakus[5], I. Coban[6], **H. Uzun**[3]
[1]Obstetrics and Gynecology, Abant Izzet Baysal University, Faculty of Medicine, Bolu, [2]Obstetrics and Gynecology, Duzce University, School of Medicine, Duzce, [3]Biochemistry, [4]Central Research Laboratory, [5]Obstetrics and Gynecology, [6]Experimental Animal-Research and Breeding, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Purpose : The purpose of this study was to analyze the effects of estrogen deficiency and hormone replacement therapy (HRT) on fibrinolytic activity in a rat model of surgically induced menopause.

Methods: Twelve-week-old, sexually mature female Sprague-Dawley rats, each weighing 200–250 g, were randomly divided into four groups: (1) sham-operated group, (2) ovariectomy group, (3) ovariectomy group followed by oral administration of daily 17β-estradiol (0.02 mg/kg/day) (E2) + norethisterone acetate (0.01 mg/kg/day), and (4) ovariectomy group followed by oral administration of daily 17β-estradiol (0.01 mg/kg/day) + drospirenone (0.02 mg/kg/day). Tissue plasminogen activator (tPA) antigen, plasminogen activator inhibitor-1 (PAI-1) antigen, and PAI-1/tPA levels were measured as markers of fibrinolysis in plasma and liver and brain tissue.

Results: Compared with sham-operated rats, ovariectomized rats showed higher levels of fibrinolytic activity; however, the increased fibrinolytic activity in plasma and liver tissue was significantly reduced by HRT regimens. No change was observed in the levels of fibrinolytic activity in brain tissue.

Conclusions: HRT showed beneficial effects by decreasing fibrinolytic activity related to surgically-induced menopause. Short-term HRT treatment was associated with a shift in the procoagulant-anticoagulant balance toward a procoagulant state.

TUE-394

Effects of resveratrol and melatonin on metabolic disturbances induced by a high-fructose diet in rats

F. S. Bircan[1], N. Türközkan[2], B. Balabanli[1], S. Kantar[2]
[1]Biology, [2]Clinical Biochemistry, Gazi University, Ankara, Turkey

Metabolic syndrome is a disease characterized by hypertension, dyslipidemia, hyperinsulinemia, glucose intolerance, insulin resistance, and is associated with increased risk for development of both cardiovascular diseases and type 2 diabetes. It was determined that a close relationship between incidence of metabolic syndrome and increased fructose consumption in human and animal studies. In the present study, investigation of possible protective effects of resveratrol and melatonin treatment on metabolic changes caused by high-fructose diet in rats were aimed. For this purpose, 48 male adult Sprague-Dawley rats were randomly divided into six groups (n = 8); control, fructose, resveratrol, mel-

© 2014 The Authors. FEBS Journal © 2014 FEBS

atonin, fructose + resveratrol and fructose + melatonin. Metabolic syndrome was induced in rats by 20% (w/v) fructose solution in tap water for 8 weeks. Melatonin (20 mg/kg) or trans-resveratrol (10 mg/kg) were administered by oral gavage. Systolic blood pressures were measured by tail-cuff method, and fluid/food intakes were measured daily. At the end of 8th week, the animals were sacrificed under anesthesia, and blood samples obtained by intracardiac puncture. Serum lipids, glucose and insulin levels were evaluated using appropriate enzymatic analysis kits. Serum asymmetric dimethylarginine (ADMA) and homocysteine (Hcy) levels, which are known to be reliable markers of especially cardiovascular diseases as well as other numerous metabolic disorders, were quantified by HPLC. In comparison with control group, fructose consumption increased systolic blood pressure, serum triglyceride and insulin levels and insulin resistance significantly, and metabolic syndrome model was successfully demonstrated. Moreover, important changes, including increase of the serum ADMA and Hcy levels were observed following fructose treatment. Resveratrol administration showed a protective/therapeutic effect on hypertension which is an important criteria of metabolic syndrome, by preventing the systolic blood pressure rise caused by fructose. However, it did not show a protective effect on atherogenic lipid profile, hyperinsulinemia and increased ADMA levels induced by high-fructose diet. Melatonin administration prevented the increase in systolic blood pressure, insulin resistance, serum insulin, ADMA and Hcy levels. These results show that melatonin administration compared with resveratrol treatment can be useful for the prevention/treatment of the cardiovascular complications of metabolic syndrome by its beneficial effects on not only the well-known criteria of the disease, but also on the reduction of plasma ADMA and Hcy levels.

Disclosure of Interest: None Declared.

Effects of testosterone replacement therapy on impaired redox homeostasis of aged brain

K. Yanar[1], P. Atukeren[1], T. Ozan[2], U. Çakatay[1], S. Aydın[1]
[1]Medical Biochemistry, [2]Istanbul University, Istanbul, Turkey

Production of endogenous testosterone gradually decreases in aging males. Not only spermatogenesis but also androgen synthesis in testicle adversely affected by impaired redox homeostasis. Thus, optimal regulation of antioxidant enzyme activity is crucially important in the aging process. Our aim to study effects of testosterone replacement therapy on neuronal redox homeostasis in aging.

We analyzed various oxidative stress biomarkers including protein carbonyl groups (PCOs), lipid hydroperoxides (LHPs), malondialdehyde (MDA), advanced glycation end products (AGEs) and antioxidant status parameters such as total thiol groups (T-SH) and Cu-Zn superoxide dismutase (Cu,Zn-SOD) in different anatomical parts of rat brain Experimental animals divided into three groups: naturally aged rats (NA:% 0.9 saline), testosterone administrated naturally aged rats (TNA:25 mg/kg testosteron) and their corresponding young controls (YC:% 0.9 saline).

PCO, LHP, MDA concentrations in hippocampus tissue of NA rats were significantly higher than TNA and YC rats (NA vs YC and NA vs TNA $p < 0.001$ for each parameters). Additionally, TSH levels in NA rats were significantly lower than TNA and YC groups ($p < 0.001$ and $p < 0.01$ respectively). Cu, Zn-SOD activities in TNA group were significantly higher than NA group ($p < 0.01$). LHP and AGEs concentrations in parietal lobe of NA rats were significantly higher than TNA and YC groups ($p < 0.001$; YC and NA for both parameters and $p < 0.05$; $p < 0.01$ NA vs TNA respectively). MDA levels in young controls were significantly lower than NA rats. Although, there was a trend toward higher MDA levels in NA rats, MDA levels were not found to be significantly higher than TNA. TSH levels in NA rats were lower than TNA and YC groups ($p < 0.05$). Both MDA and LHP levels in peduncle of NA rats were significantly higher than other groups ($p < 0.001$YC vs NA for both parameters and $p < 0.001$ and $p < 0.01$ NA vs TNA). Additionally LHP concentrations in TNA group were significantly higher than corresponding young controls ($p < 0, 001$). MDA, LHP and AGEs concentrations in cerebellum of NA rats were significantly higher than TNA and YC rats ($p < 0.001$ NA vs TNA and YC vs NA for each parameters and $p < 0.001$; $p < 0.001$ and $p < 0.05$ YC vs NA respectively).

Our results related to TNA rats show that testosterone replacement therapy has a positive impact on establishment of redox homeostasis in different anatomical parts of aged brain.

TUE-396
Enhancement of bioethanol production from peanut shells with soy flour supplementation

C. Bostanci[1], N. Koçberber Kilic[1], S. Donmez[2], G. Dönmez[1]
[1]Biology, [2]Food Engineering, Ankara Üniversitesi, Ankara, Turkey

Today, fossil fuels are exhausting with a high rate according to the energy demand. Therefore, alternative energy sources like biofuels are very important to being explored to replace fossil fuels. Among biofuels, bioethanol is considerable according to the usage of it as petrol additive or substitute. In the current study, bioethanol production from peanut shells was investigated and the efficiency optimization of the production was induced by nitrogen rich additive. In Turkey, peanut is produced in abundance; therefore the waste of it (peanut shell) can be used for ethanol production which would be a very cheap way to produce biofuels. In this study, peanut shells were pretreated with acid hydrolysis and autoclave. Then, soy flour was added into this pretreatment solution. Bioethanol production experiments were carried out with *Saccharomyces cerevisiae* at pH 5, 30°C in a rotary shaker (100 rpm). Ethanol production was determined by Gas Chromatography (GC; Shimadzu Japan). Reducing sugar content was determined by spectrophotometrically. Optical density and dry biomass of the yeast were also investigated. The data obtained from the trials showed that with an increase in peanut shell, yeast growth and usage of sugar were also increased. In media with 10% (w/v) shell and 0.1% (w/v) soy flour, usage of sugar was 40% and alcohol production were two times higher than in media with 10% (w/v) shell and without soy flour. This data indicated that soy flour increased bioethanol production.

Keywords: Bioethanol, Peanut shells, Yeast.

TUE-398
Expression and activity of extracellular ectoenzymes (CD39 and CD73) in aortic valves cells and in endothelial cells under the shear stress conditions

E. D. Kaniewska[1], A. Sielicka[2], P. Sarathchandra[3], I. Pelikant-Malecka[2], A. H. Chester[3], M. H. Yacoub[3], R. T. Smolenski[1]
[1]Biochemistry, Medical University of Gdansk, [2]Biochemistry, Medical Univeristy of Gdansk, Gdansk, Poland, [3]Heart Science Center, Imperial College London, London, United Kingdom

Extracellular nucleotides have major impact on various pathological processes like thrombosis or inflammation. Ectonucleoside triphosphate diphosphohydrolase 1 (CD39) and ecto-5′-nucleotidase (CD73) are ectoenzymes involved in extracellular nucleotide

© 2014 The Authors. FEBS Journal © 2014 FEBS

breakdown cascade. Changes in activity of those enzymes affect the concentrations of adenosine which mediates anti-inflammatory response as well as influence the levels of ATP which is known pro- inflammatory mediator. The deregulation of ratio between adenosine and ATP might be involved pathological valve calcification.

Therefore, we characterise extracellular nucleotide metabolism in valve cells and the area of expression of ectoenzymes in healthy and calcified valves was determined. Aortic valves were analyzed for CD39 and CD73 expression. In order to verify presence and activity of CD39 and CD73, we characterised nucleotide metabolism by incubation of aortic valve endothelial (AVEC) and interstitial cells (AVIC) – human and porcine origin – with AMP and ATP *in vitro* and conversion of substrates into products was analysed by HPLC. Moreover, we hypothesised that expression and activity of enzymes might be regulated by blood flow and therefore we investigated the effect of flow on different types of endothelial cells in bioreactor mimicking ventricular and aortic flow.

Our results prove that CD39 and CD73 are highly expressed in healthy valves and expression of both enzymes is downregulated in calcified valve, an exception is calcified regions of human valve where CD73 is upregulated. Enzyme activity assay showed a high activity of CD39 and CD73 in both types of cells. We found upregulation of CD73 expression (pic.) and high concentration of adenosine in valve interstitial cells, what might be of great importance as this enzyme is typically absent in fibroblast-like cells. In response to shear stress significant upregulation of both enzymes was found in endothelial cells in comparison to static culture conditions.

In conclusion, these findings highlight a novel role of CD39 and CD73 in heart valve physiology. High activity of those enzymes and in consequence higher levels of anti-inflammatory adenosine could be adaptive and protect heart valves from inflammation and calcification. Ventricular and aortic flow could play an important role in regulation of ectoenzymes expression in endothelial cells what induces increase in nucleotide metabolism. Our data from shear stress system indicate that disturbance of flow has impact on the expression and activity of ectoenzymes in endothelial cells.

Keywords: adenosine, ATP, valve.

Expression of genes responsible for the synthesis of nucleic acids precursors, methionine and cysteine metabolism in human placenta of the first and the third trimesters of gestation

K. Kornieieva[1], R. Rodriguez[1], S. Ralchenko[2], A. Vakylenko[2]
[1]Systems Biology, Institute of Molecular Biology and Genetics National Academy of Sciences of Ukraine, [2]Taras Shevchenko Kyiv National University, Kiev, Ukraine

Introduction: The folate-mediated interdependent reactions responsible for the synthesis of nucleic acids precursors, mitochondrial translation, the utmost majority of methylation reaction, the oxystatus and the maintainance of the balance of methionine and common amino acides play an essential role in placental physiology and in ethiology and pathogenesis of pregnancy complications and birth defects. However, the physiological characteristics of folate-mediated players in human placenta and their pathological counterparts are not still well known.

The aim of the study: was to examine the expression of the genes encoding the enzymes catalysing the synthesis of nucleic acids precursors (*GART, ATIC)*, methionine *(MTR)* and cysteine metabolism viz. its catabolism to taurine (*CDO, CSAD)* and the synthesis of glutathione (*GCL)*. The object of the study was human placenta from the first and the third trimester of uncomplicated pregnancies.

Methods: Gene expression was evaluated by the amount of individual RNAs detected with RT-PCR in real-time using standard curves for absolute quantification of the values.

Results: The analysis of gene expression at mRNA level has revealed that in the first trimester the abundance of examined RNAs is in the range between the minimal values of 7.0 copies per ng of total RNA and the maximal one – 320.0 copies.The abundance of all examined RNAs but *CDO* decrease with the rate of changes characteristic for each RNA: the levels of *GART* and *ATIC* mRNAs responsible for the two sequentional steps of purine ring synthesis, are 3 times less though the ratio *ATIC*/*GAR*≈3/1 remains constant at both periods of gestation; the level of *MTR* RNA decreases two times thus being the precursor of SAM synthesis it points to the potential diminished requirements for SAM activity at term; the nearly two times down-regulated *GCLC* mRNA raises the question on the oxystatus in the term placenta; the opposite changes in the abundance of CDO and CSAD RNAs (CDO/CSAD ≈3 in the first trimester and 70 at term due to the 10-fold increase of CDO and 2-fold decrease of CSAD levels) attract the attention and requires the further studies to explain the role of these unexpected enormous changes during development of placenta.

Conclusions: The results have given a new insight into the regulation of gene expression in the developing placentae. They may be used as reference marks for the study of placental metabolism in complicated pregnancies.

Keywords: folate-mediated 1-carbon metabolism, human placenta.

TUE-400
Expression of pro-proliferative factors in subcutaneous adipose tissue of obese men with and without glucose intolerance

O. O. Ratushna[1], D. O. Minchenko[2], Y. M. Bashta[2], O. H. Minchenko[2]
[1]ESC "Institute of Biology", Taras Shevchenko National University of Kyiv, [2]Molecular Biology, Palladin Institute of Biochemistry National Academy of Science of Ukraine, Kyiv, Ukraine

Obesity, metabolic syndrome, and type 2 diabetes result from interactions between genes and environmental factors and are the most profound public health problems. In obese individuals adipose tissue is at the center of metabolic syndrome. We sought therefore to clarify the molecular mechanisms of subcutaneous adipose tissue growth and development of impaired glucose tolerance in men through investigation of pro-proliferative gene expressions. The expression of *SPARC, CYR61, MYLK, HSPA6, CTGF, UBD,* and *ALCAM* genes was studied in subcutaneous adipose tissue from 18 adult males divided into three equal groups: lean controls and obese men with normal glucose tolerance (NGT) and impaired glucose tolerance (IGT). We have shown that the expression levels of *CYR61, MYLK, CTGF, UBD,* and *ALCAM* genes were increased in subcutaneous adipose tissue of obese (NGT) men versus lean controls and these changes positively correlated with increased body mass index (BMI). More robust effect was shown on *CTGF, UBD,* and *ALCAM* gene expressions. At the same time, no significant changes were observed in *SPARC* and *HSPA6* gene expressions in adipose tissue of this group of patients. We also demonstrated that the expression of *SPARC, HSPA6,* and *ALCAM* genes in subcutaneous adipose tissue of obese men with glucose intolerance is increased versus obese (NGT) individuals, with more robust effect on *HSPA6* gene. However, in this group of patients the expression of *CYR61, MYLK, CTGF,* and *UBD* genes is decreased versus obese (NGT) individuals.

Present study demonstrates that increased expression of *CYR61, MYLK, CTGF, UBD,* and *ALCAM* genes in subcutaneous adipose tissue of obese men with NGT is associated with obesity because positively correlated with increased BMI and possibly participate in development of obesity. At the same time, glucose intolerance in obese men is associated with strong increase of *SPARC, HSPA6,* and *ALCAM* gene expressions as well as with suppression of *CYR61, MYLK, CTGF,* and *UBD* gene expressions in subcutaneous adipose tissue of obese men.

Keywords: Metabolic syndrome, Obesity, Pro-proliferative factors.

TUE-401
Extramitochondrial oxidative phosphorylation: characterization and quantification of cardiolipin in myelin sheath

M. Bartolucci, S. Ravera, D. Calzia, A. Morelli, I. Panfoli
DIFAR, University of Genova, Genova, Italy

Cardiolipin is a phospholipid with unique properties, usually associated with the inner mitochondrial membrane. It was demonstrated that Cardiolipin plays an important role in the membrane structure and function. In particular, the presence of cardiolipin is essential for the energy metabolism, since it is associated with many complexes of the respiratory chain, which are involved in the transfer of electrons and protons for the production of ATP in the mitochondrial inner membrane. Our laboratory recently speculated on a role for cardiolipin as H^+ shuttle between F_oF_1-ATPsynthase and the electron transport complexes [1]. Furthermore, cardiolipin is necessary for the maintenance of oxidative phosphorylation (OXPHOS) supercomplex, which consist of multiple OXPHOS complexes resulting in efficient clustering of this metabolic pathway. In this work, we searched for cardiolipin in myelin, the sheath which surrounds axons in central and peripheral nervous system. In fact, our studies showed that, besides mitochondria, also myelin expresses functional OXPHOS complexes [2]. Thin layer chromatography analyses were performed on lipid-enriched fractions extracted from myelin. Also immunohistochemistry and spectrophotometric analyses on optic nerve sections and isolated myelin, respectively, were carried out, employing the specific cardiolipin probe 10-N-Nonyl acridine orange (NAO). Native electrophoresis analyses were preformed on isolated myelin to assess the presence of the OXPHOS supercomplex. The positive preliminary data as well as our previous observations, reinforce the hypothesis of a specific energetic role played by myelin toward the axon.

TUE-402
Fatty acid composition and functional state of mitochondria from hardened and unhardened winter wheat seedlings after a cold shock

O. Grabelnych, **K. Kirichenko**, O. Borovik, T. Pobezhimova, N. Zabanova, I. Lyubushkina, N. Koroleva, V. Voinikov
Laboratory of Physiological Genetics, Siberian Institute of Plant Physiology and Biochemistry SB RAS (SIPPB SB RAS), Irkutsk, Russian Federation

The relation among the oxidative stress development, fatty acid composition, membranes intactness and functional activity of mitochondria in winter wheat seedlings under cold hardening and freezing temperatures has been studied in this work. Mitochondria were isolated from control and hardened at 2°C for 7 days (the first phase of cold hardening) and 2°C for 7 days with subsequent −2°C for 2 days treatment (two phases of cold hardening) etiolated winter wheat seedlings subjected to the action of the freezing temperature −8°C. Duration of the exposure temperature −8°C for 6 h was lethal to unhardened seedlings, while hardened seedlings successfully resisted the destructive action of the freezing temperature. Hardening of winter wheat seedlings, accompanied by increased frost hardiness, prevented the development of oxidative stress in the tissues of shoots during subsequent cold shock. The content of reactive oxygen species (ROS) and products of lipid peroxidation (LP) in mitochondria of hardened winter wheat seedlings, subjected the cold shock was less than in the mitochondria from the unhardened seedlings. Analysis of fatty acid composition displayed the highest content in winter wheat mitochondria of the palmitic (14.6%), linoleic (46%) and α-linolenic (26.1%) acids. The content of α-linolenic acid was maintained at a high level in the mitochondria of hardened seedlings subjected the cold shock, while it decreased in mitochondria from the unhardened seedlings after the cold shock. Higher content of α-linolenic acid in mitochondria corresponded to higher intactness of the outer membrane. The freezing temperature effect on the unhardened seedlings resulted in a significant decrease of oxidative and phosphorylating activities in the isolated mitochondria, while the respiration rate and energy activity in mitochondria of hardened seedlings subjected the cold shock, remained stable. Thus, the functional activity of mitochondria under the cold shock depends on the ROS content and is

© 2014 The Authors. FEBS Journal © 2014 FEBS

determined by the fatty acid composition, among which the α-linolenic acid plays an important role for the preservation of mitochondrial activity. The entire complex of the parameters (the contents of ROS and LP products, fatty acid composition and oxidative and phosphorylating activity of mitochondria) determines the development of properties of winter wheat cold and frost hardiness.

Keywords: fatty acid composition, mitochondria, reactive oxigen species.

TUE-403
Fatty acid composition of maternal blood and cord blood of women who delivered preterm babies, and full-term small for gestational age infants

R. Bobinski, M. Mikulska
Faculty of Health Sciences, University of Bielsko-Biala, Bielsko-Biala, Poland

Background & Aims: Fatty acids are required by the developing fetus as a source of energy, to maintain the fluidity, permeability and conformation of membranes and as precursors of many compounds which are necessary in structural and metabolic processes, especially in the central nervous system. The fatty acid composition of maternal blood and cord blood throughout the period of pregnancy is fairly well understood. What is not known, however, is the fatty acid composition of the above-mentioned biological fluids at the interface of physiology and pathology of pregnancy. We therefore decided to analyse and compare the differences in the FA profile of mothers who delivered small for gestational age neonates born at term and infants delivered at 35–37 weeks of gestation, that is "late preterm".

Subject/Methods: The study population was selected randomly. To obtain a homogeneous group of women, the following inclusion criteria were applied: Polish nationality (excluding naturalised Polish citizens); single pregnancy; pregnancy I-III; stable socioeconomic status; secondary or higher level of education; living in a highly industrialised urban region. Women who participated in the research program were classified into two groups according to the following criteria: Group PTB: mothers who gave birth prematurely – between 35–37 weeks (bw 10th–90th percentile). Group SGA: mothers who gave birth to full-term but small for gestational age (SGA) neonates (bw <10th percentile). The fatty acids were analysed by gas chromatography equipped with MS detector.

Results: Maternal peripheral blood contained higher levels of C18:3n6, C20:1, C22:0, C20:5n3 and C24:1 in group B. On analysis of the fatty acid profile of the cord blood, C10:0, C12:0, C14:0, C16:1c, C18:1c, C20:3n6, C20:4n6, C22:6n3 and ∑n6 differed statistically between the two groups. C18:1c, C22:6n3 and ∑n6 were higher in group C. Other fatty acids were more prominent in group B. $P \leq 0.05$.

Conclusion: In our research we have undertaken to determine the dynamics of changes in the fatty acid profile of maternal blood and cord blood of mothers who gave birth to babies at term but small for gestational age, and to infants born between 35 and 37 weeks of gestation. Our studies have shown that the fatty acid profiles of the studied biological materials differed. The FA profiles of both maternal blood and cord blood undergo changes in response to pregnancy duration and the presence of reduced fetal growth. The differences in the FA composition of these groups lead to the conclusion that both "late prematurity" and reduced neonatal weight of children born at term affect the FA composition of maternal and cord blood. Despite a slight degree of deviation groups B and C are not generic against each other.

Keywords: Fatty acids, low birth weight, preterm, SGA.

TUE-404
Features of metabolism of arginine and its derivatives in placenta

T. Pogorelova, **V. Gunko**, V. Linde, S. Selutina
Rostov Scientific-Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russian Federation

Background: An important problem of perinatal biochemistry is the detection of the functional role of amino acids and their derivatives in the provision of the normal development of placenta. One of the leading places among free amino acids is taken during gestation by arginine, which may be an essential amino acid for a fetus (especially under pathologic conditions) delivered to him from placenta – an intermedium between organisms of a mother and fetus. The role of arginine as a plastic, energy material as well as an independent signaling molecule determines negative consequences of the disturbance of its placental metabolism.

The aim of this research is the study of content of arginine, proline, nitric oxide (NO) and its derivatives as well as activity of arginase and NO-synthase in placenta of women in placental insufficiency (PI).

Methods: Full-term placentas were obtained after delivery from women with physiological pregnancy ($n = 25$) and PI ($n = 30$). Arginine and proline content in extracts of placental tissue was determined using an automatic analyzer. The activity of enzymes, content of NO metabolites, peroxynitrite and other nitro compounds were evaluated using kits.

Results: Arginine level and arginase activity in placenta in PI are rapidly reduced as compared with the control values. At the same time, the production of NO and NO-synthase activity under these conditions are reduced resulting in the change of the balance of vasoactive components and disturbance of the feto-placental blood circulation. In addition to modification of hemodynamic processes, deviations in arginine metabolism may be accompanied with structural changes in vascular connective tissue as a result of reduction of proline concentration (required for the synthesis of collagen). The interrelation between changes in the content of arginine and proline is confirmed by the direct correlation between them. Significant changes are also detected for NO derivatives: peroxynitrite, S-nitrosoglutathione and nitrotyrosine, the placental level of which increases in PI. Oxidative properties of these products increase the disturbance of placental homeostasis (especially in case of NO-protein modification).

Conclusion: The received results indicate an important role of disturbances of metabolism of arginine and its derivatives in the mechanisms of PI formation.

Keywords: arginine and its derivatives, placenta.

TUE-405
Fibroblast growth factor receptor 2 gene, tumor's hormone receptor status and breast cancer risk in Kazakhstan population

V. Nigmatova, A. Neupokoeva, A. Khanseitova, T. Balmukhanov, N. Aitkhozhina
Aitkhozhin Institute of Molecular Biology and Biochemistry, Almaty, Kazakhstan

Fibroblast growth factor receptor 2 (*FGFR2*) encodes a transmembrane tyrosine kinase receptor and its expression is increased in 5–10% cases of all breast tumors. Some SNPs in *FGFR2* gene have the clear relevance to breast cancer (BC) as was shown by GWAS. The associations described by GWAS are not universal for all word populations. Therefore three polymorphisms (rs2981582, rs17542768, rs17102287) of *FGFR2* gene were investigated in Kazakhstan population in this study. Multinational pop-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ulation of Kazakhstan totals 16.9 million with main ethnic groups presented Kazakhs (Asians) – 65.1% and Russians (Europeans) – 21.9% according to statistical data.

The case-control study of 615 BC cases (376 Kazakhs – 49.7 ± 11.2 years, 239 Russians – 51.6 ± 9.0 years) and 530 controls (283 Kazakhs – 49.2 ± 7.5 years, 247 Russians – 49.7 ± 7.5 years) was performed by PCR-RFLP. Estrogen receptor (ER+/ER-), progesterone receptor (PR+/PR-) and HER2 status were estimated in tumors. The informed consent was obtained from BC patients and donors. Pearson χ^2 p value (P) and Fisher's exact test p value (P_f), odds ratios (OR), 95% confidence intervals (CI) tests, dominant and recessive models were applied to data analysis.

The association of rs17542768 with BC was revealed in Russians. Significant difference was detected in allele distribution ($P=P_f=0.04$). The risk G allele has OR value 1.49 (95% CI=1.02–2.16) in Russians. No significant differences were registered in alleles and genotypes distributions at rs2981582, rs17102287 variants of *FGFR2* gene in Russian and Kazakh ethnic groups by dominant and recessive model analysis. All investigated groups were in Hardy-Weinberg equilibrium. Further we examined the association of genotypes and hormone status of BC patient's tumors. This part of analysis have revealed the statistically significant association of *FGFR2* rs17542768 polymorphism with BC in PR+/ER+/HER2- case subjects in the Kazakh ethnic group (P = 0.01 for alleles, P = 0.04 for genotypes, P_f=0.02 for both). The A allele of rs17542768 can be considered as a risk factor in ER+/PR+/HER2- Kazakh BC patients (OR=3.81; 95% CI=1.25–11.64). But these data should be clarified additionally to validate rs17542768 as the hormone related cancer risk factor in Kazakhs because of CI's wide range.

In conclusion, the effect of rs17542768 on risk BC is limited to PR+/ER+/HER2- tumors only in Kazakhs. The G allele of rs17542768 has association with BC without regard for tumors hormone status in Russians.

Keywords: FGFR2, hormone-related breast cancer, Kazakhstan population.

TUE-406
FT-IR spectroscopy in the search for specific metabolic biomarkers for the identification of micromycetes

E. Golovina, P. Nikitin, L. Panina, V. Stefanov
Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Introduction: Identification of micromycetes is time-consuming due to cultivation and microscopic examination of culture morphology and can be relatively expensive due to application of molecular techniques. Moreover, some of these micromycetes are dangerous, because fungal spores have been found to contain specific toxic and non-toxic metabolites which can lead to development of several diseases. Therefore, direct, accurate and robust detection of fungi and their specific metabolic biomarkers is very essential. Fourier-transform infrared (FT-IR) spectroscopy appears very promising as a perfect tool to detect and characterize the main components of such chemically very complex probes as micromycetes.

Purpose: The aim of this study was to find species-specific metabolic biomarkers of micromycetes using FT-IR spectroscopy. For this purpose, the chemical composition of spores from five species of micromycetes – *Pichia pastoris, Ulocladium chartarum, Saccharomyces cerevisiae, Trichoderma viride* and *Penicillium sp.* – was characterized.

Method: The infrared analysis was performed using Nicolet 8700 FT-IR spectrometer (Thermo Scientific). All the spectra were acquired in the range of 4000–400 cm^{-1} at a resolution of 4 cm^{-1} and analyzed using OriginLab 9 (OriginLab Corporation) and MatLab 7.12.0 (The MathWorks) software. This study was carried out in the Centre for optical and laser materials research of St. Petersburg State University.

Results: The FT-IR analysis enabled us to identify differences and similarities for all five fungal species in the spectral regions known to be characteristic for certain chemical structures and groups. All the examined fungi show the characteristic infrared absorbance of C-H region dominated by fatty acids (3050–2800 cm^{-1}), polypeptide bonds (amide I at 1600–1700 and amide II at 1540 cm^{-1}), and polysaccharide groups (1200–900 cm^{-1}). Another small band appears at 1587 cm^{-1}, possibly due to deacetylated chitin. Bands at 550–900 cm^{-1} region are typical for low-molecular-weight organic compounds. Of particular interest are regions 1200–1500 cm^{-1} and 1700–2700 cm^{-1} which are different for the examined micromycetes and can be considered as fingerprint regions for their identification. FT-IR profile of strong bands at these regions rules out the presence of short aliphatic structures and suggests the occurrence of acid and/or conjugated groups, compatible with fungal metabolites and other aromatic structures.

Conclusion: Our data suggest that FT-IR spectra display a fingerprint of micromycetes under study. As FT-IR spectroscopy is less time-consuming and less expensive method compared to microscopic and molecular techniques, it can be successfully applied for the routine identification of fungal species.

Keywords: FT-IR spectroscopy, Metabolism, Micromycetes.

TUE-407
Generation, release and uptake of the NAD precursor nicotinic acid riboside by human cells

A. Nikiforov[1,2], V. Livinskaya[2], K. Shabalin[2,3], K. Nerinovski[2], C. Doelle[4], M. Niere[4], M. Khodorkovskiy[2], M. Ziegler[4]
[1]*Institute of Cytology, Russian Academy of Sciences,* [2]*Institute of Nanobiotechnologies, St. Petersburg State Polytechnical University, St. Petersburg,* [3]*Petersburg Nuclear Physics Institute, NRC Kurchatov Institute, Gatchina, Russian Federation,* [4]*Department of Molecular Biology, University of Bergen, Bergen, Norway*

Nicotinamide adenine dinucleotide (NAD) is essential for cellular metabolism and has also a key role in a variety of central signaling pathways. It is used as substrate by several classes of enzymes including ADP-ribosyltransferases and protein deacetylases (Sirtuins) that control gene expression, progression of the cell cycle, DNA repair, cell death and aging. Given the considerable turnover, NAD must be permanently resynthesized. The vitamin B3 precursors for NAD biosynthesis in humans are nicotinamide (Nam) and nicotinic acid (NA) as well as their corresponding ribosides (NR and NAR). So far, little is known about the relationships between intra- and extracellular pools of NAD and its key metabolites in human cells. Our recent studies have established that all known NAD metabolites can serve as extracellular precursors of intracellular NAD. However, nucleotides are degraded to the ribosides NR or NAR, which then enter cells as NAD precursors.

In this work we observed that human cells convert NA to its riboside, NAR, which is subsequently released into the culture medium. HepG2 cells lack NAPRT activity (converting NA to the mononucleotide NAMN) and are therefore normally unable to utilize NA as NAD precursor. Transient transfection with a vector encoding NAPRT enables these cells to survive in the presence of NA as the single usable source for NAD synthesis. Surprisingly, transient expression of NAPRT rescued not only the transfected

© 2014 The Authors. FEBS Journal © 2014 FEBS

cells, but essentially all cells in the culture. Since NA could not be metabolized by the NAPRT-deficient cells, an alternative NAD precursor must have been produced and released by the transfected cells. NMR-based analyses of NAD metabolites in the culture medium revealed that the riboside NAR was released by the NAPRT-positive HepG2 cells. These results have important implications: Since NAPRT converts NA to the NAMN, an intracellular 5′-nucleotidase must have cleaved NAMN to generate the riboside, NAR. Moreover, the observed survival of untransfected cells suggests that, in the presence of sufficient amounts of a suitable precursor (such as NA for the transfected cells), human cells can produce and release riboside derivatives. Importantly, these ribosides are taken up by neighboring cells to support their NAD metabolism.

Aging is a multifactorial event resulting from the accumulation of cellular damage over time, which leads to physiological deterioration, increased mortality and eventual death. Primary human diploid fibroblasts (HDFs) undergo a limited number of cell divisions in culture and ten reach the replicative senescence. Senescent HDFs have some features such as cell cycle arrest, limited cell division, morphological change, increase of reactive oxygen species (ROS) levels and no response to mitogenic stimuli. Ginsenoside, a class of steroid glycosides and triterpene saponins, found primarily in the roots of *Panax ginseng*, has many remedial effects such as anti-inflammation and anti-tumor.

In this study, we examined the effects of ginsensodies 20(S)-Rg3 on the replicative senescence of HDFs. When the senescent HDFs were incubated with 20(S)-Rg3 for 48 h, the senescence associated-b-galactosidase (SA-b-gal) activity was dramatically decreased only in 20(S)-Rg3-treated HDFs. Moreover, 20(S)-Rg3 reduced ROS level and changed protein expression level of superoxide dismutase (SOD) in senescent HDFs. Western blot analysis demonstrated that 20(S)-Rg3 led to the inactivation of p53 and subsequently down-regulated the expression of $p21^{waf1/cip1}$ in senescent HDFs. In additions, 20(S)-Rg3 inhibited the phosphorylation of Akt/mTOR and AMPK whereas 20(S)-Rg3 improved expression of downstream effectors of mTORC1 such as eukaryotic initiation factor 4E-binding proteins (4E-BPs) and S6 kinase (S6K). On the other hand, 20(S)-Rg3 treated in HDFs influenced Sirtuins and GSK3β expression. Taken together with preliminary data, ginsenoside 20(S)-Rg3 suggests inducing the rejuvenation of senescent HDFs by scavenging ROS and restoring cellular senescence via enhanced cell cycle progression and modulated Akt/mTOR/AMPK signaling.

Keywords: ginsenoside Rg3, human dermal fibroblast, rejuvenation.

Globotriaosylceramide and globotriaosylsphingosine induce epithelial to mesenchymal transition in kidney cell lines

Y.-J. Jeon, N. Jung, H.-Y. Park, S.-C. Jung
EWHA Womans University, Seoul, Korea

Fabry disease is a lysosomal storage disorder caused by deficiency of α-galactosidase A (α-gal A), resulting in deposition of globotriaosylceramide (Gb3) in the vascular endothelium. Deacylated Gb3, globotriaosylsphingosine (lyso-Gb3), also accumulated and increased it plasma level in the patients with the Fabry disease. According to renal and cardiac pathological findings, fibrosis due to epithelial-to-mesenchymal transition (EMT) could be a possible pathogenic mechanism in Fabry disease. However, the association of EMT with Fabry disease has not been elucidated yet. Expression level of EMT markers such as E-cadherin, N-cadherin, β-catenin and α-SMA in mouse renal glomerular mesangial cell (SV40MES13) significantly increased when treated with Gb3. Whereas, in human proximal renal tubular epithelial cell (HK-2), expression of EMT markers were significantly altered when treated with lyso-Gb3 rather than treated with Gb3. Additionally, we observed that the activation of TGF-β, phospho-AKT, and PI3K were highly elevated in these cells. Also, inhibitor of the TGF-β signaling and recombinant α-galA have been shown to block EMT-like processes according to Gb3 or lyso-Gb3, and following knockdown of α-galA gene expression by siRNA, high TGF-β expression as well as high Gb3 expression were observed, suggesting that EMT was induced. Our study demonstrates that Gb3 and lyso-Gb3 can potentiate EMT-like processes through AKT/PI3K signaling pathway in kidney mesangial cell and tubular epithelial cell, respectively. Moreover, these findings suggest that not only accumulated Gb3 but also plasma lyso-Gb3 might be a crucial role for nephropathy of Fabry disease by inducing EMT and may contribute to a better understanding of the renal fibrosis.

Keywords: epithelial-to-mesenchymal transition (EMT), Fabry disease, lyso-Gb3.

TUE-411
Glucose concentration is distinctive for *Escherichia coli* hydrogenase 4 (hyf) activity

K. Trchounian[1], A. Trchounian[2]
[1]Biophysics, [2]Microbiology, Plants & Microbes Biotechnology, Yerevan State University, Yerevan, Armenia

Escherichia coli produces molecular hydrogen (H_2) during sugars (glucose), glycerol or other carbon sources fermentation [1]. This production of H_2 occurs via special enzymes namely hydrogenases (Hyd) which reversibly oxidize H_2 to $2H^+$. *E. coli* is able to encode four membrane-bound [Ni-Fe]-hydrogenases [1]. Hyd-1 (*hya*) and Hyd-2 (*hyb*) are reversible enzymes which can operate in different mode depending on carbon source: during glucose or glycerol fermentation they operate in H_2 uptake or producing mode, respectively [2]. Hyd-3 (*hyc)* and Hyd-4 (*hyf*) are H_2 producing enzymes upon glucose fermentation but these enzymes operate in reverse mode during glycerol fermentation [3]. Dependence of Hyd-4 H_2 producing activity (V_{H2}) on glucose concentration at different pHs was studied.

During growth on 0.2% glucose at pH 7.5 in Hyd-4 defective mutants *hyfA-B* and *hyfB-R* V_{H2} was decreased ~6.7 and ~5 fold, respectively, compared to wild type. Only in *hyfB-R* mutant at pH 6.5 and 5.5 V_{H2} was severely decreased ~7.8 and ~3.8 fold, respectively. But surprisingly when cells were grown on 0.8% glucose no any difference between wild type and mutant strains were

© 2014 The Authors. FEBS Journal © 2014 FEBS

detected at different pHs. Inhibitory effect of glucose on Hyd-4 activity was shown when cells were grown on 0.8% glucose. Taken together these results indicate that *E. coli* Hyd-4 H_2 producing activity is inhibited by high concentration glucose mainly at pH 7.5.

Glutathione biosynthesis in a cold-adapted microorganism

D. Desiderio[1], A. Albino[2], A. De Angelis[1], S. Marco[2], R. Rullo[3], G. Raimo[1], M. Masullo[4], E. De Vendittis[2]
[1]DBT, University of Molise, Pesche (IS), [2]DMMBM, University of Naples Federico II, [3]ISPAAM, CNR, [4]DSMB, University of Naples "Parthenope", Naples, Italy

Glutathione (GSH) is a powerful regulator of the physiological redox environment in eukaryotes and prokaryotes. Its antioxidant action, including defence against oxidative damages, detoxification of foreign compounds and toxic metals, preservation of reduced state of protein sulfhydryls, is involved in several cellular pathways. The mechanism of redox homeostasis is mainly based on the intracellular balance between GSH and its oxidised form, GSSG. Biosynthesis of GSH occurs with a mechanism conserved throughout prokaryotes and eukaryotes and involves two sequential steps, both coupled to ATP hydrolysis. The first step, catalysed by g-glutamyl-cysteine ligase (GshA), leads to the formation of g-glutamylcysteine and the second one, producing GSH, is catalysed by glutathione synthetase (GshB).

GSH has a more crucial role in microorganisms exposed to oxidative stress conditions, such as the psychrophile *Pseudoalteromonas haloplanktis* isolated from the Antarctic sea. To characterize the enzyme system for GSH biosynthesis in the first cold-adapted microorganism, recombinant forms of GshA and GshB from *P. haloplanktis* (r*Ph*GshA II and r*Ph*GshB, respectively) were produced and characterized (Albino et al. *Mol BioSys* 8, 2012, 2405–2414; *Biochimie*, in press). The investigation covered the study of the substrate specificity of both enzymes, setting up the best ionic and pH conditions for triggering their activities, determination of K_m values for all substrates of the catalysed reactions. Both enzymes were already active at 15°C, as required for their cold adaptation. Interestingly and differently from what observed in eukaryotic systems, the reaction rate of r*Ph*GshA II was higher than that reported for r*Ph*GshB, thus suggesting that formation of g-glutamylcysteine was not the rate limiting step of GSH biosynthesis in *P. haloplanktis*. The inhibitory effect of GSH and GSSG on glutathione synthesis was investigated. Indeed, GSH acted as a non-competitive inhibitor of r*Ph*GshA II and GSSG caused the mono-glutathionylation of the enzyme on the target residue Cys 386; vice versa, GSSG acted as an irreversible inhibitor of r*Ph*GshB, forming a disulfide adduct with the enzyme. When compared to r*Ph*GshB, r*Ph*GshA II possessed more typical features of a psychrophilic enzyme, as it was endowed with lower thermodependence and higher heat sensitivity. Curiously and differently from other prokaryotes, *P. haloplanktis* harbors another redundant g-glutamyl-cysteine ligase (*Ph*GshA I), whose characterization is in progress.

Keywords: cold-active enzymes, Glutathione biosynthesis, Pseudoalteromonas haloplanktis.

TUE-413
Heat shock protein 72 protects against lipid-induced insulin resistance via upregulation of AMPK in skeletal muscle

K. Kolczynska, K. Hanzelka, A. Gajda, A. Dobrzyn
Laboratory of Cell Signaling and Metabolic Disorders, Nencki Institute of Experimental Biology, PAS, Warsaw, Poland

Heat shock protein 72 (Hsp72) is known to protect against obesity-induced insulin resistance, a condition in which cells fail to respond to insulin. Insulin resistance is associated with many health related complications, including type 2 diabetes and heart disease. It is also known that expression of Hsp72 in human skeletal muscle is positively correlated with insulin sensitivity but the underlying molecular mechanisms are not well understood. Therefore, the aim of this study was to investigate the molecular mechanisms involved in Hsp72-associated regulation of insulin sensitivity in skeletal muscle. Herein we show that overexpression of Hsp72 decreases both palmitic acid- (16:0) and C2 ceramide-induced insulin resistance in C2C12 cells. Additionally, C2C12 cells overexpressing Hsp72 are characterized by decreased lipid content and increased phosphorylation of 5′AMP-activated protein kinase (AMPK), as well as acetyl-coA carboxylase (ACC), its downstream target. Inhibition of AMPK with compound C attenuated the Hsp72-induced improvement in insulin sensitivity in C2C12 myotubes. We also observed that overexpression of Hsp72 with an inactive ATPase domain does not affect insulin sensitivity in C2C12 myotubes. Moreover, the phosphorylation of AMPK was significantly decreased in these cells. Overall, this study showed that overexpression of Hsp72 decreases lipid accumulation and improves insulin sensitivity *via* upregulation of AMPK pathway in C2C12 cells. Furthermore, active ATPase domain in Hsp72 is required to increase insulin sensitivity and AMPK phosphorylation in myotubes.

Hemorphins regulate the activity of nuclear factor-kappa B (NFκB)/p65 in streptozotocin-induced diabetic rats

F. Sarukhanyan, N. Barkhudaryan
H. Buniatian Institute of Biochemistry Nas Ra, Yerevan, Armenia

In the present work we have studied the effect of hemorphins (hemorphin-7 and LVVYPW) on expression level of NFκB transcription factor in the brain of streptozotocin (STZ)-induced diabetic rats. Recently, we have demonstrated the antidiabetic effect of LVVYPW in pathophysiology of streptozotocin (STZ)-induced diabetes. It has also been revealed that the regulatory influence of hemorphins in pathophysiology takes place on transcriptional level. Determination of NFκB/p65 in brain tissue lysates was performed using rat NFκB/p65 ActivELISA Kit (Imgenex Corpora-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tion, San Diego, CA, USA) according to manufacturer's recommendations. The intraperitoneal injections of LVVYPW and hemorphin-7 (1 mg/kg) into fasting STZ-induced diabetic rats (male, Wistar line, 180–220 g) significantly decrease the expression level of NFκB/p65, increased in nuclear fraction of brain tissue of STZ-induced diabetic rats. In contrast, the significant increase in expression level of NFκB/p65 was found in the brain tissue cytoplasmic fraction, obtained from hemorphin-treated diabetic rats. It should be noted that we didn't observed such an increase in NFκB/p65 expression level in the brain tissue cytoplasmic fraction of rats, which didn't received hemorphin treatment.

Recently, we have demonstrated the involvement of Ca^{2+}/calmodulin/calcineurin signaling pathway in the molecular mechanisms of antidiabetic effect of LVVYPW. Calcineurin was reported to regulate the activity of NFκB by affecting the phosphorylation of IκBs (nuclear factor κB inhibitors). Earlier it has also been reported the involvement of calcineurin/NFκB pathway in pathophysiology of diabetes. Thus, data obtained indicate that hemorphins, by modulation of Ca^{2+}/calmodulin/calcineurin signaling pathway, are able to regulate the activity of NFκB in pathophysiology of diabetes. It should be emphasized that one of the molecular mechanisms of antidiabetic effect of famous antidiabetic drug metformin is inhibition of nuclear translocation of NFκB as well.

Hepatic mitochondrial content in malondialdehyde may be a marker of sea lamprey contact with atrazine

M. Candeias[1,2], I. Alves-Pereira[1,2], M. J. Lança[1,3], P. R. Almeida[4,5], A. F. Ferreira[5], B. Quintella[5,6], R. Ferreira[1,2]

[1]*Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Universidade de Évora,* [2]*Departamento de Química,* [3]*Departamento de Zootecnia,* [4]*Departamento de Biologia, Escola de Ciências e Tecnologia, Universidade de Évora, Évora,* [5]*Centro de Oceanografia,* [6]*Departamento de Biologia Animal, Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal*

The atrazine attracts special attention as pollutant because of its persistence in the aquatic environment. Although this herbicide has been studied in teleost, its toxicity in the sea lamprey, *Petromyzon marinus* is still poorly understood. Oxidative stress may occur if chemical pollutants contribute to block the capacity of mitochondria to generate ATP with continuous production of reactive oxygen species (ROS), disturbing the success of *P. marinus* seawater acclimation. So, the aim of this study was to evaluate how atrazine influences the malondialdehyde (MDA), glutathione (GSH) and glutathione disulfide (GSSG) contents of gills and liver mitochondria of juveniles from Lima river basin, Portugal during salt acclimation. Sampling occurred at the beginning of the *P. marinus* downstream migration. The sampled juveniles were transported alive to the laboratory and maintained in 200 l tanks with LSS 8life support system. Two groups of 40 specimens were hold in tanks with 50 or 100 μg/l atrazine, during 30 days. The salinity was gradually increased from 0 to 35 psu, following a three step procedure during a 30 days period. The control group was maintained in freshwater without atrazine. Mitochondria obtained by centrifugation at 15000 *g*, 30 min, 4°C, of tissues homogenates prepared in 50 mM Tris-HCl pH 7.5 buffer were used in determination of ROS, MDA, GSH and GSSG by fluorescence. The statistical analysis were performed by ANOVA I and Duncan ($p < 0.05$), using SPSS 22 for Windows. The results showed that in *P. marinus* juveniles, no significant changes in the markers of oxidative stress and cell damages were detected in the mitochondrial gills. Nevertheless, in the animals exposed to 50 μg/l atrazine the content in glutathione and GSSG increased. A similar pattern of stress markers was detected in hepatic mitochondria. However, in the presence of atrazine, the MDA level of the mitochondria of liver increased threefold in the animals during salt acclimation. The high level of mitochondrial damages, detected in the hepatic mitochondria of macrophthalmia treated with atrazine, suggests that herbicide exposure caused metabolic failures which can disturb the adaptation of these specimens to the oceanic feeding phase. The hepatic mitochondrial MDA levels of *P. marinus*, may eventually detect sea lamprey contact with chlorine herbicides.

Hepatocyte-specific knockout of Cyp51 from cholesterol synthesis results in sex-specific metabolic adaptations and liver pathologies

D. Rozman[1], G. Lorbek[1], M. Perše[2], J. Jeruc[2], P. Juvan[1], S. Horvat[3]

Cholesterol is a key molecule in mammals serving as a major component of cell membranes and a precursor of various signaling molecules. The most striking examples of cholesterol deficiency are the inborn errors of cholesterol biosynthesis that, when compatible with life, manifest with severe whole body phenotypes. Surprisingly, liver as the principal site of cholesterol homeostasis has rarely been investigated in these pathologies. We focus on the hepatocyte-specific deletion of lanosterol 14α-demethylase (CYP51) catalyzing the rate-limiting step in the post-squalene part of cholesterol synthesis. The hepatic loss of *Cyp51*

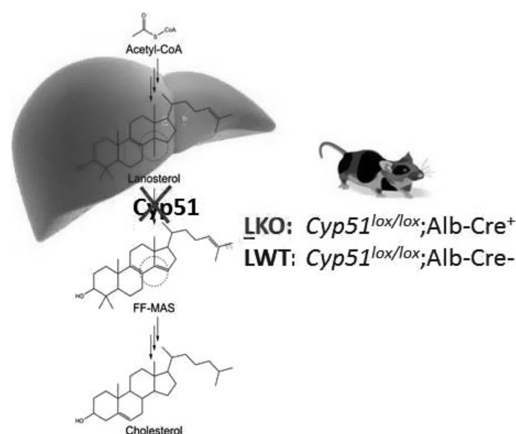

Fig. 1. Hepatocyte-specific ablation of Cyp51 from the cholesterol synthesis pathway leads to accumulation of immediate substrates lanosterol and 24,25 dihydrolanosterol and diminished hepatic cholesterol production.

© 2014 The Authors. FEBS Journal © 2014 FEBS

in mice causes sex-specific whole body effects with prominent hepatomegaly and hepatic ductular reaction with bridging periportal fibrosis and inflammation, but without steatosis. Accumulation of lanosterol and 24,25-dihydrolanosterol and a depletion of cholesterol esters in the liver could represent the underlying mechanistic events. Transcriptome analysis further suggested hepatocyte senescence and identified a female-specific down-regulation of peroxisome proliferation, fatty- and amino acid metabolism that probably fuel a stronger ductular reaction than in the males. The addition of dietary fats improved liver injury in the females, whereas the addition of fat and cholesterol rescued the phenotype in both sexes. *Conclusion:*

The hepatic loss of *Cyp51* in mice causes hepatic accumulation of CYP51 substrates and lack of cholesterol esters that affected the liver lipid homeostasis and extended to the entire body. The liver-specific *Cyp51* knockout mice represent a new model to study cholesterol-associated liver pathologies in the context of sex and diet. The model shows unequivocally that the disrupted post-lanosterol cholesterol synthesis represents another risk factor for liver pathologies.

Hexokinase IV and its regulatory protein in the hypothalamus

M. Garcia-Robles[1], M. Salgado[1], E. Tarifeño[1], P. Ordenes[1], M. Villagra[1], R. Elizondo-Vega[1], A. Uribe[2]

[1]Cell Biology, [2]Biochemistry, Concepcion University, Concepcion, Chile

Glucokinase (GK), the hexokinase involved in glucose sensing in pancreatic β cells, is also expressed in hypothalamic tanycytes, which cover the ventricular walls of the basal hypothalamus and are implicated in an indirect control of neuronal activity by glucose. Previously, we demonstrated that GK was preferentially localized in tanycyte nuclei in euglycemic rats, which has been reported in hepatocytes and is suggestive of the presence of the GK regulatory protein, GKRP. In the present study, GK intracellular localization in hypothalamic and hepatic tissues of the same rats under several glycemic conditions was compared using confocal microscopy and Western blot analysis. In the hypothalamus, increased GK nuclear localization was observed in hyperglycemic conditions; however, it was primarily localized in the cytoplasm in hepatic tissue under the same conditions. Both GK and GKRP were next cloned from primary cultures of tanycytes. Expression of GK by *Escherichia coli* revealed a functional cooperative protein with a $S_{0.5}$ of 10 mM. GKRP, expressed in *Saccharomyces cerevisiae*, inhibited GK activity *in vitro* with a K_i 0.2 mM. We also demonstrated increased nuclear reactivity of both GK and GKRP in response to high glucose concentrations in tanycyte cultures. These data were confirmed using Western blot analysis of nuclear extracts. Results indicate that GK undergoes short-term regulation by nuclear compartmentalization. Thus, in tanycytes, GK can act as a molecular switch to arrest cellular responses to increased glucose.

TUE-418
Hierarchical classification of glycoside hydrolases

D. G. Naumoff

Winogradsky Institute of Microbiology, Russian Academy of Sciences, Moscow, Russian Federation

Glycoside hydrolases or glycosidases (EC 3.2.1) are a widespread group of enzymes hydrolyzing various carbohydrates and glycoconjugates. They are represented in almost all living organisms. Their catalytic domains are grouped into 133 sequence-based families in the CAZy database (http://www.cazy.org/): GH1–GH133. 52 of these families compose 14 clans (GH-A–GH-N) at a higher hierarchical level. Enzymes of the same clan have common evolutionary origin of their genes and share the most important functional characteristics: composition of the active center, anomeric configuration of the hydrolyzed glycosidic bond, and molecular mechanism of the catalyzed reaction (either inverting, or retaining). The subfamily level of the classification exists only for GH5, GH13, and GH30 families in the CAZy database. However, extensive data on relationship between glycosidase families belonging to different clans and/or non-included into any clans are available in the literature, as well as information on phylogenetic protein relationship within particular families. Based on this information and on our complementary data we propose a multilevel hierarchical classification of glycosidases and their homologues.

According to the SCOP database, the catalytic domains of almost all families of glycoside hydrolases have one of six basic folds: β/α-barrel, β-propeller, β-jelly roll, α/α-barrel, β-solenoid, and lysozyme-type. Extensive comparative analysis of the primary and tertiary protein structures suggests the common evolutionary origin of essentially all glycosidase domains having the same type of the three-dimensional structure. This fact allows us to classify glycoside hydrolases into six main primary groups based on homology of their catalytic domains. Grouping of glycoside hydrolase families into clans at the Pfam database suggests the subsequent level in the hierarchical classification of glycosidases. Clans from the CAZy database represent a lower level, combining together the closest families. Useful information about homology-based grouping of glycosidases can be obtained from many other on-line protein classifications, including COG, KOG, PANTHER, and Génolevures. Intrafamily phylogenetic analysis of proteins suggests the lowest classification level – the subfamily level. Iterative screening of the protein database by PSI-BLAST program results in finding of interfamily relationships and, in some cases, allows to distinguish additional intermediate level(s) in the classification. Evolutionary connections of glycosidase families with other families, including families of functionally uncharacterized domains (for example, GHL1–GHL50, FURAN1–FURAN39, COG1306, COG1649, COG2342, PF11790), also can be traced by the iterative screening of the database. The obtained results allow to extend the hierarchical classification of glycoside hydrolases on their homologues.

Keywords: CAZy database, protein classification, protein evolution.

High-pressure and functional studies of glyoxylate-hydroxypyruvate reductases from different Thermococcal species indicate clue to understanding the energy metabolism of deep sea Archaea

L. Lassalle[1], S. Engilberge[1], A.-C. Dhaussy[2], B. Franzetti[1], E. Girard[1]
[1]ELMA, Institut de Biologie Structurale, Grenoble, [2]CRISMAT, ENSICAEN, Caen, France

The thermococcales representent a large part of the archaea associated with deep-sea hydrothermal vents. Previously, the archaeal glyoxylate-hydroxypyruvate reductases (GRHPR) were described as glyoxylate reductases [1]. This assignment is not consistent with the metabolic pathway of thermococcales. To specify the functional identity of this important metabolic enzyme we determined its specific activities and enzymatic parameters. For this, we cloned and expressed in E. coli of various purified recombinant GRHPR enzymes arizing from from *P.furiosus*, *P.horikoshii* and *P.yayanosii*. After purification to homogeneity, we determined their respective specific activities and enzymatic parameters, by using different substrate-cofactors combinations. The results showed unambiguously that, at atmospheric pressure, the GRHPR from Pyrococcus species are in fact NADH-dependent hydroxypyruvate reductases. Together with a survey of the presence/absence of the GRHPR enzyme in the archaeal genomes, this study allowed to place HPR enzyme in the metabolism of *Pyrococcus*. Based on this study, a model for the metabolism of thermococcales species will be presented.

The discovery of obligate piezo-hyperthermophilic archaeon such as *Pyrococcus yayanosii* suggests the existence of specific metabolic or structural adaptations with respect to high pressure [2]. We examined whether or not high-pressure conditions could influence GRHPR activity as well as their substrate specificity or NADPH/NADH requirement. Since *P.furiosus*, *P.horikoshii* and *P.yayanosii*, were isolated at different depth and display different pressure optima for their cultivation, we characterized the HPR enzymatic properties at different pressures. This work revealed a modulation of the HPR activities by high pressure. Interestingly, the behavior of HPR enzymes under pressure is modulated by the substrates and the cofactors and we showed that NADPH tends to protect the enzymes from high-pressure inhibition. In order to understand the molecular basis of this pressure the X-ray structures of PfuGRHPR and PyaGRHPR were solved and compared. High pressure X ray crystallography was also employed to study the effect of high pressure on the HPR active sites and quaternary structures. These analyses will be presented and discussed.

Human carbamoyl phosphate synthetase: structure, function and pathology

V. Rubio[1,2], S. De Cima[1,2], L. M. Polo[1], C. Díez-Fernández[1,3], J. Cervera[2,3], I. Fita[4]
[1]Instituto de Biomedicina de Valencia (CSIC), [2]Group 739, Centro de Investigación Biomédica en Red para Enfermedades Raras (CIBERER-ISCIIII), [3]Centro de Investigación Príncipe Felipe, Valencia, [4]Instituto de Biología Molecular de Barcelona (CSIC), Barcelona, Spain

Carbamoyl phosphate synthesis from bicarbonate, ammonia and two molecules of ATP, catalyzed by carbamoyl phosphate synthetase 1 (CPS1), is the first step of of the urea cycle, which detoxifies the ammonia produced in protein catabolism. CPS1, a large (1462-residue) multidomain protein having two ATP-binding phosphorylation sites, is very abundant in liver mitochondria (20% of the matrix protein), and is inactive in the absence of the allosteric activator N-acetyl-L-glutamate (NAG). CPS1 deficiency (CPS1D) is an inborn error causing hyperammonemia leading to death or mental retardation. The report of CPS1 regulation by multiple lysine acylation and by deacylation by sirtuin 5 connected the urea cycle with the age-control machinery (Nakagawa et al. Cell 2009; 137:560). The only structure known for a CPS was that of the *Escherichia coli* enzyme, which only has 40% sequence identity with CPS1 and differs from it in key traits such as the use of glutamine instead of ammonia as preferred sub-

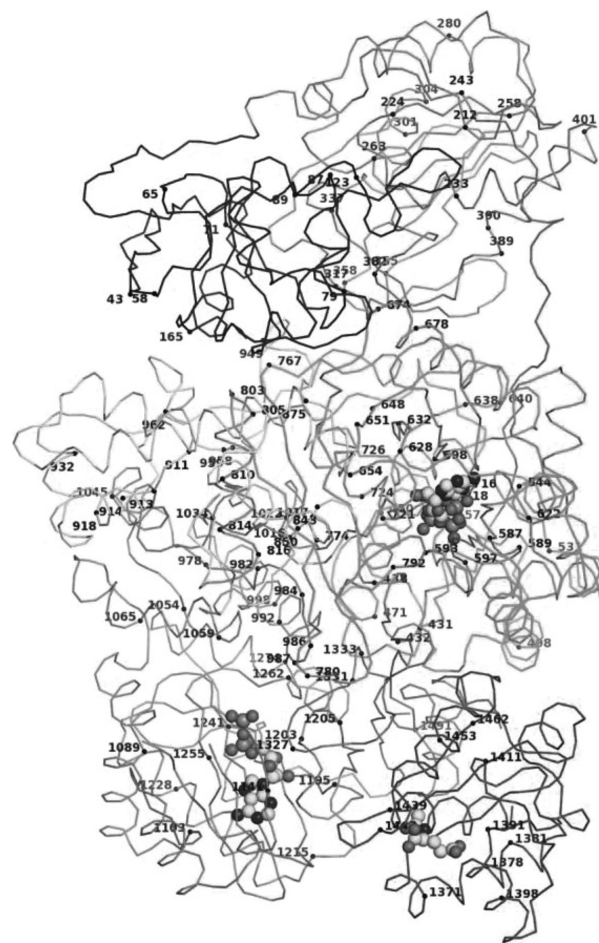

Fig. 1. Structure of active human CPS1 with spheres and residue numbers marking clinical mutations.

© 2014 The Authors. FEBS Journal © 2014 FEBS

strate (CPS1 cannot use glutamine), its insensitivity to NAG, and for being active in the absence of effectors. Thus, determination of the CPS1 structure appeared essential for understanding CPS1 function and its control by the NAG switch (an extreme case of allosteric activation) and by acylation, and to judge about the pathogenicity of the >130 CPS1 missense mutations reported in CPS1 deficiency. Exploiting our recent baculovirus/insect cell system for recombinant human CPS1 production (Diez-Fernández et al., Hum Mutat. 2013; 34:1149–59), we have crystallized the human enzyme and determined its X-ray structure at up to 2.4 Å-resolution, in apo and ligand-bound (NAG and ADP/Pi) forms. The liganded structure revealed how does NAG bind in a pocket of the C-terminal domain and has identified elements that are stabilized by ADP binding, as well as conformational changes induced by NAG and ADP binding that lead to define the carbamate tunnel, which in the apo form is heavily branched and open to the environment. Our structures decipher the CPS1 inability to use glutamine and reveal a potential channel for ammonia intake. Furthermore, they help rationalize the disease-causing role of most clinical CPS1 mutations. *Supported by Fundación Alicia Koplowitz and Valencian (Prometeo 2009/051) and Spanish (BFU2011-30407; FPU to CD-F) governments.*

Hypothalamic stearoyl-CoA desaturase-2 (SCD2) controls whole body energy expenditure

R. F. Moura[1], L. F. Nascimento[1], L. M. Ignacio-Souza[1], D. S. Razolli[1], J. Morari[1], C. Solon[1], G. F. P. Souza[1], W. T. Festuccia[2], L. A. Velloso[1]
[1]University of Campinas, Campinas, [2]University of São Paulo, São Paulo, Brazil

Stearoyl-CoA desaturase 2 (SCD2) is the main δ9 desaturase expressed in the central nervous system. Knockout SCD mice unveil a tissue-specific role of this gene on obesity. However, hypothalamic SCD role on obesity has not yet been addressed. Because of its potential involvement in the control of whole body adiposity, we evaluated the expression and function of SCD2 in the hypothalamus of mice. The levels of SCD2 in the hypothalamus are similar to other regions of the central nervous system and are approximately ten-fold higher than in any other region of the body. In the arcuate nucleus, SCD2 is expressed in POMC and AgRP neurons. Upon eight weeks on high fat feeding the levels of hypothalamic SCD2 are increased in mice. Inhibition of hypothalamic SCD2 by two distinct approaches, antisense oligonucleotide and a short hairpin RNA delivered by a lentivirus directly in the arcuate nucleus, resulted in the reduction of body mass gain in control and in diet-induced obese mice mostly due to increased energy expenditure and increased spontaneous activity. Increasing hypothalamic SCD2 by a lentiviral approach resulted in no change in body mass and food intake. Thus, SCD2 is highly expressed in the hypothalamus of rodents and its knockdown reduces body mass due to increased whole body energy expenditure.

TUE-422
Identification of a haloacid inducible regulation of transcription of a glycolate operon in a *Burkholderia caribensis*

N. Zheng
School of Biological Sciences, The university of Hong Kong, Hong Kong, China

Burkholderia caribensis MBA4 was able to utilize toxic haloacids as the carbon and energy sources. Monochloroacetate (MCA) is one of them. Genes of an inducible dehalogenase (Deh4a) and a haloacid transporter (Deh4p) were found arranged in a transcript. They were involved in dehalogenation and uptake processes, respectively.

Glycolate is a metabolite of MCA which was transformed by Deh4a. Glyoxylate was produced from oxidation of glycolate by glycolate oxidase. Three glycolate oxidases were found in *Burkholderia* species MBA4: ETY79679-81, ETY80271-3 and ETY25123, ETY84258-59. Reads per kilobase transcript per million (RPKM) of the analysis of RNA-seq technology indicated that ETY79679-81 was produced at a level of around 100 regardless of the carbon sources: pyruvate, glycolate or MCA. It seems that the production of ETY79679-81was not affected by any of the substrates. The RPKM values of ETY80271-3 were 7 in pyruvate-, 867 in chloroacetate- and 1260 in glycolate-grown cells. This is quite conventional, as expression of glycolate oxidase of model microorganism, such as *Escherichia coli* K-12, was induced by its substrate: glycolate.

Most interestingly, ETY25123 and ETY84258-59 showed its highest value (1880) in chloroacetate- grown cells which was 10 folds of that in glycolate-grown cells (178), and around 100-fold in pyruvate- grown cells (20). A malate synthase G gene, ETY84261, situated downstream of ETY25123 and ETY84258-59 gave similar response as that of ETY25123 and ETY84258-59. It is envisaged that ETY84261 and ETY25123 and ETY84258-59 were expressed in a single transcript. Putative regulator GlcC genes, ETY80275 and ETY84257 were found, located upstream of ETY80271-3, and ETY25123, ETY84258-59 andETY84261, respectively. ETY84257 was found to express more in chloroacetate-grown cells, respectively. The behaviors of the regulators were possibly different. With the differential expression, ETY84257, it is further characterized to have a complete picture of the regulatory mechanism of this glycolate operon.

Keywords: glycolate operon, regulation, monochloroacetate.

TUE-423
Identification of the main regulatory factors involved in the protective role of thiamine in baker's yeast *Saccharomyces cerevisiae* under stress conditions

N. Wolak, A. Kozik, M. Rapala-Kozik
Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Thiamine (vitamin B_1) is an essential compound for all living organisms, mainly owing to the cofactor role of thiamine diphosphate in the central cellular metabolism. From numerous recent studies a hypothesis has emerged that thiamine, at least partly independently from the cofactor role, functions as a protectant against stress factors, e.g., by affecting the overall cell viability, the expression of antioxidant enzymes and the generation of reactive oxygen/nitrogen species under cellular stress conditions. Depending on the type of stress, the expression changes were more profound in different subcellular compartments, suggesting

© 2014 The Authors. FEBS Journal © 2014 FEBS

the involvement of various regulatory pathways. Hence, the current study was undertaken to identify the regulatory proteins related to the protective functions of thiamine in baker's yeast exposed to the oxidative and osmotic stress factors, i.e., 1 mM hydrogen peroxide and 1 M sorbitol, respectively.

Two main regulatory pathways associated with stress responses in baker's yeast depend on the Hog1 and Yap1 proteins. In order to test whether they could be involved in the observed protective thiamine action, two mutated strains, *hog1Δ* and *yap1Δ*, were studied. As expected, both regulatory proteins seemed to affect the stress responses, with Hog1 being predominant under osmotic stress and Yap1 under oxidative stress. Both mutated strains showed an elevated accumulation of thiamine (up to 220%) and deregulated expression of several stress markers, as compared to the wild type strain.

Further analyses aimed at the identification of transcription factors, possibly involved in the observed effects. Searching through the promoter regions of selected thiamine-associated genes using the YEASTRACT database revealed several candidates, mainly Msn2, Skn7, Sko1, Hsf1, Gis1 and Stb5. The analysis of mutated strains showed that one of them, *stb5Δ*, was severely impaired when grown without thiamine. Moreover, it was the only mutant that in the presence of thiamine and under oxidative stress was not found to downregulate common stress markers such as superoxide dismutase (*SOD2*) and glycerol dehydrogenase (*GPD1*). Some other connections to the thiamine functions under stress conditions could also be suggested for *msn2Δ* and *skn7Δ* strains.

Taken together, the current study has presented a novel insight into the contribution of thiamine to the stress responses, pointing for the first time at the possible regulatory proteins, involved in these effects in *S. cerevisiae*.

TUE-424
Impacts of toxic metals on glutathione *S*-transferase activities and glutathione and protein levels in selected barley varieties

E. Oztetik
Biology, Anadolu University, Eskisehir, Turkey

Accumulation of heavy metals (HM) in soils has an important impact on the health of animals and humans via food chains. Either directly or indirectly, HM cause oxidative damage in plants through reactive oxygen species (ROS) formation. However, cells can detoxify the harmful effects of ROS with the help of enzymatic or nonenzymatic antioxidant defense mechanisms. Of those, glutathione *S*-transferases (GST) are a diverse group of enzymes catalyzing the conjugation of electrophilic xenobiotic substrates with the tripeptide glutathione (GSH) and found to be present from early embryogenesis to senescence in different plant tissues. On the other hand, GSH is considered as one of the most important metabolite for intracellular defense against ROS induced oxidative damage. It is also important for regulation of sulfate transport, signal transduction and detoxification of xenobiotics through GSTs. In this study, the effects of different concentrations of $CdCl_2$ and $PbCl_2$ treatments on contents of GSH, protein and GST activities in the roots and shoots of *Hordeum vulgare* L. cultivars cv. Bilgi-91 and cv. Kalayci-97 were assessed in hydroponic solutions. The application of HMs to plants caused an increase in protein contents by comparing to their control groups. While the increase in shoots were higher than in the roots of Bilgi-91, protein contents were increased more in roots of Kalayci-97. In GSH concentration measurements, the shoots of Bilgi-91 has shown a dose dependent manner with Cd treatment. However, the dose dependent characteristic was observed with Pb for their roots and 538% increase was noted as the highest increase in GSH levels by comparing to controls. On the other hand, Kalayci-97 shoots and roots have shown the highest GSH concentration with Pb treatment. As a result of GST activity measurements, the highest activities were observed in both plants shoots with 300 μM Cd treatment (123 and 166% of control for Bilgi-91 and Kalayci-97, respectively) and in roots with 150 μM Pb treatment (282 and 291% of control, respectively). Our results indicate that, depending on the plant origin, plant parts, HM used and treatment conditions, HMs had an effect on the parameters measured. The variable results which observed in GST activities and GSH contents are reflecting a difference in the rate of metabolism with regard to HMs between varieties. However, the presence of high GST activities and GSH contents have shown a general adaptability to stress conditions.

TUE-425
Impairment of glycogen metabolism by thiocarbamates pesticides through inhibition of brain glycogen phosphorylase

C. Mathieu, L. C. Bui, J.-M. Dupret, F. Rodrigues-Lima
Univ Paris Diderot, Sorbonne Paris Cité, BFA unit CNRS UMR8251, 75205 cedex 13, Paris, France

Glycogen (Gln) is a glucose polymer found primarily in liver, muscles and brain where it represents the main storage-form of glucose. In brain, Gln is mainly found in astrocytes and appears to be critical for certain neurological processes such as learning and long term memory consolidation. Brain glycogen phosphorylase (bGP) is the key enzyme involved in mobilization of Gln. This enzyme is thighly regulated by both phosphorylation and binding of allosteric effectors.

Dithiocarbamates (DTC) are organosulfur compounds widely used as fungicide. These chemicals are known to be neurotoxic and have been linked to Parkinson's disease. Interestingly, recent data have shown that Gln metabolism in brain could be altered by DTC.

In order to better understand the molecular and cellular mechanisms of neurotoxicity linked to DTC, we studied the impact of a panel of known DTC on human recombinant bGP. Thiram (TH) was found to be the most potent inhibitor of bGP. Chemical-labelling, electrophoretic and mass spectrometry analyses showed that inhibition of purified bGP by TH occured through modification of critical cysteines residue and formation of intramolecular disulfide bonds. A sulfoxide-metabolite of TH (DEDTC-sulfoxide) was also found to inhibit bGP through modification of cysteine residues. In agreement with these data, exposure of a human astrocyte cell line to TH led to the inhibition of endogenous bGP with concomitant impairment of glycogen mobilization in treated cells.

Altogether our data indicate that certain DTC inhibit the glycogenolytic activity of bGP through the modification of key cysteine residues with subsequent impairment of Gln catabolism. This may lead to altered energy metabolism or toxic accumulation of Gln in astrocytes. More broadly, owing to the important role of Gln in neurological processes, impairment of bGP functions in brain could contribute to the neurotoxic effects of DTC.

Keywords: Glycogen phosphorylase, Parkinson's disease, Thiram.

TUE-426
In vivo adenovirus-mediated inhibition of MCT1 and MCT4 in tanycytes affects the brain glucose sensing mechanism

R. Elizondo-Vega, C. Cortes-Campos, M. Barahona, C. Carril, M. Garcia-Robles
Cell Biology, Concepcion University, Concepcion, Chile

Hypothalamic glial cells, or tanycytes, are involved in the brain glucose sensing mechanism, a process based on glia-neuron interactions and mediated by lactate. We evaluated the effect of adenoviral-mediated inhibition of tanycytes monocarboxylate transporters (MCT1 and MCT4) expression on the glucosensing mechanism. Here we show that tanycytes are metabolically coupled with neurons of the arcuate nucleous (AN) and that MCT1 inhibition changes feeding behavior. We generated an adenovirus expressing MCT1 shRNA (AdshMCT1-EGFP), MCT4 shRNA (AdshMCT4-tdTomato), and *E. coli* ß-galactosidase shRNA (control). MCT expression and loss of function was analyzed in primary tanycyte cultures using qRT-PCR, Western blot, ^{14}C-lactate uptake and lactate efflux by HPLC. We also characterized the organization of hypothalamic cytoarchitecture by confocal-spectral microscopy. We used qRT-PCR to analyze orexigenic and anorexigenic neuropeptide expression in the AN in response to intracerebroventricular glucose injections, in rats receiving the AdshMCT1-EGFP or AdshMCT4-Tomato. Finally, we evaluate the effects of MCT1 inhibition in feeding behavior in response to fasting-refeeding cycles. Our results indicate that the decreased MCT1 and MCT4 expression and activity was observed in primary tanycyte cultures after transduction with AdshMCT1-EGFP and AdshMCT4-Tomato, respectively. Inhibition of MCT1 and MCT4 expression *in vivo* altered the normal expression of neuropeptides in response to increased glucose concentration. The *in vivo* inhibition of MCT1 altered the normal response to a fasting-refeeding cycle. Inhibition of the expression of glial MCTs alters neuropeptides mRNA levels in the AN, involved in feeding behavior. MCT1 inhibition, produces changes in the normal feeding behavior, supporting the participation of monocarboxylates in the glucosensing mechanism, based on a metabolic interaction between tanycytes and neurons in the hypothalamus.

TUE-427
In vivo toxicity studies of dextran coated iron oxide nanoparticles

A. M. Prodan[1,2], S. L. Iconaru[3], C. L. Popa[3], D. Predoi[3]
[1]Science and Engineering of Oxide Materials and Nanomaterials, University Politehnica of Bucharest, Faculty of Applied Chemistry and Materials Science, [2]Emergency Hospital Floreasca, Bucharest, [3]National Institute of Materials Physics, Magurele, Romania

The goal of this study was to develop dextran coated iron oxide nanoparticles (DIO-NPs) by an adapted coprecipitation method and evaluate the in vivo toxicity after intratracheal instillation in rats. The adsorption of dextran on surface of iron oxide was evidenced by FTIR spectroscopy analysis. The average size, deduced from the XRD data refinement, has a value of 7.08 nm for DIO-NPs consistent with the mean sizes deduced from TEM observations. To examine the cytotoxicity of the iron oxide nanoparticles, the MTT assay was used. The HeLa cells were treated on/in a medium containing different concentrations (5, 10, 15, 20, 25 and 30 μg/ml) of the suspension of iron oxide nanoparticles. At the tested concentrations, the nanoparticles proved to be not cytotoxic on HeLa cells. On the other hand, we also evaluated the toxicity of dextran coated iron oxide nanoparticles by histological evaluation of the nanoparticles effects on rat tissues after a single intratracheal instillation of DIO-NPs in male Brown Norway rats at concentrations of 10, 20 and 30 mg/kg. All animals survived the administration of dextran coated iron oxide on all tested concentrations, and did not show any sign of discomfort (lethargy, nausea, vomiting or diarrhea) during the whole duration of the experiment. The lung examination at 24 h after the intratracheal instillation with 30 mg/kg of DIO-NPs the lung parenchyma of the rats shows preserved alveolar architecture with rare macrophages in the alveolar septa, discreet anisokaryosis and anisochromia of type II pneumocytes with rare nucleoli. On the other hand, the pathological micrographs of lung in rats after the intratracheal instillation with 10 and 20 mg/kg dose of DIO-NPs show that the lung has preserved the architecture of the control specimen. Pathological sections of spleen after the intratracheal instillation of the rats with a 10 ml/kg and 20 ml/kg dose of DIO-NPs show that the architecture of the spleen was not affected by DIO-NPs compared with the architecture of the control specimen. After the intratracheal instillation of the rats with a 30 ml/kg dose of DIO-NPs, we observed the splenic red pulp with increased number of monocytes, with nuclear contour irregularities.

TUE-428
Inhibition of doxorubicin metabolizing enzymes by selected cytostatic drugs

J. Hofman, A. Skarka, J. Havrankova, V. Wsol
Department of Biochemical Sciences, Charles University in Prague, Faculty of Pharmacy in Hradec Kralove, Hradec Kralove, Czech Republic

To date, several studies have demonstrated that the elevated activities of carbonyl reducing enzymes followed by increased enzymatic reduction of doxorubicin to its less potent C13-hydroxy metabolite constitute one of the mechanisms causing pharmacokinetic doxorubicin resistance in tumors. However, possible interactions of carbonyl reducing enzymes with cytostatic drugs that are administered concomitantly with doxorubicin in combination chemotherapy regimens, have not been investigated in detail to date and remain to be elucidated. In this study, we investigated the inhibition of recombinant cytosolic carbonyl reducing enzymes by 5-fluorouracil, paclitaxel, docetaxel, tamoxifen, cyclophosphamide and its pre-activated form, 4-hydroperoxycyclophosphamide. These cytostatic drugs are included in first-line breast cancer chemotherapy regimens together with doxorubicin. First, we explored the ability of selected cytosolic carbonyl reducing enzymes to metabolize doxorubicin to doxorubicinol. Regarding their activity, the tested enzymes can be ranked as follows: AKR1C3 > > CBR1 = AKR1A1. Other tested enzymes (CBR3, AKR1B1, AKR1B10, AKR1C1, AKR1C2, AKR1C4) exhibited only negligible activity toward doxorubicin and, therefore, were not further evaluated in subsequent study that investigated possible inhibition of AKR1C3, CBR1 and AKR1A1 by selected anticancer agents. AKR1C3 was shown to be significantly inhibited by paclitaxel, tamoxifen and 4-hydroperoxycyclophosphamide. CBR1 inhibition was induced by the presence of paclitaxel and 4-hydroperoxycyclophosphamide. The last tested enzyme, AKR1A1, was inhibited by paclitaxel and cyclophosphamide. In the follow-up cellular studies, we will focus on the changes in the expression of AKR1C3, CBR1, AKR1A1

TUE-429
Inositol phosphates induce DAPI fluorescence shift

B. Kolozsvari
LMCB, UCL, London, United Kingdom

The polymer inorganic polyphosphate (polyP) and inositol phosphates, such as phytic acid (IP6), share many biophysical features. These similarities must be attributed to the phosphate groups present in these molecules. Given the ability of polyP to modify the excitation-emission spectra of DAPI (4′,6- diamidino-2-phenylindole) we decided to investigate if inositol phosphates possess the same property. We discovered that DAPI-IP6 complexes emit at around 550 nm when excited with light of wavelength 410–420 nm. Inositol pentakisphosphate (IP5) is also able to induce a similar shift in DAPI fluorescence. Conversely, inositol trisphosphates (IP3) and inositol tetrakisphosphates (IP4) are unable to shift DAPI fluorescence.

We have employed this newly discovered feature of DAPI to study the enzymatic activity of the inositol polyphosphate multikinase (IPMK) and to monitor phytase phosphatase reactions. Finally, we used DAPI-IP6 fluorescence to determine the amount of IP6 in plant seeds, facilitating the biotechnology industry in their efforts to obtain low phytic acid grain. Using an IP6 standard curve this straight forward analysis revealed that among the samples tested, borlotti beans possess the highest level of IP6 (9.4 mg/g) while the Indian urad bean the lowest (3.2 mg/g). The newly identified fluorescence properties of DAPI-IP5 and DAPI-IP6 complexes allow the levels and enzymatic conversion of these two important messengers to be rapidly and reliably monitored.

We believe that this reliable method can be easily adapted to IP_6 measurement from any biological samples. By degrading polyP, treating the acid extract at high temperature, since IP_6 is not degraded in these conditions and DNA does not induce DAPI shift at 550 nm, the only fluorescent signal will derive from inositol phosphates such as IP_6. However, some caution and adjustment should be taken considering the presence of IP_5 and inositol pyrophosphates in many biological samples. Since inositol pyrophosphates usually represent 4–6% of their IP_5 or IP_6 precursor pools they will influence minimally the fluorescence signal that will be mainly a reflection of both IP_5 and IP_6 presence.
Keywords: inositides, phytic acid, signalling.

TUE-430
Insight on the interaction of an agmatinase-like protein with Mn2+ and evidence for the agmatinase activity of the protein Limch 1

E. Uribe, M. Quiñones, J. Cofre, D. García, J. Benitez, N. Romero, A. González, N. Carvajal
Bioquímica y Biología Molecular, Universidad de Concepción, Concepción, Chile

Agmatine results from decarboxylation of L-arginine by arginine decarboxylase and can be hydrolyzed to putrescine and urea by agmatinase. Putrescine is required for polyamines biosynthesis, being essential for cell replication.Agmatine is involved in modulation of insulin release and inhibition of nitric oxide synthesis. It is also considered a neurotransmitter and has been associated to anticonvulsant, antineurotoxic and antidepressant actions in the brain.We have described a protein, detected in hypothalamic and hippocampal region of rat brain, which hydrolyzes agmatine, although its sequence greatly differs from all known agmatinases and lacks the typical Mn^{2+} ligands of the urea hydrolase family of proteins. This agmatinase-like protein (ALP) exhibits a LIM-like domain, whose removal results in a 10-fold increased k_{cat}, and a 3-fold decreased K_m value for agmatine.We have now examined the interaction of ALP with the catalytically required Mn^{2+} by using mutagenic and kinetic approaches. Purified preparations of wild-type, LIM-domain truncated-ALP, and histidine mutants (H65A, H127A, H206A, H394A and H435A),were active even in the absence of added Mn^{2+}, but were further activated by incubation with $MnCl_2$(2 mM) at 60°C; the activation was not accompanied by changes in K_m for agmatine. We propose that, like arginase and agmatinase,fully activated species of ALP contain 2 Mn^{2+}/active site and that heating at 60°Cprovides the structural flexibility which is required for optimal binding of the Mn^{2+} ions in the active site. With the exception of the H206A variant, K_d values for Mn^{2+} dissociation for all other species were in the order of 10^{-8} M. Considering a 10-fold increased K_d value for the H206A variant, we suggest that His206 is involved in the stabilization of the activating Mn^{2+} ions. Interestingly, a gene data base analysis revealed at least two rat transcripts (designated Limch 1 isoforms I y II), with a 3‘extremes which are identical to ALP. These transcripts contain 3918 and 2871 pb, respectively, whereas ALP contain 1569 pb.We have cloned the Limch 1-isoform II from cDNA of rat brain hypothalamus and the gene was expressed in *S.cerevisiae* strain TRY104Δspe1 (unable to synthesize polyamines, due to the lack of ornithine decarboxylase, which needs exogenous polyamines for growth). The agmatinase activity of the LIMCH 1-isoform II was demonstrated by its ability to support polyamine biosynthesis*in vivo*. Grant Fondecyt 1120663.

TUE-431
Insights into the catalytic mechanism of PfECT by thermodynamic, kinetic and structural analyses

A. Contet[1], S. Maheshwari[1], E. Pihan[2], G. N. Nagy[3], B. Vertessy[3], D. Douguet[2], H. Vial[1], R. Cerdan[1]
[1]*DIMNP, University Montpellier 2 – CNRS, Montpellier,* [2]*IPMC, University Nice Sophia Antipolis – CNRS, Sophia Antipolis, France,* [3]*Institute of Enzymology, Hungarian Academy of Sciences, Budapest, Hungary*

Malaria is caused by the infection and destruction of red blood cells by protozoan parasites belonging to the genus *Plasmodium*. Among the five species infecting humans, *Plasmodium falciparum* is by far the deadliest one, accounting for approximately 95% of deaths. During its intra-erythrocytic development, *P. falciparum* requires massive biosynthesis of membranes which are composed of phospholipids and lack cholesterol unlike the host cell membranes. Phosphatidylethanolamine (PE) represents ~ 35% of the total membrane phospholipids and inhibition of its biosynthesis leads to parasite death. PE is synthesized by the parasite's machinery mainly through the *de novo* CDP-ethanolamine (Kennedy) pathway using ethanolamine as precursor. Our studies focus on the rate limiting step of this pathway catalyzed by CTP: phosphoethanolamine cytidylyltransferase (*Pf*ECT, EC 2.7.7.14). *Pf*ECT catalyzes the formation of CDP-ethanolamine (CDP-Etn) from CTP and phosphoethanolamine (P-Etn) and its accurate

© 2014 The Authors. FEBS Journal © 2014 FEBS

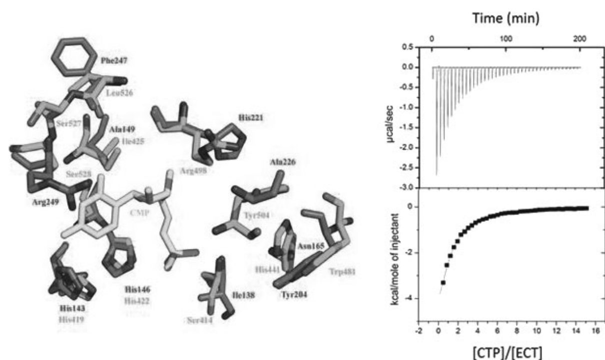

Fig. 1.

mechanism of catalysis has still not been described. Like all ECTs studied so far, *Pf*ECT contains two catalytic cores (CT domains) separated by a long linker. By site-directed mutagenesis of key residues involved in catalysis, we shown that only the N-terminal CT domain of *Pf*ECT is active. This feature raises the question of the role of the C-terminal CT domain. Ligand binding studies by isothermal titration calorimetry showed that *Pf*ECT binds only one molecule of CTP substrate or one molecule of CDP-Etn product with similar affinities while the binding of P-Etn substrate could not be detected. Interestingly, the enzyme is also able to accommodate two molecules of CMP. These results suggest that the C-terminal CT domain lost the ability to bind CTP substrate but retained the binding ability for an analogue like CMP. Analyses of the structural model of *Pf*ECT pointed out critical amino acid differences between the substrate binding sites of both CT domains. By the combination of kinetic, biophysical and structural studies, we now aim at deciphering the precise mechanisms of catalysis and regulation of *Pf*ECT in order to develop inhibitor compounds with anti-malarial activity by rational drug design.

Insights into the sesquiterpenes lactone biosynthetic pathway in *Cynara cardunculus* L.

K. Eljounaidi[1], K. Cankar[2], C. Comino[1], A. Moglia[1], A. Hehn[3], F. Bourgaud[3], H. Bouwmeester[4], B. Menin[5], S. Lanteri[1], J. Beekwilder[2]
[1]*Dipartimento di Scienze Agrarie, Forestali e Alimentari, University of Turin, Grugliasco, Italy,* [2]*Plant Research International, Wageningen UR, Wageningen, Netherlands,* [3]*UMR 1121 Agronomie et Environnement, Université de Lorraine, Nancy, France,* [4]*Laboratory of Plant Physiology, Wageningen UR, Wageningen, Netherlands,* [5]*Rice Genomics Unit, PTP, Lodi, Italy*

Globe artichoke (*Cynara cardunculus* var. *scolymus* L., Asteraceae) is a perennial crop traditionally consumed as a vegetable in the Mediterranean countries and it is rich in secondary metabolites, such as phenolic and terpenoid compounds. Its bitter taste is caused by its high content in cynaropicrin, a sesquiterpene lactone that has attracted attention because of its therapeutic potential as anti-tumor and anti-photoaging agent. One germacrene A synthase (GAS) and two cytochrome P450 genes (CYP71AV9 and CYP71BL5) were isolated in a set of *Cynara cardunculus* unigenes and the encoded enzymes were assessed on their ability to catalyze two consecutive hydroxylation steps leading to costunolide synthesis. When heterologously expressed in *E. coli*, the globe artichoke GAS converted the f*arnesyl* pyrophosphate (FPP) into (+)-germacrene A while the co-expression of CYP71BL5 and CYP71AV9 with GAS led to biosynthesis of the free costunolide in yeast and costunolide conjugates in *N. benthamiana,* demonstrating their involvement in STLs biosynthesis as GAO and COS enzymes. To elucidate the accumulation site of cynaropicrin, we measured its concentration in different tissues at varying developmental stages. The biochemical analyses highlighted that cynaropicrin is mainly concentrated in the leaves, its content decreases progressively during the inflorescence development with almost undetectable levels in roots and stems.

On the basis of the remarkable concentration of cynaropicrin detected in the leaves as compared to the other tissues, we further investigated its localization by isolating the apoplastic fluids and the trichomes. Our results confirmed that cynaropicrin mainly accumulates in the trichomes. Transcript level patterns of the three genes involved in STLs biosynthesis CcGAS, CcGAO and CcCOS were analyzed through q-PCR experiments in leaf and stem tissues respectively characterized by high and undetectable levels of cynaropicrin. The quantitative expression analysis revealed that all three genes involved in cynaropicrin biosynthesis are much more expressed in the leaves, confirming their correlation with the high accumulation of sesquiterpenes in this tissue.

Keywords: globe artichoke, sesquiterpenes, secondary metabolism.

TUE-433
Interaction between the Aryl hydrocarbon receptor pathway and alcohol metabolism enzymes in the liver

E. Attignon, A. Leblanc, H. Rouach, M. Aggerbeck, E. Blanc
Laboratoire INSERM U1124 Pharmacologie, Toxicologie et Signalisation Cellulaire Centre Universitaire des Saints Pères, Paris Descartes, Paris, France

TCDD (2,3,7,8-TetraChlorodiBenzo-*para*-Dioxin) is a persistant xenobiotic pollutant which is classified as a human carcinogen. TCDD binds to and activates the Aryl hydrocarbon Receptor (AhR) which then interacts in the nucleus with ARNT (AhR Nuclear Translocator) to form a transcription factor. This factor regulates the expression of genes involved in the degradation and elimination of xenobiotics. In order to determine whether TCDD can alter hepatic cell function, we performed a transcriptome analysis using a model of differentiated human hepatic cells (HepaRG). Treatment of cells with 25 nM TCDD for 30 h decreased (by 60%) the expression of genes for alcohol metabolism enzymes: cytochrome P450 2E1 (CYP2E1) and the alcohol dehydrogenases ADH1, 4 and 6. In hepatocytes, ADHs and CYP2E1 oxidize ethanol. The overconsumption of alcohol may lead to alcoholic liver diseases (ALD) which are manifested by steatosis, alcoholic cirrhosis and hepatocarcinoma. However, the role of ADHs and CYP2E1 in the toxicity of alcohol is not completely known. Alcohol may exert opposing effects. Its metabolism is toxic due to the production of aldehydes and reactive oxygen species whereas free ethanol itself is toxic. Our objective is to decipher the mechanisms by which alcohol metabolism enzymes are regulated by AhR signaling in HepaRG cells.

We found that ADH and CYP2E1 gene expression decreased as soon as 8 h after treatment with TCDD over a wide range of concentrations (0.1 to 25 nM). The ADHs and CYP2E1 proteins decreased after 72 h of treatment with 25 nM TCDD. The half-lives of the ADH proteins were not modified by treatment with TCDD which suggests a transcriptonal regulation of ADH expression. The AhR antagonist CH-223191 completely inhibits the regulation of expression of ADHs by 25 nM TCDD. The AhR-ARNT complex mediates expression of ADHs as shown by siRNA experiments directed against AhR and ARNT. Finally, the non-canonical pathway of AhR that is mediated by c-Src, is

© 2014 The Authors. FEBS Journal © 2014 FEBS

not involved in the ADH and CYP2E1 regulation. Similar regulation was observed using other AhR ligands (3-MethylCholanthrene, Benzo(a)pyrene and PolyChloroBiphenyl-126) highlighting the importance of this pathway.

Our results suggest that TCDD regulates expression of ADHs by activation of the AHR/ARNT complex. However, the links between this pathway and the decreases in enzyme expression are still unknown. Study of the promoters of the ADH genes to determine the mechanisms by which transcription factors (AhR or other factors) act in the regulation of ADH expression will help to elucidate how the exposure to pollutants which act through the AhR and which deregulate the expression of ADHs is involved in alcoholic liver disease pathogenesis.

Keywords: ADH, Alcohol, TCDD.

TUE-434

Interactions of tetrapyrrolic antitumor compounds with human serum albumin and low density lipoproteins

G. Rychkov[1,2], G. Golovina[3], A. Akimova[3], N. Durandin[3], A. Shtil[4]

[1]Saint-Petersburg State Polytechnic University, Saint-Petersburg, [2]Petersburg Nuclear Physics Institute, Gatchina, [3]Emanuel Institute of Biochemical Physics, RAS, [4]Blokhin Cancer Center, Moscow, Russian Federation

Tetrapyrrole containing compounds (porphyrins, chlorins, chlorophylls) are accumulated predominantly in metabolically active cells, in particular, malignant tumors. These compounds and their derivatives are perspective as photosensitizing agents due to light absorption in the long wavelength spectral region and a deep photodamage of tumor tissues. Boronated porphyrins emerged as promising dual photo- and radiosensitizers for both photodynamic therapy (PDT) and boron neutron capture therapy (BNCT).

However, the question as to how to deliver the bulky molecules to the tumor site remains open. Human serum albumin (HSA) and low density lipoproteins (LDL) are two major carriers of many endogenous and exogenous compounds in the body. In this work the quantitive parameters of interaction of four tetrapyrrole containing compounds (two pheophorbide *a* and two bacteriochlorophyll *a* derivatives; figure 1) with HSA and LDL were determined. Investigated compounds have been synthesized in Nesmeyanov Institute of Organoelement Compounds, RAS (Moscow).

Figure 1. Structures of compounds (**1**) and (**2**), derivatives of pheophorbide *a*; (**3**) and (**4**) derivatives of bacteriochlorophyll *a*.

Adsorption spectra showed that, unlike (**2**) and (**3**), compounds (**1**) and (**4**) were in the aggregated form in aqueous buffer. Increase of HSA or LDL concentrations shifted the equilibrium towards the complex of the monomeric form of these compounds with proteins. Diboronated compound (**2**) did not form complexes with HSA. The estimated values of binding constants K_b to HSA were 5×10^4 M^{-1}, 1×10^4 M^{-1} and 1×10^5 M^{-1} for (**1**), (**3**) and (**4**), respectively. In contrast, (**1**) and (**2**) were similarly affine to LDL with binding constants ~10^8 M^{-1}.

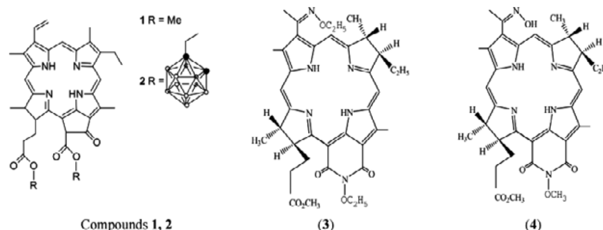

Fig. 1.

Molecular docking showed that (**1**), (**3**) and (**4**) fit tightly into the HSA hemin binding site. In contrast, for the diboronated derivative (**2**) such interactions were sterically hindered by boron polyhedra. Hydrophobic interactions made the main contribution to the binding free energy. Based on their binding free energy, the compounds can be ranked from less to more preferential): (**2**), (**4**), (**3**), (**1**) that is in a good agreement with experimental data.

These results suggest that: A) HSA can be a potential transporter for methylpheophorbide *a* (**1**) and bacteriopurpurinimide (**3**) whereas boron cages might impede the formation of stable drug-protein complexes; B) LDL might be the preferred carrier for polycarborane containing methylpheophorbide *a* derivatives.

Keywords: boron neutron capture therapy, human serum albumin, photodynamic therapy.

TUE-435

Interleukin-10, mean arterial blood pressure and insulin resistance in normal pregnancy

A. Sotoodeh Jahromi

Jahrom University of Medical Sciences, Jahrom, Iran

Problem statement: The purpose of this study was to investigate whether serum of Interleukin-10 (IL-10) Concentration change during normal pregnancy and, if so, to relate these changes corresponding alterations in insulin resistance and blood pressure.

Approach: This cross sectional study was carried out on 86 healthy pregnant women including 26, 23 and 37 individuals in the 1st, 2nd and 3rd trimesters, respectively and in 21 healthy non pregnant women. Serum IL-10 concentration was measured by Enzyme Linked Immunosorbent Assay (ELISA) method. Insulin resistance value was calculated using the homeostasis model assessment, HOMA-IR.

Results: Serum IL-10 concentration was found to be significantly higher in patients in all gestational age as compared non pregnant women. Il-10 level was significantly increased with increase in gestational age. Pregnant women exhibited higher score of HOMA IR compared non pregnant women, but there were no difference in this score between pregnant subjects in different gestational age. There were not significant correlation between IL-10 level with IR and blood pressure.

Conclusion: The results of the study show maternal IL-10 level increase with further increase in gestational age and there is no significant correlation between IL-10 level with Mean Arterial blood Pressure (MAP) and IR.

Keywords: blood pressure, interleukine, pregnancy.

TUE-436

Intracellular localization of Ncb5or, a novel flavoheme reductase likely involved in fatty acid desaturation

V. Zámbó[1], É. Kereszturi[1], M. Tóth[1], G. Lotz[2], M. Csala[1]

[1]Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, [2]2st Depertment of Pathology, Semmelweis University, Budapest, Hungary

Cytochrome b_5 (b_5) and Cyb_5 reductase (b_5R) are integral membrane proteins in the endoplasmic reticulum (ER). Their concerted action in fatty acid desaturation is well characterized. The recently discovered NADH cytochrome b_5 oxidoreductase (Ncb5or) is a soluble natural fusion protein, which contains both b_5R-like and b_5-like domains. This structural homology along with the marked alterations in lipid metabolism observed in Ncb5or (-/-) mice strongly suggest the involvement of Ncb5or in fatty acid desaturation. The enzyme likely transfers electrons

© 2014 The Authors. FEBS Journal © 2014 FEBS

from NADPH to the desaturase enzyme in the ER membrane. However, controversial data have been published regarding the cytosolic or ER localization of the protein. In order to clarify whether Ncb5or uses the common cytosolic NADPH or utilizes the separate pyridine nucleotide pool of the ER lumen, we aimed to elucidate the intracellular localization of this soluble protein.

Green fluorescent EGFP-Ncb5or fusion protein was expressed in transiently transfected human HEK293T cells and detected by fluorescent microscopy. The localization of endogenously expressed Ncb5or was assessed in HEK293T cells by two methods. Cells were harvested and homogenized to separate the subcellular fractions by differential centrifugation. Ncb5or and specific marker proteins of various cellular organelles were detected by Western blot. In addition, the endogenous protein was also localized by using in vitro immunocytochemistry.

Endogenous expression of Ncb5or could be demonstrated in HEK293T cell line both at mRNA and protein levels. Purity of the generated nuclear, microsomal, mitochondrial and cytosolic cell fractions were confirmed by immunoblot with characteristic organelle proteins. Ncb5or could only be detected in the cytosolic fraction using an antibody either against the protein, or against the GFP tag. This observation was confirmed using fluorescent microscopy. Ncb5or fusion protein was detected in the cytoplasm of the cells but no co-localization could be detected with fluorescent markers labeling either the nucleus or the endoplasmic reticulum. Similar localization was observed in case of endogenous Ncb5or protein by immunocytochemistry as well.

Or results clearly prove that Ncb5or is localized in the cytoplasm. Therefore, the utilization of ER luminal reducing equivalents by this enzyme can be ruled out. Further research is needed to confirm the putative role of Ncb5or in the fatty acid desaturation, which in turn will help to understand the contribution of this novel protein to the protection of pancreatic β-cells against lipid-induced oxidative and ER-stress.

Keywords: Endoplasmic reticulum, Intracellular localization, Ncb5or.

TUE-437

Investigation of the effect of rosiglitazaonon asymmetric dimethylargnine levels and dimethylarginine dimethylaminohydrolase activity in acute liver failure

D. Vardağli[1], S. Bekpınar[2]

[1]Medical Laboratory Technologies Program, İstanbul Esenyurt University, [2]Biochemistry, Faculty of Medicine, Istanbul University, İstanbul, Turkey

Liver metabolizes ADMA, which is an endogenous NOS inhibitor, by means of DDAH enzyme. Accumulation of ADMA in circulation due to the liver dysfunction has a serious negative impact on the vascular system and perfusion of organ. In our study, we aimed to investigate the effect of acute liver failure on the hepatic handling of ADMA. Beside that, it was invastigated that which direction rosiglitazone (RGZ), a PPAR-g agonist, change the dysfunction developed due to liver damage. Before generating damage with 500 mg/kg body weight,ip, we applied rosiglitazone (5 and 10 mg/kg body weight per day) by way of gavage during 7 days. Acute liver damage has been evaluated by measuring liver DDAH activity, plasma ADMA levels besides plasma ALT and AST activity. Change in the oxidative stress has been determined by tissue levels of malondialdehyde (MDA) and total sulphydryl (t-SH). TAA treatment in this dose, has generated acut liver damage. While increasing the level of MDA in the liver, this treatement has inhibited DDAH enzyme and raised increased the plasma ADMA levels. 5 mg RGZ administration before the liver damage has an antioxidant effect by decreasing tissıe MDA levels and increasing t-SH levels. Moreover, in the DDAH activity it has totally eliminated the inhibition occured due to the damage. However, positive effect of 10 mg RGZ on oxidative stres accuring due to the damage and DDAH inhibition has not been improved. In conclussion, our finding indicates that acute liver damage can seriously affect the hepatic handling of ADMA caused by DDAH inactivation. 5 mg dose of RGZ can improve this function possibly by preventing oxidative stress.

Keywords: acute liver failure, asymmetric dimethylargnine, dimethylarginine dimethylaminohydrolase.

TUE-438

IRBIT, a Inositol 1,4,5-trisphosphate receptor (IP3R) binding protein specifically binds to and inactivates *S*-adenosyl-L-homocysteine hydrolase

I. Grbeša, L. Kovačević, R. Belužić, A. Lepur, J. Knežević, J. Trmčić Cvitaš, P. M. Munoz Torres, **O. Vugrek**

Division of Molecular Medicine, Rudjer Bošković Institute, Zagreb, Croatia

Predominantly, *S*-adenosylhomocysteine hydrolase (AHCY) is a cytoplasmic, homotetrameric enzyme, but some portion of the protein is located to the nucleus. Indeed, it is proposed that the efficiency of transmethylation might profit from a close proximity between methyltransferases and AHCY due to its particular function of rapid removal of S-adenosyl homocysteine (SAH), the byproduct of transmethylation reactions. Rapid removal of SAH is crucial to avoid product inhibition of methyltransferases as it is one of the most potent methyltransferase inhibitors. Very little is known in terms of regulation of enzymatic activity of AHCY, nor its intracellular dynamics. Devogelaere et al (2008) hypothesized that AHCY might interact with a homologous protein, namely S-adenosyl-L-homocystein hydrolase-like protein (AHCYL1, IRBIT). In an effort to evaluate putative interactions between AHCY and AHCYL1 we used molecular, biochemical and cell biological approaches. We performed functional studies of recombinant proteins, Co-IP experiments, FRET in combination with confocal microscopy and live cell imaging, and mass spectrometry. In view of our studies we have confirmed that AHCYL1 specifically binds to and inactivates *S*-adenosylhomocysteine hydrolase. Our results show that besides documented functions of AHCYL1 as inhibitor of inositol 1,4,5-trisphosphate receptor (IP3R), and activator of $Na^+/HCO3^-$ co-transporters (NBC), AHCYL1 has an additional role thus interacting with AHCY and regulating its function. This indicates crosstalk between Ca^{2+} regulation, intracellular pH, methylation potential regulation, and signaling between cytoplasm and the nucleus shedding new light on the AHCY family of proteins.

Keywords: AHCY, IRBIT, S-Adenosyl homocysteine.

Is human dietary methanol an evil that can do good?

I. Petrunya[1], A. Shindyapina[2], E. Sheshukova[2], T. Komarova[3], Y. Dorokhov[3]

[1]The Vavilov Institute of General Genetics (VIGG), [2]The Vavilov Institute of General Genetics (VIGG), [3]Moscow State University, Moscow, Russian Federation

Methanol (MeOH) is considered to be a poison in humans because of the alcohol dehydrogenase (ADH)-mediated conversion of MeOH into toxic formaldehyde (FA). Our recent genome-wide analysis of the mouse brain demonstrated that an

© 2014 The Authors. FEBS Journal © 2014 FEBS

increase in endogenous MeOH after ADH inhibition led to a significant increase in the plasma MeOH concentration and the modification of mRNA synthesis. These findings suggest endogenous MeOH involvement in homeostasis regulation by controlling mRNA levels.

Here, we demonstrate directly that study volunteers displayed increasing concentrations of MeOH and FA in their blood plasma when consuming citrus pectin, ethanol and red wine. Experiments with volunteers after ethanol intake as an ADH "inhibitor" can assess lower-level MeOH production by endogenous sources. Ignoring the low contribution of renal and pulmonary clearance, we estimated the approximate lower level of endogenous MeOH production is at least = 1.66 mg/kg/h. A microarray analysis of white blood cells (WBC) in volunteers after pectin intake showed various responses for 30 differentially regulated mRNAs. Most of the mRNAs were somehow involved in the pathogenesis of Alzheimer's disease (AD). There was also a decreased synthesis of hemoglobin mRNA, *HBA* and *HBB*, the presence of which in WBC RNA was not a result of red blood cells contamination because erythrocyte-specific marker genes did not show significant change. A qRT-PCR analysis of volunteer WBC after pectin and red wine intake confirmed the complicated dependence between plasma MeOH content and the mRNA accumulation of previously identified genes, namely *GAPDH* and *SNX27*, and *MME*, *SORL1*, *DDIT4*, *HBA* and *HBB* genes revealed in this study. The identification of human genes, the transcriptional activity of which varies with the blood levels of MeOH, would lie between three possible functions of MeOH in humans as follows: (a) MeOH, a poisonous waste product, (b) MeOH, a signaling molecule that regulates the life processes, and (c) MeOH, a Janus-like substance similar to carbon dioxide that is released from the body during respiration, but without which the brain respiration centers cannot be activated. Our microarray analysis allows us to cede to the third hypothesis, which includes not only the inevitable involvement of MeOH-to-FA toxic metabolite formation but also the participation of MeOH in the regulation of gene involved in AD pathogenesis and signaling.

Keywords: diet, human health, regulation of gene expression.

TUE-440
Is there a relation between hemoglobin concenteration and blood lipid profiles?

A. H. Doustimotlagh[1], **R. Jannesar**[2], A. Sadri[3]
[1]*Biochemistry, Tehran University of Medical Sciences, Tehran,*
[2]*Pathology, Yasouj University of Medical Sciences, Yasouj,*
[3]*Microbiology, Islamic Azad University, Jahrom, Iran*

Objectives: Both anemia and dyslipidaemia are broadly prevalent public health problems, particularly in the Iranian population. Anemia is defined by the World Health Organization (WHO) as the reduce in haemoglobin concentration under 120 g/l for women and 130 g/l for men. Hyperlipidaemia has been implicated as a risk factor in coronary heart disease (CHD) and atherosclerosis. The aim of this study was to evaluate the plasma lipids and lipoprotein patterns and hemoglobin concenterations in the patients refered in our laboratory.

Design and Methods: In this study participants were selected from those people who refered to Laboratory Dena. Plasma total cholesterol (CHO), HDL-C, and triglyceride (TG) concentrations were measured using enzymatic kits, standardized reagents, and standards (Pars Azmoon Co, Tehran, Iran). The red blood cell (RBC) count and blood concentrations of Hb were assayed.

Results: Out of 102 participates, 50.98% were men and 49.02% were women. The mean serum total CHO level was 4.88 mM, The mean serum TG level was 1.79 mM and the men had Hb and RBC count higher than women. RBC count which takes into account for anemia correlated with HDL-C (r = 0.32, p less than 0.001). There was not a significant correlation between Hb values and the lipid profiles (Total CHO, TG, HDL-C and LDL-C).

Discussion: The present findings indicate that lipid profiles modification generally not be associated with the alteration of RBC count and concentration of hemoglobin (Hb). Conversely, there was a correlation between RBC count and HDL-C.

TUE-441
Isothiocyanates impair the bioactivation of carcinogenic aromatic amines through irreversible inhibition of arylamine *N*-acetyltransferase

R. Duval, X. Xu, L. C. Bui, J. Dairou, J.-M. Dupret, F. Rodrigues-Lima
Unite BFA, RMCX, Universite Paris Diderot, Paris, France

Aromatic amines (AA) such as 4-aminobiphenyl (4-ABP) are environmental procarcinogens. These chemicals undergo metabolic activation by N-oxidation followed by O-acetylation to form N-acetoxy arylamine that binds to DNA to give carcinogen-DNA adducts. Arylamine N-acetyltransferase (NAT) are xenobiotic metabolizing enzymes that play a key role in both detoxication and bioactivation of AA such as 4-ABP. Isothiocyanates (ITCs) found in cruciferous vegetables including benzyl-ITC (BITC) and phenetyl-ITC (PEITC) with cancer chemopreventive activity. One of the principal mechanisms of action of ITC is to perturb the metabolism of carcinogenic chemicals to limit their metabolic activation. Recent data have shown that ITC inhibit DNA damage induced by 4-ABP in part through Nrf2 activation.

We report here an additional mechanism that may contribute to the chemoprotective effects of ITCs towards AA carcinogens. We found that ITCs such as BITC and PEITC are strongly irreversibles inhibitors of human NAT1 and NAT2 that covalently bind to the active site cysteine of the enzymes. Further mechanistic charaterization was carried out with human NAT1 and we found that BITC was slightly more potent at inhibiting the enzymes than PEITC (k_{inact}=11400 M^{-1} min^{-1} and 3700 M^{-1} min^{-1} for BITC and PEITC, respectively). As expected, both N- and O-acetyltransferase activities of NAT1 were inhibited by BITC. More importantly, we found that BITC inhibited NAT acetylation pathway in MCF-7 cells with concomitant significant decrease in 4-ABP-DNA adducts.

Overall our data suggest direct irreversible inhibition of NAT enzymes by ITCs may alter the NAT-bioactivation pathway of AA thus contributing to the chemopreventive action of ITCs.

Kinetic characterization of enolase enzyme from *Theileria annulata*

E. Cayir, A. Erdemir, E. Ozkan, M. Topuzogullari, Z. B. Bolat, A. Akat, **D. T. Balik**
Department of Bioengineering, Yildiz Technical University, Istanbul, Turkey

Tropical theileriosis is caused by infection with a tick-borne parasite *Theileria annulata* and this disease has economically considerable importance for livestock industries in many regions of the world. In recent years, parasite resistance has been reported against the most effective antitheilerial drug used for the treatment of tropical theileriosis. This situatuion has given rise to requirement for novel antitheilerial drugs. Enolase (2-phospho-D-

© 2014 The Authors. FEBS Journal © 2014 FEBS

glycerate hydrolase) is a crucial enzyme that involved in glycolytic pathway for energy production. Therefore, it can be selected as a molecular target for novel antitheilerial therapy methods. In this study, steady state kinetic parameters of the enzyme were determined for the first time. Enzyme kinetic measurements using 2-PGA as substrate gave a specific activity of ~40 U/mg, K_m: 106 μM, k_{cat}: 37 s^{-1} and k_{cat}/K_m: 3.5 × 105 M^{-1} s^{-1}. Determination of kinetic properties of enolase from *Theileria annulata* enables application of further studies on new antitheilerial drug design.

Keywords: drug design, enolase, *Theileria annulata*.

TUE-443
Kinetic mechanism of smooth muscle cell plasma membrane Ca^{2+}, Mg^{2+}-ATPase selective inhibition by calixarene C-90

A. Shkrabak, T. Veklich, I. Mazur, S. O. Kosterin
Muscle Biochemistry, O.V. Palladin Institute of Biochemistry, Kyiv, Ukraine

Today a great attention of scientists is paid to calixarenes as original molecular platforms which are perspective for designing of biologically-active compounds. Calixarenes are macrocyclic oligophenolic compounds and some of them possess bactericidal, antiviral, antitumoral, antithrombotic activity, they almost have no toxic action on cells.

In our previous investigation carried out on the suspension of myometrium cell plasma membranes we found that calixarene C-90 efficiently inhibited Ca^{2+}, Mg^{2+}-ATPase ($I_{0.5}$ is about 20 μM) and did not influence on activity of other membrane-bound ATPases. Considering further development conception about mechanisms of inhibition of the plasma membrane Ca^{2+}, Mg^{2+}-ATPase of uterus cells by this calixarene we have more thoroughly investigated the influence of this compound on kinetic properties of the Ca^{2+}, Mg^{2+}-ATPase activity of myometrium plasma membrane.

We have shown that calixarene C-90, while inhibiting Ca^{2+}, Mg^{2+}-ATPase, did not influence on kinetic parameters (K_M, n_H) of reaction velocity dependence on substrate concentration. Changes of ATP concentration also did not effect on kinetic of Ca^{2+}, Mg^{2+}-ATPase inhibition by calixarene C-90 and its respective constants (K_i, n_H). The growth of calixarene concentration up to 100 μM caused the slight increase of enzyme activation constants by $MgCl_2$ (K_{Mg}) and by Ca^{2+} (K_{Ca}). The Hill cooperativity coefficients (n_H) of activation by both $MgCl_2$ and Ca^{2+} did almost not varied in the presence of mentioned calixarene. Both $MgCl_2$ and Ca^{2+} also slightly influenced on Ca^{2+}, Mg^{2+}-ATPase cooperativity coefficient n_H and coefficient of inhibition by calixarene C-90 (K_i). The most considerable impact of calixarene C-90 was observed to change the maximal velocity of enzyme reaction. In all cases calixarene C-90 proportionally itself concentration decreased mentioned kinetic parameter. Therefore, we can conclude that inhibitory action of calixarene C-90 on Ca^{2+}, Mg^{2+}-ATPase has mainly uncompetitive character because interaction of calixarene C-90 with enzyme leads to decrease of enzyme turnover number.

We consider that calixarene C-90 is perspective for creation of new pharmaceuticals in order to regulate intracellular Ca^{2+} concentration and therefore muscle tone and contractility.

We are thankful to professor V.I. Kalchenko for helpful discussion and scientific cooperation.

Keywords: Ca^{2+}, Mg^{2+}-ATPase, calixarene, plasma membrane.

TUE-444
Lack of association between genetic variation of -2548G/A of leptin gene polymorphismand hypertension in obese adult Saudi subjects

A. Osama
Medical Biochemistry, Assiut University, Assiut, Egypt

Background: Leptin is a polypeptide hormone synthesized mainly by white adipose tissue. Common polymorphism -2548G/A of leptin (LEP) gene has been associated with obesity, but its association with cardiovascular diseases including hypertension has been little studied. Thereforeour study aimedto investigate whether the polymorphism -2548G/A of (LEP) gene is associated or not with hypertension in obesity in a sample of Saudi adult patients.

Patients and Methods: A total of 206 Saudi adult subjects (112 women and 94 men) their aged 40–60 years were recruited and subdivided into three groups: 50 normotensive ND controls (age: 47.9 ± 5.4 y; BMI 22.9 ± 2.1 kg/m^2), 80 normotensive obese ND (age: 47.7 ± 6.0 y; BMI 34.1 ± 4.2 kg/m^2) and 76 hypertensive obese patientswith T2DM (age: 49.4 ± 5.9 y; BMI: 35.1 ± 4.7 kg/m^2). Analyses of -2548G/A polymorphism of LEP gene were made by the polymerase chain reaction restriction-fragment length polymorphism technique (PCR-RFLP). Anthropometric data were collected from all subjects. Serum leptin and insulin concentrations were determined by Luminex as well as fasting blood glucose and serum lipids were determined by a chemical auto analyzer Konelab.

Results: Our study showed that the AA genotype of −2548G/A variant of LEP gene was significantly associated in individuals with higher fasting glucose levels ($p < 0.04$), and HOMA-IR ($p = 0.03$), as well as the A allele of LEP gene variant (−2548G/A) is more prevalent among the subjects with elevated fasting glucose [OR 1.9 (1.2, 3.0), $p = 0.006$], while GA genotype was more common in individuals with hyperleptinemia ($p = 0.04$). On the other hand no association was elicited with either systolic or diastolic blood pressure.

Conclusion: The study showed that the genotypes distribution of −2548G/A variant of LEP gene (GA and AA) are associated with plasma leptin, and glucose levels in set of Saudi individuals. Moreover, these genotypes as well as A allele of this gene might be an important risk factor predisposing healthy subjects to T2DM.

Keywords: gene polymorphism, leptin, obesity.

TUE-445
Lindane disturbs the capacity of *Saccharomyces cerevisiae* to scavenge lipid hydroperoxides via phospholipid hydroperoxide glutathione peroxidase causing cell death

T. Pita, I. Alves-Pereira, **R. M. A. Ferreira**
Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Departamento de Química, Universidade de Évora, Évora, Portugal

Reactive oxygen species (ROS) are by-products of aerobic metabolism in cells. Pollutants such as lindane may raise its production, causing cell damages in biomolecules as lipids. Cells possess defence systems to counter oxidative stress including glutathione and glutathione peroxidases (GPx). Phospholipid hydroperoxide glutathione peroxidase (PHGPx) is considered to be the main line of enzymatic defence against membrane damage. The experimental advantages of the yeast model *Saccharomyces cerevisiae* have been exploited extensively for advancing our understanding about

© 2014 The Authors. FEBS Journal © 2014 FEBS

cell defences against ROS, because the yeast genome sequencing revealed genes that encode GPx which exhibit great homology with other eukaryotes, including man. Lindane has been used as pesticide in agricultural and human health applications. Several factors have contributed in concern over the use of lindane including its persistence, toxicity and bioaccumulation. Thus, the aim of this study was to evaluate the response to lindane mediated by yeast GSH and PHGPx. *Saccharomyces cerevisiae* UE-ME_3, a wild-type yeast deposited in the collection of laboratory of Enology, University of Évora, at mid-exponential phase, were inoculated in YEPD medium, 2% (w/v) glucose, at 28°C, and shaken 150 rpm for 72 h in presence of 5 μM or 50 μM lindane and compared with control. Cell viability was determined by cfu and the biomass by dry weight. Yeasts harvested were suspended in 10 mM phosphate buffer pH 7.0 and disrupted by sonication. The post-12000 *g* pellets were used for determination of malondialdheyde (MDA), glutathione (GSH) and glutathione disulfide (GSSG) by fluorescence and the post-12000 *g* supernatant for PHGPx determination by spectrometry. Statistics were performed by ANOVA I and Duncan ($p < 0.01$) using SPSS for Windows, version 22. The results showed that lindane, at 72 h of exposure, inhibited yeast growth decreasing biomass produced and cell viability. On the other hand, it was observed, for both levels of exposition, an increase in the GSH/GSSG ratio and in the level of proteins, total glutathione, GSH, and MDA of mitochondria as well as a decrease in the PHGPx. The increase in GSH/GSSG ratio of mitochondria probably resulted from the incapacity of the cell to scavenge lipid hydroperoxides, *via* PHGPx, preventing cell damages in mitochondrial membranes. This effect may have determined an increase in the mitochondrial MDA content. This response probably contributed to slowdown the energetic metabolism and over express mitochondrial proteins. So, lindane was toxic to *Saccharomyces cerevisiae* UE-ME_3, probably causing cell death by an active process.

TUE-446
Lipid profile of the red blood cell membranes in acute pancreatitis: effects of traditional therapy

I. Azarova, A. Konoplya
Biochemistry, Kursk State Medical University, Kursk, Russian Federation

The pancreatic acinar cell synthesizes, stores, and secretes digestive enzymes. Observing pancreatic cells is difficult due to time and physiological problems, however, by comparing the red blood cell membranes of people with acute pancreatitis (AP) and those without it is possible to see the damage caused by the activated enzymes to the blood cells and thus conclude that similar damage is taking place in the acinar cells themselves.

In this study the erythrocyte membranes of 110 AP patients were examined before and after traditional therapy. Two study groups comprising 58 patients with acute biliary pancreatitis (ABP) and 52 patients with acute non-biliary pancreatitis (ANBP) were compared. 26 age matched volunteers were used as a control group.

The lipid bilayer is composed of cholesterol and phospholipids in equal proportions by weight. These lipids were separated using the method of thin layer chromatography. Only cholesterol esters (CE), monoacyl glycerol (MAG), and diacyl glycerol (DAG) levels fall into the normal range in patients with ABP on admission. Elevated cholesterol (C) level indicates decreased mobility of fatty acids and deterioration of lateral diffusion; decreased sphyngomyelin (SM) concentration is a sign of impaired lipid phase micro viscosity; reduction in phosphatidyl choline (PC) indicates the decrease in membrane permeability and is a sign of impaired cholesterol metabolism. In contrast, patients with ANBP had normal values of C, TAG, and phospholipids. Decrease in CE, MAG and DAG and rise in FFA indicate the activation of the lipolytic processes.

There is strong correlation between ankyrin and PC levels and clinical symptoms in all the AP patients, whereas in ANBP there is an additional link between the clinical picture and MDA concentration.

In total, 80% of lipids of the RBC membranes were altered in ABP, whereas 50% of lipids were damaged in ANBP. In ABP, traditional therapy improved 25% of lipids, 37.5% fell into the normal range. In ANBP, traditional therapy was less effective and only improved and normalized up to 40% of lipid profile.

The present studies provide evidence that oxidative damage to both lipids and proteins of the RBC membrane occurs in acute pancreatitis. Traditional treatment corrects the structural aberrations in ABP more effectively than in ANBP. This suggests that there is much to be gained by introducing into the traditional therapy drugs with immunomodulating, antioxidant and membrane protective properties.

Keywords: membrane lipids, pancreatitis, red blood cell.

TUE-447
Localization of plasminogen-binding site in fibrin fragment DD

T. Yatsenko, V. Rybachuk, S. Kharchenko, T. Grinenko
Department of Enzyme Chemistry and Biochemistry, Palladin Institute of Biochemistry of NASU, Kyiv, Ukraine

Fibrinolytic system ensures the destruction of blood clots, but in addition perform other physiological and pathological functions and participates in the process remodulation tissues, reproduction, angiogenesis, inflammation, tumor cell invasion and others.

In order to investigate the mechanism of fibrinolysis and its regulation pathways we studied the potentiating effect of cross-linked fibrin fragments on Glu-plasminogen activation by tissue-type plasminogen activator (t-PA). It was found all plasmic degradation products of fibrin including DDE-polymers, DDE-complexes, fragments E_1E_2 (dissociation products of non-covalent DDE-complexes) and core product DD, apart from core fragment E_3, have potentiating effect on plasminogen activation by t-PA. These results indicate that plasminogen- and t-PA-binding sites on fibrin surface which is exposure under conversion of fibrinogen to fibrin remain on the fibrin fragments during fragmentation by plasmin. Thus, the process is irreversible.

Multifunctional fragment DD molecule is of particular interest because it inhibits platelet aggregation, slows fibrin polymerization, shows an affinity for fibrin clot and stimulates Glu-plasminogen activation.

Using method of izomolar-series, we have established the maximum potentiating effect of fragment DD on activation system plasminogen by t-PA. The effect is observed at a molar ratio of plasminogen to fragment DD 1.0–1.3. Considering this data and structure of fragment DD (identical D-domains of two neighboring covalently cross-linked by γ-chains fibrin molecules) we conclude that the plasminogen-binding site is located in region of γ-γ-cross-linking.

The results of this study can be the basis for the creation of new fibrinolytic drugs and the development of test systems to determine the fibrinolytic system parameters.

Keywords: fibrin fragments, fibrinolytic system, plasminogen activation.

TUE-448
Low salt intake during pregnancy alters glucose metabolism and DNA methylation in the offspring

F. R. Siqueira, L. N. S. Furukawa, I. B. Oliveira, J. C. Heimann
Laboratory of Experimental Hypertension, University of Sao Paulo – School of Medicine, Sao Paulo, Brazil

It is known that some maternal nutritional alterations during pregnancy are associated with metabolic disorders in adult offspring, such as insulin resistance, type 2 diabetes mellitus, obesity and arterial hypertension. The period of pregnancy in which these nutritional alterations influence adult offspring remains uncertain. Epigenetic changes are proposed to underlie these metabolic disorders. Twelve-week-old female Wistar rats were fed a low-salt (LS – 0.15% NaCl) or normal-salt (NS – 1.3% NaCl) diet since the first day of gestation until delivery or LS during the first (LS10) or second (LS20) half of gestation. Body weight, food and water intake were weekly evaluated during gestation. Blood glucose, insulin (ITT) and glucose (GTT) tolerance tests, HOMA-IR were performed in adult offspring. Gene expression and DNA methylation were mapped using bisulfite treatment evaluated by pyrosequencing in the male and female neonates and adult offspring. Weight gain was lower in LS and LS20 dams than in NS and LS10 dams in the third week of pregnancy. Birth weights were lower in male and female LS20 and LS rats compared with NS and LS10 neonates. HOMA-IR was higher in 12-week-old LS males compared with NS and in 20-week-old male LS10 rats compared with NS and LS20 rats. In 12-week-old LS10 females, HOMA-IR was higher than in LS. Serum insulin levels were higher in 20 week-old LS10 male compared with NS rats and in 12-week-old LS10 female compared to LS rats. The area under the curve of GTT indicated glucose intolerance in 12- and 20-week-old LS male. Methylation of CpG islands of the *Insr*, *Igf1*, *Igf1r*, *Ins1* and *Ins2* genes in liver in neonates male and female offspring and liver, white adipose tissue and muscle in 20-week-old male offspring were influenced by low-salt intake during pregnancy. None of these alterations was identified in 20-week-old females. In conclusion, low-salt diet consumption in the second half of pregnancy can result in low birth weights in the males and females offspring. Glucose intolerance observed in adult offspring occurred only if low salt intake was given throughout pregnancy. However, insulin resistance in response to low salt intake during pregnancy is related to the time at which this insult occurs and to the age of the offspring. Alterations in the DNA methylation of *Igf1* were observed to be correlated with low birth weight in response to low salt feeding during pregnancy.

Keywords: DNA methylation, fetal programming, Insulin-like growth factor 1.

Low-doses dioxin chronic exposure promotes liver fibrosis development in the C57BL6/J DIO mouse model

C. Duval[1], F. Teixeira-Clerc[2], A. Leblanc[1], C. Emond[3], M. Guerre-Millo[4], S. Lotersztajn[2], M. Aggerbeck[1], R. Barouki[1], X. Coumoul[1]
[1]INSERM UMR-S1124, Université Paris Descartes, Paris, [2]INSERM U955, Université Paris-Est, Créteil, France, [3]Université de Montréal, Montréal, Canada, [4]INSERM UMR-S872, Université Paris Descartes, Paris, France

Non-alcoholic fatty liver disease (NAFLD) is strongly associated with obesity, and includes a wide histological spectrum of diseases, ranging from benign steatosis towards pathological non-alcoholic steatohepatitis (NASH) and fibrotic complications, which may progress to end-stage liver diseases. The Aryl hydrocarbon Receptor (AhR) is a ligand-activated transcription factor which binds to a broad variety of environmental pollutants such as the 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Beside its detoxification function, a role for AhR has emerged in the regulation of lipid metabolism and hepatic steatosis. Furthermore, previous work from our lab has shown that chronic exposure to high doses of TCDD (25 μg/kg) leads to liver fibrosis. Our aim was to study the effect of low-doses TCDD chronic exposure on NAFLD progression in the C57BL6/J diet-induced obesity (DIO) mouse model. In a preliminary part of the study, a TCDD dose-response (0.1-1-2.5-5-10-25 μg/kg) was performed in C57BL6/J mice to establish that 5 μg/kg TCDD is the threshold dose for liver collagen deposition after chronic administration. Interestingly, a computer modeling of our experimental procedure predicts a final TCDD plasma concentration below 70 ppt, a dose which is relevant to human exposure risk assessment. Then, C57BL6/J male mice were either fed a 10% low fat (LFD) or 45% high fat (HFD) purified diet during 14 weeks and injected once a week with 5 μg/kg TCDD or vehicle in the last 6 weeks of the diet intervention. Histological liver stainings reveal that co-exposure to HFD and TCDD aggravates hepatic lipid accumulation and, more importantly, promotes liver fibrosis development compared to HFD or TCDD alone. In line with these observations, mRNA expression levels of lipid markers, quantified by real-time PCR, were strongly impaired by the co-treatment. Remarkably, TCDD acts in synergy with HFD to increase Cd36 (fatty acid transport), Pparg (lipid storage) and to decrease Srbf1, Acaca (lipogenesis), while it counteracts the HFD-induced increase in Ppara, Cpt1a (fatty acid catabolism) mRNA levels. Moreover, TCDD increases pro-fibrotic (Tgfb1, Col1a1, Col3a1, aSMA) and inflammatory (Il1b, Mcp1, Cd68, Cd11b) gene expression levels although there was no additive effect upon HFD. In conclusion, even if further analyses are needed to better understand the underlying molecular mechanisms, our data strongly support the hypothesis that environmental pollutants could promote liver fibrosis development in obesity-related NAFLD.

Luteolin 7-glicoside treatment in normal human keratinocytes: a metabolomic approach

R. Palombo[1], **L. Avigliano**[1], I. Savini[1], E. Candi[1], G. Melino[1], A. Terrinoni[2]
[1]Experimental Medicine and Surgery, University of Rome Tor Vergata, Italy, [2]IDI – Istituto Dermopatico dell'Immacolata, Rome, Italy

Flavonoids are a class of plant secondary metabolite. Recent interest in these polyphenolic compounds has been stimulated by the potential health benefits; in particular their antioxidant and anti-inflammatory properties have been shown to protect keratinocytes from environmental stresses.

The epidermis of the skin is a dynamic tissue in which keratinocytes proliferate in the basal layer and undergo a tightly controlled differentiation program upon movement into the suprabasal layers. The final differentiation step of epidermal keratinocytes is the conversion of living cells into corneocytes. The balance between keratinocyte proliferation, differentiation and death it is important in avoiding pathologic changes of the epidermis. Wide-spread skin diseases such as psoriasis, atopic dermatitis and certain forms of ichthyosis are characterized by epidermal defects leading to keratinocyte hyperproliferation or

© 2014 The Authors. FEBS Journal © 2014 FEBS

hyperkeratinization which are accompanied by inflammatory reactions.

Since it has been reported that topically applied chamomile exert beneficial effects on skin health we selected luteolin-7glucoside (-7G) and apigenin-7glucoside (-7G), the major flavonoids present in this officinal plant, to evaluate the effects on cell death, cell cycle, metabolism, and redox level in normal human keratinocytes (HEKn).

The results of the experiments showed that only treating cells with apigenin-7G leads to the induction of the apoptosis program. Treatment with luteolin-7G do not induce apoptosis in keratinocyte cells, but it leads to a modification of cell cycle, with a consistent accumulation of cells in G1 phase. Luteolin-7G induces also a differentiative stimulus in keratinocytes, indeed demonstrated by the production of differentiation specific molecules such as keratin1, keratin 10 and involucrin. The treatment of human keratinocytes with this flavonoid also induces metabolic alteration (the data sets comprises a total of 279 componds of known identity). The study highlights a decrease in polyamines, a generalised block of energy metabolism (both glycolysis and Krebs cycle) and alteration of fatty acid metabolism. Finally a higher cholesterol level was observed in luteolin treated cells and may be associated with differences in lipid raft generation as well as to the production of the anti-inflammatory glucocorticoid cortisol.

This study demonstrate that flavonoid can deeply modify the normal homeostasis of epidermal tissues, aging on metabolism and differentiation program. The results leads to consider luteolin-7G in the possible treatment of diseases in which the homeostasis of the epidermis is compromised.

MAO activities and relationships with antioxidant status and lipid peroxidation in human glioma and meningioma type tumours

E. Zengin[1], D. Vardağli[2], **A. Yilmaz**[3]
[1]Department of Biochemistry, Faculty of Medicine, Health Sciences Institute, İstanbul University, [2]Medical Laboratory Technologies Program-Biochemistry, İstanbul Esenyurt University, [3]Department of Neurosurgery, Sisli Etfal Educational and Research Hospital, İstanbul, Turkey

Monoamine oxidase (MAO) located in the outer membrane of mitochondria is responsible for oxidative deamination of biogenic and xenobiotic amines, especially in the peripheral and central nervous system. Recent studies revealed that MAO activities were incerased in neurodegenerative diseases as a result of the enhanced metabolism of dopamine leading to lipid peroxidation and membrane damage via H_2O_2 and ROS formations.

In our study, MAO activities, antioxidant status and lipid peroxidation products in brain tumours (glial and meningiomal) were determined. Otherwise the relationships were intevtigated.

Our study was performed with 16 patients hospitalized due to brain tumour surgery in Sisli Etfal Hospital Neurosurgical Department. Working group were generated from 8 gliomas and 8 meningiomas. Peritumoral tissues (8) were used as control group.

Superoxide dismutase (SOD), MAO, glutathione (GSH) and lipid peroxidation (TBAR-S) were studied spectrophotometrically .ELISA method was used for the determination of the glutathione reductase (GR).

MAO and GR activities and TBAR-S were found statistically significant ($p < 0.05$) in gliomas. On the other hand SOD activity was found highly significant, whereas no statistically significant result were obtained in GSH level in gliomas.

In meningiomas MAO and SOD activities were found statistically significant ($p < 0.05$), TBAR-S levels high significant ($p < 0.001$), and no significant values in GSH levels ($p > 0.05$).

Significant İncreased in MAO and antioxidant enzyme activities and lpid peroxidation level were obtained in both type of tumours compared to peritumoral tissues. TBAR-S levels reflecting the lipid peroxidation suggests that MAO activity might increase lipid peroxidation via the H_2O_2 in human brain tumour.

TUE-453
Metabolic changes in soybean roots inoculated by *Bradyrhizobium japonicum* strains

A. Levishko, P. Mamenko, S. Kots
Department of Symbiotic Nitrogen Fixation, Institute of Plant Physiology and Genetics of NAS of Ukraine, Kyiv, Ukraine

Unique way to enrich the soil with biological nitrogen as well as to increase yield capacity and quality of agricultural products is the creation of effective symbiotic systems of legumes with nodule bacteria. The development of symbiotic interrelations between legumes and nodule bacteria is one of the most important periods in the life of these plants. At the same time the metabolite profile is poorly studied.

The aim of our investigations was to estimate the metabolic profile of soybean roots, inoculated with active and inactive strains of *Bradyrhizobium japonicum* during symbiosis formation under different nitrogen doses. The analysis of metabolites was performed using GC-MS.

Experimental data showed that the soybean roots inoculated with active nodule bacteria had a lot of polyhydric alcohol, amino acids and sugars as compared to roots treated with inactive strain. Inoculation with active strain caused the changes in the quantitative ratio of succinic acid and malonic acid. Application of active nodule bacteria led also to increasing all the metabolites, especially organic acids, in the soybean roots while the enhancing nitrogen fixation was observed. There were some differences in the composition of root metabolites of plants, which were supplied with different doses of nitrogen. The formation of free fatty acids may be due increasing activity of cell biosynthesis of membrane lipids. It is known that the level of membrane fatty acids influences essentially on plant resistance to drought. The increase of contents of osmoprotector proline under water stress promotes the water retention in plant cells and prevents protein dehydration as well as increases the irrigation of membranes and stabilizes the structure of latter.

The studies suggest that the effective inoculation of soybean seeds induces the synthesis of physiological active products in plants affected by stress and thereby creates conditions for increasing plant resistance to moisture deficiency.

Thus, our findings contribute to the understanding of some aspects of the interaction between legumes and nodule bacteria. Besides, these data can be used to develop the strategy for the creation of plants with high ecological plasticity.

Keywords: *Bradyrhizobium japonicum*, metabolic profile, soybean.

TUE-454
Metabolomic analysis of fission yeast at the onset of nitrogen starvation

K. Sajiki, T. Pluskal, M. Yanagida
G0 Cell Unit, Okinawa Institute of Science and Technology Graduate University (OIST), 1919-1 Tancha, Onna-son, Okinawa 904-0495, Japan

Microorganisms naturally respond to changes in nutritional conditions by adjusting their morphology and physiology. The cellular response of the fission yeast *S. pombe* to nitrogen starvation has been extensively examined by genetic, transcriptomic and proteomic studies. However, since nitrogen starvation is ultimately a metabolic condition, complete understanding of its effect cannot be achieved without studying the intracellular metabolome. In addition, the most immediate response to nitrogen starvation might not be mediated on the transcriptional level, as the transcription/translation machinery responds with an inevitable delay. In this study, we conducted time course metabolomic analysis immediately after nitrogen starvation, prior to any visible changes in cell morphology. We semi-quantitatively measured 75 distinct metabolites, 60% of which changed their level over 2-fold. The most significant changes occurred during the first 15 min after nitrogen source removal, are the rapid increase of trehalose, 2-oxoglutarate, and succinate, and the sharp decline of purine biosynthesis intermediates. At 30–60 min, free amino acids decreased, although several modified amino acids, including trimethylated amino acids, increased. Most energy metabolites such as ATP, S-adenosylmethionine or NAD^+ remained stable during the first 1 h. The fast shut-off of purine biosynthesis and the sharp rise of 2-oxoglutarate and succinate may be caused by the depletion of NH_4Cl from the culture medium. Glutamate dehydrogenase catalyzes the reaction of 2-oxoglutarate and NH_4Cl to synthesize glutamate and subsequently succinate. The gene *gdh1* + encodeing glutamate dehydrogenase is essential for *S. pombe* enter the G0 phase under nitrogen starvation. The level change of key metabolites such as 2-oxoglutarate, succinate and glutamate, may represent an important mechanistic step to trigger subsequent cellular regulations under nitrogen starvation. We extened our metabolome experiments for longer time after nitrogen starvation (6, 12 and 24 h), and will present results that suggest the importance of 2-oxoglutarte udner long-term nitrogen starvation.

Metformin reduces palmitate induced endoplasmic reticulum stress and apoptosis in rat insulinoma cell line

M. Kokas[1,2], L. Simon-Szabo[1], J. Mandl[1], G. Kéri[2,3], M. Csala[1]
[1]*Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University,* [2]*MTA-SE Pathobiochemistry Research Group, Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, MTA,* [3]*Vichem Chemie Research Ltd, Budapest, Hungary*

Lipotoxicity refers to cellular dysfunctions caused by elevated free fatty acid levels playing a central role in the development and progression of obesity related diseases. Saturated fatty acids cause insulin resistance and reduce insulin production in the pancreatic islets, thereby generating a vicious cycle, which potentially culminates in type 2 diabetes. The underlying endoplasmic reticulum (ER) stress response can lead to even β-cell death (lipoapoptosis). Since improvement of β-cell viability is a promising antidiabetic strategy, the protective effect of metformin, a known insulin sensitizer was studied in rat insulinoma cells. We measured palmitate induced cell death using Tryphan Blue exclusion method. Assessment of palmitate-induced lipoapoptosis by detection of caspase-3 showed a significant decrease in metformin treated cells. Attenuation of β-cell lipotoxicity was also revealed by lower induction/activation of various ER stress markers, e.g. phosphorylation of eukaryotic initiation factor 2α (eIF2α), c-Jun N-terminal kinase (JNK), splicing of X box binding protein 1 mRNA and induction of CCAAT/enhancer binding protein homologous protein (CHOP). Our results indicate that the β-cell protective activity of metformin in lipotoxicity can be at least partly attributed to suppression of ER stress.

Keywords: apoptosis, Endoplasmic reticulum stress.

TUE-456
Microbial removal of remazol blue by different bacteria

S. Ertuğrul Karatay, N. Koçberber Kilic, **G. Dönmez**
Biology, Ankara Üniversitesi, Ankara, Turkey

Textile, pulp, paper, tanning, and dyeing wastewaters include toxic many substances such as highly colored chemicals. These wastewaters affect the environment negatively and need to be treated. In the current study, 3 different bacteria (isolate A, isolate B, and isolate C) were isolated from dye containing textile wastewaters. These bacteria were tested with their possible usage in treating wastewaters including dyestuff. For this purpose, molasses media was prepared and Remazol Blue (RB) was used as the pollutant. Experiments were carried out in a rotary shaker (100 rpm) with an incubation period of 7 days at 30°C. Isolate A, isolate B, and isolate C were investigated with regards to different pH levels (6, 7, 8, and, 9) and dye concentrations (approximately 25, 50, 75, and 100 mg/l). All the tested bacteria were cultivated in molasses media with approximately 25 mg/l dye at different pH levels. The residual dye concentration and optical densities of the bacteria were determined spectrophotometrically. According to the data from the experiments, all the three bacteria removed this dye with the maximum levels at pH 7. In the experiments investigating the effect of initial dye concentration onto dye removal, with an increase in pollutant concentration removal of dye decreased. Within the three bacteria, isolate C, removed dye with higher efficiencies than other bacteria tested.

TUE-457
Modulation of global gene expression profile with resveratrol in rat liver tissues

M. C. Baloglu[1], G. Sadi[2]
[1]*Department of Genetic and Bioengineering, Kastamonu University, Kastamonu,* [2]*Department of Biology, Karamanoglu Mehmetbey University, Karaman, Turkey*

Analyzing gene expression profile by using microarray technology is one of the fastest-growing new technologies in genetic researches. Resveratrol, a strong antioxidant in plants, is a natural phytoalexin and polyphenolic compound and regulates the expression of various genes. In this study, microarray analysis was performed to indicate effects of resveratrol treatment on global gene expression profiles of rat liver tissues. RMA algorithm (Robust Multiarray Analysis) was used for microarray raw data normalization. Significantly expressed probe sets with p-values lower than 0.05 were determined by One way ANOVA. Among

© 2014 The Authors. FEBS Journal © 2014 FEBS

significantly expressed probe sets, fold change of at least two was considered as differentially expressed probe sets. Principal components analysis (PCA) was used to simplify the analysis and visualization of multidimensional data sets. PCA revealed that three biological replicates within a one group clustered together and separated from control group. The Venn diagram was constructed to indicate the number of separated and overlapping probe sets between resveratrol and control groups. After the resveratrol treatment, 186 and 494 transcripts were up and down regulated, respectively. Gene Ontology Enrichment Analysis Software Toolkit (GOEAST) was used for determination of annotation and biological processes for significantly different probe sets. According to the GO database, after resveratrol treatment, upregulated differentially expressed probes were functionally categorized into 10 groups. These included not only functionally well-defined categories, such as cell part, cytoplasm, positive regulation of biological process but also response to stress, organic substance, immune system, and biotic stimulus. Resveratrol treatment led to an increase in the expression of genes including Lcn2 and Usp2 which are responsible for regulation of apoptosis. Additionally, expression level of cellular mobility element genes (Akta1-Mylpf), and acute inflammation of the calcium binding protein gene (S100a9) increased. So, it can be concluded that resveratrol reduced apoptosis and increased cell motility, and immune response. Expression levels of genes involved in the synthesis of the proteins found in the nucleus and nucleolus reduced after resveratrol treatment. Expression level of Pdcd4 gene acting as an inhibitor of apoptosis and Tp53 bp2 gene encoding tumor protein p53 binding protein decreased by 8.8 and 2.8 folds, respectively. It can be suggested that resveratrol has ability to reduce cell death. Finally, microarray results were validated with qRT-PCR using selected genes such as Cat, Usp2, Igfbp2, Cyp1a1, and Cyp8b1.

Keywords: Microarray, Rat Liver Tissue, Resveratrol.

TUE-458
Modulation of metallothionein and apoptotic activities in zinc nanooxide exposed mussel by heat stress and nifedipine

O. Stoliar[1], H. Falfushynska[1], I. Sokolova[2], L. Gnatyshyna[1], O. Fedoruk[1], A. Ivanina[2]
[1]Ternopil National Pedagogical University, Ternopil, Ukraine,
[2]University of North Carolina at Charlotte, Charlotte, USA

Nanooxide ZnO (n-ZnO) is one of the most common types of used nanoparticles. N-ZnO can be a source of Zn for the aquatic organisms. Zn is an essential co-factor of many metalloezymes and transcription factors and can also modulate function of ionic channels; however, it is toxic at high concentrations. This study investigated the effects of n-ZnO and Zn^{2+} on metal binding and cellular stress response, and possible modulation of these effects by heat stress (25°C) or Ca-channel blocker nifedipine (NFD) in a model organism, a mussel *Unio pictorum*. Male *U. pictorum* were exposed for 14 days to Zn^{2+} (3.1 μM), NFD (10 μM), n-ZnO (3.1 μM), combination of n-ZnO and NFD at 18°C (n-ZnO + NFD), and n-ZnO at 25°C (n-ZnO + T). Metal binding capacity was determined by measuring levels of metallothioneins (MT) in the digestive gland tissue. Cellular stress response was assessed in the digestive gland by measuring levels of antioxidants (reduced and oxidized glutathione, GSH & GSSG, respectively) and activity of superoxide dismutase (SOD), levels of oxiradicals and oxidative lesions of proteins (carbonyls, PC) and lipids (LPO), DNA fragmentation, and activity of the main effector enzymes in the apoptotic cascades, caspase-3 and cathepsin D (total and free). Exposure to Zn, n-ZnO and n-ZnO + NFD induced significant upregulation of MT levels by ~ 30%, while NFD alone depleted the MT level. Notably, the upregulation of MT in response to n-ZnO exposure was abolished at the elevated temperature (25°C). All exposures except n-ZnO + T led to upregulation of the activity of an antioxidant enzyme, SOD, accompanied by a 2–3-fold decrease in the levels of PC, while the concentrations of LPO products did not change. In contrast, the combined exposure to n-ZnO + T abolished upregulation of SOD activity and induced oxidative stress as indicated by elevated levels of protein carbonyls (by ~40%), LPO products (by over 100%) and a ~2-fold increase in the levels of oxidized glutathione (GSSG). Exposures to the Zn, n-ZnO + T and NFD led to a significant increase in DNA fragmentation. Cathepsin D-related apoptotic activity was induced by all exposures except n-ZnO + T and NFD, while the caspase-3 mediated cascade was induced prominently by n-ZnO + T and decreased by n-ZnO, NFD and n-ZnO + NFD. NFD exposure alone caused elevation of oxyradical formation and release of cathepsin D. Overall, our data show that in the complex exposures, the heat stress drastically impacts MT-dependent metal binding and oxidative stress responses on the exposure to n-ZnO, whereas NFD leads to a change in the apoptotic activity and doesn't affect MT functions.

Keywords: apoptosis, heat stress, metallothionein.

TUE-459
Molecular characterization of nicotinate phosphoribosyltransferase from *Mycobacterium tuberculosis* H37Rv, and inhibition of its activity by pyrazinoic acid

S. Mori[1], H. Kim[1], E. Rimbara[1], Y. Arakawa[2], K. Shibayama[1]
[1]Bacteriology II, National Institute of Infectious Diseases, Tokyo,
[2]Bacteriology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Nicotinate phosphoribosyltransferase (NAPRTase) catalyzes the reaction of nicotinic acid (NA) with 5-phosphoribosyl-1-pyrophosphate (PRPP) to produce nicotinic acid mononucleotide and diphosphate. It plays an important role in nicotinamide adenine dinucleotide biosynthesis. Recently, two enzymes in *Mycobacterium tuberculosis* H37Rv—PncB1 (Rv1330c) and PncB2 (Rv0573c)—were reported to exhibit NAPRTase activity. In this study, we investigated the properties and kinetics of PncB1. PncB1 requires bivalent metal ions for its catalytic activity, and its optimal temperature is 40°C. In addition, PncB1 exhibits ATP hydrolysis activity. PncB1 can catalyze the NAPRTase reaction in the presence and absence of ATP. However, by comparing the PncB1 kinetic values in the presence and absence of ATP, it was found that ATP affects the reaction by altering the apparent K_m values, whereas, the K_{cat} values were only slightly affected. The K_m values for NA and PRPP in the presence of ATP were 0.16 mM and 0.22 mM, respectively; and 3.22 mM and 2.71 mM, respectively, in the absence of ATP. On the other hand, the K_{cat} values for NA and PRPP in the presence of ATP were 0.14 and 0.15 s^{-1}, respectively; and 0.13 and 0.09 s^{-1}, respectively, in the absence of ATP. The K_{cat}/K_m values for both NA and PRPP were approximately 25-fold greater in the presence of ATP than in the absence of ATP. Hence, it is suggested that PncB1 utilizes the energy obtained through its facultative ATPase activity for effective catalysis. Pyrazinamide (PZA) is an anti-tuberculosis drug, which is converted to its active form, pyrazinoic acid (POA), by pyrazinamidase/nicotinamidase. PZA and POA are nicotinamide and nicotinic acid analogs, respectively. Although PZA and POA cannot be used as substrates for PncB1 instead of NA, the enzymatic activity of PncB1 is strongly inhibited by POA at pH 5.4. The results of molecular modeling and molecular simulation of PncB1 revealed that the binding site of POA is the same as that of NA. POA requires an acidic environ-

Molecular diagnosis of mental retardation in children: our experience in Algeria

H. Siham, B. Imessaoudene, M.A. Ghouali, M. Djeddou, F. Benchaib, Z. Chami, A. Berhoune
Pharmacy, Laboratory of biochemistry of the Hospital University of Mustapha-Algiers-, Algeria, Algeria

Mental retardation (MR) is a major handicap, it may be syndromic involving neurological abnormalities, morphological, biochemical or visceral. Or more frequently non syndromic, defined by a single RM, without other clinical abnormalities.

The number of genes responsible for RM is estimated at about 1000, only 90 of them have been identified.

Our laboratory performs the last few years the molecular diagnosis of some syndromes such as Fragile X syndrome (FMR1 gene), the Prader Willi syndrome (SNRPN), Angelman syndrome (UBE3A) and Rett syndrome (MECP2).

Although the evocation of these syndromes is clinical, the identification of the molecular defect responsible for the RM is required to confirm the diagnosis.

Our study was conducted on 857 childrens from the different departments of pediatrics and neurology of the country, over a period that spans six years (2009–2014).

The analysis of our activity report shows that these affections are not rare in our population. A reliable etiologic diagnosis of RM is essential, ensuring better care for patients, and provide a suitable genetic counseling to affected families.
Keywords: genes, Mental retardation, molecular abnormality.

TUE-461
Molecular targets and pharmacokinetics of cucumarioside A2-2

E. A. Pislyagin[1], P. S. Dmitrenok[1], R. V. Gladkikh[1], T. Y. Gorpenchenko[2], **D. L. Aminin**[1]
[1]G.B.Elyakov Pacific Institute of Bioorganic Chemistry, Far Eastern Branch of the Russian Academy of Sciences, [2]Institute of Biology and Soil Science, Far Eastern Branch of the Russian Academy of Sciences, Vladivostok, Russian Federation

At this moment the significant growth of acute and chronic infectious diseases of bacterial, fungal, protozoal and viral nature is observed. Application of highly effective modern antibiotics does not always give a good clinical effect, but may cause a further suppress of immunity. Therefore, the creation of new effective immunostimulants is an important scientific aim. One of the promising immunomodulatory candidates are holothurian triterpene glycosides. Despite the large number of works related to the physiological activity of triterpene glycosides the available data does not give a clear picture of the molecular mechanisms underlying the immunomodulatory effect.

This study reports the investigation of triterpene glycoside cucumarioside A_2-2, the main glycoside isolated from the holothurian *Cucumaria japonica*. It describes a study of pharmacokinetic behavior of cucumarioside A_2-2, its spatial distribution in mouse spleen tissue and some peptide/protein molecular targets of its immunomodulatory action. The methods of radiospectroscopy, MALDI-MS and MALDI-IMS was applied for this purpose.

Cucumarioside A_2-2 is reliably detected by MALDI-MS in the mouse spleen tissue after single intraperitoneal (*i.p.*) injection at a dosage of 5 mg/kg. The glycoside is stable in the spleen and does not undergo metabolic transformation in either tissue homogenates or in the intact organ within 24 h after *i.p.* injection. The cucumarioside A_2-2 was absorbed and eliminated fairly rapidly. It was established by MALDI-IMS that glycoside was mainly located in the tunica serosa part of the spleen and only a small amount was detected within the red and white pulp of the organ. MALDI-MS images obtained 15–30 min post dosage clearly reflect high drug concentrations in the regions surrounding the organ followed by its decline in the surface part and a very slight redistribution to the internal part of the spleen. It has been shown that stimulation of animals with LPS (positive control) or cucmarioside A_2-2 leads to marked changes in the mass-spectrometric peptide/proteine profile of the spleen. These changes were accompanied by notable morphological alteration in spleen reflecting the immune response. The characteristic m/z peaks the intensity of which significantly varied after exposure to immunostimulants were revealed. It is possible that established peptides/proteins are the specific targets (biomarkers) for studied compounds.

Nephrin, a transmembrane protein, is pivotal for pancreatic beta-cell survival signaling

A. Kapodistria[1], E.-P. Tsilibary[1], P. Politis[2], P. Moustardas[3], A. Charonis[3], P. Kitsiou[1]
[1]Institute of Biosciences & Applications, National Centre for Scientific Research "Demokritos", [2]Center for Basic Research, [3]Center for Clinical, Experimental Surgery and Translational Research, Biomedical Research Foundation Academy of Athens (BRFAA), Athens, Greece

Nephrin, a cell surface signaling receptor, contributes to regulation of podocyte function in health and disease. Pancreatic β-cells express nephrin, however its function remains largely unknown. We used a mouse pancreatic β-cell line (βTC-6 cells), to study the role of nephrin in β-cell survival signaling. Beta TC-6 cells express nephrin which is associated and partly co-localized with PI3-kinase. Incubation of βTC-6 cells with functional anti-nephrin antibodies induced nephrin clustering at the plasma membrane and recruitment of a considerable portion of PI3K to clustered nephrin, as indicated by a significant increase of nephrin-PI3K co-localization. This process led to activation of PI3K which associated with increased phosphorylation of Akt; this effect was inhibited by wortmannin and LY294002, indicating that Akt activation was PI3K-dependent. Akt activation resulted in increased phosphorylation/inhibition of pro-apoptotic Bad and FoxO transcription factors; apparently then, nephrin–mediated PI3K-Akt activation triggered anti-apoptotic signaling. Pre-treatment of cells with PP1, a selective inhibitor of Src kinases, inhibited the interaction of nephrin with PI3K and Akt activation, demonstrating that Src kinases mediate nephrin downstream signaling. Silencing of nephrin expression by nephrin-siRNA abolished nephrin-mediated Akt activation and increased susceptibility of cells to apoptosis, as indicated by enhanced caspase-3 activity. High glucose concentration impaired nephrin-mediated Akt activation without affecting nephrin expression; this effect was accompanied by increased nephrin endocytosis and up-regulation of PKCα expression. Interestingly, a marked decrease in nephrin expression was found in pancreatic islets of *db/db lepr-/-* diabetic mice. Our findings revealed that nephrin plays a major role in pancreatic β-cell survival and suggest that glucose-induced changes in nephrin signaling and/or expression may contribute to gradual pancreatic β-cell loss which occurs

New insights into the function of the uncharacterized gene aim4 using NMR based metabolomics

M. Palomino-Schätzlein[1], M. M. Molina-Navarro[2], M. Tormos-Pérez[2], S. Rodriguez-Navarro[2], A. Pineda-Lucena[1]
[1]Structural Biochemistry Laboratory, [2]Gene Expression and RNA Metabolism, Centro de Investigación Príncipe Felipe, Valencia, Spain

The functionally uncharacterized gene *AIM4* of the eukaryote model organism *Saccharomyces cerevisiae* seems to play a key role in mitochondrial activity and stress response[1]. In this study, Nuclear Magnetic Resonance (NMR) based metabonomics is used to get a closer insight in the metabolic routes in which this gene is involved. To this end, an optimized method to extract and analyze *S. cerevisiae* metabolites has been developed, allowing the identification of a wide range of yeast metabolites.[2] In addition, analysis of intact *S. cerevisiae* cells by HRMAS has been optimized as a complementary method. The metabolic profiles of wildtype versus *aim4*Δ mutant cells have been studied after induction of diverse stress situations (oxidative stress, osmotic stress and glucose deprivation). Interestingly, *aim4*Δ cells show a characteristic delayed stress response enabling metabolomics to be efficiently used to test stress adaptation in yeast. Moreover, metabolic differences between wildtype and mutant cells suggest a crucial role for *AIM4* in fermentative and lipid metabolism as well as in membrane organization.

Keywords: intact cell analysis, lipid metabolism, stress regulation.

New tools for the analysis and biocatalytic synthesis of central metabolites

R. Wohlgemuth
Sigma-Aldrich, Buchs, Switzerland

Metabolites and metabolic enzymes have been of fundamental importance in the history of biochemistry and the life sciences as components of metabolism in healthy and diseased biological cells. Although a large number of milestone discoveries in classical biochemistry have revealed the molecular details of many metabolic pathways, many central metabolites of well-established pathways have not been available in pure and stable form. It is however essential to synthesize pure metabolites in sufficient amounts, not only for robust functional bioassays and for investigating stability issues, but also to discover novel enzyme functions, other biological functions, metabolic pathways and systems. The widening gap between the human metabolites annotated in databases and the number of compounds with synthesis references underlines the need to focus attention also on the small molecule space of molecular biology. Therefore the Metabolite Synthesis Initiative has been started to address this gap and to synthesize the required metabolite standards of central biochemical pathways. The expansion of enantiomerically pure metabolites enables better stereochemical characterizations of pathway steps in healthy biological systems as well as in inborn errors of metabolism and acquired diseases. Thereby new chiral separation techniques, quantitative NMR, LC-MS of enzymatic reactions and the use of metabolic enzymes have enabled successful biocatalytic asymmetric syntheses of central and chiral metabolites with high step economy. The most recent discoveries on the stability, synthesis and analysis of metabolites in central biochemical pathways will be presented.

Like all living things, plants require nitrogen (N) throughout their development. The N incorporated as NO_3^- and NH_4^+ represents about 2% of total plant dry matter, and is a component

© 2014 The Authors. FEBS Journal © 2014 FEBS

of proteins, nucleic acids, cofactors, signalling molecules, storage and numerous plant secondary products. The availability of N to plant roots is often an important limiting factor for plant growth. Plants obtain N from nitrogen fixing bacteria and decomposition of dead tissues of both plants and animals by microorganisms. It is unclear, however, how plants obtain nitrogen from these endophytic bacteria within tissues of leaves, stems, and roots. Recent observations suggest that plants may degrade bacteria associated with their tissues in order to extract nutrients. Although, uncertainty still exists as to whether microbial degradation in plant tissues functions in nutrient acquisition or instead is a defensive response to microbes. Here we present experimental data that supports the hypothesis that plant degradation of endophytic diazotrophic bacteria functions as a means to acquire organic nitrogen. We further show that the degradation process is associated with secretion of reactive oxygen, H_2O_2. In these experiments we used *Agave tequilana* and its diazotrophic endophyte *Bacillus tequilensis* to elucidate nitrogen transfer from ^{15}[N]-labeled bacteria to plants. *Bacillus tequilensis* cells grown in a medium with $^{15}NH_4Cl$ as nitrogen source were inoculated into plants growing in sand. We traced incorporation of ^{15}N into tryptophan and pheophytin derived from chlorophyll *a* using liquid chromatography coupled to mass spectrometry. Direct microscopic observations of bacteria in plant tissues visualize the bacterial oxidation process using probes for H_2O_2. These findings challenge the current paradigm for autotrophs, suggesting that plants may degrade endophytic microbes as a nutrient source to maintain growth under circumstances where adequate nitrogen cannot be extracted from soils. Supported by FAPESP (2012/12663-1, 2009/51850-9), CAPES, INCT Redoxoma (FAPESP/CNPq/CAPES; 573530/2008-4), NAP Redoxoma (PRPUSP; 2011.1.9352.1.8), CEPID Redoxoma (FAPESP; 2013/07937-8).

TUE-466
Nitrosative stress effect on the development of alimentary osteoporosis in rats

O. Zaitseva, S. Shandrenko, M. Veliky
Palladin Institute of Biochemistry NAS of Ukraine, Kyiv, Ukraine

The alimentary osteoporosis remains a serious clinical problem, and the underlying mechanism has not been completely understood yet. The aim of the research was the investigation of nitrosative stress influence on the bone metabolism under alimentary osteoporosis development.

White female W*istar* rats were used in the research. The experimental model of alimentary osteoporosis was performed by using of a synthetic diet without vitamin D_3 combined with balanced content of calcium (1.2%) and phosphorus (0.7%). Rats were divided into 3 groups. 1st – control rats were kept on vitamin D_3 balanced diet, 2nd and 3rd groups were held on vitamin D_3-deficiency diet for 45 days, additionally animals of 3rd group were intraperitoneal injected with 0.05 mg of Bacillus Calmette-Guérin (BCG) vaccine for nitrosative stress development at 30 day of experiment. After decapitation at 45 day in blood samples were determined the level of NO with DAF-2DA by flow cytometry, total calcium, inorganic phosphate and alkaline phosphatase. Also osteometric and X-ray analyses were performed.

Results: In rats with alimentary osteoporosis level of NO in leukocytes was elevated by 17% as compared to control. Level of alkaline phosphatase was also increased more than 2-fold (291 ± 50 U/l) vs. control (134 ± 22 U/l). Total calcium and inorganic phosphate level was decreased by 23 % ((2.3 ± 0.2) mmol/l, control (3.0 ± 0.3) mmol/l) and 79% ((0.4 ± 0.1) mmol/l, control (1.9 ± 0.2) mmol/l) respectively.

In animals of 3rd group with nitrosative stress the level of NO in leukocytes was increased by 17% vs. 2nd group. It was also observed normalization of the main mineral parameters. Thus, the level of total calcium and inorganic phosphate was increased by 22% and 25% relatively, alkaline phosphatase level was decreased by 41% compared to 2nd group – osteoporosis.

Results of osteometric investigation indicated about significant development of osteoporosis. The femur decreased in weight and shortened in length by 47% and 32%, the vertical femoral head diameter decreased by 14% compared to control. The X-ray investigation showed some significant changes in the structure of experimental animal's skeleton. So, in control rats it was normal X-ray picture unlike in animals of 2nd group. The rats with alimentary osteoporosis have unexpressed cortical layer of the tubular bones, deformed thorax, "square" vertebral bodies and rough spine line. In rats with nitrosative stress were normalized the form of thorax, became visible the iliac bone wings and transverse outgrowth of the caudal vertebrae.

Thus, vitamin D_3 deficiency diet caused osteoporosis development. Induced nitrosative stress led to positive effect in mineral metabolism and in structure of rat's skeleton with alimentary osteoporosis.

Keywords: nitrosative stress, osteoporosis.

Oncolytic adenovirus loaded with L-carnosine as a drug delivery system for cancer therapy

M. Garofalo[1,2], B. Iovine[2], M. Orefice[2], L. Kuryk[1], M. Hirvinen[1], C. Capasso[1], D. Romanyuk[1], V. Cerullo[1], G. Oliviero[3], N. Borbone[3], G. Piccialli[3], M. A. Bevilacqua[2]
[1]*Biopharmaceutical Biosciences & CDR, University of Helsinki, Helsinki, Finland,* [2]*Molecular Medicine and Medical Biotechnology,* [3]*Department of Pharmacy, University of Naples Federico II, Naples, Italy*

L-carnosine (β-Ala-His) is a naturally occurring histidine dipeptide, normally found in brain, kidney and in large amounts in muscle. L-carnosine has biological functions, including antioxidant activity, ability to chelate metal ions, as well as anti-inflammatory and anti-senescence properties. Recently, we have found that 50–100 mM of L-carnosine decreases cell proliferation in a colon cancer cell line HCT116, bearing a mutation in codon 13 of the RAS proto-oncogene. In addition, pre-treatment with L-carnosine decreases the intracellular concentration of Adenosine Triphosphate (ATP) and Reactive Oxygen Species (ROS) and inhibits the cell cycle progression in the G1 phase. The proto-oncogene KRAS is mutated in a wide array of human cancers and is important both in tumour progression and resistance to anticancer drugs. From this point of view, L-carnosine could represent a good adjuvant candidate for the treatment of colon cancer. To overcome treatment limitations due to the high intracellular concentration required we have hypothesized that L-carnosine cellular uptake could be enhanced by conjugation with the capsid of oncolytic viruses. Indeed, by using L-carnosine-coated oncolytic viruses we believe we can exert a positive anticancer synergistic effect. In fact, it is known that peptides can be used for anti-cancer vaccine, though they require an adjuvant to work, while oncolytic adenoviruses are very efficient in killing cancer cells and have also a strong adjuvant effect. First, we developed a strategy to conjugate peptides on the viral capsid based on electrostatic interaction. Then, using A549 cell line we have demonstrated that oncolytic virus coated with L-carnosine with a tail of positively charged polylysine was able to reduce cell viability compared to the virus alone. In conclusion, we have developed a model to use oncolytic adenovirus as a scaffold to deliver active

© 2014 The Authors. FEBS Journal © 2014 FEBS

drugs. Once validated the proposed model could be used as a novel drug delivery system for cancer therapy.

Keywords: L-carnosine, Cancer therapy, Oncolytic adenoviruses.

TUE-468
Organotypic cultures of HepG2 spheroids for toxicological studies *in vitro*

J. Ulrichová[1], M. Havlikova[2], J. Vrba[1]
[1]Department of Medical Chemistry and Biochemistry, [2]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University in Olomouc, Olomouc, Czech Republic

Predictive *in vitro* models alternative to *in vivo* experiments will have a significant impact in future toxicological studies. However, conventional 2D models do not reflect the complexity of a 3D organ resulting in discrepancies between experimental *in vitro* and *in vivo* data. Hence, 3D models are becoming more popular.

In our laboratory, we tried to compare the toxic profile of palmatine and the effect of palmatine on the expression of cytochromes P450 1A1 and 1A2 (CYPs) in primary cultures of human hepatocytes and in HepG2 cells growing as a monolayer or spheroids (Vrba et al.: *Toxicology In Vitro 28*: 693–699, 2014). HepG2 spheroids were produced using the hanging drop method.

Our results suggest that the effect of palmatine on HepG2 spheroids in terms of toxicity and the expression of CYPs is comparable with the results obtained in experiments with primary cultures of human hepatocytes, i.e. in a cell system, which is closer to the *in vivo* situation. Moreover, HepG2 spheroids are more suitable for long-term cultivation than cells growing as a monolayer. Suitability of HepG2 spheroids for longer cultivation was verified by live/dead staining and Alamar blue assay.

Based on our experiments with palmatine we can confirm that organotypic cultures of HepG2 cells are a more complex system useful in toxicology, which better reflects *in vivo* experiments than a conventional cell monolayer.

We gratefully acknowledge financial support of grants LO1304 and NT 13591.
Keywords: cytochromes P450, HepG2, palmatine.

TUE-469
Oxidative stress gene glutathione peroxidase 1 (GPX1) Pro198Leu polymorphism is associated with the gender-specific risk for panic disorder

M. Cengiz[1], B. Bayoglu[1], **S. Cengiz**[2], N. Kocabasoglu[3]
[1]Medical Biology, Istanbul University Cerrahpasa Medical Faculty, [2]Science Department, Istanbul University Institute of Forensic Science, [3]Psychiatry, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Oxidative stress (OS) plays a crucial role in the pathophysiology of psychiatric disorders. Recently, antioxidant system have been shown to affect some brain pathologies. Panic disorder (PD) is an anxiety disorder characterized by sudden attacks of intense fear. Biochemical and genetic studies suggest that oxidative stress index is significantly higher in PD patients, and also the role of OS genes in anxiety-like behavioural phenotypes have been reported. The aim of the present study is to investigate the role of the polymorphisms in OS gene, glutathione peroxidase-1 (GPX1), and DNA repair enzyme gene, 8-oxoguanine glycosylase-1 (OGG1), in PD patients. In this study 127 patients with PD and 151 disease-free controls were included to analyse GPX1 Pro198Leu (rs1050450) and OGG1 Ser326Cys (rs1052133) polymorphisms. The severity of PD symptoms was assessed by Panic and Agoraphobia Scale (PAS). GPX1 Pro198Leu and OGG1 Ser326Cys polymorphisms were analysed with real-time polymerase chain reaction (RT-PCR). No significant relationship was observed in genotype distributions of OGG1 Ser326Cys and GPX1 Pro198Leu polymorphisms between PD and control groups ($p > 0.05$). There was also no significant relationship between OGG1 and GPX1 polymorphisms and age onset, agoraphobia, or PAS scores in PD group ($p > 0.05$). However, in GPX1 Pro198Leu polymorphism, C allele was found to be more frequent in female subgroup of PD patients compared to males ($p = 0.027$). In conclusion, GPX1 Pro198Leu and OGG1 Ser326Cys polymorphisms were not associated with PD risk in Turkish patients. However, a gender specific effect was found in the C allele frequency of GPX1 Pro198Leu polymorphism for the PD risk.

Keywords: GPX gene, Oxidative stress, Panic disorder.

TUE-470
Oxygen-independent regulation of HIF-1 and its role in metabolic adaptation of cancer cells to hypoxia

G. Simos
Laboratory of Biochemistry, Faculty of Medicine, University of Thessaly, Larissa, Greece

Hypoxia-inducible factors (HIFs) are transcriptional activators essential for adaptation to low oxygen conditions. They mediate changes in O_2 delivery and consumption by regulating erythropoiesis, angiogenesis and reprogramming of cellular metabolism under both physiological and pathological conditions. Cancer cells take advantage of HIFs in order to proliferate in the hypoxic microenvironment of solid tumors. HIFs are, therefore, considered promising targets of anticancer therapy.

The activation of HIFs, and especially HIF-1, in cancer cells is often mediated by oncogenic signaling pathways in an oxygen-independent manner. We have previously identified two kinases that phosphorylate and regulate the activity of HIF-1α. ERK1/2 modifies the C-terminal domain of HIF-1α and stimulates its transcriptional activity by blocking its CRM1-dependent nuclear export (1), inhibiting its interaction with non-nuclear proteins or promoting its binding to chromatin. On the other hand, CK1δ modifies the PAS-B domain of HIF-1α and impairs its association with ARNT, thereby inhibiting the formation of an active nuclear HIF-1 heterodimer (2). Our recent microscopical and live-cell imaging studies confirm the operation of these mechanisms in vivo and their importance for hypoxia target gene expression and cancer cell adaptation to low oxygen conditions.

Major characteristic of this adaptation is the shift from oxidative (aerobic) to glycolytic (anaerobic) metabolism, which cancer cells can employ even when grown under normal O_2 levels (Warburg effect). Although the role of HIF-1 in carbohydrate metabolism is well established, much less is known about the part that HIFs play in the metabolism of lipids. We, therefore, examined their involvement in regulation of lipid synthesis under hypoxia. We could show that hypoxia stimulates triglyceride formation and identified lipin 1, a phosphatidate phosphatase isoform that catalyzes the penultimate step in triglyceride synthesis, as a direct transcriptional target of HIF-1 (3). This HIF-1-dependent up-regulation of lipid formation may serve to safely store toxic free fatty acids that accumulate due to deficient oxidative degradation. Inhibitors of ERK-dependent HIF-1α phosphorylation impair this process and also reduce cancer cell viability under hypoxia.

TUE-471
Phosphoglucomutase1 is necessary for sustained cell growth under repetitive glucose depletion

K.-S. Kim[1], E. Bae[2], E. Koh[1], Integrated Genomic Research Center for Metabolic Regulation
[1]Biochemistry & Molecular Biology, Integrated Genomic Research Center for Metabolic Regulation, [2]Brain Korea 21 PLUS Project for Medical Sciences, Yonsei University College of Medicine, Seoul, Korea

Phosphoglucomutase (PGM) 1 catalyzes the reversible conversion reaction between glucose-1-phosphate (G-1-P) and glucose-6-phosphate (G-6-P). Although both G-1-P and G-6-P are important intermediates for glucose and glycogen metabolism, the biological roles and regulatory mechanisms of PGM1 are largely unknown. In this study we found that T553 is obligatory for PGM1 stability and the last C-terminal residue, T562, is critical for its activity. Interestingly, depletion of PGM1 was associated with declined cellular glycogen content and decreased rates of glycogenolysis and glycogenesis. Furthermore, cells lacking PGM1 showed suppressed proliferation under long-term repetitive glucose depletion. Our results suggest that PGM1 is required for sustained cell growth during frequent nutritional changes, probably through regulating the balance of G-1-P and G-6-P in order to satisfy the cellular demands during nutritional stress.
Keywords: cell growth, glucose depletion, phosphoglucomutase.

Photoperiodic control of carbon distribution during the floral transition in *Arabidopsis thaliana*

M. I. Ortiz-Marchena[1], T. Albi[1], E. Lucas-Reina[1], F. J. Romero-Campero[2], F. E. Said[1], B. Cano[1], T. Ruíz[1], J. M. Romero[1], F. Valverde[1]
[1]Instituto de Bioquímica Vegetal y Fotosíntesis, CSIC, [2]Department of Computer Science and Artificial Intelligence, University of Seville, Seville, Spain

Flowering is a crucial process that demands substantial resources. Carbon metabolism must be coordinated with development through a fine-tuning control that optimises fitness for any physiological need and growth stage of the plant. The circadian-regulated gene *CONSTANS* (*CO*) plays a central role in the photoperiodic control of the floral transition. Recently, a *CO* homologue gene present in the genome of the unicellular green alga *Chlamydomonas reinhardtii* (*CrCO*) was identified. *CrCO* has a conserved role in the coordination of processes regulated by photoperiod and the circadian clock [1]. To study the rate of conservation of the photoperiodic signaling, the analysis of transitory starch accumulation and glycan composition during the floral transition in *Arabidopsis* were analyzed. *As GBSS* (Granule Bound Starch Synthase) expression is controlled by *CrCO* in *Chlamydomonas reinhardtii* [2], in order to study the same effect in *Arabidopsis thaliana*, we followed the expression of the *GBSS* gene in several mutants in short and long day conditions [3]. Moreover, *GBSS* was fused to GFP to study its tisular localization during a 24 h period. *CO*-overexpressing and *CO* mutant plants were crossed to *GBSS* mutant and their floral phenotype observed. The effect of *CO* on *GBSS* could be part of a new regulatory mechanism connecting photoperiodic signaling with carbon metabolism in plants [4]. Photoperiod modification of starch homeostasis by CO may be crucial to increase the sugar mobilization demanded by the floral transition, contributing to our understanding of the flowering process [5].

Photoperiodic control of carbon distribution during the floral transition in *Arabidopsis thaliana*

Physiological-biochemical adaptation of herbs

M. Zhivetyev[1], **K. Kirichenko**[2], I. Graskova[1]
[1]Laboratory of Phytoimmunology, [2]Laboratory of Physiological Genetics, Siberian Institute of Plant Physiology and Biochemistry SB RAS (SIPPB SB RAS), Irkutsk, Russian Federation

The research of state of ecological systems both Lake Baikal and area, testing climate-generate influence of this lake, was actually. The plant adaptation to unfavorable factors of environment, including a low temperature, touch on protein, lipids, carbohydrate metabolism. Some signal molecule is necessary to switching on adaptive process. One of them are oxygen active forms. So long as active forms of oxygen play the important role in beginnings of adaptation, the peroxidase is attract attention of researcher. We was research leafs of plants of fives species, growing in Irkutsk and on the southeastern shore of Lake Baikal. These species are *Achillea asiatica* Serg., *Taraxacum officinale* Wigg., *Plantago major* L., *Veronica chamaedrys* L., *Alchemilla subcrenata* Buser. In leafs of it we was identify the activity of peroxidase, sugars, stress-induced proteins. The variation of activity of weak-associated with plant cell wall and soluble peroxidases of five species of medicinal herbs has been identified for the first time subject to thermal regime and subject to place of growth. In October the coming of negative temperature led to slump of peroxidase activity of plants, growing in Irkutsk. Inversely, plants, sprouting on shores of Lake Baikal, were intensifying activity of this ferment. All described above can be evidence of initiation of unlike adaptation mechanisms in Irkutsk and at Baikal shores subject to environmental conditions. Also the activity of peroxidase was variable during vegetation period. Dehydrine expression

© 2014 The Authors. FEBS Journal © 2014 FEBS

was followed by spike of peroxidase activity. Dehydrine into leafs in August and middle of October was shown. The reinforcement of dehydrine biosynthesis to medium of October was observed. Also synthesis of dehydrine in summer was happened and this may take place under dehydration of both tissues end cells under sunlight end high temperature. Increase of content of sugar, doing cryoprotector function, was shown to end of vegetation period. The accumulation of sugars on shores of Lake Baikal was going on greater than it in Irkutsk. In August plants of shores of Lake Baikal was being adapt for soft autumn climate better than plants, growing in Irkutsk, and the former are maintaining the prolonged adaptation to frost. Differences of plants adaptation mechanisms at the time and the power were detect. These differences apparently are related to distinctions in both power and combination of stressors in spots of sampling. Particularly, at Lake Baikal the peroxidase activity inside leafs of majority of studied plants was more than it in Irkutsk. In autumn, the accumulation of sugars, stressful proteins (stress-induced proteins) in leafs of plants have been registered in Lake Baikal larger then in Irkutsk.

Keywords: activity of peroxidase, content of sugars, dehydrine biosynthesis.

PKD links golgi to nutrient starvation response in pancreatic β cells

A. Goginashvili[1], E. Erbs[1], A. Pasquier[1], N. Schieber[2], K. Krupina[1], P. Kessler[1], I. Sumara[1], C. Settembre[3], Y. Schwab[2], R. Ricci[1]

[1]IGBMC, Illkirch, France, [2]EMBL, Heidelberg, Germany, [3]TIGEM, Naples, Italy

Pancreatic β cells lower insulin release in response to nutrient depletion. Whether nutrient-deprived β cells induce macroautophagy, a predominant cellular mechanism maintaining energy homeostasis upon starvation, remains poorly explored. We demonstrate herein that, in contrast to other mammalian cells, macroautophagy in β cells is suppressed upon nutrient deprivation. Instead of macroautophagy, starved β cells induce lysosomal degradation of nascent secretory insulin granules in the vicinity of the Golgi. Starvation-Induced Nascent Granule Degradation (SINGD) is controlled by Protein Kinase 1 (PKD1), a key player in Secretory Granule (SG) biogenesis. SINGD in turn triggers lysosomal recruitment and activation of mechanistic Target Of Rapamycin (mTOR) that suppresses macroautophagy. Switching from macroautophagy to SINGD is important to keep insulin secretion low under nutrient-poor conditions. Hence, β cells employ a PKD1-dependent mechanism to adapt to nutrient availability coupling autophagy flux to secretory function.

Keywords: autophagy, mTOR, secretory granules.

TUE-475

Polyglucosan molecules induce testis degeneration and apoptosis in germ cells without affecting the integrity and functionality of sertoli cells

F. Villarroel-Espíndola[1], J. J. Guinovart[2,3], I. I. Concha[1], J. C. Slebe[1]

[1]Bioquímica Y Microbiología, Universidad Austral De Chile, Valdivia, Chile, [2]Institute for Research in Biomedicine (IRB Barcelona), [3]University of Barcelona, Barcelona, Spain

Glycogen is the main storage form of glucose for most tissues; however, the accumulation of aberrant polyglucosan molecules can lead to degeneration and death in some cell types. Previously, we reported that the accumulation of glycogen in testis of transgenic animals overexpressing a constitutively active form of glycogen synthase (KIN-GS) enhances the apoptosis of pre-meiotic cells in seminiferous tubules. Similarly, the activation of endogenous glycogen synthase (GS) in a germ cell line (GC-1) stimulates the deposition of glycogen and triggers the activation of caspase 3. Here we sought to further identify the effects of glycogen storage in GC-1 and Sertoli cells (42GPA9 cell line) and the mechanism behind the pro-apoptotic activity induced. By spectrophotometric analysis, we found that glycogen synthesized in both cell lines—by expression of a superactive form of GS or by activation of endogenous GS by PTG (*Protein Targeting to Glycogen*) expression—is poorly branched. In addition, the immunodetection of cleaved caspase 3/9 suggests that cellular death induced by polyglucosan molecules affects GC-1 but not 42GPA9 cells. The former cells showed changes in intracellular ATP and cytochrome C content after polyglucosan accumulation, thereby suggesting mitochondrial impairment and activation of an intrinsic apoptotic pathway. Furthermore, we analyzed the effects of glycogen deposition during the establishment of an *in vitro* blood-testis barrier. The results using a non-permeable fluorescent molecule (Evans blue) showed that, in conditions of over-synthesis of glycogen, 42GPA9 cells do not lose their capacity to generate an impermeable barrier. In the same cell line, immunodetection showed that the levels of connexin43 (Cnx43), occludin (Occl), and ZO1 proteins were not affected by glycogen accumulation. Similarly, in the KIN-GS mice, the distribution and intensity of signals for Cnx43, Occl, and ZO1 point to a Sertoli cell-only syndrome in this model, affecting the viability of male germ cells but not the viability or stability of Sertoli cells, as shown by confocal microscopy analysis. These results confirm that the accumulation of polyglucosan molecules has a selective effect—triggered by the intrinsic activation of the apoptotic pathway—in germ cells. Polyreactivity of human milk catalytic antibodies as a result of HL-fragments exchange

S. Sedykh, V. Buneva, G. Nevinsky

Laboratory of Repair Enzymes, SB RAS ICBFM, Novosibirsk, Russian Federation

The key feature of antibodies is monoreactivity of the antigen binding sites within a single molecule. Monospecific antibodies play a key role in the removal of antigens from the organism. Catalytically active antibodies were found in the blood of patients with autoimmune, viral and bacterial infections, as well as in the human milk. We propose that the human milk bispecific antibodies exhibit other function than the excretion of the antigens.

We have demonstrated that human milk contain substantial amounts of the catalytic bispecific IgG and polyspecific sIgA. We have shown that IgG and sIgA of the human milk eluted from the DNA-cellulose, ATP-Sepharose, casein-Sepharose posess hydrolysis of DNA, ATP, oligosaccharides and phosphorylation of proteins, lipids and oligosaccharides.

In the preparations of human milk IgG and sIgA we have found chimeric antibodies which contain kappa and lambda light chains simultaneously, the chimeric κλ-IgGs were presented by all subclasses (IgG1-IgG4). Adding of the reduced glutathione and the components of milk plasma to the immunoglobulin fractions with different affinities to the DNA-cellulose leads to transi-

© 2014 The Authors. FEBS Journal © 2014 FEBS

tion from the one fraction to the other. This phenomenon can be explained by the HL-fragments exchange between different immunoglobulin molecules, but not the exchange of light chains.

We plan a detailed study of the human milk factor, providing such HL-fragments exchange.

The reported study was partially supported by RFBR, research projects 13-04-00205, 13-04-00208.

TUE-477
Possible implications of copper chelation on iron homeostasis in Wilson disease patients. Penicillamine effect on ceruloplasmin ferroxidase activity

J. Usta[1], T. Majarian[1], O. El-Rifai[1], K. Barada[2]
[1]Biochemistry & molecular Genetics, [2]Division of Gastroenterology, Department of Internal Medicine, American University of Beirut, Beirut, Lebanon

Introduction: Ceruloplasmin (Cp) belongs to multi-copper ferroxidase family of proteins. It is involved in Fe loading into serum transferrin. Defective copper loading into apo-ceruloplasmin (apo-Cp) may result from mutations in the ATP7B gene characterizing Wilson disease (WD). Patients with WD are treated with copper chelators such as penicillamine (PA)

Goals & Methods: We postulate that Cu- chelators will reduce copper incorporation into apo-Cp which will affect ferroxidase activity; consequently disturb iron homeostasis. We hereby investigate the *in vitro* effect of Cu, & Cu-PA on HepG2 viability (MTT assay), ferroxidase activity of Cp (pPD oxidase assay) and expression of Cp, ferritin and transferrin (Western blotting). In addition we examine the activity of serum Cp ferroxidase activity in 5 WD patients who are homozygous for a mutation in WND gene & are treated by PA.

Results & conclusions:

In vitro: Cu decreased (50%) viability of HepG2 cells while co-treatment with Cu-PA altered cell morphology significantly, decreased further cell viability (70%) and induced cell cycle arrest at G2/M phase.

Cp expression in HepG2 cells increased with Cu, decreased with PA, & did not vary with Cu-PA.

Ferritin expression in HepG2 cells decreased with Cu, PA and Cu-PA treated cells

Transferrin expression show qualitative decrease in PA and Cu-PA treated cells

In Vivo: All patients had very low serum Cp ferroxidase activity (0.007–0.01 units) compared to a control (0.022–0.027 units). Mild elevation was noted in 2 patients while transferrin level was in normal range.

Cp Ferroxidase activity in both HepG2 cells and Serum of WD patients was significantly decreased. The recommended life treatment with Cu chelators would influence Fe incorporation into transferrin that may consequently lead to Fe deposition in liver.

The implication of our findings necessitate the re-evaluation of PA treated WD patients for iron complications.

TUE-478
Potential role of Focal Adhesion Kinase in lipid metabolism

D. Gnani[1], N. Panera[2], S. Ceccarelli[1], A. Crudele[1], C. De Stefanis[2], R. Rota[3], V. Nobili[2], A. Alisi[1]
[1]Liver Research Unit, [2]Hepato-Metabolic Disease Unit, [3]Department of Oncohematology, Bambino Gesù Children hospital, Rome, Italy

Non alcoholic fatty liver disease (NAFLD) is a common metabolic disorder in Western countries, characterized by pathological hepatic lipid accumulation in the absence of alcohol abuse. Simple steatosis can progress to non alcoholic steatohepatitis (NASH), which includes hepatocyte ballooning, inflammation and hepatic fibrosis.

The NAFLD multifactoriality has been profoundly investigated, highlighting a complex network of interactions between genetic, epigenetic and environmental factors. However, the full mechanism underlying NAFLD onset and progression remains still unclear.

Interestingly, the Focal Adhesion Kinase (FAK) family interacting FIP200 protein, active as FAK inhibitor and autophagy inductor, has been recently associated to liver steatosis development. Although the role of FAK as mediator of integrin signalling is well known in liver cancer, its involvement in hepatic lipid metabolism during NAFLD has not been investigated so far.

To study the relationship between FAK and hepatic lipid accumulation, we performed an *in vitro* silencing of FAK in HepG2 cells. Oil-red-O staining, Real-Time PCR and Western Blotting were performed to assess the effect of FAK silencing on lipid accumulation and expression of lipid metabolism-related genes.

Interestingly, FAK-silenced HepG2 cells accumulated more lipids than control cells, but they showed a decreased expression of genes involved in lipid synthesis such as *SREBF1, FASN* and *LIPIN1*. These results suggest that the excessive lipid storage in FAK-silenced cells could be dependent on defects in the β-oxidation pathway.

In a recent study, we showed that inhibition of the histone-lysine N-methyltransferase EZH2 caused increased lipid accumulation and up-regulation of inflammatory genes encoding for TNF-α and TGF-β and mir-200b in *in vitro* NAFLD. So, we hypothesize a possible link between FAK and EZH2 in fatty liver development. Interestingly, we found a down-regulation of EZH2 at the transcript level in FAK silenced HepG cells. Since we found no changes in the protein levels of EZH2, a deregulation of its activity is expected. In fact, we found an increased expression of the EZH2-targeted mir-200b in FAK-depleted cells. Furthermore, FAK silencing, similarly to EZH2 inhibition, induced an up-regulation of TNF-α and TGF-β expressing genes.

In conclusion our results suggest a direct/indirect link between steatogenic effects of FAK silencing and EZH2 inhibition. However, further experiments are needed to better understand the molecular nexus between FAK and EZH2 Lys-27 Histone3 trimethylation activity and the down-stream targets involved in the control of lipid homeostasis.

Keywords: Focal Adhesion Kinase, lipid metabolism, NAFLD.

TUE-480
Prognostic significance of serum angiopoietin-2 levels and protein redox regulation in chronic lymphocytic leukemia patients

M. Kutnu[1], H. Uzun[1], T. Soysal[2], D. Keskin[2], N. S. Esatoglu[2], **S. Civelek**[1]
[1]Biochemistry, [2]Hematology, Istanbul University, Cerrahpasa Medical University, Istanbul, Turkey

Chronic lymphocytic leukemia (CLL) is a lymphoproliferative disorder with the highest incidence in adult population and it has a wide variety of clinical manifestations among the suffers. The aim of current study is to reveal the prognostic importance of 20S proteasome and angiopoietin-2 (Ang-2) parameters and the relationship of those parameters with other prognostic markers of CLL. The systemic levels of oxidative protein damage markers such as advanced oxidative protein products (AOPP) and protein carbonyl (PCO), and proteasome concentrations were also evaluated to clarify protein redox homeostasis in CLL patients. The patient group was formed by the 60 patients who were admitted to Istanbul University Cerrahpasa Medical Faculty, Hematology Clinic. 20 individuals were considered as healthy volunteers to form control group. In patient group, Ang-2, AOPP, PCO and proteasome concentrations were significantly higher than corresponding healthy controls (for all parameters $p < 0.001$). According to modified Rai grading system high risk grade was accepted as state variable, thus diagnostic performance of Ang-2, AOPP, PCO parameters were evaluated by using ROC analysis and Ang-2 levels showed highest specificity (% 82.9) and sensitivity (% 84.6) ($p < 0.001$). There was no significant variation among grades for AOPP. In conclusion, because of high levels of PCO, AOPP and proteasome; redox homeostasis may be impaired in patients with CLL. Systemic Ang-2 and 20S proteasome concentrations may be used for better evaluation of clinical grade and as well as independent of grade, for the purpose of rutine clinical laboratory analysis. Further clinical studies are needed to support our current findings and conclusions.

Keywords: angiopoietin-2, protein redox regulation, chronic lymphocytic leukemia.

TUE-481
Properties and conformational changes in mutants from *Spodoptera frugiperda* midgut trehalase

W. Silva, W. R. Terra, C. Ferreira
Department of Biochemistry, Universidade de São Paulo-USP, Sao Paulo, Brazil

Trehalase specifically hydrolyses trehalose to the two constituent glucose units. The enzyme is important for metabolism, since trehalose is the insect main circulating sugar. Previous studies amassed evidence that *S. frugiperda* midgut trehalase has substantial conformational changes on binding different substances. These changes may be responsible for our failure in obtaining the enzyme crystal. Our goal is to produce mutants with less molecular mobility and compare its properties with the wild type enzyme. Based in molecular modeling of *S. frugiperda* trehalase with *Escherichia coli* enzyme we found an N-terminal and a C-terminal region with no defined structure. Two deletion mutants were produced, one lacking 102 residues from the N-terminus (NT) and other lacking this portion plus 31 residues from the C-terminus (NCT). The wild type (WT, 64.7 kDa), NT (52.6 kDa) and NCT (49.6 kDa) were actively expressed. Both mutants have similar Km values (NT 0.85 mM; NCT 0.68 mM) lower than the WT (1.1 mM). The interaction with inhibitors are different among the enzymes. As a rule, the inhibition Ki of amygdalin (WT= 0.21, NT= 0.40 and NCT= 0.48 mM) and mandelonitrile (WT= 13, NT= 27 and NCT= 12 mM) is higher in the mutants. The overall results show that the removal of 102 or 133 amino acids does not greatly change the interaction with ligands, but leads to a considerable decrease in the kcat value, resulting in the following kcat/Km values: WT 74 500 M^{-1} s^{-1}; NT 647 M^{-1} s^{-1} and NCT 1044 M^{-1} s^{-1}. Changes in the molecular folding on ligand binding affects the fluorescence emission of Sypro Orange dye, which binds to hydrophobic regions increasing its fluorescence. The enzymes were incubated with or without substrate, glucose and several inhibitors (gentiobiose, methyl-alpha-mannoside, methyl-alpha-glucoside, amygdalin, prunasin, mandelonitrile and mandelonitrile plus gentiobiose) in the presence of the dye. Trehalose did not cause any change in fluorescence of the enzymes. Two substances increase the fluorescence when WT is present, whereas 5 and 6 compounds affected the fluorescence when respectively NT and NCT are present in the medium. This means that WT was the less affected enzyme and that the shorter enzyme (NCT) is the more mobile one. Four compounds decrease, whereas 5 compounds increase the fluorescence of the dye when respectively NT and NCT are present, pointing out that on binding, NCT exposes hydrophobic residues, whereas the contrary is true for NT. The data suggest that conformational changes occur only in the vicinity of the active site. The wild type has external loops that hinder the mobile region, which is more exposed in the truncated mutants.

TUE-482
Properties of arginase-NO-synthase system in peripheral blood lymphocytes of ovarian cancer patients

Z. Vorobets[1,], N. Vorobets[1], O. Yakubets[1], M. Kalinski[2]
[1]Department of Medical Biology, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine, [2]Department of Applied Health Science, Murray State University, Murray, KY, USA

Peripheral blood lymphocytes, which provide compensatory-adaptive reactions in the body are important objects for research, related to study of the toxic effect of the products from the tumor cells. In particular, the role of NO-dependent mechanisms in the development of cancer, is relatively novel topic. For the synthesis of NO by involving the enzyme NO-synthase, L-arginine is used as a substrate, as well as a substrate for arginase. Arginase, as a competing substrate for the enzyme is able to significantly influence the activity of NO-synthase reaction and represents an important link in the development of several pathological conditions. Thus, arginase-NO-synthase system may also be involved in the mechanisms of anticancer drugs effects. The aim of this work was to study the properties of arginase and the kinetic characteristics of this enzyme in the peripheral blood lymphocytes of female subjects suffering from ovarian cancer before and after treatment with cyclophosphamide ((RS)-2-[bis(2-chloroethyl) amino] tetrahydro -2H-1,3,2-oksazafosforyn 2-oxide). Cyclophosphamide is a cytostatic drug. Its mechanism of action involves the formation of the transverse cross-links between the chains of DNA and inhibition of protein synthesis. This drug also has a strong immunosuppressive effect on predominant inhibition of B- and T-lymphocytes. Lymphocytes were extracted from freshly received, heparin treated blood, from patients with ovarian cancer and a control group (clinically healthy female patients) using fikol-urohrafin concentration gradient. To reveal of the latent enzymatic activities, they were trea-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ted with 0.2% saponin. It was shown that arginase activity of lymphocytes in female patient with ovarian cancer increased by 3.8 times, and eNOS activity was reduced by 4.1 times compared to the control values. We found a significant increase in activity of iNOS in ovarian cancer patients with inhibited eNOS in blood lymphocytes. After surgical and chemotherapeutic treatment with cyclophosphamide, arginase activity remained higher compared to control values by 1.7 times. While the activity of eNOS was increasing, iNOS activity was decreasing in these patients. The use of cyclophosphamide chemotherapy in ovarian cancer patients in this study led to the normalization of the arginase and NOS activities.

Key words: lymphocytes, ovarian cancer, NO-synthase

TUE-483
Protective effects of exogenously administered testosteron on oxidative damage in rat testicular tissue

T. Ozan[1], K. Yanar[2], T. Cebe[1], A. Kunbaz[1], P. Atukeren[2], U. Çakatay[2], S. Aydın[2]
[1]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]Medical Biochemistry, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Spermatogenesis is a lifelong process which requires approximately 64 days. Reduction in the number of Leydig and Sertoli cells, diminished capacity of testosterone synthesis, thickening of the basal membrane of the seminiferous tubules and accumulation of lipofuscin granules by oxidative stress are commonly seen in testicular aging. Not only spermatogenesis but also androgen synthesis in testicular tissue adversely affected by impaired redox status. Thus, the optimal regulation of various antioxidant enzymes and the efficiency of the free radical scavenger systems play a critically important role in aging males.

Experimental animals divided into three groups: naturally aged rats (NA:% 0.9 NaCl), testosterone administrated naturally aged rats (TANA: single dose, 25 mg/kg testosterone subcutaneously administered) and their corresponding young controls (YC:% 0.9 NaCl subcutaneously). We analyzed protein oxidation markers: protein carbonyl (PCO) and thiol groups (P-SH); lipid peroxidation markers: lipid hydroperoxides (LHP) and malondialdehyde (MDA); glycoxidation markers: advanced glycation end products (AGEs); antioxidant status parameters: total thiol (T-SH), low-molecular weight nonprotein thiol (NP-SH) groups and Cu,Zn-superoxide dismutase (Cu-Zn,SOD) activity in rat testicular tissue.

As a protein oxidation biomarker, only the levels of PCO groups of TANA rats were found to be significantly lower compared to those in the NA ($p < 0.001$). Although there was a trend toward higher P-SH levels in TANA rats compared to those in NA rats, P-SH levels were not found to be significant. Both TANA and YC groups showed significantly lower LHP and MDA levels as compared to NA rats ($p < 0.01$ NA vs TANA for LHP and MDA; $p < 0.01$, $p < 0.001$ NA vs YC for LHP and MDA respectively). Testicular protein-bound AGEs levels of TANA rats were found to be significantly lower compared to those in NA rats ($p < 0.001$). As antioxidant status parameters only NP-SH concentrations in TANA rats were significantly higher than NA rats ($p < 0.001$). Although there was a trend toward higher T-SH and Cu,Zn-SOD activities, they were not found significant among the groups.

Our results showed that exogenous testosteron administration to the aged rats restored redox homeostasis of proteins, lipids, and low-molecular weight non-protein thiol groups in rat testicular tissue without any alteration Cu,Zn- SOD activity. Additionally, decreased protein bound AGEs levels in TANA rats may play a protective role in keeping the optimal status of protein redox regulation.

Keywords: aging, testicle, testosterone.

Grenoble Alpes-EMBL-CNRS, Grenoble, France, [7]Institute of Complex Systems (ICS-6), Juelich, Germany, [8]Joint Institute for Nuclear Research, Dubna, Russian Federation, [9]Institut de Biologie Structurale J.-P. Ebel, Grenoble, France

Here, we study the mechanism of iron metabolism in ferritin using complimentary techniques for structural studies of multi-subunit protein complexes in solution, such as the small-angle scattering (SAS) method and computational docking. The interest in studying ferritin (apoferritin) arises because it is very likely to be a candidate for cancer and biological age marker [1]. Some apoferritin constructions could also be used as a vaccine against influenza diseases [2].

The function of ferritins in living organisms is iron storage. The fundamental problem is associated with the question of solving ferritin/apoferritin structure, which is essential for understanding molecular mechanisms of iron metabolism activity of these proteins. Despite the intensive research, the large-scale arrangement of the protein complexes is still unknown.

We studied the heavy-water solutions of apoferritin with the help of SAS X-Rays and neutrons. Three instruments have been used for the experiments: BM29, ESRF, Grenoble, France; installation Rigaku, Laboratory of Advanced Studies of membrane proteins, MIPT, Russia; and YuMO spectrometer, IBR-2, Dubna, Russia [3]. We obtained radii of gyration, volume, and the intensity extrapolated in zero value of modulus scattering vector. We demonstrated that in water solutions the proteins interact

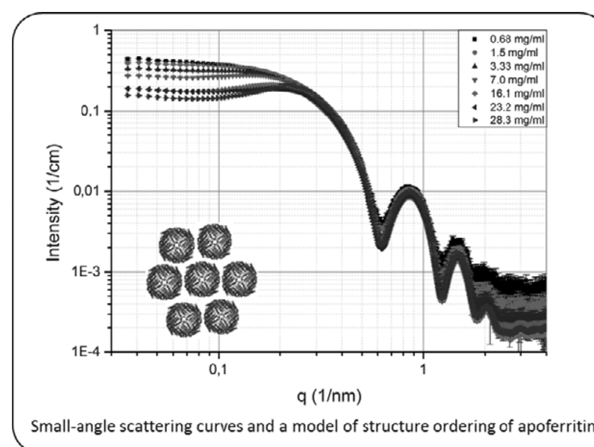

Fig. 1. Small-angle scattering curves and a model of structure ordering of apoferritin.

© 2014 The Authors. FEBS Journal © 2014 FEBS

with each other even at low concentrations. Also, we recovered the form-factor and the structural factor from the SAS curves. It follows that the distance between individual protein assemblies is about 150 Å for some of the highest concentrations. This allowed us to suggest a model of structure ordering for protein molecules in solution. Finally, we studied the sensitivity of SAS curves to fluctuations in protein structure by computational methods of molecular docking.

Proteomics and biochemical strategies for the development of breast cancer biomarker and treatment selection

K. V. Kaliasniova[1], Y. S. Bakakina[1], M. M. Molchan[1], N. A. Kazlouskaya[2], N. A. Shukanova[2], E. V. Shapoval[2], L. V. Dubovskaya[1], I. Volotovski[1]
[1]Institute of Biophysics and Cell Engineering, [2]N.N. Alexandrov National Cancer Centre of Belarus for Oncology and Medical Radiology, Minsk, Belarus

Breast cancer is one of the most common women oncological heterogeneous disease subdivided into different subtypes. Very often its therapy depends on early diagnostics. Proteomics analysis is known to be an effective approach for identification of disease biomarkers. 2D gel-electrophoresis represents a powerful and widely used proteomic method for the analysis of complex protein mixtures extracted from cells, tissues, or other biological samples. The diagnostic profile of protein expression in blood plasma of breast cancer patients has been defined previously. But all of differentially expressed proteins were nonspecific markers and corresponded to acute phase response.

In this work we tried to compare the secretome of breast tumor cells with blood plasma proteome of breast cancer patients to find unique biomarkers for each breast cancer subtypes. All patients were divided into groups according to breast cancer subtypes (Luminal A, Luminal B, Triple negative/basal-like and HER2 type). Patients with fibroadenoma (a benign breast tumor) were considered as a control group. The method of primary culturing of breast tumor cells from surgery and bioptic samples of patient have been developed. It was found that cell secretome and proteome composition profiles strongly depend on type of cell culture. The qualitative compositions of blood plasma proteins of patients were also different for each group of patients. The correlation analysis of 2D maps for obtained cell culture and blood plasma revealed potential markers some of which were identified by mass spectrometry.

It was also shown that acetylcholinesterase activity of breast cancer cells correlates with their proliferative activity. The biochemical parameters characterizing the influence of drugs on metabolic processes in primary culture of breast cancer cells have been determined. Thus, acetylcholinesterase activity can be used as criterion for assessment of tumor cells sensitivity to anticancer drugs during the treatment selection. We suppose that obtained results can be used in breast cancer diagnosis and choice of the treatment

TUE-486
Proton translocating ATPase activity of *Escherichia coli* membrane vesicles under mixed carbon fermentation at alkaline and acidic pHs

S. Blbulyan, A. Trchounian
Microbiology & Plants and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia

Escherichia coli is able to ferment glycerol and to produce molecular hydrogen (H_2) by using different hydrogenases (Hyd). Hyd-3 and Hyd-4, together with formate dehydrogenase H (Fdh-H), forms the formate hydrogenlyase (FHL) complexes, which are responsible for H_2 evolution by intact cells. Hyd-4 activity has been shown to be inhibited by *N,N'*-dicyclohexylcarbodiimide (DCCD) [1]. The requirement of F_0F_1-ATPase for Hyd activity has been shown for glycerol fermentation conditions depending on pH, and some relationship of F_0F_1 with Hyd enzymes is suggested [2].

In this study was investigated overall and DCCD-sensitive ATPase activity of mixed carbon fermented (glucose and glycerol) *E. coli* wild type BW25113, *E. coli* FM460 (with deficiency of Fdh-H, Fdh-O, Fdh-N), and *E. coli* KT2110 (with Fdh-H, Fdh-O, Fdh-N, HyaB, HybC deficiency) mutant strains membrane vesicles at different pHs.

ATPase activity of wild type was ~10-fold higher ($p \leq 0.05$) at pH 7.5 compared with that at pH 5.5. DCCD inhibited ATPase activity of wild type ~2.5-fold ($p \leq 0.02$) at pH 7.5, but at pH 5.5 – ~1.2-fold ($p \leq 0.025$). In mixed carbon grown cells, compared with wild type cells, ATPase activity at pH 7.5 was lowered ~1.3-fold ($p \leq 0.02$) in FM460 and ~5-fold ($p \leq 0.025$) in KT2110 mutants. At pH 5.5 ATPase activity of FM460 mutant membrane vesicles was shown to be ~3-fold lower ($p \leq 0.05$) compared with those at pH 7.5. Moreover, ATPase activity of KT2110 at pH 5.5 was ~1.7-fold higher compared with those at pH 7.5. Note that ATPase activity of FM460 and KT2110 mutants at pH 5.5 was similar. DCCD inhibited ATPase activity of FM460 and KT2110 mutants ~3-fold and ~1.2-fold ($p \leq 0.05$) at pH 7.5, respectively.

The suppressed ATPase activity in KT2110 mutant membrane vesicles suggests the cooperation of different components of F_oF_1-FHL supercomplex upon mixed carbon fermentation at alkaline pH. The results also show that alkaline pH is more optimal for the *E. coli* F_oF_1-ATPase activity upon mixed carbon (glucose and glycerol) fermentation.

TUE-487
Purification of Euphorbia characias endochitinase III

D. Spanò[1], K. Pospiskova[2], I. Safarik[3], G. Floris[1], R. Medda[1], **F. Pintus**[1]
[1]Department of Sciences of Life and Environment, University, Monserrato (CA), Italy, [2]Regional Centre of Advanced Technologies and Materials, University, Olomouc, [3]Department of Nanobiotechnology, Institute of Nanobiology and Structural Biology of GCRC, Ceske Budejovice, Czech Republic

Chitinases, enzymes hydrolyzing β-1,4 glycosidic bonds of chitin, have been found animals, plants, insects, fungi, bacteria, and viruses. *Euphorbia characias* is a shrub growing abundantly in vast Mediterranean areas. *E. characias* is characterized by the presence of laticifers highly specialized cells. Laticifers contain a sticky milky sap called latex. A Class III endochitinase from *E. characias* latex (ELC) was purified. The purification method includes an effective step using magnetic chitin particles. *E. characias* latex was collected into test tubes and centrifuged at 19000 rpm for 30 min. The supernatant was incubated with magnetic chitin equilibrated in 10 mM KPi buffer, pH 7.0. The incubation was carried out for 1 h, at 4°C, under continuous stirring. Afterwards, the complex enzyme-magnetic chitin was separated from latex using a strong magnetic separator; this complex was washed with 10 mM KPi buffer pH 7.0 to remove the ballast proteins. Then, the chitinase was eluted from magnetic chitin with 100 mM acetic acid, pH 2.8. The solution was immediately adjusted to pH 7.0 with 1 M NaOH and dialyzed against 10 mM KPi buffer pH 7.0. The dialyzed chitinase was loaded on DEAE cellulose column equilibrated with the same buffer. In these conditions the enzyme was not bound to the column and was eluted and collected until the A_{280} became ≤0.01. SDS-PAGE profile reveals a unique protein band of 36.5 ± 2 kDa. The optimal chitinase activity is observed at pH 5.0 in 100 mM NaOAc buffer and at 40°C. *E. characias* latex chitinase hydrolyzes colloidal chitin, and N-acetyl D-glucosamine, chitobiose and chitotriose are observed as reaction products. ELC has both endo and exo chitinase activities. Calcium ions enhance chitinase activity 5–8 times and magnesium ions 2–3 times.The partial ELC cDNA contained an open reading frame of 762 bp, encoding a protein of 254 amino acids (GenBank JX564541). ELC amino acid sequence showed a very high degree of identity (92–99%) to chitinases isolated from several other higher plants. It also contained the conserved sequence of the catalytic domain of family 18 glycoside hydrolases, LDGIDFDIE, from position 145–154 and the presence of six cysteine residues at conserved positions in all class III chitinases.

Keywords: Euphorbia characias; magnetic particles; chitinase.

TUE-488
Recombinant microbial creatinine deiminase as a bioanalytical tool

M. Gonchar[1,2], A. Zakalskiy[1], Y. Rzhepetskyy[3], O. Hryniv[4]
[1]Analitycal Biotechnology, Institute of Cell Biology, Lviv, Ukraine, [2]Biotechnology, Institute of Applied Biotechnology and Basic Sciences, Rzeszow University, Kolbuszowa, Poland, [3]Cell Signaling, [4]Molecular Genetics and Biotechnology, Institute of Cell Biology, Lviv, Ukraine

Creatinine is one of the most important diagnostic biomarkers for detection of kidney and muscle dysfunctions. To determine creatinine content in biological fluids, creatinine deiminase can be used as a bioanalytical tool. This enzyme is also very important for the construction of creatinine-sensitive biosensor to be used in hemodialysis control. Up to now, the unsolved problem is insufficient stability of commercial available creatinine deiminase, so overproduction of the stable form of this enzyme is very important.

The recombinant strain of *Escherichia coli* that is capable of overproducing microbial creatinine deiminase has been constructed. The $(His)_6$-tagged enzyme was purified in one step from the cell-free extract of the recombinant *E. coli* strain by metal-affinity chromatography. The specific activity of the purified enzyme is 10 μmoles per min and mg of protein. The yield of the recombinant protein is approx. 50 mg from 1 l of culture.

The isolated recombinant creatinine deiminase can be applied for the determination of creatinine in clinical samples using enzymatic method, as well as an automated biosensor-based system.

Keywords: recombinant creatinine deiminase, over-production, purification.

TUE-489
Redox regulation mechanisms in cardiac tissue of testosterone administrated rats

T. Cebe[1], K. Yanar[2], A. Kunbaz[1], T. Ozan[1], M. Mengi[3], P. Atukeren[2], S. Aydın[2], U. Çakatay[2]
[1]İstanbul University Cerrahpaşa Medical Faculty, [2]Medical Biochemistry, [3]Physiology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

We analyzed various oxidative stress biomarkers including protein carbonyl groups (PCOs), lipid hydroperoxides (LOOHs), malondialdehyde (MDA), advanced glycation end products (AGEs) and antioxidant status parameters such as total thiol (T-SH), non-protein thiol (NP-SH), protein thiol groups and Cu,Zn superoxide dismutase (Cu,Zn-SOD) activity in cardiac tissue of rats. Experimental animals divided into three groups: naturally aged rats (NA) (IP: %0.9 saline), testosterone administrated naturally aged rats (TANA: 25 mg/kg testosteron) and their corresponding young controls (YC:% 0.9 saline).

PCO, LOOHs, MDA, AGE concentrations in cardiac tissue of NA rats were significantly higher than TANA and YC rats (Both NA vs YC and NA vs TANA: $p < 0.05$; $p < 0.001$; $p < 0.01$ and $p < 0.05$ respectively for each parameters). T-SH and P-SH concentrations in NA rats were significantly lower than YC groups ($p < 0.05$ for both parameters). On the other hand, T-SH and P-SH concentrations significantly lower and LHP in testosterone administered group significantly higher than YC ($p < 0.05$; $p < 0.001$ respectively). NP-SH concentrations were not different among groups. Cu,Zn-SOD activities in NA group were significantly lower than YC group ($p < 0.05$). Additionally Cu-Zn SOD activities in TANA group tended to increase but they did not reach the statistical significance levels.

Our current results related to TANA rats show that the testosterone administration has a positive effects on redox status of the aged cardiac tissue.

Keywords: cardiac tissue, oxidative stress, testosterone.

Regulation and dynamics of human serine racemase

M. Marchetti[1], S. Bruno[2], B. Campanini[2], A. Peracchi[1], S. Bettati[3,4], A. Mozzarelli[2,4]
[1]Department of Life Sciences, [2]Department of Pharmacy, [3]Department of Neurosciences, University of Parma, Parma, [4]Institute of Biostructures and Biosystems, Rome, Italy

Human serine racemase (hSR), predominantly localized in neurons and astrocytes, is a dimeric pyridoxal 5'-phosphate (PLP)

© 2014 The Authors. FEBS Journal © 2014 FEBS

enzyme that catalyzes the reversible racemization of L-serine to D-serine, the physiologically relevant co-agonist of N-methyl-D-aspartate receptors. Because both high and low D-serine levels are associated with neuropathologies, hSR is a promising drug target. We have shown that that:

- ATP, an allosteric effector of hSR, binds in a strongly cooperative fashion, with a Hill coefficient close to 2, and causes a 30-fold increase in enzyme efficiency by reducing K_m and increasing k_{cat}.

- Ligands of the active site, such as glycine or malonate, allosterically increase ATP affinity by 100 fold, and, conversely, ATP binding increases malonate and glycine affinity by 9 and 15 fold, respectively.

- Binding of ATP to the external aldimine intermediate, formed by hSR with glycine, stabilizes a closed conformation of the active site, as probed by the coenzyme fluorescence quenching by iodide.

- Chloride and fluoride anions increase 1.5- and 3-fold, respectively, the beta-elimination activity of hSR, whereas iodide abolishes it. Unlike with other PLP-dependent enzymes, monovalent cations do not have significant effects on catalysis.

- Metal chelators (such as EDTA), phosphate, and, to a lesser extent, imidazole, strongly stabilize the enzyme.

These findings were interpreted on the basis of a model in which different ligands bring about the selective stabilization of alternative enzyme conformations, characterized by high and low affinity and reactivity.

TUE-491
Regulation of GLUT transporters in prostate cancer cells

P. Gonzalez-Menendez, D. Hevia, J. C. Mayo, R. M. Sainz
The University Institute of Oncology of Asturias (IUOPA)/ Morphology and Cell Biology, University of Oviedo, Oviedo, Spain

Cancer cells show different metabolic requirements than normal cells and this metabolic switch was already described by Otto Warburg in the 20's. One of the most important aspects of tumor metabolism is the high rate of glucose uptake by cancer cells. An increase in glucose uptake has been associated mainly with GLUT1 overexpression but may also involve other glucose transporters, including GLUT4. Despite this, the regulation of GLUT transporters in cell culture has been scarcely studied. In prostate cancer, particularly, glycolytic metabolism differs in androgen-responsive and nonresponsive cells. GLUT1 expression was previously described in prostate cancer cells but functional GLUT4 was recently found in our laboratory. Thus, the aim of this work was to study the regulation of GLUT transporters in prostate cancer cells and its relation with the glycolytic pathway. GLUT1/4 protein levels were analyzed by immunoblot with different glucose concentration in cell media at different times and with constant medium renewal. Actinomycin D (AD) and cicloheximide (CX) were used to evaluate the half-lives of these proteins. Synchronization of cell culture in G1/S and in G2/M was realized using respectively thymidine (DTB) and DTB plus nocodazole (Noc), and analysis of cell cycle phases was evaluated by flow cytometry. Glucose uptake was measured using nonradiolabeled 2-deoxyglucose. The evaluation of subcellular distribution of GLUT1/4 was analyzed by immunocytochemistry. Finally, nucleotides concentration was estimated by HPLC. Results show that both GLUT1 and GLUT4 are glucose and time-dependent, changing their levels along with time after medium renewal. Differences were found among cell lines and GLUT proteins. GLUT levels increased with time of culture and with glucose concentration in LNCaP cells while they decreased in PC-3 cells. Constant medium renewal caused a decrease in GLUT levels at 24 h in LNCaP cells but an increment in PC-3 cells, being similar to levels at 6 h. Half-life of GLUT1 was found to be 18 h while GLUT4 has a posttranscriptional regulation. Finally, GLUT1/4 levels changed differently in G1/S and G2/M cells synchronized cells. In conclusion, GLUT1/4 protein levels and glycolytic metabolism of prostate cancer cells are carefully regulate and they change in relation to the availability of glucose in culture media and more importantly depending of proliferation status of culture cells.

Keywords: GLUT transporters, Metabolism, prostate cancer.

TUE-492
Regulation of retinoid metabolism by FoxO transcription factors in retinal pigment epithelium

Y. Kim[1], S. Kim[1], H. Baek[2], S.-J. Lee[2], H. You[3], J. W. Kim[1]
[1]Department of Biological Sciences, Korea Advanced Institute of Science and Technology, Daejeon, [2]Department of Life Sciences, Postech, Pohang, Korea, [3]School of Life Sciences, Xiamen University, Xiamen, China

The inactivation of phosphatase and tensin homolog (PTEN) and consequent hyperactivation of Akt not only elevated a chance for tumorigenesis, but also caused age-related macular degeneration (AMD)-like retinal degeneration by triggering degeneration of retinal pigment epithelium (RPE) in mice. The activated Akt in PTEN-inactivated RPE phosphorylates various cellular proteins, including the forkhead box O (FoxO) transcription factors, to induce a series of changes in the cell. In this study, we investigated roles of FoxO in RPE homeostasis. The mice lacking *FoxO1,3,4* genes specifically in RPE develop retinal degeneration in a delayed time course of that observed in *Pten-cko* mice. We discovered retinol dehydrogenases are one of the targets of FoxO and were significantly reduced in *Pten-* and *FoxO*-deficient RPE. The importance of retinoid metabolism regulated by PTEN-Akt-FOXO axis in RPE was proven by the inhibition of RPE degeneration in *Pten-* and *FoxO-cko* mice after dietary alteration of retinoid. Furthermore, *daf-16* mutant *C. elegans* also showed hypersensitivity to retinoid toxicity, implicating a potential inhibitory role of PTEN-FOXO-RDHs in aging. Together, our study not only provides a mechanistic understanding to RPE degeneration, but it further disclosed a link between retinoid metabolism and aging.

Keywords: age-related macular degeneration (AMD), forkhead box O (FoxO), retinal pigment epithelium (RPE).

REPTOR and REPTOR-BP regulate organismal metabolism and transcription downstream of mTORC1

M. Tiebe[1], M. Lutz[1], A. De La Garza[1], T. Büchling[2], M. Boutros[2], A. Teleman[1]
[1]Signal Transduction in Cancer and Metabolism, [2]Signaling and Functional Genomics, German Cancer Research Center (DKFZ), Heidelberg, Germany

mTORC1 is a central integrator of nutrient, energy and stress information in a cell. It regulates cellular growth and metabolism

© 2014 The Authors. FEBS Journal © 2014 FEBS

on a short timescale by post-translationally modifying key signaling components, and on a longer timescale by influencing transcriptional programs. We identify here the two so far uncharacterized fly genes REPTOR and REPTOR-BP and their mammalian orthologs as transcription factors downstream of mTORC1. REPTOR and REPTOR-BP are required for almost all of the transcriptional induction that occurs upon mTORC1 inhibition in *Drosophila*. We find that when mTORC1 is active, it phosphorylates REPTOR on two serine residues, leading to its cytoplasmic retention. Upon mTORC1 inhibition, REPTOR becomes dephosphorylated in a PP2A dependent manner, shuttles into the nucleus, joins its partner REPTOR-BP to bind target genes, and activates their transcription. *In vivo* functional analysis using knockout flies reveals that REPTOR and REPTOR-BP play critical roles in maintaining energy homeostasis and promoting animal survival upon nutrient restriction.

TUE-494

Resveratrol ameliorates fatty liver by reducing the size of lipid droplet without changing liver fat species

K. Nishikawa[1], M. Hashimoto[2], Y. Itoh[2], S. Hiroi[3], T. Sakamoto[1], K. Iwaya[4]

[1]Traumatology and Critical Care Medicine, National Defense Medical College, Saitama, [2]JEOL, Tokyo, [3]Laboratory Medicine, [4]Pathology, National Defense Medical College, Saitama, Japan

Resveratrol has been suggested to have various beneficial health effects. We focussed on its effects in protecting the liver against lipid accumulation induced by a high-fat (HF) diet because fatty liver is closely associated with lifestyle-related diseases, such as type 2 diabetes and coronary heart disease. Among lipids, triacylglycerols (TGs) are a major component of food and animal fats. TGs are a diverse class of molecules, and structural isomers also exist. In the present study, we characterised the components and structures of TGs in lipid droplets by matrix-assisted laser desorption/ionisation spiral orbit-type time-of-flight mass spectrometry (MALDI-SpiralTOF) to investigate the effect of resveratrol on TGs in liver. Mass spectrometry (MS) analysis was used to characterise lipid components and structures, and imaging MS (IMS) then provided distribution maps of selected *m/z* values.

The most intense peak identified in liver and food extracts from both HF (50% fat) and resveratrol-supplemented diet (HF + Res; 50% fat, 0.2% resveratrol) was located at *m/z* 881.7 (52:2). Notably, tandem MS (MS/MS) analysis revealed structural differences between the food and liver TGs, despite apparently having the same precursor at *m/z* 881.7. Palmitic acid (16:0) was located at either of the exterior sites on the glycerol backbone in liver TGs, but at the central site in dietary TGs. These results suggest that dietary TGs affect liver TGs, but that structural differences exist between them. Dietary TGs are digested and hydrolysed after oral intake, and then the hydrolysed TG is re-synthesised before it accumulates in the liver. In this process, resveratrol showed no effect on the components and strucutres of

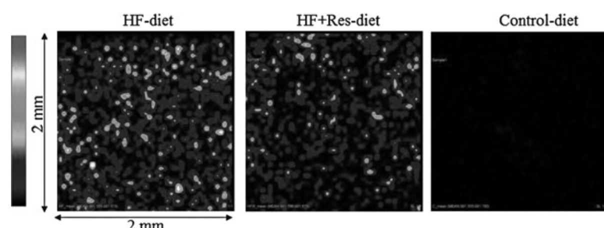

Fig. 1.

TGs in the liver. In contrast to the MS/MS analysis, resveratrol did show differences in IMG and histology analyses. The TG peak at *m/z* 881.7 was found throughout the liver specimens on the HF diet. However, the HF + Res diet diminished the peak intensity. Peak intensity also reflected the amounts of TGs in lipid droplets. These results were consistent with the liver histology, as assessed by haematoxylin and eosin (H&E) staining. IMG also provided better semi-quantitative visualisation of the TG peak. Resveratrol effectively reduced the size of the lipid droplets. In conclusion, we investigated the effects of resveratrol on TGs in fatty liver. Resveratrol did not change the composition or structure of the TG species accumulated in the liver, but did ameliorate fatty liver by reducing the size of lipid droplets.

Keywords: resveratrol, fatty liver, lipid droplets.

TUE-496

Role of cardiac lipid metabolism in the development of hypertension-induced heart steatosis

T. Bednarski, A. Opasinska, A. Olichwier, **P. Dobrzyn**

Nencki Institute of Experimental Biology, Warsaw, Poland

Spontaneously hypertensive rat (SHR), an animal model of hypertension and cardiovascular disease, is characterized by increased cardiac triglyceride (TG) level, however the mechanism responsible for the development of heart steatosis in this model is unknown. Therefore, we investigated the expression of lipogenic and oxidative factors in the hearts of SHR and nonrmotensive Wistar-Kyoto rats (WKY). Plasma and cardiac TG contents were significantly higher in SHR than in WKY rats at 18 weeks of age. The protein levels of sterol regulatory element-binding protein 1 and fatty acid synthase were not different, whereas levels of stearoyl-CoA desaturase 1 and acetyl-co carboxylase were decreased in the heart of SHR when compared with WKY rats. Obtained results showed that lipogenesis is not upregulated in the myocardium of SHR rats. AMP-activated protein kinase (AMPK) and peroxisome proliferator activated receptor α (PPARα) are important regulators of mitochondrial fatty acid oxidation. AMPK phosphorylation level was lower and PPARα protein level was decreased in the myocardium of SHR rats when compared with WKY control indicating decreased fatty acid oxidation in the heart of SHR rats. Together, obtained results suggest that decreased rate of fatty acid oxidation but not increased lipogenesis contributes to the TG accumulation in the myocardium of SHR rats.

Supported by: NCBR LIDER/19/2/L-2/10/NCBiR/2011.

Keywords: fatty acid oxidation, hypertension, lipogenesis.

TUE-498

Screening of anti-oxidative effects of boron treatment in *Camellia sinensis* L

I. Ismailoglu[1], Z. M. Coskun[2], M. Ersoz[3], M. A. Turan[4]

[1]Biology, [2]Molecular Biology, Marmara University, [3]Molecular Biology, Istanbul Bilim University, Istanbul, [4]Soil Science and Plant Nutrition, Uludag University, Bursa, Turkey

Camellia sinensis L. (tea) is one of the most widely consumed drinks in the World. It is suggested that *C. sinensis* have varial medicinal properties one of which is its anti-oxidative attribute. Treatments with Boron, an essential element for plants, has been reported to increase this anti-oxidative property. The present study aims to evaluate the alteration of anti-oxidative effects of boron treated *C. sinensis* L. leaves extracts.

This experiment was carried out in Rize, Turkey. The experiment area was divided into four groups. Each group was grown

© 2014 The Authors. FEBS Journal © 2014 FEBS

in five randomly organized sample areas (2 m-line) and the tea samples were collected from those five areas. The first group is the control. Boron in concentration range of 0, 100, 300 or 500 g B da^{-1} in sodium tetraborate buffer were applied as a single dose in March 2013. *C. sinensis* leaves were collected in two different periods (May and July 2013). The levels of malondialdehyde (MDA) and reduced glutathione (GSH), the activities of superoxide dismutase (SOD) and catalase (CAT) were measured in *C. sinensis* leaf samples.

MDA level in tea leave extracts showed a significant decrease in all groups at first period. At second period, it was seen that MDA level increased at 100 g B da^{-1} concentration of boron although MDA level was lower in 300 g B da^{-1} concentration of boron. There was a significant decrease in GSH levels of all groups at first period. The reduction of GSH levels in second period was less than in the first period. A difference was not determined in SOD levels among 100, 300, 500 g B da^{-1} concentration of boron at both periods. However, CAT levels elevated at 500 g B da^{-1} concentration of boron at first period.

In conclusion, it is suggested that boron treatment may cause the elevation of antioxidant status of *Camellia sinensis* at the second collection period.

Keywords: *Camellia sinensis*, boron, antioxidant.

TUE-499

Selective inhibitors of glycogen synthase, a key enzyme in glycogen metabolism

M. Díaz-Lobo[1,2], J. Garcia-Amorós[3], I. Fita[4], D. Velasco[5], J. J. Guinovart[2], J. C. Ferrer[1]

[1]*Department Biochemistry and Molecular Biology, University of Barcelona,* [2]*Institute for Research in Biomedicine, Parc Científic,* [3]*Department Química Orgànica, Universitat de Barcelona,* [4]*Institut de Biologia Molecular de Barcelona, Parc Científic de Barcelona,* [5]*Department Química Orgànica, University of Barcelona, Barcelona, Spain*

Owing to the vast number of functions performed by oligo- and polysaccharides and glycoconjugates, the ability to selectively inhibit the enzymes that catalyse the synthesis of these glycoderivatives, namely glycosyltransfereases (GTs), is of great interest in biology and medicine. Specifically, disorders related to glycogen metabolism, such as Lafora disease or type 2 diabetes mellitus, might be treated using specific inhibitors of glycogen synthase (GS) or glycogen phosphorylase (GP), which are responsible for the synthesis and degradation of glycogen, respectively. GS catalyses the successive addition of glucose moieties to the non-reducing end of glycogen, while GP catalyses the phosphorolytic cleavage of the α-1,4-glycosidic bonds of the polymer.

With the aim to find novel inhibitors of these two GTs, we have analysed the effect of several glycocompounds, which mimic the donor or the acceptor substrates, on the catalytic activity of glycogen synthase from *E. coli* (*Ec*GS) and glycogen phosphorylase from rabbit muscle (RMGP). Among the compounds studied, ascorbic acid, whose structure resembles that of the glucose unit of the donor substrate, showed the greatest inhibitory potential of *Ec*GS with an IC_{50} of 4.5 nM, a value that was further reduced by 100-fold in the presence of 0.15 mM ADP. Kinetic studies indicate that ascorbic acid mimics the glucosil donor. Interestingly, ascorbic acid did not show any inhibitory effect on RMGP activity.

We also report on the synthesis and biological evaluation of a novel photo-active and selective inhibitor of GS. The designed molecule consists of a glucose molecule with an appended azobenzene moiety, which not only contributes to mimic glycogen, but also enables the photocontrol of the enzyme activity, through a conformational change of this part of the molecule upon irradiation with UV-light. The more stable form of the azoglucoside (*E*) had a slight inhibitory effect of both RMGP (IC_{50} = 4.9 mM) and *Ec*GS (IC_{50} = 1.6 mM). After irradiation and conversion of the azoderivative to the *Z* form, its inhibitory potency of RMGP activity did not significantly change (IC_{50} = 2.4 mM), but its effect on *Ec*GS increased by 50-fold (IC_{50} = 32 μM).

The ability to photo-regulate the activity of key enzymes of glycogen metabolism, such as GP and GS, may provide a way to modulate cellular glycogen content and a new promising tool for biomedical purposes.

Keywords: glycogen metabolism, glycogen synthase, inhibitors.

TUE-500

Serine-arginine protein kinase 1 (SRPK1) is resilient to nuclear translocation under different metabolic stimuli

S. Drakouli[1], I. Mylonis[1], E. Nikolakaki[2], T. Giannakouros[2], E. Georgatsou[1]

[1]*Faculty of Medicine, University of Thessaly, Larissa,* [2]*Faculty of Chemistry, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Serine-arginine protein kinases (SRPKs) are a subfamily of serine-threonine kinases that specifically phosphorylate serine residues located in regions rich in Ser-Arg/Arg-Ser dipeptide motifs, known as RS domains. SRPK1 was the first SR protein kinase to be purified and characterized. The first known and basic role of SRPK1 is the regulation of mRNA splicing. More recently, however, it is well established that SRPK1 is involved in other cellular activities such as chromatin reorganization, cell cycle regulation and metabolic signaling. Additionally, SRPKs emerge as interesting pharmaceutical targets since they show increased expression in several types of cancers.

Although the most prominent functions of SR protein kinases are nuclear, their sub-cellular localization is primarily cytoplasmic in all tissues and cell lines examined. Additionally, SRPKs are considered to be constitutively active kinases and the way of their regulation is not completely clarified. A factor reported as determining their regulation is their sub-cellular partitioning.

The aim of this work was to study the intracellular localization of SRPK1 under metabolic stimuli such as glucose and amino acid deprivation, oxidative and osmotic stress, hypoxia and others. To this end, HeLa and MCF-7 cells were cultured under the above mentioned conditions or their combinations and their effect on SRPK1 protein levels and intracellular localization was determined by western blotting, immunofluorescence and biochemical fractionation.

Interestingly, under only osmotic stress and glucose deprivation, a low range reorganization of SRPK1 molecules was detected, whereas no changes were detectable either in the localization or the levels of the protein under any of the other stimuli implemented.

Our results show that SRPK1 remains mainly cytoplasmic under most of the conditions tested, implying a fine tuning cellular mechanism that precisely controls the number of SRPK molecules temporarily residing in the nucleus.

Co-financed by the European Union (ESF) and Greek national funds (Education and Lifelong Learning-NSRF, Program THALIS)

Keywords: metabolic stimuli, nuclear translocation, SRPK1.

TUE-501

Short treatment with a grape-seed procyanidin extract, in two different rat models of metabolic syndrome, reduces weight gain and leads to metabolic lipid oxidation

J. Serrano, À. Casanova-Martí, M. T. Blay, X. Terra, M. Pinent, A. Ardévol
Departament de Bioquímica i Biotecnologia, Universitat Rovira I Virgili, Tarragona, Spain

Procyanidins are phenolic compounds with several benefits against risk factors of the metabolic syndrome (MS), but their effects in weight loss haven't been sufficiently studied. In this work we evaluated the effects of two intragastric doses of a grape seed procyanidin extract (GSPE) on weight gain and energy metabolism in two different rat models of MS.

In the first study, 32-weeks-old male Wistar rats were daily treated (1 h before the dark onset) with 0.5 g or 1 g GSPE/kg during 8 consecutive days. Afterwards, rats were subjected to 30 days of a recovery phase without any treatment. Thereafter, each rat underwent an equal treatment period in a staggered design and metabolic energy expenditure and substrate utilization were assessed by indirect calorimetry at the last day of treatment.

In the second study, 12-weeks-old female Wistar rats were treated (1 h before the dark onset) with 0.5 g or 1 g GSPE/kg during 10 consecutive days, with concomitant access to a high-sucrose tasty solution (33 kcal/day). After 18 days of a recovery phase on standard diet, rats were fed a hypercaloric cafeteria diet ($\approx$75 kcal/day). Indirect calorimetry was performed between days 25 and 30 of the cafeteria period to assess energy expenditure and substrate utilization. In both studies, body weight was measured during all the stages.

In male Wistar rats, GSPE administration reduced body weight gain since the 4th to the last day of treatment. The 1 g/kg dose reduced body weight gain more markedly than the 0.5 g/kg dose, but also produced a rebound effect during the recovery phase. After the second treatment, indirect calorimetry revealed a lower respiratory quotient in both treated groups, but only significant in the 0.5 g/kg group. This lower dose also showed a higher energy expenditure.

In female Wistar rats, GSPE administration didn't produce changes in body weight gain during the treatment period or its recovery phase. However, after introducing the cafeteria diet, the 0.5 g/kg group presented a lower body weight gain from the 10th day of the cafeteria. There was no effect in body weight gain in the 1 g/kg group, thus pointing out to a dose-specific preventive effect of GSPE against hypercaloric diet challenges. Indirect calorimetry of the 0.5 g/kg group revealed a lower respiratory quotient than the control group.

GSPE effects on energetic metabolism were highly dependent on the metabolic situation without a dose-response effect. The 0.5 g/kg dose showed very interesting effects for its preventive action after large resting intervals and should be further analyzed to better understand the molecular mechanisms of GSPE activity.

(AGL2011-23879 from the Spanish Government).

Keywords: body weight loss, procyanidins, respiratory quotient.

Some aspects of respiratory metabolism of winter wheat seedlings treated by atmospheric surface dielectric barrier discharge plasma

I. Lyubushkina[1], A. Lazukin[2], **K. Kirichenko**[1], S. Krivov[2]
[1]*Laboratory of Physiological Genetics, Siberian Institute of Plant Physiology and Biochemistry SB RAS (SIPPB SB RAS), Irkutsk,* [2]*Department of Electrophysics and High Voltage Technique, National Research University "Moscow Power Engineering Institute", Moscow, Russian Federation*

The studies concern actions of the exogenous reactive oxygen species (for example, ozone) on biological objects, including seeds of agricultural plants, have established a big presence. One way of the ozone synthesis is the surface dielectric barrier discharge (SDBD). In this work the impact of plasma products of SDBD on the samples of winter wheat (variety Irkutskaya) is examined. The electrode system consists of three strip electrodes radially located via 120 degrees of 1 mm wide and 10 microns thick, the length of the discharge zone on one electrode is 85 mm. Electrodes were located on the surface of the alumina ceramics of 1 mm thick (dimensions of the alumina ceramics plate is 14*95 mm). The sinusoidal voltage was applied to the stripe electrodes, amplitude is 4.2 kV, frequency is 14 kHz. Ceramic barriers placed on a grounded disk, which also served as a radiator for this system. The distance between processed samples, located on a grounded plate, and high voltage electrodes was 8 mm. Exposure time of the sample in ambient air with humidity of 60% was 15 min. Gas flow through the treatment zone was absent. The treatment of wheat seeds was carried out through one day after the beginning of germination. It was shown that the studied type of exposure caused inhibition of growth of winter wheat seedlings: after three days of germination the inhibition of growth was 25%. At the early stages of germination in the absence of light required for the formation of the photosynthetic apparatus and processes of photosynthesis, the main source of ATP and reduced equivalents for metabolic processes in etiolated seedlings is the respiration process. The products of SDBD plasmas action on the winter wheat seedlings resulted in an almost 2-fold increase of the alternative cyanide-resistant pathway contribution in the process of respiration, while the rate of phosphorylating respiration did not change. At the same time, a decrease of non-phosphorylating respiratory rate and an increase of the respiratory control coefficient. Probably, such changes of the respiratory metabolism like increased activity of alternative oxidase, were due to the intensification of the reactive oxygen species generation process in the cells of seedlings, caused by the studied type of the treatment, since its activation occurs under conditions of inhibition of the electron transport by the main cytochrome pathway.

Keywords: respiratory metabolism, surface dielectric barrier discharge, winter wheat.

Structural and functional studies of a high-activity [NiFeSe] hydrogenase

M. C. Marques[1], O. Gutiérrez-Sanz[2], A. De Lacey[2], P. Matias[1], I. Pereira[1]
[1]Biological Chemistry, ITQB-UNL, Oeiras, Portugal, [2]Instituto Catalisis y Petroquímica, CSIC, Madrid, Spain

Hydrogen (H2) is an energy carrier with the potential to become an environment-friendly fuel in the future. However, its production at present still relies on the thermocatalytic transformation of fossil fuels. The biological production of H2 offers the opportunity of generating H2 as a clean technology from renewable sources [1,2]. The [NiFeSe] hydrogenases belong to a subgroup of the [NiFe] proteins in which a selenocysteine is a ligand of the Ni atom. These enzymes are attractive candidates for the biological production of hydrogen, since they display faster reactivation after O2 exposure than the standard [NiFe] Hases and also exhibit much higher H2 production activities [4,5]. For the first time, we developed a homologous system for recombinant expression of a [NiFeSe] Hase in *Desulfovibrio vulgaris* Hildenborough. In this work we fully characterize the recombinant [NiFeSe] Hase, presenting also high-resolution 3D structures obtained by X-ray crystallography that provide further insights into the process of O2 inactivation of this group of enzymes. This expression system will enable the production of mutant variants of the [NiFeSe] Hase that will permit more detailed functional studies. Moreover, this study will contribute to the design and improvement of biocatalysts for H2 production.

TUE-506
Structural characterization of multidrug resistance protein 6 (MRP 6) and its involvment in the ectopic calcification

F. Cuviello, A. Ostuni, R. Miglionico, M. A. Castiglione Morelli, M. Monnè, M. Carmosino, A. Salvia, M. F. Armentano, F. Bisaccia
Department of Science, University of Basilicata, Potenza, Italy

In humans, ATP-binding cassette (ABC) transporter superfamily includes 48 proteins divided into 7 subfamilies (A-G) that hydrolyze ATP and transport a wide variety of substrates across membranes. Multidrug Resistance Protein 6 (MRP6) is codified from ABCC6 gene and it is expressed primarly in liver and kidneys at the basolateral membrane [1].

MRP6 transports glutathione S-conjugates, but its natural substrates remain undefined; it confers low levels of resistance to several anticancer drugs leading to multidrug resistance [2]. Mutations of ABCC6 gene cause Pseudoxanthoma Elasticum (PXE), a recessive genetic disorder characterized by ectopic calcification of connective fibers [3].

MRP6 topology presents three transmembrane domains (TMDs) and two nucleotide-binding domains (NBDs), that function cooperatively to bind and hydrolyze ATP for the transport of substrates across biological membranes. Studies performed on isolated NBD domains demonstrated that NBD1 has a higher tendency to form an active homodimer while NBD2 binds ATP and presents ATPase activity although significantly lower compared with isolated NBD1. The mixture of NBD2 and NBD1 exhibited an activity similar to NBD2 alone [4–6]. Moreover, since the role of the additional NH_2-terminal domain (TMD0) is not characterized, we decided to investigate about its function.

As the pathophysiological mechanism whereby MRP6 deficiency results in the onset of PXE is unknown [7], we evaluate in ABCC6-knockdown HepG2 the expression of genes involved in the pathogenesis of ectopic mineralization.

Structure elucidation of novel cold-adapted esterase with unusual thermostability from psychrophilic bacterium *Psychrobacter cryohalolentis* K5T

K. Boyko[1,2], M. Gorbacheva[1,2], D. Korgenevsky[2], L. Petrovskaya[3], K. Novototskaya-Vlasova[4], **D. A. Korzhenevskiy**[5], D. Dolgikh[3], V. Popov[1,2]
[1]A.N Bach Institute of Biochemistry RAS, [2]National Research Centre "Kurchatov Institute", [3]Institute of Bioorganic Chemistry RAS, [4]Institute of Physicochemical and Biological Problems in Soil Science RAS, [5]National Researc Center Kurchatov Institute, Moscow, Russian Federation

Cold environments cover more than 75% of the Earth's surface and include Arctic and Antarctic ice, soils and sediments, ocean water and others. Cold-adapted microorganisms are known to produce cold-active enzymes with highest activity at low and moderate temperatures and easy inactivation upon heating. Elucidation of structural aspects responsible for such enzymes characteristics has fundamental interest and from the other hand could be useful for development of taylor-made industrial biocatalysts.

Psychrophilic bacterium *Psychrobacter cryohalolentis* $K5^T$, was isolated from 110 000-year old cryopeg in Kolyma lowland and was capable of growth in the wide temperature interval from −10°C to +30°C and increased salinity (up to 13% NaCl). Examination of *P. cryohalolentis* $K5^T$ genomic sequence revealed the presence of several genes coding for potential lipases/esterases. A potential esterase EstPc, belonging to lipase Family V was identified in bacterial genome and subsequently cloned and expressed in *E. coli* cells. Recombinant esterase displayed high

© 2014 The Authors. FEBS Journal © 2014 FEBS

activity at 0–35°C as well as relative thermostability. It was half-inactivated only after 45 min heating at 90°C.

To reveal molecular basis of EstPc unusual characteristics we have solved its 3D structure by X-ray crystallography. Structure was solved at 2.15 Å resolution and refined to R_f=18.7% and R_{free}=25.4%. Despite the protein has typical α/β hydrolase fold and its structure is similar to known esterases, comprehensive structure analysis revealed some special features possibly responsible for unusual enzyme characteristics.

This work is supported by scholarship of the President of Russian Federation (СП-1390.2012.4) and RFBR grant 14-04-31573 mol_a.

Structure features of TBN1, a P1/S1-like nuclease

T. Koval'[1], J. Stránsky[2], P. Lipovová[3], T. Podzimek[3], J. Matoušek[4], J. Dušková[2], T. Skálová[2], J. Hašek[2], K. Fejfarová[1], P. Kolenko[1], J. Dohnálek[1,2]
[1]Institute of Macromolecular Chemistry, AS CR v.v.i., [2]Institute of Biotechnology, AS CR v.v.i., [3]Institute of Chemical Technology, [4]Institute of Plant Molecular Biology, Biology Centre, AS CR v.v.i., Praha, Czech Republic

Tomato bifunctional nuclease 1 is a multifunctional zinc-dependent, acidic, plant nuclease with P1/S1-like fold. Exact role of TBN1 is not known but it plays an important role in specific apoptotic functions, cell senescence vascular system development, stress response and tissue differentiation in plants. It shows anti-cancerogenic properties which were proven using mice bearing human tumours [1]. Variants of TBN1 used in our studies were produced recombinantly in *Nicotiana benthamiana* leafs. Presence of zinc in the protein was confirmed by X-ray fluorescence and absorption edge scan. The phase problem was solved using a combination of multi-wavelength anomalous dispersion and real space molecular replacement [2]. TBN1 has a P1/S1-like nuclease fold with a zinc cluster placed in the active site in the centre of the wide groove. Three oligosaccharides bonded on the surface serve primarily as a shielding of the hydrophobic regions and therefore contribute to solubility and stability of the enzyme. TBN1 acts as phosphodiesterase (and phosphomonoesterase) cleaving the bond between phosphorus and 3' hydroxyl group in both single stranded and double stranded forms of DNA and RNA and it also shows 3'-nucleotidase activity. Newly, a phospholipase C-like activity was also discovered. Comparison of TBN1 with single-strand specific P1/S1-like nucleases and other zinc dependent enzymes led to our better understanding of their substrate promiscuity and natural properties [3].

TUE-509
Study of anti-Warburg effect of AMPK activators and antimetabolite drugs on MCF7 cell model

T. Fodor[1], M. Szántó[1,2], J. Márton[1], L. N. Nagy[1], P. Bai[1]
[1]Department of Medical Chemistry, University of Debrecen, 4032 Debrecen, Hungary, [2]MTA-DE Cell Biology and Signaling Research Group of the Hungarian Academy of Sciences, 4032 Debrecen, Hungary

AMPK is an energy sensor that regulates cellular metabolism. When activated by a deficit in nutrient status, AMPK stimulates mitochondrial energy production, while turning off energy-consuming processes to restore energy balance. We analyzed AMPK activation in MCF7 ductal breast cancer cells.

AMPK can work as an anti-Warburg agent via enhancing mitochondrial biogenesis.

In MCF7 cells we studied the combined action of the AMPK activator 5-aminoimidazole-4-carboxamide-1-β-D-ribofuranoside (AICAR), and the antimetabolite folate analog, Methotrexate. We observed increased mitochondrial activity, while glycolytic flux decreased. The combination of drugs also disrupted the phases of the cell cycle, and the cells were accumulated in the G1 and G2 phase. These data suggest that the combined application of AICAR and MTX brings about synthetic lethality through an anti-Warburg effect.

TUE-510
Study of enzyme activity in mutant lines of soft wheat obtained under the surfactants action

N. Omirbekova, A. Zhusupova, Z. Zhunusbayeva
Molecular Biology and Genetics, Al-Farabi Kazakh National University, Almaty, Kazakhstan

Over the past decade, a large number of mutants were obtained experimentally for agricultural crops, which differ from the original in several features. One of the most reliable indicators of changes in the genetic apparatus is enzyme activity alteration. Those are the enzymes, influencing the intensity of the most important parts of metabolism, leading to an accurate estimation of the viability of obtained mutant genotypes.

It has been shown that exposure to aqueous solutions of various surfactants (1%) prior to sowing induced changes in traits, which are inherited through generations M_1-M_4.

The aim of this work is study on activity of key enzymes of nitrogen and energy metabolism in the obtained mutant lines (glutamate dehydrogenase – GDH, enzyme complex of malate dehydrogenase and glutamate aminotransferase – EC MDH-GOAT, malate dehydrogenase – MDH, alcohol dehydrogenase – ADH). Seeds of third generation mutant lines of common wheat and the original varieties Zhenis, Kazakhstanskaya 3, Shagala were used as research material. The reaction mixtures for estimation of enzyme activity contained: for GDG – NADH, 2-oksoglyutarat, ammonium sulfate for EC MDH-GOAT – NAD, malate, glutamate, for MDH – NAD and malate, for ADH – NAD and 96% ethanol. Estimation of enzyme activity (μM coenzyme/mg protein per min) was determined at the length of 340 nm, the total protein content (mg/ml) – at 330 nm.

It has been noted that mutant lines differ in content of soluble protein. For instance, in Shagala variety lines 3,4,5 its content is

© 2014 The Authors. FEBS Journal © 2014 FEBS

increased up to 9% (0.198 ± 0.02 mg/ml, 0.205 ± 0.01 mg/ml, 0.200 ± 0.02 mg/ml, respectively, in control – 0.188 ± 0.01 mg/ml). Study of four enzyme systems activity shows the lines variation in their spectrum of activities. Lines selection on decreased GDH activity (10 lines in the range of 53.22 ± 0.01 to 64.51 ± 0.01 mM/mg; the initial variety Shagala-72.58 ± 0.01 mM/mg) and increased activity of EC MDH-GOAT (5 lines in the range of 403.17 ± 0.01 to 443.27 ± 0.01 mM/mg; the initial variety Shagala-344.44 ± 0.01 mM/mg) was conducted. For genetic and breeding work mutants with reduced GDH activity are interesting, since this enzyme releases toxic ammonia destroying biomembrane. MDH-GOAT plays an important role in the detoxification of products of protein degradation under abiotic and biotic stresses such as salinity, drought, etc. Plants with reduced GDH and high MDH-GOAT activities survive better in case of infection and maintain high productivity. Also the number of lines displayed an increase in ADH and MDH enzyme activity in comparison to the initial variety, the latter might indicate the activation of the respiratory processes. All of this suggests a large term use of surfactants for creation of valuable genotypes of major crops.

Keywords: crop breeding, enzyme activity.

TUE-511
Study of the expression pattern of L-Dopa decarboxylase (DDC) in human β-pancreatic cells: indications of involvement in the insulin-biosynthesis pathway

M.-I. Christodoulou[1], E. Maratou[2], G. Pantoleon[1], C.-D. Zorba[1], A. Scorilas[1], E. G. Fragoulis[1]
[1]Department of Biochemistry and Molecular Biology, National and Kapodistrian University of Athens, [2]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications, Athens, Greece

The link between the dopaminergic system and glucose metabolism is largely supported by in-vitro and in-vivo studies in animals, and clinical data from psychiatric individuals. However, little is known about the exact molecular pathways underlying this relationship. Herein, we sought to investigate the expression pattern of 3,4-Dihydroxy-L-phenylalanine (*L*-Dopa) decarboxylase (DDC), the enzyme catalyzing the biosynthesis of the neurotransmitters dopamine and probably serotonin, under insulin-pathway stimulating conditions in human β-pancreatic cells.

Methods: The 1.2B4 immortalized human β-cell line was subjected to a titration of human insulin concentrations corresponding to normal insulin blood levels (0–100 μU/ml). In another set of experiments, insulin was added in higher concentration (14.5 mU/ml) with and without the presence of the LY294002 PI3K inhibitor (50 μM). The DDC mRNA and its predicted regulator miR-145 levels were estimated by qRT-PCR, while DDC protein levels by Western blot. The intra- and extra-cellular insulin contents were measured with a commercial ELISA assay. Each condition was tested in duplicates and in 3 independent experiments.

Results: Our data revealed negative correlation between the *DDC* mRNA levels and the amount of insulin added to the culture ($r = -0.88$, $p = 0.01$), as well as the intra- ($r = -0.78$, $p = 0.03$) and extra-cellular insulin content ($r = -0.99$, $p < 0.0001$). Yet, when insulin was added in higher concentration the DDC mRNA levels were increased (~1.5-fold) compared to untreated cells, and that was reversed by the addition of the LY294002 insulin pathway inhibitor. MiR-145 levels were by ~2-fold up-regulated by insulin addition, and by ~4-fold following LY294002 treatment. Likely changes in DDC protein levels were proved not possible to be detected by the method used.

Conclusion: Our preliminary data indicate significant association of the mRNA levels of *DDC*, the key-molecule in neurotransmitters' biosynthesis, with the insulin pathway in human β-cells supporting the widely accepted notion of communication between the dopaminergic system and glucose metabolism, that is, herein, for the first time studied in-vitro on cells of human origin. Further investigation is needed to elucidate the subtending molecular mechanisms that may serve as potential targets for the treatment of type 2 diabetes.

Co-funded by the European Union (ERDF) & Greek national funds: Operational Program *Competitiveness & Entrepreneurship*, National Strategic Reference Framework-Research Funding Program: COOPERATION 2011-11ΣΥΝ-10-1821, and partially (presentation expenses) by the Athens University Special Research Account (#10812).

Keywords: human β-pancreatic cells, insulin biosynthesis, L-Dopa decarboxylase.

TUE-512
Study on responses of ceramide metabolism pathway enzymes in mice liver tissue culture treated with withaferin A and withanolide A

F. Mashhadi Akbar Boojar[1], N. Najarpor[2], M. Karimi[2]
[1]Department of Biology, [2]Faculty of Biological Science, Kharazmi University, Tehran Iran., Tehran, Iran, Islamic Republic Of

Ceramide play important roles in intracellular signaling involve in differentiation, proliferation and apoptosis. Withaferin A and Withanolide A are main bioactive compound that traditionally use to cure ulcer, rheumatism and leucoderama. In this investigation, we evaluated ceramide synthase, serine-palmitoyl transferase and dihydroceramide desaturase as anabolic pathway enzymes and ceramidase activity as anabolic enzyme in liver tissue culture treated with 0 to 120 μg/kg. Results showed markedly significant inhibition on ceramidase activity (61%) at 80 to 120 μg/kg of withaferin A and slightly increase (18%) on ceramide synthase and dihydroceramide desaturase (15%) activities with respect to control. There was no considerable effect on activity of serine-palmitoyl transferase in liver for both of these compounds. In addition, sphingosine level did not vary considerably in response to each compound. However, ceramide level increased in a dose dependent manner of withaferin A treatment and reached the highest level at 80 μg/kg exposure. On the other hand Withanolide A treatment did not elevated ceramide considerably as compared with control.

Our findings clarified the role of ceramide elevation in response to withaferin A in comparison to Withanolide A treatment that may involve in reported biological activities of this medicinal plant compound.

Keywords: Withaferin A, ceramide synthesis, sphingosine, liver tissue.

TUE-513
Substrate specific gene expression profiles on different kidney cell types associated with Fabry disease

N. Jung, Y. J. Shin, Y.-J. Jeon, J.-W. Park, S.-C. Jung
Department of Biochemistry, EWHA Womans University, Seoul, Korea

Fabry disease is an X-linked inborn error of glycosphingolipid metabolism associated with deficient alpha-galactosidase A activity. The major clinical feature of fabry disease, such as fibrosis in

© 2014 The Authors. FEBS Journal © 2014 FEBS

cardiomyopathy and renal failure has been observed with abnormal accumulation of globotriaosylceramide (Gb3) in biological fluids, vascular endothelium, heart and kidney. In addition to Gb3, increased concentration of deacylated Gb3 (lyso-Gb3) in the plasma of symptomatic patients also has been suggested as a causative molecular event. However, the correlation between fibrogenesis and elevated levels of these sphingolipids is poorly understood.

To identify the genetic mechanisms involved in renal fibrosis in fabry disease, we analyzed the changes of global gene expression before and after Gb3 or lyso-Gb3 treatment on two types of kidney cell lines, human proximal renal tubular epithelial cells (HK-2) and mouse renal glomerular mesangial cells (SV40MES13), using microarray. The results showed that Gb3 and lyso-Gb3 regulate the expression of 199 and 328 genes in each cell type, with at least 2.0-fold change considerations. To identify key biological functions, we classified all the genes into 4 groups based on the expression patterns (1) Gb3 up, (2) Gb3 down, (3) lyso-Gb3 up, (4) lyso-Gb3 down regulated genes and performed functional annotation analysis using the DAVID tool. Most biological functions were related to fibrogenesis or epithelial-mesenchymal transition (EMT). Interestingly, the gene expression patterns were significantly different between treated with Gb3 and treated with lyso-Gb3. The expressions of EMT related genes (F8, FOXP2, HOXA11, DLL1 and WT1) were confirmed by realtime-PCR or western blot. These findings suggested that Gb3 and lyso-Gb3 lead to renal fibrosis in Fabry disease with different biochemical modulations.

Keywords: EMT, Fabry disease, Gb3.

TUE-514
Surprise effects of Beta-blocker timolol on diabetes-induced pancreas tissue

N. N. Ulusu[1], **M. Gok**[2], B. Turan[3]
[1]Department of Medical Biochemistry, School of Medicine, Koc University, Istanbul, [2]Department of Medical Biochemistry, Faculty of Medicine, Hacettepe University, , [3]Department of Biophysics, Faculty of Medicine, Ankara University, Ankara, Turkey

Almost 40 years ago, Timolol was a novel drug proposed as an antihypertensive, antiarrhythmic, antiangina, and antiglaucoma agent. And during these years, it was proposed that no significant side effects were observed. It is also used in the treatment of migraine and tremor. β-blockers have beneficial effects on heart dysfunction by neutralizing reactive oxygen species.

In this current study, we have investigated the Timolol treatment of streptozotocin-induced diabetic rats (timolol for 12-week with 5 mg/kg daily following diabetes-induction) has efficiency to prevent hyperglycemia-induced pancreas damage by enhancing the depressed antioxidant defense in pancreas.

Intracellular $NADP^+$/NADPH ratio is of critical importance for maintaining not only cellular homeostasis but also in regulation of many metabolic pathways and Pentose Phosphate Pathway (PPP) accounts for almost %60 production of reducing molecule, NAPDH. One of the main role of NADPH is regeneration of reduced Glutathione and thereby preventing oxidative stress. It is for that reason, enzymes associated with antioxidant defense system, namely Glucose-6-phosphate dehydrogenase (G6PD) and 6-Phosphogluconate Dehydrogenase (6PGD), were analyzed in pancreas tissues. Both of these enzymes have key roles in the synthesis of ribose 5-phosphate, which is required for cell proliferation, and in NADPH production, which participates in biosynthetic and detoxification pathways.

Polypharmacology is a rising, innovative concept that describes the activity of compounds at numerous targets. By this study, we have investigated the Timolol-treatment also significantly normalized these antioxidant enzyme levels in diabetic rat pancreas tissues. By this way we have concluded that Timolol has a beneficial effect on diabetic rat tissues by up-regulating the activities of antioxidant enzymes G6PD and 6PGD. Therefore, increased concentration of NADPH enables pancreas cells to reverse the oxidative stress by the action of the glutathione system.

TUE-515
The activity of band 3 protein of erythrocytes in patients with chronic kidney disease

Y. Kolesnikova[1], L. Muravlyova[1], V. Molotov-Luchanskiy[1], D. Klyuyev[1]
[1]Department of Biochemistry, Karaganda State Medical University, Karaganda, Kazakhstan

Development of chronic kidney disease (CKD) is accompanied by a change in physical and chemical properties of erythrocytes membranes.

The aim of the study was to assess the activity band 3 protein of erythrocytes in patients with CKD 1 and 2 stages depending on the initial etiological nosology.

Two groups were formed. The 1st – patients with chronic glomerulonephritis (CG), CKD 1, 2. The 2nd – patients with chronic pyelonephritis (CP), CKD 1, 2. The activity of the Cl^-/HCO_3^- exchanger of band 3 protein was judged by the dynamics of changes in the erythrocytes volume during the incubation of ammonium medium by the method of Mindukshev (2010). Ammonium load run for 15 min with the measurement of MCV in every odd minute of incubation. Was determined the difference between the initial value of MCV (without ammonium load) and maximum MCV, obtained during the incubation. The distribution of ΔMCV values was described by median and quartiles. Statistically significant differences of data in the comparison groups were assessed using the Mann-Whitney test.

In patients with CG value of ΔMCV Md = 9.3 fl (8.2, 11.2) was higher than this indicator in patients with CP Md = 8.0 fl (5.4, 8.1), these changes were not significant, $p = 0.09$.

In patients with CG in 42.8% of cases the swelling of erythrocytes occurred during the initial minutes of incubation, with maximum MCV in the 3rd minute. In 28.6% of cases maximum MVC was determined in the 5th minute and 28.6% in the 7th minute of incubation.

In patients with CP in 44.4% of cases maximum MCV reached in the 3rd minute, and in 55.6% of cases – in the 5th minute.

The incubation of erythrocytes in ammonium medium leads to activation of band 3 protein. The degree of increase in MCV doesn't depend on nosological forms of CKD. However, in the 1st group there are the patients with resistant erythrocytes, which can survive during 7 min of incubation in ammonium medium. Further research is needed for studying this phenomenon.

Keywords: band 3 protein, chronic kidney disease, erythrocytes.

TUE-516
The binding of phycocyanobilin to human hemoglobin and serum albumin: comparison with bilirubin

S. L. Minić, on behalf of Nikolić Ćirković Veličković, D. Stanić-Vučinić, on behalf of Ćirković Veličković, T. Ćirković Veličković, on behalf of Ćirković Veličković, M. Nikolić, on behalf of Nikolić
Department of Biochemistry, Faculty of Chemistry, University of Belgrade, Belgrade, Serbia

Phycocyanobilin (PCB) is covalently attached linear tetrapyrrole chromophore of phycocyanin, a major protein of filamentous cyanobacteria Spirulina (genus *Arthrospira*). Phycocyanin shows a wide range of antioxidant, anti-inflammatory and immunomodulatory properties, and promising anti-cancer and hypocholesterolemic activity. Most of the mentioned effects are ascribed to phycocyanobilin. Blue phycocyanobilin is very similar in chemical structure to bile pigment bilirubin, the end product of heme metabolism. It is well documented bilirubin binding to human serum albumin (HSA).

The present study was undertaken to determine whether the PCB molecule binds to HSA and hemoglobin (Hb), and to partially characterize its binding to these proteins. High purity PCB was isolated from commercial *Spirulina pacifica* powder. OxyHb and HSA were purified from the fresh blood of healthy donors.

Influx of both bilirubin and PCB was detected into erythrocytes' cytosol under simulated physiological conditions. Spectrophotometry data indicated binding of PCB (a red spectral Soret band shift) and bilirubin (a blue shift and decrease in Soret band intensity) to Hb, and also PCB for HSA (a red spectral shift of pigment at 360 nm). Analysis of the data obtained by spectrofluorimetry and equilibration dialysis revealed the similarity in binding, stoichiometry (approx. 1:1) and chromophores binding constants (10^6 for HSA and 10^5 for Hb). The binding of PCB does not cause dramatic changes in the structure of proteins (CD spectra) or hemoglobin oxidation (MetHb formation).

Our results could contribute to the biochemistry of bilins in the systemic circulation, as well as to physiological and pharmacological effects of protein components of Spirulina, as a highly valuable functional foods.

Disclosure of Interest: None Declared.
Keywords: hemoglobin, human serum albumin, phycocyanobilin.

Cobalamin deficiency type C with methylmalonic aciduria and homocystinuria (Cbl-C; MMACHC; MIM#s 277400 and 609831;) is the most frequent genetic disorder of vitamin B12 metabolism (1). Even if the exact function of the MMACHC protein is still unclear, recent studies reported that it may act both as an intracellular cobalamin trafficking chaperone and as a decyanase, catalysing the reductive decyanation of cyanocobalamin thus generating the substrate for assimilation into the active cofactor forms of methylcobalamin (meCbl) and adenosylcobalamin (AdoCbl) (2). Moreover, the MMACHC protein may catalyse the dealkylation of newly internalised methylcobalamin and 5'-deoxyadenosylcobalamin, the naturally occurring alkylcobalamin present in the diet (3). To improve metabolic abnormalities, Cbl-C patients were treated with a combined therapy, which included hydroxocobalamin (OHcbl), betaine, and folic acid. Nevertheless, despite this treatment, the long-term follow-up is unsatisfactory (4). In the present study, the in-vivo proteome of MMACHC patients was quantitatively examined by two dimensional difference in-gel electrophoresis (2D-DIGE) and mass spectrometry. Six biological replicates of protein lysates from lymphocytes from CblC patients were used to identify deregulated proteins employing as a control lymphocytes from healthy donors. The experimental procedure allowed us to identify 63 proteins differentially expressed in pathological tissues. Western blot analyses were used to validate deregulated proteins. Consistent with in-vivo studies showing relevant disturbance of glutathione metabolism (5), we found a deregulation in protein involved in cellular detoxification, especially in glutathione metabolism. Our study demonstrate an in-vivo relevant changes in the proteome profile of treated cblC patients, and confirms previous results observed in-vitro (6). These observations may be helpful for better understanding the pathophysiology of the disease and in addressing future research and novel therapeutical strategies.

TUE-518
The degree of genetic variability on zinc in mutation germpasm of spring wheat (M5 generation) obtained through gamma irradiation

S. S. Kenzhebayeva[1], G. Doktyrbay[1], R. Alybayeva[1], S. Atabayeva[1], M. Khasen[2], S. Asrandina[1]
[1]*Biotechnology,* [2]*Kazakh National University named after al-Farabi, Almaty, Kazakhstan*

Zinc (Zn) deficiency associated with low dietary intake is a well-documented public health problem, resulting in serious health and socioeconomic problems. Wheat is a crop of major importance and supply the bulk of nutrients in the diets. It is known that genotypic variation for Zn content in grain among wheat cultivars relatively low. Mutation breeding is one of an important tool in crop improvement with increased agronomic values. We developed high-yielding M_5 mutant lines on yield components such as grain weight per plant and thousands grain weight through gamma radiation by 100 Gy doses of and 200.

We found in screening results on grain zinc content that extensive variation exists for grains Zn concentrations in germplasm developed by 100 and 200 Gy having its spectrum from 14.6 to 60.93 mg kg^{-1} with mean = 30.78 mg kg^{-1}, SD = 3.17 mg kg^{-1}; n = 15) and from 17.9 to 91.40 mg kg^{-1} with mean = 53.05 mg kg^{-1}, SD = 23.70 mg kg^{-1}; n = 15). respectively. The parental cultivar zhenis has 13.11 mg kg^{-1} ± 1.85. Thus, the variations in Fe content in germplasm induced by treatment of 200 Gy with number of significant positive lines was higher than in germplasm developed by 100 Gy. In 100 Gy germplasm seven lines (■5(4), ■6(4), ■6(13), ■18(5), (■24(2), ■25 (2) and ■26(1) had significantly enhanced grain zinc content compared to cv. Zhenis. In these lines the Zn content was by 4.7, 4.6,

© 2014 The Authors. FEBS Journal © 2014 FEBS

3.3, 3.4, 3.0, 2.1, and 2.3 times higher than in cv. Zhenis, respectively. Thirteen M5 lines from 200 Gy germplasm were by from 2.1 to.6.9 times higher them that in cv. Zhenis. These results clearly indicate that enough genetic variation exists in mutation germplasm to increase Fe concentrations substantially in wheat grain. Six in each M5 mutant germplasm developed by 100 and 200 Gy showed positive correlation between this trait and such yield component as thousand grain weight (r = 0.53–0.99).

Keywords: zinc enriched mutation lines of spring wheat.

TUE-519
The effect of proteasome on c-jun mediated signaling mechanisms in hypercholesterolemia induced oxidative stress

E. Sozen, B. Karademir, B. Yazgan, P. Bozaykut, N. Kartal Ozer
Department of Biochemistry, Faculty of Medicine, Marmara University, İstanbul, Turkey

Atherosclerosis and its complications are major causes of the death all over the world. One of the major risks for atherosclerosis is hypercholesterolemia. Increased reactive oxygen species (ROS) production and the resulting oxidative cell stress that occurs in many disease states has been shown to induce signaling mechanisms. During atherosclerosis, oxLDL regulates CD36-mediated activation of JNK1 and modulates MMP induction which stimulates inflammation with an invasion of monocytes. Additionally, inhibition of proteasome leads to an accumulation of c-jun and phosphorylated c-jun and activation of AP-1 related increase of MMP expression.

We have previously reported a significant increase in CD36 mRNA levels in hypercholesterolemic rabbits and shown that vitamin E treatment prevented the cholesterol induced increase in CD36 mRNA expression. In the present study, our aim was to identify the signaling molecules/transcription factors involved in the progression of atherosclerosis following CD36 activation in an *in vivo* model of hypercholesterolemic (induced by 2% cholesterol containing diet) rabbits. In this direction, proteasomal activities by fluorometry and c-jun, phospo c-jun, JNK1, MMP-9 expressions by quantitative RT-PCR and immunoblotting were tested in aortic tissues.

The effects of vitamin E on these changes were also investigated in this model. As a result, c-jun was phosphorylated following decreased proteasomal degradation in hypercholesterolemic group. MMP-9 expression was also increased in cholesterol group rabbits contributing to the development of atherosclerosis. In addition, vitamin E showed its effect by decreasing MMP-9 levels and phosphorylation of c-jun.

TUE-520
The effect of β2-α2 surface loop deletion on thermal stability of β-1,3-1,4 endoglucanase from *Thermotoga maritima*

M. Altundağ, B. Bora, S. Evran
Department of Biochemistry, Faculty of Science, Ege University, Izmir, Turkey

Thermostable endoglucanases are of great importance for industrial applications. In this study, we cloned and purified the β-1,3-1,4 endoglucanase (EC 3.2.1.73) from *Thermotoga maritima*. We hypothesized that the β2-α2 surface loop could have an effect on thermal stability of the enzyme. We generated an enzyme mutant lacking that loop. Catalytic parameters and thermal stability of the enzyme mutant was compared with those of wild-type enzyme. We showed that deletion of the β2-α2 surface loop decreased the thermal stability of β-1,3-1,4 endoglucanase. Although it is common that deleting or shortening of loops increase thermal stability of proteins, our results showed that the surface loop contributed to the thermal stability.

TUE-521
The effects of boric acid on antioxidant enzymes

B. Yilmaz[1], S. Dogan[1], U. Alan[2], M. Doğan[3]
[1]*Molecular Biology and Genetics, Faculty of Arts and Sciences, Balikesir University,* [2]*Biology, Institute of Natural and Applied Sciences, Balikesir University,* [3]*Chemistry, Faculty of Arts and Sciences, Balikesir University, Balikesir, Turkey*

Oxidative stress is caused by the production of reactive oxygen species (ROS) or free radicals. They are formed by oxygen or other molecules. Excessive amounts of free radicals may damage lipids, proteins, and nucleic acids and may cause carcinogenesis. Boric acid is a form of boron mineral released into the environment and it is used in pharmaceuticals and industrial materials. For example, in pesticide industry it is used as food preservative against plant fungicides. Boric acid can strengthen the antioxidant defenses with an unknown mechanism that may involve changes in oxidative metabolism.

In this study, red blood cells obtained from human were exposed to different concentrations of boric acid and the effects of boric acid on antioxidant enzyme activities were investigated *in vitro*. Catalase (CAT), superoxide dismutase (SOD), glutathione-*S*-transferase (GST), glutathione reductase (GSH), glutathione peroxidase (GSH-Px) and glucose-6-phosphate dehydrogenase (G-6-PDH) which are the antioxidant enzymes that have important roles in cell defense against ROS were examined. Boric acid

© 2014 The Authors. FEBS Journal © 2014 FEBS

showed neither an activator nor an inhibitor effect on these antioxidant enzymes. The results of this study led us to conclude that there was no significant effect ($p > 0.05$) on antioxidant enzyme activities of the boric acid in the studied concentration ranges.
Keywords: Antioxidant enzymes, Boric acid, Oxidative stress.

TUE-522

The effects of fluoxetine on circulating oxidative damage parameters in rats exposed to aortic ischemia-reperfusion

R. Gelisgen[1], H. Erman[1], I. Guner[2], O. Yaman[2], D. D. Uzun[3], U. Aksu[4], N. Yelmen[2], G. Sahin[2], H. Uzun[1]
[1]Biochemistry, [2]Physiology, Cerrahpasa Medical Faculty, Istanbul University, [3]Student, Istanbul Medical Faculty, Istanbul University,, [4]Biology, Science Faculty, Istanbul University, Istanbul, Turkey

Background: Oxidative stress and reperfusion injury may develop in different ischemia-reperfusion (IR) models. Growing evidence links altered lipid protein redox-homeostasis with IR. The effect of fluoxetine (FLX; N-methyl-3-[4-(trifluoromethyl) phenoxy] benzenepropanamine), on the lipid protein redox-homeostasis mechanisms in the rats exposed to aortic IR is unclear. In the current study, we aimed to investigate the effects of FLX on circulating protein oxidation and lipid peroxidation parameters, such as ischemia modified albumin (IMA), lipid hydroperoxide (LOOH), pro-oxidant-antioxidant balance (PAB), erythrocyte glutathione (GSH), CuZn-superoxide dismutase (CuZn-SOD), ferric reducing antioxidant power (FRAP), as potential IR biomarkers.
Methods: Wistar rats were randomised into three groups ($n = 7$/group): 1) Control (sham laparotomy); 2) IR without FLX, (60 min ischemia and 120 min reperfusion); 3) IR with FLX (FLX + IR) (FLX 20 mg/kg/day, i.p. for three day before surgery). All of the aforementioned parameters (IMA, LOOH, PAB, GSH, CuZn-SOD, FRAP) were measured spectrophotometrically.
Results: IMA, LOOH, and PAB levels in IR group were significantly higher than the control ($p < 0.01$ respectively) and fluoxetine groups ($p < 0.01$, $p < 0.01$, $p < 0.05$ respectively), whereas CuZn-SOD activities, GSH and FRAP levels were significantly lower in IR groups. In addition, fluoxetine group significantly reduced IMA levels when compared to IR group ($p < 0.001$) and control group ($p < 0.01$).
Conclusion: With respect to IMA, LOOH and PAB, impaired redox homeostasis is substantially more prominent in aortic IR. The antidepressant FLX has profitable effects on circulating redox status in rats exposed to aortic IR. FLX administration before IR might decrease the surgery-enhanced free radical production; taken together, the antioxidant effects of FLX supplementation should be considered in future studies.
Keywords: Fluoxetine, aortic ischemia-reperfusion, ischemia modified albumin, lipid hydroperoxide, pro-oxidant-antioxidant balance, glutathione.

TUE-524

The effects of *Salvia absconditiflora* water extract on HepG2 liver cell line

D. Irtem Kartal[1], G. Sadi[2], T. N. Güray[3]
[1]Biochemistry Graduate Program, Graduate School of Natural and Applied Sciences, Metu, Ankara, [2]Department of Biology, Faculty of Art and Sciences, Karamanoglu Mehmetbey University, Karaman, [3]Department of Biology, Faculty of Art and Sciences, Metu, Ankara, Turkey

Salvia absconditiflora is one of the endemic Salvia species grown in Central Anatolia, Turkey, which is consumed as herbal tea. There are around 900 species of Salvia, which contain high amounts of polyphenolic/ bioactive materials and they are used traditionally to treat several diseases. Ninety five of them are present in Turkey. Salvia species have lots of phenolic and flavanoid components including Rosmarinic acid-which is the main phenolic component, catechin, caffeic acid, vanillic acid, ferulic acid, rutin, apigenin, quercetin, and luteolin.

In vitro antioxidant activity of *S. absconditiflora* leaves were determined using DPPH radical scavenging activity assay. Total phenolic and flavanoid contents of *Salvia absconditiflora* water extracts were measured spectrophotometrically and cytotoxic effects on HepG2 hepatacellular carcinoma cell lines were examined via XTT colorimetric and Trypan Dye Exclusion cell viability assay. LC-MS/MS analyses revealed the presence of rosmaniric and caffeic acid, luteolin rutin and coumaric acid. Rosmarinic acid and caffeic acid content of *S. absconditiflora* water extract was determined by using RP- HPLC.

IC_{50} value for DPPH radical scavenging activities of water extracts of *Salvia absconditiflora* leaves collected in 3 months (April-May-June) were calculated as 1071 mg/ml, 1137 mg/ml and 0.999 mg/ml respectively. Rosmarinic acid and caffeic acid content of the these extracts (April-May-June) were determined as 23.69 mg RA/g extract- 2938 mgCA/g extract; 20 395 mg RA/g extract– 2386 mgCA/g extract; 19 635 mg RA/g extract-1718 mgCA/g extract, respectively. IC_{50} value for 48 h incubation of water extracts were 3.13 mg/ml for April, 3.95 mg/ml for May and 3.57 mg/ml for June and IC_{50} value for 72 h incubation of water extracts were found as 2.87 mg/ml for April, 2.1 mg/ml for May and 2.42 mg/ml for June. IC_{50} value of water extracts for all three months were calculated as 3.55 mg/ml for 48 h incubation, 2.57 mg/ml for 72 h incubation.

Effects of *S. Absconditiflora* water extract on the expression of CYP 3A4 and CYP 1A2 in HepG2 cells were investigated with qRT-PCR technique. Treatment of HepG2 cells with different concentrations of water extract increased the expression of both CYP 3A4 and CYP 1A2 genes.

TUE-525

The extracellular free purine bases in blood of patients with chronic renal failure

D. Klyuyev, L. Muravlyova, V. Molotov-Luchanskiy, Y. Kolesnikova, L. Demidchik
Biochemistry, Karaganda State Medical University, Karaganda, Kazakhstan

The aim of the work was to study the free purine bases in blood plasma of patients with chronic renal failure depended on initial clinical form. All patients were treating with hemodialysis. Patients were divided into 2 groups. 28 patients with chronic renal failure of terminal stage (initial disease – pyelonephritis) were included in first group. 16 patients with chronic renal failure of terminal stage (initial disease – glomerulonephritis) were included in second group. The control group consisted of 32 healthy subjects. All patients and healthy subjects had received the full information on probable inconveniences at the blood sampling before giving their written informed consent.

The detection of free purine bases took place in plasma of all subjects following the protocol of Oreshnikov et al. (2008) between of hemodialysis procedures.

The tendency to an augment of free purine bases (guanine, adenine), intermediates of purine catabolism (hypoxanthine, xanthine, uric acid) concentrations in plasma of first group patients was observed. The significant increasing of free purine bases (by 2.8 times, $p < 0.001$), hypoxanthine (by 3 times, $p < 0.001$), xan-

© 2014 The Authors. FEBS Journal © 2014 FEBS

thine (by 2.2 times, $p < 0.001$) and uric acid (by 1.9 times, $p < 0.001$) was determined in blood plasma in patients of the second group in comparison with indicators of healthy subjects.

Taken together the results obtained demonstrated significant differences between free purine bases and intermediates of purine catabolism in blood of patients with chronic renal failure depended on initial clinical form.

Keywords: purine bases, blood.

TUE-526

The formation of intramolecular complex between N-terminal domain and the main protein body of L-type pyruvate kinase can be responsible for the change of catalytic properties of enzyme

I. Faustova, A. Kuznetsov, J. Järv
Institute of Chemistry, University of Tartu, Tartu, Estonia

Pyruvate kinases catalyse the final step of glycolysis, transferring the phosphoryl group of phosphoenolpyruvate (PEP) to adenosine diphosphate (ADP) and producing pyruvate and ATP. In liver tissue both glycolysis and glyconeogenesis can occur, and therefore coordination and reciprocal regulation of these metabolic pathways is necessary.

L-PK can be activated homotropically by PEP and heterotropically by fructose-1,6-bisphosphate (FBP), and both of these effects depend on phosphorylation of the N-terminal domain of this enzyme. Kinetic measurements revealed that the non-phosphorylated L-PK followed common hyperbolic Michaelis-Menten plot and the activity of the enzyme was not regulated by FBP. Phosphorylation of the protein by cAMP-dependent protein kinase switched on the cooperativity of the enzyme toward PEP (Faustova, I. *et al.*, 2010).

The regulatory phosphorylation occurs on the 12th serine residue of N-terminal domain. So it was checked whether redistribution and/or introduction of new ionic groups around the phosphorylation site can mimic the effect of phosphorylation. Some of these mutations reduced the effectiveness of PEP binding, but differently of phosphorylation, the cooperativity of the enzyme was not switched on by these mutations (Faustova, I *et al.*, 2012).

It was suggested (Fenton & Tang 2009) that the flexible N-domain may interact with the main body of the enzyme affecting substrate binding, and this interaction can be interfered by phosphorylation. Following this suggestion the computational blind docking approach was used to identify putative binding sites in L-PK subunit for peptides RRASVA and the phosphorylated derivative RRAS(Pi)VA. These peptides mimic the phosphorylatable N-terminal regulatory domain of the enzyme. Also the same docking analysis was done for both L-PK substrates: PEP, ADP, and for the allosteric activator FBP. The docking site of the peptide RRASVA was found in the enzyme active centre, while docking of the phosphorylated analogue RRAS(Pi)VA occurred preferably in the C domain of the L-PK molecule, in a site overlapping with the allosteric site for FBP binding (Kuznetsov, A *et al.*, 2013).

The formation of intramolecular complexes between N-terminal domain and enzyme body may change the equilibrium between active R-state and less active T-state of the enzyme. At the same time the induction of cooperativity by the N-domain phosphorylation could be connected with phosphopeptide intramolecular binding with the enzyme allosteric site.

TUE-527

The influence of *N*-stearoylethanolamine on fatty acid composition in rat pancreas under alimentary obesity-induced insulin resistance

O. Onopchenko, G. Kosiakova, N. Gula
Biochemistry of Lipids, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine (NASU), Kiev, Ukraine

The progression of alimentary obesity triggers the overaccumulation of fat in pancreatic islets that provokes the b-cell failure and diabetes type 2. Therefore, it is of a current interest to find a cytoprotective drug compound that could correct pancreatic dyslipidemia under obesity-induced insulin resistance (IR) conditions. We suggest that one of these compounds could be N-stearoylethanolamine (NSE) with its membrane stabilizing and protective properties. Thus, the aim of our study was to investigate the effect of NSE on pancreas fatty acid composition from rats with IR.

For the experiment, we took a rat model of prolonged high-fat diet induced IR (58% of fat). Control rats were given regular chow (4% of fat). The existence of IR was estimated by results of glucosotolerance test and plasma blood insulin content. Rats with IR were divided into 2 groups: «IR» and rats that were given per os water suspension of NSE (50 mg/kg daily) for 2 weeks («IR + NSE»). The fatty acid (FA) composition was investigated by thin-layer and gas-liquid chromatography and performed as a percentage of the total FA content. The estimated fatty acid desaturase (D) activities were calculated, using product-to-precursor indexes.

The lipid assay of IR rat pancreas showed considerable changes in the individual FA composition of phospholipid (PL), triglyceride (TG) and free fatty acid (FFA) fractions. According to the results, in "IR" rats the 16:0 content was lower in all fractions, whereas 18:0 was more than two times higher in TG and FFA fraction over intact values. The PL 18:1, FFA 18:1 and FFA 18:3, TG 18:3 content considerably increased in IR animals over controls as a possible consequence of enhanced Δ9-D and Δ6-D activities. The low level of 18:2 in all fractions was associated with up-regulation of Δ6-D (synthesizes 18:3). The TG 20:4 and FFA 20:4 level was reduced, while in PL fraction it was significantly increased. Taking into account the fact that 18:0 is toxic to β-cells under fat overload, the protective effect of NSE was in a reduction of 18:0 level. First, NSE reduced convention of 16:0 into 18:0, thus increasing 16:0 FA level and second, NSE enhanced Δ9-D activity, increasing 18:1 content in all lipid fractions from rats with IR. The NSE triggered a reduction in PL 20:4, TG 20:4, and FFA 20:4 level under IR conditions. Moreover, 18:3 (a precursor for 20:4 synthesis) was decreased in FFA and TG fractions under NSE action in comparison with "IR" rats that was associated with down-regulation of Δ6-D.

The NSE administration normalized the redistribution of the main fatty acids between lipid fractions in pancreas of rats under IR conditions. This corrective effect of NSE on FA metabolism may be through the regulation of acyl-CoA-D activity.

Keywords: experimental insulin resistance, lipid metabolism, N-stearoylethanolamine.

TUE-528

The interaction of *E. coli* thymidine phosphorylase with therapeutically important azido nucleosides

I. P. Kuranova[1], V. Timofeev[1], N. Zhukhlistova[1], Y. Abramchik[1,2], I. Fateev[2], T. Muravieva[2], R. Esipov[2]
[1]Institute of Crystallorgaphy RAS, [2]Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Thymidine phosphorylases (TP) belong to the enzymes of nucleosides metabolism. They catalyze the reversible phosphorolysis of glycosidic bond in thymidine and 2'-deoxy uridine as well as transference of deoxyribosyl moiety from one pyrimidine base to another. TP participate in the salvage pathway of the nucleosides biosynthesis and are involved in the angiogenesis in tumour cells. So the search of selective inhibitors of TP activity is of special interest.

In this work it is found that according to kinetic measurements 3'-azido-3'-deoxythymidine (AZT) which is used widely for the treatment of human acquired immunodeficiency syndrom and 3'-azido-2'-fluoro-2', 3'-dideoxyuridine (N_3FddU) are the reversible inhibitors of *E. coli* TP.

The crystalline complexes of TP with both ligands have been prepared and the crystal structures of *E. coli* TP complexed with N_3FddU and with AZT were solved by molecular replacement method and refined correspondingly to 1.50 and to 1.55 Å resolution.

Both azido nucleosides were located with full occupancy and in the similar orientation in the nucleoside binding pockets of the corresponding TP complexes. The comparison of the position of both ligands with position of substrate (thymidine) in homologous *St. aureus* thymidine phosphorylase revealed the essential difference in the arrangement of substrate and inhibitors. Although the positions of pyrimidine rings in the substrate and in the azido nucleosides are overlapped, the pyrimidine rings of both azido nucleosides are rotated by 180° relatively thymidine pyrimidine ring around the axis connecting the atoms N3 and C6 of the pyrimidines. As a result the azido ribosyl rings of both inhibitors and ribosyl ring of the substrate are removed from each other. Besides that a new hydrophobic pocket, which comprises the amino acid residues, surrounding 3'-azido group is formed in the TP active site. This finding can be used for the search of new types of selective inhibitors of thymidine phosphorylases. The results of this work conform also that 3'-azidotymidine can interact with various enzymes of the nucleoside metabolism.

This work was supported by Central Scientific Research Institute of Machine-Building of the Russian Federal Space Agency (Roscosmos), RFBR grant 13-04-01100 and Program 9 of Division of Chemistry and Material Sciences RAS (OChNM-9).

TUE-529

The investigation of oxidant and antioxidant effect of melatonin on rat liver in fructose induced-metabolic syndrome

C. Yılmaz Demirtaş[1], O. T. Pasaoglu[1], F. S. Bircan[2], N. Türközkan[1]
[1]Medical Biochemistry, [2]Graduate School of Natural and Applied Sciences, Gazi University, Ankara, Turkey

Background: A close relationship between the incidence of metabolic syndrome and increased fructose consumption was found in both human and animal studies. In this study, we aimed to evaluate the effect of melatonin on total oxidant status (TOS), paraoxonase (PON), glutathione peroxidase (GPx), superoxide dismutase (SOD), and catalase (CAT) levels in fructose-administered rats.

Method: We used 24 'Sprague-Dawley' breed of male rats and distributed equally into four groups; control (group1), fructose (group2), fructose and melatonin (group3), melatonin (group4). Fructose administration was accomplished by giving daily prepared 20% D-fructose solution in tap water, and 20 mg/kg/day melatonin by oral gavage during 8 week. Insulin resistance was evaluated by the homeostasis model assessment index. We measured TOS level, PON, GPx, SOD and CAT activities.

Results: In our study, TOS level in the liver comparison to group1 statistically significantly increased in all groups ($p < 0.05$). TOS levels were significantly higher in group2 ($p = 0.04$) than in group3 ($p = 0.01$) and the group4 ($p = 0.04$). PON activities in all groups decreased significantly when compared with the group1 ($p < 0.05$). PON activities were significantly lower in group2 ($p = 0.04$) than in group3 ($p = 0.03$) and the group4 ($p = 0.5$). GPx activities in all groups increased when compared with the group1 ($p < 0.05$). GPx activities were significantly higher in group3 ($p = 0.03$) than in group2 ($p = 0.173$) and the group4 ($p = 0.2$). SOD activities in group 2,3 and 4 increased when compared with the group1($p > 0.05$). SOD activities were significantly higher in group2 ($p = 0.03$) and 4 ($p = 0.008$). Liver CAT activities comparison to group1 showed this was not statistically significant in all groups ($p > 0.05$).

Conclusion: Metabolic syndrome model was successfully demonstrated. Fructose diet did not cause clear oxidative stress in liver. TOS level in the liver comparison to group1 statistically significantly increased in all groups. It significantly increased PON, GPx and SOD activities but no chanced CAT activities in liver tissue. Although melatonin treatment showed prooxidant effect on some parameters and has not positive effect on atherogenic lipid profile, it prevented increases in systolic blood pressure caused by high-fructose diet.

Keywords: liver, melatonin, metabolic syndrome.

The investigation of oxidative-antioxidative homeostasis in the blood of men with giardiasis

R. B. B. A. Y. G. Begaydarova, K. Yessilbayeva, **K. Yu**
Department of children's infection disease, department of molecular biology and medical genetics, Karaganda State Medical University, Karaganda, Kazakhstan

Background: The disturbance in the system of antioxidant protection (AOP) is associated with the insufficient activity of one or more enzymes, which develops to destabilization cytomembranes and enhance the lipid peroxidation (LPO). The indicatorsofLPO-AOPusedascriteriaofconditionof the body in diseases of different genesis, according to references.

Purpose of the study was toevaluate the state of activity of antioxidant enzymes and purine metabolism in the blood of men with giardiasis.

Methods: Wedetectedthecatalase (CAT) usingthemethodofM.A. Koroluketall.(1988).It isenzymesofAOP. Absorbance was measured on spectrophotometer at a wavelength of 410 nm, relative to the mixture consisting of the water and the lysate.

The determination of the activity of glutathione peroxidase (GPO) was defined according to Vlasov V.N. et al (1990). The content of GPOwas registered at a wavelength of 260 nm against water on spectrophotometer.

Wedetectedtheactivity of the enzyme of purine metabolism. Itwas adenosine deaminase (ADA), weusedthemethodofI.B.Nemechek (1993). The content of ADAwas registered at a wavelength

© 2014 The Authors. FEBS Journal © 2014 FEBS

of 265 nm against potassium phosphate buffer on spectrophotometer.

Data were processed by conventional methods of variation statistics, we calculated the arithmetic mean (M) and standard dispersion (m).t-test (t) was used to assess differences.

Results: Our study found the significant increase in the activity of all enzymes AOP in the blood of men with giardiasis compared with the control group.The greatest increase was observed in the activity of catalase in the blood of men with giardiasis. Contentof catalase was significantly higher than in control group in 5.8 times ($p < 0.05$).

The increase of activity of GPO was detected in 1.5 times in the blood of men with giardiasisvs control group. The increase of activity of ADA was detected. The main enzyme of purine metabolism, required for the biosynthesis of nucleic acids and cell proliferation was in 3.7 times higher in the blood of men with giardiasisvs control group ($p < 0.05$).

Conclusion: Thus, the mechanisms of oxidation- antioxidant homeostasis were inducted in the blood of men with giardiasis. This is confirmed by increasing the activity of enzymes of AOP and purine metabolism compared with the control group.

Keywords: enzymes of antioxidant protection, giardiasis, blood.

TUE-531
The mechanism of calcium induced inhibition of gestational diabetic fructose 1,6-bisphosphate aldolase

N. H. Aksoy[1], S. Karaca[2], O. Buyukleblebici[1]
[1]Faculty of Veterinary Medicine Department of Biochemistry,
[2]School of Health, Aksaray University, Aksaray, Turkey

An important part of proof has shown that glycolytic enzymes in many kind of cells may form metabolically active macromolecular complexes whose stability is regulated directly and indirectly by calcium ions and glycolytic intermediates. Such association not only changes the regulatory characteristics and the kinetics of glycolytic enzymes, but may also simplify the channeling of substrates between metabolically sequential enzymes increasing the velocity of the glycolytic pathway. Calcium (Ca^{2+}) is of critical importance for many biochemical processes: Ca^{2+} controls muscle contraction and relaxation and the rhythm of the heart, the formation of enzymes and hormones; also the DNA formation in chromosomes; regulates the blood clotting, urine filtration. Ca^{2+} is the main buffer used in the body to neutralize acids and maintain the proper the pH.

Gestational diabetes mellitus is defined by glucose intolerance of variable severity with onset of first recognition during pregnancy. The placenta is a temporary established organ that operates exclusively for the time of pregnancy. In diabetes, the placenta undergoes a variety of structural and functional changes.

Fructose–1,6-bisphosphate aldolase (FBPA) plays an effective role in glucose metabolism and gluconeogenetic pathway and reversibly catalyzes the split of fructose 1,6-bisphosphate into the triose phosphates D-glyceraldehyde phosphate and dihydroxyacetone phosphate. Aldolase has 160 kDa molecular weight and three tissue specific isozymes.

A partition equilibrium study has shown calcium ion to be a noncompetitive inhibitor of aldolase adsorption by placental muscle. This inhibition is interpreted quantitatively in terms of aproximately 10-fold decrease in the intrinsic association constant for the aldolase-myofibril interaction upon Ca^{2+} binding to either or both of the low-affinity troponin sites associated with regulation of muscle contraction.

In our study, we investigated inhibition effects of Ca^{2+} ion on FBPA, and the interaction of human placental aldolase with bivalent Ca^{2+} and diabetic complications. It was defined that Ca^{2+} is noncompetitive inhibitor of human placental FBPA. Ki values of diabetic human placental aldolase for Ca^{2+} was determined 1.77 ± 0.38 mM.

Keywords: Calcium, Fructose 1,6 bis-phosphate aldolase, Inhibition.

TUE-532
The relationship between respiratory burst, serum pancreatic elastase concentration and mean platelet volume, in childhood obesity

B. Virgolici, L. A. Popescu, D. Lixandru, H. Virgolici, M. Mohora
"Carol Davila" University of Medicine, Bucharest, Romania

Increased serum pancreatic elastase activity, high mean platelet volume (MPV) and increased oxidative stress are risk factors for atherothrombosis. In vitro, serum pancreatic elastase increases superoxide production by phorbol myristate acetate stimulated neutrophils.

The aim for this study is to investigate the monocyte NADPH oxidase activity (respiratory burst), the MPV value and serum pancreatic elastase concentration, and to find correlations between these parameters in childhood obesity.

Sixty obese children (9–16 years) and thirty age and sex matched lean children were involved. Chemiluminescence for respiratory burst, spectrophotometry for serum pancreatic elastase concentration were used and the MPV value was obtained from hemogram. Albumin/globulin ratio was calculated as a surrogate marker of inflammation. Pearson correlations were used for linear regression.

In the obese children versus the lean ones, the activity for monocyte NADPH oxidase (0.62 versus 0.4 RLU, $p < 0.01$), the concentration for serum pancreatic elastase (0.7 versus 0.58 ng/ml, $p < 0.04$) and the value for MPV (8.93 versus 8.13 fl, $p < 0.001$) were higher. In the obese children, serum pancreatic elastase concentration was positively correlated with MPV ($r = 0.32$, $p < 0.05$) and with respiratory burst ($r = 0.26$, $p < 0.05$). The monocyte cells number and the albumin/globulin ratio were positively correlated with MPV ($r = 0.29$ and $r = 0.4$, respectively, $p < 0.05$) and with serum pancreatic elastase concentration ($r = 0.33$ and $r = 0.39$, respectively, $p < 0.05$).

In conclusion, in the obese children there is a cluster of athrerothrombosis risk factors: the mean platelet volume, the respiratory burst and the serum pancreatic elastase concentration are higher than in the lean children.

Keywords: atherothrombosis risk, childhood obesity, respiratory burst.

TUE-533
The resin from *Protium heptaphyllum* inhibits adipogenesis *in vivo* and *in vitro*

J. D. B. Marinho-Filho, K. M. de Melo, A. J. Araujo, V. S. Rao, F. A. Santos
Fisiologia e Farmacologia, Universidade Federal do Ceará, Fortaleza, Brazil

Introduction: *Protium heptaphyllum* March (Burseraceae), popularly known as almecegueira is a medicinal plant that grows abundantly in Amazon region and in various other parts of Brazil. The resinous exudate collected from the trunk wood of this plant in its natural form is a reputed folk remedy with anti-inflammatory, analgesic, insect repellant, expectorant and wound healing actions.

© 2014 The Authors. FEBS Journal © 2014 FEBS

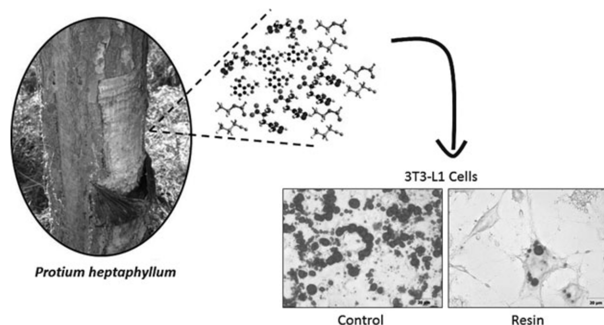

Fig. 1.

Objective: The aim of this study was to investigate the antiadipogenic effect *in vivo* and *in vitro* of the resin obtained from *Protium heptaphyllum* (RPH).

Methods: Five groups of male Swiss mice weighting 25–30 g were treated with normal diet (ND), high-fat diet (HFD, control), HFD + RPH (10 mg/kg, p.o.), HFD + RPH (20 mg/kg, p.o.) or HFD + Sibutramine (SIB, 10 mg/kg, p.o.) for 15 weeks. At the end of this period, animals were starved for 6 h and then sacrificed. The liver and abdominal adipose tissues (epididymal and parametrical) were dissected and weighed. Tissue samples of hepatic and epididymal adipose tissue were fixed and stained with hematoxylin and eosin, examined under light microscopy, and the adipocytes area was measured using the Image J software. The measures of 100 cells for each mouse (n = 6/group) were used to calculate the average cell surface area (mm^2). The cytotoxicity of the RPH was tested against the preadipocyte cell line 3T3-L1 by MTT assay, after 72 h of incubation. The differentiation of the 3T3-L1 cells to adipocytes was induced using prodifferentiative agents. Simultaneously, the cells were treated with the RPH at concentrations of 6.25; 12.5; 25 and 50 μg/ml. The results were observed by Oil-red-O stain. Results and Discussion

The RPH showed no cytotoxic effects ($IC_{50} > 50$ μg/ml) although a reduction in the adipogenesis process was observed in the 3T3-L1 cells treated with RPH. Furthermore the RPH was able to reduce the gain in body mass in RPH-treated animals compared to HFD-fed controls. Besides, RPH decreased the abdominal fat accumulation and the gain in liver weights promoted by HFD.

Conclusions: Our findings suggest that the resin obtained from *Protium heptaphyllum* has the antiadipogenic potential with no significant cytotoxicity and therefore may be a promising candidate in the development of newer antiobesity drugs. Supported by: CNPq, CAPES, FUNCAP.

TUE-534
The role of alcohol and aldehyde dehydrogenases in the control of mammalian gene activity

A. Shindyapina[1], T. Komarova[2], Y. Dorokhov[2]
[1]Bioengineering and Bioinformatics, [2]A.N. Belozersky Institute, Lomonosov MSU, Moscow, Russian Federation

Methanol (MeOH) is poisonous to humans because the enzyme alcohol dehydrogenase (ADH) converts MeOH in toxic formaldehyde (FA), which is then converted into formic acid by aldehyde dehydrogenase (AlDH). The detection of MeOH in the blood of healthy mammals suggests that MeOH could be a substance with specific functions and not simply a waste product of cell metabolism. Here, we directly demonstrate that an increase in the MeOH concentration in mouse and rat blood led to a change in the accumulation of mRNAs from genes primarily involved in detoxification processes and the regulation of the ADH/AlDH gene cluster. To test the role of ADH in the maintenance of low MeOH levels in the plasma, we used the specific ADH inhibitor 4-methylpyrazole (4-MP) and showed that intraperitoneal administration of 4-MP resulted in a significant increase in the plasma concentrations of MeOH, ethanol and FA. Removal of the intestine significantly decreased the rate of MeOH accumulation in the plasma, suggesting that the gut flora may be involved in the endogenous production of MeOH. However, data from the rat liver perfusion system did not support the hypothesis that this organ participates in the generation of endogenous MeOH. Nevertheless, liver ADH and AlDH were identified as the primary enzymes for metabolising MeOH because an increase in the MeOH and ethanol levels in the liver homogenate was observed after 4-MP administration into the portal vein. Quantification of the liver mRNA levels showed changes in the accumulation of mRNAs from genes involved in cell signalling and detoxification processes. We also confirmed the involvement of alpha lipoic acid in the detoxification process of ethanol and MeOH. Alpha lipoic acid has the potential to boost the accumulation of AlDH mRNA and mitochondrial AlDH-2 activity, both of which accelerate the conversion of FA to formic acid. We hypothesised that endogenous MeOH acts as a regulator of homeostasis by controlling mRNA synthesis. Although MeOH may be exhaled into the air as a waste product (similar to carbon dioxide), this chemical may also influence biochemical processes important for cellular function.

Keywords: methanol, alcohol dehydrogenase, intestinal microflora.

TUE-535
The role of vitamin D3 in prevention of prednisolone induced dysfunction of hepatocytes

A. Khomenko, O. Lisakovska
Laboratory of Medical Biochemistry, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine NASU, Kyiv, Ukraine

Background and Aims: Growing evidence suggests that glucocorticoid therapy associated side effects could be ascribed to inhibition of vitamin D_3 turnover, particularly due to abnormal processes of hydroxylation and 25OHD3 formation in hepatocytes. Changes in cholecalciferol hydroxylation can be linked to prednisolone induced impairments of structural and functional state of hepatocytes. Therefore, we investigated prednisolone induced impairments of vitamin D_3 25-hydroxylating systems and hepatocytes function and estimated the efficacy of vitamin D_3 treatment.

Methods: Female Wistar rats received prednisolone (5 mg per kg of b. w.) with or without 100 IU of D_3 (for 30 days). The contents of $25OHD_3$ in serum were measured by ELISA. Vitamin D_3 25-hydroxylase activity was assayed in vitro in isolated hepatocytes by method of radio-competitive binding of [^{3}H]-$25OHD_3$. The levels of CYP27A1, CYP2R1 and poly(ADP-ribose) polymerase 1 (PARP-1), poly-ADP-ribosylated, nitrated proteins in liver tissue were measured by Western-blot analysis. Expression of Bax and Bcl-2 in hepatocytes was assessed by immunocytochemistry. ROS and RNS production in isolated hepatocytes and cell viability were determined by flow cytometry with DCF-DA and propidium iodide respecively.

Results: It was shown that prednisolone administration lowered the level of $25OHD_3$ (by 70%) in serum and inhibited two-fold the total activity of vitamin D_3 25-hydroxylase in hepatocytes vs. control. Prednisolone reduced the content of CYP27A1 and

© 2014 The Authors. FEBS Journal © 2014 FEBS

CYP2R1 isoforms of 25-hydroxylase by 78% and 27% respectively. Administration of the GC led to disruption of the integrity of hepatocytes triggering destructive changes in these cells and thus reducing the number of functionally active hepatocytes. These cytological changes were further confirmed by significant increase in the number of hepatocytes capable to accumulate PI that is associated with necrotic cell death. In contrary, apoptotic index Bax/Bcl-2 was found to be markedly reduced suggesting pro-apoptotic signaling down-regulation. Prednisolone administration led to increased oxidative nitrosative stress as is evident from enhanced ROS and RNS generation in liver tissue vs. control. These alterations are most likely responsible for DNA damage-mediated activation of PARP-1 since a marked 1.77-fold rise in the level of poly-ADP-ribosylated proteins was established. Moreover, prednisolone administration also resulted in more than 1.63-fold increase in the level of 89 kDa cleaved fragment of PARP-1, indicative of apoptosis occurring in parallel with necrotic death. Normalization of vitamin D_3 availability might be considered to be perspective in reducing the negative effects of GC on function of hepatocytes.

The significance of HbA1c, fasting glucose, insulin sensitivity indices, fasting insulin and glucose/insulin ratio in the diagnosis of gestational diabetes mellitus

S. Delibas

Haydarpasa Education and Research Hospital, Istanbul, Turkey

Gestational Diabetes Mellitus (GDM) is defined as glucose intolerance first diagnosed in pregnancy. OGTT, although recommended as the gold standard test, is a cumbersome procedure and could be subjected to interferences. Therefore, use of any other test, such as the non-fasting HbA1c with low intraindividual variability and good predictive value in determining the complications of diabetes, would be a significant progress. Insulin sensitivity indices such as HOMA, HOMA-1%β and QUICKI for the evaluation of insulin resistance have also been excessively addressed in recent studies.

For this purpose, 260 pregnant women (24–28 gestation weeks), not previously diagnosed with diabetes, completed a 2-h 75 g OGTT and were assigned to groups (GDM and Control) according to their OGTT results using the ADA criteria. Insulin sensitivity indices and glucose/insulin ratios were calculated from their fasting glucose and insulin measurements. The diagnostic performances were evaluated using MedCalc11.3.3.0 and SPSS for Windows 17.0.

As a result, glucose was observed to be the parameter with the most significant difference among the groups ($p < 0.001$). HOMA, QUICKI, HbA1c, fasting insulin and HOMA-1%β followed. Considering the AUC values, fasting glucose (AUC=0.771) provided the best discriminatory test and the best overall accuracy for the diagnosis (sensitivity 80%, specificity 63.35%). HOMA and QUICKI (AUC=0.701) were also sensitive diagnostic tests for GDM showing higher specificity than fasting glucose (82.20%) but lower sensitivity. However, HbA1c (AUC=0.678) when compared to HOMA and QUICKI, demonstrated lower discriminatory values. Although fasting insulin demonstrated some diagnostic value, HOMA-1%β and glucose /insulin ratios provided no discriminatory values. Evaluating all of the statistical data, it was observed that HbA1c have not yet met the required criteria for being an ideal diagnostic test.

In conclusion, there is still not enough data including this study for these tests to be used as alternatives to OGTT. Although promising, fasting glucose, HOMA and QUICKI indices along with HbA1c to be used as alternatives to OGTT, could only be possible with evidence of their strong correlation with glucose levels in pregnancy and pregnancy outcomes and complications.

Keywords: GDM, HbA1c, HOMA.

TUE-539

Tissue-specific regulation of triacylglycerol metabolism during fasting and re-feeding in medaka

L. Wang[1], E. Tan[1], G. Kaneko[1], S. Asakawa[1], S. Watabe[2], H. Ushio[1]

[1]Aquatic Bioscience, The University of Tokyo, Tokyo, [2]Marine Biosciences, Kitasato University, Kanagawa, Japan

Fish utilize triacylglycerol (TAG) as a main energy source. They store TAGs in several sites, such as adipose tissues, liver and muscle. Fasting is known to be a natural occurrence in fish life. During fasting, TAGs stored in muscles are considered to play as one of the important energy sources for muscle functions. In addition, liver is well known as the main site of intermediate metabolism. The aim of this study was to investigate the effects of fasting and re-feeding on the TAG stores and regulation of related genes in muscle and liver of medaka (*Oryzias latipes*).

Four groups of medaka were acclimated for 3 weeks. One group of medaka was used as the control, and two groups were fasted for 4 and 8 days, while the remaining one group was re-fed for 4 days after the 8-day fasting. Fasting reduced hepatic TAG levels, followed by their recovery during re-feeding. In contrast, muscle TAG levels were increased during 4-day fasting, whereas these were decreased during 8-day fasting. Re-feeding raised the TAG levels in muscle again.

To investigate the underlying molecular mechanisms, comprehensive analysis of gene expression patterns were performed using next generation sequencing technique. The changes in expression values of the genes involved in TAG metabolism and fatty acid (FA) degradation implied that the enhanced hydrolysis of the hepatic TAGs by hepatic triacylglycerol lipase followed by β-oxidation resulted in the decreased TAG levels in liver. In contrast, the β-oxidation in muscle would be suppressed by the down-regulations of acyl-CoA synthetase and oxidase during the early fasting stage. However, the induced β-oxidation and lipolysis of intramuscular TAG pools during 8-day fasting would cause the decrease in TAG levels. Re-feeding significantly reduced the TAG hydrolysis and β-oxidation in both tissues, whereas the remarkable gene expressions related to TAG synthesis was not found.

Due to the limited capacity of muscle FA synthesis, FA transport among the tissues regulated by lipoprotein lipase (LPL) has a large effect on muscle TAG levels. In this study, LPL mRNA levels were further determined by quantitative real-time PCR. The positive correlations of LPL mRNA levels with those of TAGs in both tissues implied the potential FA transport between liver and muscle during fasting.

In conclusion, the observations in this study suggest that tissue-specific TAG accumulation is associated with the coordinated regulation of the genes involved in TAG hydrolysis as well as FA degradation and transport between liver and muscle. We will also investigate protein expression levels in order to further disclose the functions of the related genes.

Keywords: Fasting, Global gene expression patterns, Triacylglycerol metabolism.

TUE-540
TLR4 deficiency increases peroxisomal β-oxidation in LDL knockout mice livers

D. F. Ferreira[1], H. P. D. Souza[1], I. H. Prist[1], J. Fiamoncini[2], S. K. Ariga[1], **T. M. D. Lima**[1]
[1]Emergency Medicine, [2]Institute of Biomedical Sciences, University of São Paulo, Sao Paulo, Brazil

Purpose/Objetive: Non-alcoholic fatty liver disease (NAFLD) is now regarded as the most common liver illness in the developed world, affecting up 30% of the population. It comprises a spectrum of disorders ranging from simple steatosis without inflammation, to NASH, progressing to fibrosis and cirrhosis. It is closely linked to visceral adiposity, insulin resistance, dyslipidemia and type two diabetes. A growing body of evidence suggests that toll like receptors, especially TLR4, have a key role in the pathogenesis of chronic inflammatory liver diseases. Our goal was to investigate if TLR4 activation could modulate metabolic lipid pathways and alter the onset of NAFLD.

Material and Methods: We used LDL receptor-deficient mice (LDLrKO) fed with Western-style atherogenic diet as a model. The role of TLR4 activation was evaluated by crossing LDLrKO mice with the TLR4 knockout mice. Animals were fed for 12 weeks with high fat high cholesterol diet (HFHC) containing 18% saturated fat and 1.25% cholesterol. Plasma lipid levels and liver lipid content was determined with commercial kits. Gene expression of enzymes related to triglycerides synthesis and degradation were evaluated by real time PCR.

Results: LDLrKO/TLR4KO mice presented lower triglyceride levels when compared to LDLrKO, despite the type of diet ingested. High fat diet induced triglyceride and cholesterol accumulation in the liver of all mice genotypes studied, but LDLrKO/TLR4KO liver lipid content was not different from LDLrKO mice. Gene expression of ApoB100, GPAT1 e DGAT2 was not differentially altered in LDLrKO/TLR4KO and LDLrKO mice. On the other hand, TLR4 deficiency enhanced the expression of several enzymes involved in β-oxidation of fatty acids, as follows: acyl-CoA oxidase, carnitine palmitoyl transferase 1, mitochondrial trifunctional protein A and B, peroxisomal bifunctional enzyme (PBE), 3-ketoacyl-CoA thiolase A and B.

Conclusion: TLR4 can regulate directly the expression of enzymes related to lipid synthesis and degradation in the liver.

Financial support: FAPESP (#2012/07957-6).

TUE-541
TNF-α and insulin resistance in normal pregnancy

S. Sobhanian, A. Sotoodeh Jahromi
Jahrom University of Medical Sciences, Jahrom, Iran

Objective: The purpose of this study was to evaluate the role of resistin and tumor necrosis factor- α (TNF- α) in insulin resistance during pregnancy.

Study design: Serum resistin and TNF-α concentrations were measured by ELISA in 86 healthy pregnant women (26, 23 and 37 of them in the 1st, 2nd and 3rd trimesters, respectively) and in 21 healthy non pregnant women in a cross sectional study.

Results: Resistin concentration was significantly higher in the third trimester (9.5 ± 3.3 ng/ml) as compared with non pregnant women (7 ± 3.3 ng/ml). Serum TNF-α level were also significantly increase in pregnant women (2.6 ± 1.9 pg/ml) as compared with maternal healthy controls (0.8 ± 0.7 pg/ml). There were significant correlation between gestational age and BMI ($r = 0.28$, $p = 0.01$), resistin ($r = 0.36$, $p = 0.002$) and TNF-α ($r = -0.44$, $p < 0.0001$). There was not significant correlation between gestational age and insulin resistance (IR). We also did not found correlation between IR and resistin as well as between IR and TNF-α in pregnant women.

Keywords: IR, pregnancy, TNF.

TUE-542
Tumor metabolism and Docetaxel resistance in prostate cancer

L. Ippolito, M. L. Taddei, A. Marini, P. Chiarugi
Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy

Drug resistance of cancer cells is recognized as the primary cause of failure of chemotherapeutic treatment in most human cancers. Mounting evidences supports the idea that deregulated cellular metabolism is linked to drug resistance in cancer therapy. Indeed, both components of the glycolytic pathways and mitochondria are involved in altered metabolism linked to chemoresistance of several cancers [1,2]. Our aim is to evaluate the metabolic adaptations induced by the drug able to confer advantages for docetaxel-resistant PC3 cells compared to sensitive ones.

We found that docetaxel-resistant PC3 cells acquire a pro-invasive behavior and activate an EMT program and a pro-metastatic phenotype with respect to sensitive cells. Moreover, DoceRes cells show a decrease of intracellular ROS and proliferation compared to sensitive cells. These features are not linked to an induction of the pentose phosphate pathway, but are associated with an enhancement in the antioxidant response, mainly driven by increased expression of the transcription factor Nrf2 (Nuclear factor erythroid 2 related factor 2). Metabolic analysis reveals a greater utilization of glucose, glutamine and lactate by mitochondrial respiration in resistant than sensitive cells. In agreement, metformin, impairing mitochondrial complex I function, selectively decreases proliferation and invasiveness of resistant cells. Furthermore, stromal fibroblasts, which cause a "reverse Warburg" phenotype in prostate cancer cells [3], can protect sensitive and resistant cell lines to docetaxel toxicity. In keeping, an approach based on re-expression of a microRNA, the miR205, able to shift the mitochondrial respiration to a Warburg metabolism induces an increase of docetaxel toxicity in prostate cancer cells.

Taken together, these findings suggest that chemoresistance to docetaxel induces an escape from Warburg metabolism with a potential involvement of mitochondrial respiration to confer a metabolic advantage to these cells and this could be attractive as potential therapeutic target.

TUE-544
Ubiquinone lowers cholesterol level and increases expression of LDL receptor in isolated primary hepatocytes

O. El-Rifai[1], P. Karam[2], **J. Usta**[1], J. Usta[1]
[1]*Department of Biochemistry & Molecular Genetics, American University of Beirut,* [2]*Pediatrics, American University of Beirut, Beirut, Lebanon*

Introduction: Cholesterol is a component of cell membranes, precursor of steroid hormones and bile acids. Cholesterol biosynthesis occurs by Mevalonate (MVA) pathway involving intermediates farnesyl-pyrophosphate that is converted to Cholesterol, Dolichol and Ubiquinone.

Coenzyme Q (UQ) is an energy production component of the electron transport chain. Formation of the UQ molecule involves phenylalanine as precursor of the phenyl ring of UQ and Isoprene units derived from MVA pathway. Many reports showed a decrease in UQ level with age, whereas cholesterol increases.

Hypothesis: We postulate UQ as regulator of cholesterol pathway. This will be addressed by investigating the effect of UQ1 and UQ10 on:

1- Cholesterol level.

2- LDL receptor.

Methods: a. Effect of UQ1 and UQ10 on the cholesterol synthesis.

Isolated hepatocytes were pre-treated with UQ1/UQ10 and/or HMGCoA reductase inhibitors, Farnesyl Transferase inhibitors, and isoprenyl transferase inhibitors for 1 h. The level of cholesterol, lanosterol and Squalene following treatment with ^{14}C-MVA, lipid extraction, TLC was determined.

b. Quantitative and qualitative analysis for LDL receptor expression by:

LDL receptor expression of the above treatment was qualitatively and quantitatively determined by immune staining and western blotting.

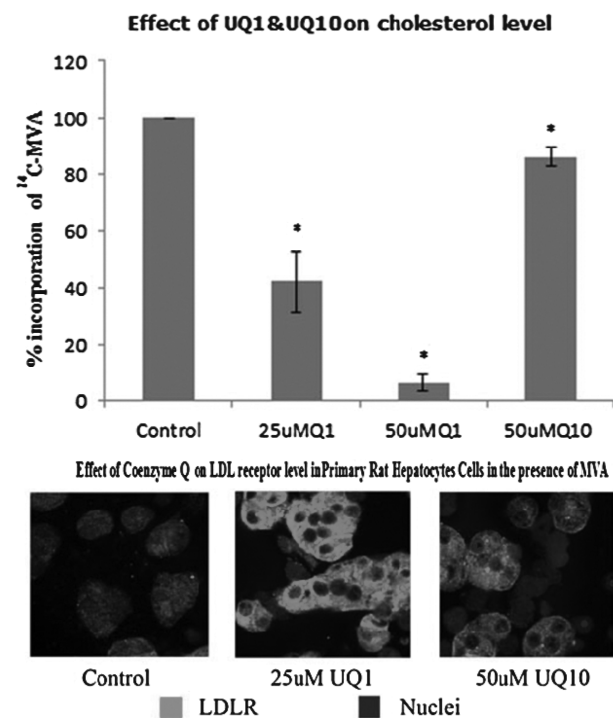

Fig. 1.

Results (Figure): - Both UQ1 and UQ10 lowered cholesterol level by 65% and 15% respectively in primary hepatocytes

- Lanosterol and Squalene were increased in UQ1 treated primary cells

- Western blotting showed 2 fold increase in the LDLR in UQ treated cells which were confirmed qualitatively by western blotting.

Conclusions: We provide evidence on the role of ubiquinone (natural product) in regulating cholesterol and up-regulating LDLR. The possible use of UQ as alternative medicine to statin, with known side effects, requires further investigation.

Keywords: cholesterol, LDL-receptor, Ubiquinone.

TUE-545
Vascular, ischemic and oxidative effects of alpha lipoic acid on experimental NSAID induced gastropathy

M. E. Sitar[1], **S. Aydın**[1], K. Yanar[1], G. Sitar, M. S. Aydın[3], M. Eşrefoğlu[3], P. Atukeren[1], U. Çakatay[1]
[1]*Medical Biochemistry, Istanbul University Cerrahpasa Medical Faculty,* [2]*Internal Medicine, Okmeydanı Education and Research Hospital,* [3]*Histology and Embryology, Bezmialem Vakif University Medical Faculty, Istanbul, Turkey*

Administration of nonsteroid anti-inflammatory arachidonate analogues, ubiquitously prescribed to treat pain, is associated with a wide range of side effects. NSAID induced gastropathy, beside usage as an experimental disease modelling, is one of the most frequent and clinically important adverse effect. We aimed to search possible effects of a strong amphipathic anti-oxidant molecule, alpha lipoic acid (LA), in NSAID induced gastropathy, on the basis of altered redox homeostasis, endothelial microcirculation and angiogenesis.

Three groups of Sprague-Dawley male rats were randomly categorized as Grup I-C (n = 7, control, omeprazole 30 mg/kg) Grup II-A (n = 8, 50 mg/kg, 8 weeks alpha lipoic acid + indomethazine 30 mg/kg) and Grup III-S (n = 8, 8 weeks serum physiologic + indomethazine 30 mg/kg). Malondialdehyde (MDA), lipid hydroperoxides (L-OOH), advanced oxidation protein products (AOPP), trans-trans cis-trans conjugated dienes (CD), albumin, uric acid, thiol fractions (T-SH, NP-SH, P-SH) and Cu,Zn-superoxide dismutase (Cu,Zn-SOD) activity parameters are measured for the assessment of redox status, together with ischemia modified albumin, vascular endothelial growth factor and prostaglandin E2(PGE2) levels to evaluate perfusion and angiogenesis. Stomach tissues of the rats were also analyzed by histopathologic examination.

Albumin ($p < 0.001$), uric acid ($p < 0.05$), serum total thiols ($p < 0.001$), tissue T-SH ($p < 0.05$), serum P-SH ($p < 0.01$), tissue P-SH ($p < 0.05$), serum and tissue NP-SH ($p < 0.05$), Cu, Zn-SOD activity ($p < 0.01$) and PGE2 levels were also significantly lower ($p < 0.05$) in A and S groups when compared to group C. Serum and tissue AOPP ($p < 0.001$), IMA albumin index ($p < 0.001$), serum L-OOH ($p < 0.01$), tissue L-OOH ($p < 0.05$), serum MDA ($p < 0.01$), tissue CD ($p < 0.05$) and VEGF-A ($p < 0.05$) levels were significantly higher in groups A and S, when compared to group C. Albumin ($p < 0.05$), serum T-SH ($p < 0.01$), serum P-SH ($p < 0.001$), serum NP-SH ($p < 0.001$) and PGE2 ($p < 0.05$) levels were significantly lower in group S, when compared to group A. Mucosal damage score correlation between those parameters were highest in serum L-OOH (r:0.70) and P-SH (r: −0.82) levels.

LA can be counted as an oxidative stress and agiogenetic stabilizing agent in NSAID induced gastropathy.

Keywords: alpha lipoic acid, NSAID, oxidative stress.

Nicotinamide adenine dinucleotide (NAD) is known as a coenzyme of redox reactions in central metabolic pathways, in which it functions as carrier of electrons and hydrogen ions. Moreover, NAD also serves as substrate of several families of regulatory proteins such as protein deacetylases (Sirtuins), ADP-ribosyltransferases and Poly-ADP-ribosyl polymerases, which govern vital processes including gene expression, progression of the cell cycle, insulin secretion, DNA repair, apoptosis, aging and many others. The proper regulation of these NAD-dependent metabolic and signaling processes depends on how efficiently cells can maintain their NAD levels. Human cells generally replenish their NAD contents through NAD biosynthesis using the vitamin B3 precursors delivered with food: nicotinamide and nicotinic acid as well as nicotinamide riboside (NR) and nicotinic acid riboside (NAR). Nicotinamide and nicotinic acid can be directly converted to the corresponding mononucleotides (NMN and NAMN) by phosphoribosyltransferases.

In this work we have tested the hypothesis that, besides being supplied with the diet, the ribosides NR and NAR are also authentic intracellular intermediates and thereby represent an integral part of NAD metabolism in humans. We found that the known human cytosolic 5′-nucleotidases CN-II and CN-III can dephosphorylate the mononucleotides NMN and NAMN and thus produce NR and NAR *in vitro*. Our results indicate that 5′-nucleotidases require high (millimolar) concentrations of nucleotides for efficient catalysis suggesting that NAMN and NMN, at their physiological concentrations, are unlikely to be substantially dephosphorylated in cells. Only under conditions when NMN or NAMN concentrations rise, the 5′-nucleotidases would be activated. In line with this assumption, overexpression of FLAG-tagged CN-IA, CN-II and CN-III in human cells resulted in the riboside NAR formation. However, NAR formation was only detectable under conditions that lead to increased NAMN production from nicotinic acid. Taken together, our observations establish human 5′-nucleotidases as physiologically important components of NAD metabolism, namely, to generate nucleosides (NAR and NR) by dephosphorylation of the corresponding mononucleotides.

Whole cell regioselective hydroxylation of *N*-heteroaromatic compounds using *Burkholderia* sp. MAK1

J. Stankeviciute, J. Vaitekunas, R. Gasparaviciute, V. Petkevicius, D. Tauraite, J. Urbonavicius, R. Meskys
Department of Molecular Microbiology and Biotechnology, Institute of Biochemistry, Vilnius University, Vilnius, Lithuania

Hydroxylated pyridines are commercially desirable compounds because of their wide application in the production of herbicides, insecticides, fungicides and plant growth regulators. Moreover, the pyridine derivatives are in great demand as synthons for pharmaceutical products. Currently, pyridines are used either as biologically active substances or as building blocks for polymers with unique physical properties. Selective hydroxylation of the *N*-heteroaromatic ring is still a very challenging task in organic synthesis, therefore biocatalysis is an attractive tool.

In this study, the hydroxylation of pyridine and its derivatives by *Burkholderia* sp. MAK1 cells has been investigated. The 2-hydroxypyridine-degrading *Burkholderia* sp. MAK1 has been isolated from soil. This whole cell biocatalyst oxidized 73 of the 110 tested aromatic compounds, mostly pyridines, pyrazines and pyrimidines. UV-VIS and HPLC-MS analyses revealed that hydroxylation occurs at 5-position of the ring of 2-hydroxy- and 2-aminopyridines containing methyl-, chloro-, bromo- and other substitutions. In order to prove the position of regioselctive hydroxylation several products have been purified and identified by 1H and 13C NMR spectroscopy. Biosynthesis of aminopyridinols has been shown for the first time. In addition, it has been discovered that *Burkholderia* sp. MAK1 is capable of oxidizing pyridine, pyrazine and their methylated derivatives to corresponding *N*-oxides.

Fig. 1. Regioselective hydroxylation of pyridine derivatives by whole cells of *Burkholderia* sp. MAK1.

X-ray structure analysis of *Acinetobacter* sp. L-ribose isomerase for metabolizing non-natural sugar L-ribose

H. Yoshida[1], A. Yoshihara[2], M. Teraoka[1], Y. Terami[1,2], G. Takata[2], K. Izumori[2], S. Kamitori[1]
[1]*Life Science Research Center,* [2]*Rare Sugar Research Center, Kagawa University, Kagawa, Japan*

L-Ribose is non-natural sugar, so-called rare sugar, and is not generally used in metabolic pathway as a carbon source. An enzyme, L-ribose isomerase from *Acinetobacter* sp. strain DL28 was reported as a new enzyme nearly a couple of decades ago, which can constitutively produce L-ribose isomerase [1]. L-Ribose isomerase catalyzes the reversible aldose-ketose isomerization between L-ribose and L-ribulose. L-Ribulose could be an intermediate toward D-xylulose 5-phosphate in pentose phosphate pathway by utilizing L-ribulokinase and L-ribulose-5-phosphate 4-eipimerase. The strain, DL28 was isolated as a mutant strain from *Acinetobacter* sp. strain LR-7c that could utilize D-lyxose as a carbon source and produce inductive L-ribose isomerase. The cloned gene of *Acinetobacter* sp. DL28 L-ribose isomerase (L-RI) had no significant amino acid sequence similarity to known protein structures [2,3]. Since L-RI uses L-ribose as the most favorable substrate for isomerization reaction while it uses D-lyxose with almost 50% for L-ribose. *Acinetobacter* sp. DL28 may have a novel metabolic pathway to assimilate L-ribose as a carbon source.

L-ribose has a potential usage as a precursor for the synthesis of L-nucleoside analogues, which are widely used as pharmaceutical compounds such as antiviral and anticancer drugs. An interest in the industrial production of L-ribose is increasing, and effective enzymatic production of L-ribose is quite expected. Therefore, an enzyme like L-RI, which is capable of recognizing and catalyzing L-ribose, is attractive.

So far, we have determined the crystal structure of L-RI (tetramer) and found that the subunit structure of L-RI showing cupin-type barrel fold is similar to that of D-lyxose isomerase (dimer) from the pathogenic *E. coli* O157:H7 (D-LI) by Dali search, though their sequence identity and r.m.s.d. are 18% and

© 2014 The Authors. FEBS Journal © 2014 FEBS

2.8, respectively. In this study, to further understand the difference of favorable substrate recognition, we determined the crystal structures of L-RI in complex with L-ribose, L-ribulose, or ribitol, and an inactive mutant form (E204Q) in complex with L-ribose or L-ribulose. Based on these complex structures, we propose the catalytic reaction mechanism including ring-opening of substrate in L-RI. In addition, site-directed mutagenesis study of L-RI showed that E211 and R243 are involved in substrate recognition of L-ribose and D-lyxose.

X-ray studies of the phosphopantetheine adenylyltransferase from *M. tuberculosis*

V. Timofeev[1], R. Esipov[2], L. Chupova[2], I. P. Kuranova[1]
[1]Institute of Crystallography RAS, [2]Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Phosphopantetheine adenylyltransferase from *Mycobacterium tuberculosis* (PPAT *Mt*) is involved in the coenzyme A (CoA) biosynthesis, catalyzing the penultimate step of the process, resulting in the formation of the dephosphocoenzyme A (dPCoA) from 4′phosphopantetheine (PhP) and ATP. Reduction of the intracellular level of CoA prevents the bacterium growth. Therefore PPAT that catalyses the key step of CoA biosynthesis is suitable therapeutic target for the rational drug design.

In the presented study, the crystal structures of recombinant PPAT *Mt* in two crystal modification of apo form and in complex with ATP, CoA, and dPCoA were determined using the crystals grown in the microgravity by counter-diffusion method [1,2]. The peculiarities of the arrangement of the ligands in the active site cavity of PPAT *Mt* are described. The conformational states of the PPAT molecule at the consequent steps of the catalyzed reaction in apo enzyme, enzyme-substrate, enzyme-product complexes are characterized. It is shown that the ATP and dPCoA binding induces the rearrangement of the short part of polypeptide chain restricting the active site cavity in the subunits of the hexameric enzyme molecule. The changes in the quaternary structure caused by this rearrangement are accompanied by the variation of the size of the inner water-filled channel which crosses the PPAT molecule along the three-fold axis of the hexamer. The molecular mechanism of the observed changes have been described. The crystal packing and its influence on the conformation of the enzyme molecule have been studied through the comparison of different crystal forms of apo form of enzyme.

Zinc-dependent estrogenic effect and high apoptotic activity in frog *Rana ridibunda*

O. Stoliar, H. Falfushynska, L. Gnatyshyna, O. Fedoruk
Ternopil National Pedagogical University, Ternopil, Ukraine

Despite well-known vulnerability of amphibians to the chemical impacts that is related to endocrine disruption (ED), the molecular reasons for this phenomenon aren't clear. Particular instability and easy loss of zinc (Zn) by Zn-sequestering intracellular protein metallothionein (MT) in frog was shown recently (Falfushynska et al., 2008, 2010). Hypothetically it could be of concern for the dysfunction of Zn-dependent signaling, including the induction of vitellogenesis and apoptotic activity. To study the possibility of this dependence, male frogs, *Rana ridibunda* were exposed to Zn^{2+} (Zn, 3.1 μM), nano zinc oxide (nZnO, 3.1 μM), Ca-channel blocker nifedipine (Nfd, 10 μM) and combination of nZnO and Nfd (nZnO + NFD) for 14 days. MTs from the liver were estimated from coordinated metals (MT-Me (Zn, Cu, Cd)), thiols (MT-SH) and by *ELISA Kit* (MTi). ED effects were characterised from the level of vitellogenin-like protein (Vtg-LP), and thyrotropin (TSH) levels in serum, activity of Zn-dependent 5-deiodinase in the liver. Cellular injury was assessed in the liver by measuring level of oxiradicals, CYP1A1-dependent ethoxyresorufin-*O*-deethylase (EROD) activity, DNA fragmentation, and activity of the main effector enzymes in the apoptotic cascades, caspase-3 and cathepsin D (total and free).

Common responses for all exposed groups were detected as an increase in the levels of MT-SH (up to 2 times) and caspase-3 activity (in 6 times in ZnO + Nfd-group). The comparison of MT-SH, MTi and MT-Me levels shown their simultaneous increase in Zn- and ZnO + Nfd groups (with the increase of MTi by ~ 50%) and discrepancy in Nfd group (the decrease of MTi by 40%) and consequently, the increase in MTs unsaturated form, apothionein. Importantly, concentrations of Vtg-LP and deiodinase activity were increased only in the exposures to Zn-contained compounds. nZnO caused particular responses: decreased level of cathepsin D (total and free), whereas it was increased in all other exposed groups, and the absence of differences in the levels of TSH and EROD with control group, whereas in all other groups they were increased. Antioxidant potential of Zn- and ZnO and prooxidant effect of Nfd were detected by the evaluation of oxiradical level. Hence, Zn-contained compounds affected specifically estrogenic activity in male specimens (vitellogenesis) and thyroid activity in the liver of frog. Particular effect of nZnO on apoptosis was related lysosome protease cathepsin D, whereas well-known anti-apoptotic effect of Zn on caspase-3 was not realized.

WED-001
A fully enzymatic method for site-directed spin labeling of long RNA: a tool to investigate structural and dynamical properties of complexes involved in biological processes

I. Lebars[1], B. Vileno[2], S. Bourbigot[1], P. Turek[2], P. Wolff[3], B. Kieffer[1]
[1]Integrated Structural Biology, IGBMC, Illkirch, [2]POMAM, Institut de Chimie, [3]Architecture et Réactivité des ARN, IBMC, Strasbourg, France

The elucidation of the mechanisms of recognition between RNAs and their interacting partners remains a major objective in molecular and structural biology. Nuclear Magnetic Resonance (NMR) provides an efficient method to unravel both structural and dynamical aspects of RNAs and their complexes. However, the study of large RNA molecules by NMR remains challenging, due the combined effect of efficient relaxation and spectral crowding. One promising route to the application of NMR methodologies to larger RNA systems relies on the incorporation of paramagnetic probes, coupled to the measurement of the induced effects on nuclear spins (1). At the same time, Electronic Paramagnetic Resonance (EPR) has rapidly expanded to study structure and dynamics of macromolecules (2–4). During recent years, several spin labeling techniques of RNA relying on partial or complete solid-phase chemical synthesis methods were developed (5–11).

We propose here a fully enzymatic method, which allows the insertion of a paramagnetic center at a specific position in an RNA molecule. The technique is based on a segmental approach using a ligation protocol with T4 RNA ligase 2. One transcribed acceptor RNA is ligated to a donor RNA in which a thio-modified nucleotide is introduced at its 5′-end by *in vitro* transcription with T7 RNA polymerase. The efficiency of the coupling reaction and the quality of the resulting spin-labeled RNA were assessed by Mass Spectrometry, EPR and NMR. This method enables various combinations of isotopic segmental labeling and spin labeling schemes, a strategy that will be of particular interest to investigate, by NMR and EPR, the structural and dynamical properties of large RNA complexes involved in biological processes.

A general model for fibrinogen cleavage by thrombin

A. Kopylov[1], G. Pavlova[2], A. Golovin[1], E. Zavyalova[1]
[1]Chemistry, LTD APTA-PHARM, MGU, [2]Neurobiology, IBG RAS, Ltd Apta-pharm, Moscow, Russian Federation

Thrombin is a key enzyme in the blood coagulation cascade. The thrombin hydrolyzes fibrinogen into fibrin, the later specifically associates into the fibers which finally build up a thrombus scaffold. This multistep process could be described as a set of stepwise reactions and needs a complete and detail kinetic portrait. The earlier kinetic models were focused on some particular parts of the process, for example either on the mechanism of enzyme action itself, or on the kinetic of formation of fibrin associates.The study provides a general model of fibrinogen cleavage by thrombin, taking into account some peculiarities as the dimeric nature of fibrinogen, association of desAA-fibrin, and stepwise removal of fibrinopeptides as well as application of the quasi-equilibrium approach. The model could be easily updated with forthcoming data on fibrinogen hydrolysis and fibrin association. The research provides an example of thorough description of the set of reactions with several intermediates. The developed algorithm could be applied to model some sophisticated systems with branch points and feedbacks: the blood coagulation cascade and signal transduction.

A model of the multilayer structure of GBM and low-oxygen induced invasion: implications for tumor growth and invasion during anti-angiogenic therapy

H. M. Fathallah-Shaykh[1], O. Saut[2], T. Colin[2]
[1]Neurology, University of Alabama at Birmingham, Birmingham, USA, [2]Mathematics, University of Bordeaux, Bordeaux, France

The recent use of anti-angiogenesis (AA) drugs for the treatment of glioblastoma multiforme (GBM) has uncovered unusual tumor responses. Here, we derive a new mathematical model that takes into account the ability of proliferative cells to become invasive under hypoxic conditions; model simulations generate the multilayer structure of GBM, namely proliferation, brain invasion, and necrosis. The model replicates key features of GBM including a proliferative rim, necrotic center, and an an invasice. The model is interrogated to derive fundamental insights on the dynamics of GBM and on the clinical and biological effects of AA drugs. Invasive cells promote tumor growth; furthermore, AA drugs increase the fraction of invasive cells leading to rebound rapid growth when the tumor becomes resistant to AA therapy. These results justify the lack of efficacy of Bevacizumab on overall survival times.

A novel proteomic assay for identification of amyloid-forming proteins

A. A. Nizhnikov[1], A. Alexandrov[2], T. A. Ryzhova[1,3], O. Mitkevich[2], M. Ter-Avanesyan[2], S. G. Inge-Vechtomov[1,3], A. P. Galkin[1,3]
[1]Genetics and Biotechnology, St. Petersburg University, [2]A.N. Bach Institute of Biochemistry, RAS, [3]St. Petersburg Branch, Vavilov Institute of General Genetics, RAS, St. Petersburg, Russian Federation

Amyloids are ordered fibrillar protein aggregates with characteristic cross-beta structure. Prions are specific subgroup of amyloids possessing infectious properties. These protein aggregates are currently extensively studied not only due to their pathological features (about 40 incurable human amyloid-related diseases are known), but also due to important functional roles, which have recently been discovered. One of the central problems for amyloid studies is the lack of universal methods that could provide efficient identification of novel amyloids. Thus, identification of each novel amyloid remains a notable event in biology. We developed a method, which allows identification of a wide range of amyloid-forming proteins in cells or tissues of different organisms. This method is based on the unusual resistance of amyloids to ionic detergents and has very high resolution due to of the use of 2D-DIGE technology. We validated our method by identification of reference amyloids (PrP, Aβ, Htt, Bgl2p, as well as prions of Sup35 and Rnq1). In addition, we identified a set of novel proteins that are capable of forming detergent-resistant polymers in *Saccharomyces cerevisiae*, and can be considered as candidates for novel functional amyloids. The amyloids of Sup35 were found to possess resistance to chaotropic agents (urea and thiourea) and formic acid.

Overall, the method developed in this study opens wide opportunities for characterization of novel functional and pathological amyloids in different organisms from prokaryotes to human.

WED-005
A quantitative model of nucleocytoplasmic dynamics and turnover of mRNA

T. Chen, B. van Steensel
Gene Regulation, Netherlands Cancer Institute, Amsterdam, Netherlands

Eukaryotic mRNA undergoes a procedure of transcription, nuclear export, translation and decay. Although studies have provided important insights into these fundamental processes, we still lack accurate quantitative models of the chain of events that determines the abundance and nucleoplasmic distribution of mRNA for each individual gene.

Here, we measured the genome-wide dynamics and nucleocytoplasmic distribution of mRNA in Drosophila cells by 4-thiouridine labeling and fractionation. Through mathematical modelling, we obtained rates of transcription, nucleocytoplasmic permeability and cytoplasmic decay for ~6500 genes.

Studying relationships between kinetic steps, we found physiologically meaningful correlations along the whole chain of gene expression: globally, genes that are highly transcribed tend to produce mRNAs that are more efficiently transported and degraded less quickly. This is particularly true for all genes that encode cytoplasmic ribosomal proteins. We are currently investigating whether this 'kinetic consistency' is an optimization outcome of evolution and/or due to a dedicated molecular imprinting mechanism that coordinates the three consecutive steps. Overall, we found that cytoplasmic decay explains ~20% of abundance variance, which is markedly more than previously estimated.

To considerable degree, transcript length correlates negatively with transcription rate but positively with cytoplasmic decay rate. The latter observation revives a 'stochastic decay model' that involves the random activity of endonucleases, a historically proposed but still unconfirmed mechanism.

We also tested whether the mRNA kinetics parameters are linked to the chromatin type in which the genes are embedded. As expected, transcription rates are low in known repressive types of chromatin, and high in euchromatin. Surprisingly, nucleocytoplasmic transport of mRNA also correlates with the chromatin state. We found that transcripts from HP1-containing chromatin tend to be more readily transported, while those from Polycomb-marked chromatin tend to be much less. We speculate that some chromatin protein complexes, of which some have been reported to have RNA-binding activity, could function to either facilitate nucleocytoplasmic export or retain transcripts in the nucleus.

Keywords: chromatin proteins, mRNA dynamics, Systems biology.

WED-006
A RNA binding score for predicting RNA binding probabilities of protein residues

Z. Miao[1,2], E. Westhof[1,2], on behalf of Eric Westhof
[1]Architecture et Réactivité de l'ARN, Institut de biologie moléculaire et cellulaire du CNRS, [2]Université de Strasbourg, Strasbourg, France

The understanding of the recognition principles of RNA binding to proteins is necessary to predict the binding interfaces. In the past decade, tens of computational prediction algorithms have been developed to predict RNA binding sites based on either protein sequences or protein structures. Most of the state-of-art methods depend on machine learning approach based on PSSM and other residue propensities, ranging from SVM, neural network to random forest and Naive Bayes. However, in order to discriminate RNA binding sites from non-binding sites, the existing programs are all-or-none classifications. Here, we propose a simple score to predict RNA binding probabilities based on a combination of protein sequences and structures.

The prediction score is based on physico-chemical and evolutionary principles. As amply demonstrated, RNA binding residues are accessible on protein surface, tend to be positively charged and are highly conserved in sequence. The derived score is a combination of residue accessibility surface, electrostatics potential and conservation entropy.

Importantly, the prediction score avoids comparison of all RNA binding residues and non-binding residues of different proteins together. Instead, it maximizes the prediction accuracy for each protein separately. It achieves similar or even better accuracy than the other best prediction programs.

Further, we have found that the RNA binding residues, when defined by commonly used distance cut-off, even for the same protein can vary in different PDB complexes. We define the residues that are always considered as RNA binding residues in different PDB complexes as conserved RNA binding residues. And the prediction score is also useful in predicting such residues.

With the prediction score, the residues around the RNA binding position can be plotted as an energy funnel: residues farther away from the binding position are scored lower. Therefore, it helps in the localization of the most central RNA binding region in a protein.

Keywords: Bioinformatics, prediction, RNA-protein interaction.

An encyclopaedia of protein complexes

B. Meldal, O. Forner Martinez, M. Dumouseau, S. Orchard, H. Hermjakob
EMBL-EBI, Cambridge, UK

Understanding the role and make-up of protein complexes is integral to understanding biological processes. While the scientific literature contains a wealth of information on the role and function of protein complexes no central resources existed for searching and depositing information about macromolecular complexes. The IntAct molecular interaction database now includes a new resource, the Complex Portal (www.ebi.ac.uk/intact/complex), through which an encyclopaedia of protein complexes from major model organisms is available for search, viewing and download. Each entry contains information about the participating molecules (including small molecules and nucleic acids integral to the complex), their stoichiometry, topology and structural assembly. Complexes are annotated with details about their function, properties and complex-specific Gene Ontology (GO) terms. Consistent nomenclature is used throughout the resource with systemic names, recommended names and a list of synonyms all provided. Complexes are extensively cross-referenced, e.g. to PDB, Reactome, ChEMBL and OMIM. The use of the Evidence Code Ontology allows us to indicate for which entries direct experimental evidence is available in a protein-protein interaction databases such as IntAct (www.ebi.ac.uk/intact) or if the complex has been inferred based on homology or orthology. The data is searchable using (lists of) standard identifiers such as UniProt, ChEBI and GO IDs, protein, gene and complex names or synonyms as well as complex cross-references (e.g. PDB IDs) and species IDs and names. Data is available in the community standard interaction format (PSI-MI XML) and downloadable from our ftp site. Other formats can be made available on request. This reference resource will be maintained and grow to encompass an increasing number or organisms. Input from the representative model organism communities is welcome.

Keywords: database, protein complex, systems biology.

WED-008
Analysis of binding of porphyrins to heme proteins by molecular docking method

L. Gyulkhandanyan, A. Gyulkhandanyan
Institute of Biochemistry of NAS of Armenia, Yerevan, Armenia

The method of molecular modeling, docking, which an aim is to find the most accurate orientation and conformation of the ligand in the binding center of the target protein, in bioinformatics is one of the important tools. Porphyrins are low molecular weight natural compounds which are included in the structure and plays a key role in the function of various proteins. On the other hand free exogenous porphyrins are essential elements of the energy transfer to oxygen and the formation of singlet oxygen in photodynamic therapy of tumors (PDT) [1]. Study of complexes formation of porphyrins with carrier proteins and their delivery into malignant cells are important tasks for PDT [2]. The recognized carrier proteins are serum albumin, lipoproteins, and hemoglobin, such a function the least investigated for hemoglobin.

To study the binding sites of cationic porphyrins on macromolecule of protein as a model was chosen model of molecule of human hemoglobin (Hb). To construct a model of a molecule of Hb we were use the web site of Protein Data Bank www.pdb.org (file ID: 1KOY.pdb). Study of the binding sites on the hemoglobin were carried out with cationic porphyrins containing various peripheral functional groups with different hydrophobicity and the content of hydroxyl groups (TOE4PyP, TBut4PyP and TAll4-PyP), as well as with the most important fatty acids of blood plasma (palmitic and stearic).

By method of molecular docking has been shown that:

1. From the comparison of the minimum binding energy for porphyrins and fatty acids follows that binding of all three porphyrins with the interior of the macromolecule Hb significantly preferable than for fatty acids.

2. When embedding of complexes [porphyrin + fatty acid] in the internal cavity of the macromolecule Hb they bind to a macromolecule Hb significantly stronger than porphyrins or fatty acids separately, as evidenced by lower values of minimum binding energies for the complexes [porphyrin + fatty acid] with the macromolecule Hb, than for porphyrins or fatty acids.

It follows a very important conclusion:

-when adding the fatty acids in the hemoglobin solution with porphyrins can form complexes [porphyrin + fatty acid] which binds significantly more probabilities with Hb, than with porphyrins and thus complexes [porphyrin + fatty acid] can displace porphyrins from the interior of the macromolecule Hb.

Thus, the molecular docking method can give much new information about the possibilities of binding the porphyrin, fatty acids, and their complexes with hemoglobin and complement the NMR and X-ray structural studies.

Atomistic molecular dynamics simulations of the Shiga toxin B subunit binding to its receptor in a lipid bilayer

W. Pezeshkian[1,2], V. Chaban[1], L. Johannes[3], H. Khandelia[1], J. C. Shillcock[4], J. H. Ipsen[1]
[1]*FKF, Memphys, University Of Southern Denmark, Odense, Denmark*, [2]*Transpol Molecular Neurobiochemistry, Ruhr Universitat Bochum, Bochum, Germany*, [3]*Institut Curie, Paris, France*, [4]*Blue Brain Project, Brain Mind Institute, EPFL, Lausanne, Switzerland*

Atomistic molecular dynamics simulations of the DOPC-Gb3 and DOPC-Gb3-Shiga toxin B subunit (STxB) systems are performed to investigate the structure of the complexes.

The results for DOPC-Gb3 lipid bilayer show a strong tendency for the Gb3 with a saturated acyl chain to phase separate into a domain enriched in Gb3, while for the Gb3 with an unsaturated acyl chain de mixing with a slow rate is seen.

Also, increasing the Gb3 concentration, results in ordering of both the DOPC and Gb3 lipid chains and a dramatic reduction of these diffusion constants.

Simulations of the DOPC-Gb3-STxB complex show that Gb3 in a lipid bilayer can not fully bind to all STxB binding sites,

due to the hight difference of the STxB binding sites and the two dimensional structure of the lipid bilayer.

As well, we show that hight difference between the STxB binding sites is a prerequisite for curvature generation.

Biochemical and immunological blood parameters in dynamics under esophageal acid burn model of 2nd degree

R. Yana, I. Tetiana, S. Oleksiy, O. Ludmila, O. Dzhus
ESC "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Exogenous poisoning with alkalis takes the leading position among causes of acute poisoning. About 75% of the affected persons are children. There are many pathologies and complications following esophageal burns: scar stricture, esophageal deformations, corrosive esophagitis, gastroesophageal reflux and others. Nowadays there are not enough adequate experimental models of esophageal acid burns for investigation of this pathogenesis. Thereby the burn disease is an important issue that needs solution immediately.

The purpose of the work was to reproduce the model of an esophageal acid burn of 2nd degree experimentally in rats and to characterize the biochemical and immunological blood parameters in dynamics.

In experiments, we used nonlinear white mature rats (weight 90 ± 10 g). The animals were administered with CH3COOH (30% solutions) to induce esophageal burn. Rat blood samples were obtained after 1, 3 and 7 days after alkali administration.

The biochemical parameters were determined with analyzer Humalyser 3000. The level of the blood antibodies was assessed by ELISA analysis which was performed in 96-well microplates (Dynatech, Sweden).The level of circulating immune complexes (CIC) in serum was determined by precipitation with 4.5% solution of polyethylene glycol-6000.

After 2nd degree acid burn simulation the level of investigated biochemical parameters (content of total protein, albumin) statistically decreased on the 1st – up to 7th day. The level of urea, creatinine and potassium concentrations were increased during all research duration. The most significant changes of biochemical parameters were observed on the 1st day after 2nd degree acid burn simulation. It was confirmed serum blood ALAT and ASAT activities increasing, as well as increasing of IgG antibodies and CIC levels the 1st- up to 7th day compare to the control datas. In that way the most pronounced pathological process development was observed on the 1st day of acid treatment.

So in the experiments, we reproduced an acid esophageal burn model of 2nd degree in rats. The changes of basic blood biochemical and immunological parameters in experimental animals with acid burn of esophagus were established. Obtained results allow us to conclude that the acid model used is adequate for human esophageal burns research. Our approach can be used for study molecular mechanisms of acid esophageal burn pathogenesis of 2nd degree.

Keywords: burn, biochemical parameters.

Breaking down DNA allostery: a protein-DNA binding computational study

A. E. Balaceanu, P. D. Dans, M. Orozco
Structural Computational Biology, IRB Barcelona, Barcelona, Spain

The accessibility of the genetic information stored in DNA is dependent on the flexibility and conformational constraints of the macromolecule as well as on its energy landscape. The view that DNA acts as an inert template onto which proteins assemble to replicate or transcribe genes has evolved to acknowledge an active role for the DNA through its capacity to undergo conformational changes in response to protein binding.

Novel evidence from a single-molecule study reopened the issue of DNA alostery (Kim S et al, 2013). However, mechanistically understanding how this ranged cooperative protein binding takes place is a challenge experimentally, but it is at last possible by molecular dynamics (MD) techniques. Up to this point atomistic MD were not employed for the study of allosteric effects and simplified models were used in order to circumvent the big amount of calculations needed.

Using state-of-the-art force fields, MD gives the most precise computational reproduction of DNA-protein-solvent interactions at near physiological conditions. We performed full-scale detailed simulations at large enough time scales to encompass the characteristic times of structural distortions and information transfer upon protein binding to DNA. By analyzing the induced perturbations, we were able to explain the propagation of medium and long-range conformational transitions that modulate the affinity and specificity of subsequent protein-DNA binding events. We chose a variety of systems based on the length and sequence of the DNA and studied the binding of BamHI, a type II major groove binding endonuclease, as well as the relaxation upon removal of the protein. We characterized the spatial and temporal propagation of information along DNA, in terms of both energetics and structural deformations. The results lead to the description of an information transfer process as a proposed operating mechanism for allostery. We distinguished between the nature of perturbation propagation along different special sequences of DNA depending on their intrinsic flexibility properties.

It was found that the flexibility pattern and base pair correlation decay length of protein bound DNA is oscillatory with a periodicity of approximately 10 base pairs. We also concluded that the induced distortions in the DNA conformation measured by deviations in the major groove width propagate through the backbone and they affect the ability of DNA to bind to a second protein. The results confer significant agreement with the experimental data while providing new valuable insight into the functional basis of the process and validatind the efficiency of an all-atom molecular dynamics simulation approach to the meaningful issue of DNA allostery.

Keywords: DNA allostery, information transfer mechanism, molecular dynamics.

Channel-forming activity of amyliod peptides is affected by phloretin

S. Efimova, O. Ostroumova
Laboratory of Ionic Channels of Cell Membranes, Institute of Cytology Russian Academy of Sciences, St.-Petersburg, Russian Federation

Amyloid precursor protein (APP) is an integral membrane protein expressed in many tissues and concentrated in the synapses of neurons. Its primary function is not known, though it has been implicated as a regulator of synapse formation [Priller et al., Neurosci., 2006], neural plasticity [Turner et al., Neurobiol., 2003] and iron export [Duce et al., Cell, 2010]. APP is best known as the precursor molecule whose proteolysis generates amyloid β-peptides (Aβ), amino acid peptides whose amyloid fibrillar form is the primary component of amyloid plaques found in the brains of Alzheimer's disease patients. The aim of our study was the investigation of the influence of the membrane active agents, flavonoids and styryl dyes, on the channel-forming

© 2014 The Authors. FEBS Journal © 2014 FEBS

activity of amyliod β-peptide fragment 25–35 (Aβ25-35) in planar lipid bilayers. Virtually solvent-free bilayer lipid membranes were prepared from binary mixtures of dioleylphosphoserine and dioleylphosphoethanolamine in 0.1 M KCl (pH 7.4) using monolayer-opposition technique. Aβ25-35 was added to aqueous solution at one side of the bilayer to obtain a final concentration ranging from 1/10 μM. We found that both-side addition of 20 μM of phloretin to the bilayer bathing solution which decrease the membrane dipole potential on 90 ± 10 mV, was accompanied by more than 10-fold increase in the Aβ25-35-induced steady-state transmembrane current (Iop). The introduction of 20 μM of other flavonoids, phloridzin, quercetin, genistein or 2′,4′,6′-trihydroxy-acetophenone, reducing the membrane dipole potential in the different rates, did not change the Iop. At the same time, increasing the membrane dipole potential more than on 80 ± 10 mV due to the introduction of 5 μM RH 421 or RH 237 also did not affect the Aβ25-35-induced steady-state transmembrane current. Comparing the results of measurements of the dipole potential of membranes and the influence of dipole modifiers (flavonoids and styryl dyes) on the channel-forming activity of Aβ25-35 one can conclude that the observed effect of phloretin is not caused by the changes in the membrane dipole potential. The possible mechanisms of phloretin action on the channel-forming activity of Aβ25-35 comprising the influence of phloretin on the oligomerization/aggregation of amyloid peptides were discussed. The study was supported in part by RFBR (#14-04-31738), the Program of the RAS «MCB» and SS-1721.2014.4.
Keywords: amyliod peptides, phloretin, planar lipid bilayer.

Cold-denaturation of a protein dimer monitored at atomic resolution

M. Jaremko[1], L. Jaremko[2], H.-Y. Kim[1], M.-K. Cho[1], C. D. Schwieters[3], K. Giller[1], S. Becker[1], M. Zweckstetter[2]
[1]NMR-Based Structural Biology, Max-Planck Institute for Biophysical Chemistry, [2]DZNE e.V, Goettingen Site, Goettingen, Germany, [3]Division of Computational Bioscience, Building 12A, NIH, Bathesda, USA

Protein folding and unfolding are crucial for a range of biological phenomena and human diseases. Defining the structural properties of the involved transient species is therefore of prime interest. Using a combination of cold-denaturation with nuclear magnetic resonance spectroscopy we reveal detailed insight into the unfolding of the homodimeric repressor protein CylR2. Seven three-dimensional structures of CylR2 at temperatures from 25°C to -16°C reveal a progressive dissociation of the dimeric protein into a native-like monomeric intermediate followed by transition into a highly dynamic, partially folded state [1]. The core of the partially folded state appears critical for biological function and misfolding.

Combined in vitro and *in silico* evolution of the organophosphate metabolizing reactibody A17

I. Smirnov[1,2], A. Stepanova[1], S. Terekhov[1], A. Golovin[3], Y. Mokrushina[1], A. Belogurov[1,2,4], N. Ponomarenko[1], A. Gabibov[1,2,4]
[1]Shemyakin–Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, [2]Kazan Federal University, Kazan, [3]Moscow State University, [4]Institute of Gene Biology RAS, Moscow, Russian Federation

Reactibody A17 was selected from Griffin library against arylphosphonate. The deep structural and functional analysis has revealed the architecture of its active center to have a cholinesterase-like anion binding site, hydrophobic pocket, and reactive Tyr residue. Reactibody A17 showed high reactivity with parent substrate, an aryl-phosphonate. As expected, the reaction was non-catalytic. We found that reactibody A17 does not react with echothiophate and p-nitrophenyl phosphocholine, but does interact with DFP, AEBSF and paraoxon. Moreover we observed paraoxon hydrolysis by A17 and showed that this process involves covalent intermediate formation. Although our selection method was designed primarily to provide covalent binding, our general task remains to obtain catalytic antibodies. To that end, we have identified one substrate which is hydrolyzed with catalytic turnover. We have established that the for initial non-covalent binding and proper orientation, the positive amino acids is preferred, the hydrolysis require the negative charged amino acids for stabilization of hydroxyl ion and decreasing of proton transfer. To engineer an abzyme based on the A17 reactibody to turn over organophosphorus substrates we used two approaches of active center evolution. We created the sub-library of reactibody active center and developed the computational maturation to provide best driving forces for paraoxon hydrolyzing antibody. We confirmed that arginine mutant showed high reactivity with paraoxon. It was two orders of magnitude more compared to wild type. But no catalysis was observed. Thus our results were in line with our computed predictions. A histidine-35 mutant improved covalent binding with paraoxon and retained same catalytic activity. Glutamic acid-35 mutant blocked interaction with both phosphonate and paraoxon molecules.

Comparison of assembly efficiency of cognate and artificial *Potexvirus ribonucleoproteins*

E. K. Petrova, E. A. Trifonova, N. A. Nikitin, O. V. Karpova, J. G. Atabekov
Virology, Faculty of Biology Lomonosov Moscow State University, Moscow, Russian Federation

Potato virus X (PVX) (helical filamentous plant virus, genus *Potexvirus*, family *Alphaflexiviridae)* has the possibility of reversible dissociation of virions into coat proteins (CP) and RNA followed by the *in vitro* self-assembly of viral particles which save the structure and biological activity of the virus. Previously we showed that *in vitro* incubation of PVX CP with the RNAs of various plant and animal viruses results in the viral ribonucleoproteins (vRNP) formation (Arkhipenko *et al.*, 2011). The helical structure, morphology and translational properties of these artificial vRNP were identical to cognate vRNP assembled from PVX RNA and PVX CP and to PVX virions. However, the widely used methods do not allow us to estimate the efficiency of assem-

© 2014 The Authors. FEBS Journal © 2014 FEBS

bly of artificial vRNPs formed by PVX CP and different plant and animal RNAs. To obtain data about the particles size (hydrodynamic diameter) and concentration the method of Nanoparticle Tracking Analysis (NTA) was used. PVX CP was incubated with PVX RNA and different viral RNAs. Formed cognate and artificial vRNP were analyzed by NTA. This method based on laser-illuminated optical microscopy enables to detect the RNPs assembly in real-time in liquid. The detected number of formed particles indicates the assembly efficiency. For the first time the information about efficiency of the potato virus X particles assembly was obtained by NTA. The assembly efficiency of RNPs formed by PVX CP with PVX RNA and heterologous viruses RNA was compared. The proposed method allows studying the mechanisms of initiation and elongation of the viral ribonucleoproteins.

Computer simulation method to generate the variant sequences of influenza viruses using the time series substitution pattern

I. Ahn[1], H. S. Son[2]
[1]High-Performance Biocomputing Team, Korea Institute of Science and Technology Information, Daejeon, [2]Graduate School of Public Health, Seoul National University, Seoul, Korea, Republic Of

Since the outbreak of novel influenza pandemic in 2009, various kinds of simulation methods have been developed. Most of the developments, however, are focused on the determination of the spreading patterns of influenza viruses over time. In this study, we introduce a novel approach to predict the possible variants of influenza viruses using the empirical data of nucleotide sequences determined by experimental methods. We developed a simulation tool named SimFlu (simulation tool for influenza virus) to predict possible future variants of influenza viruses. SimFlu can create variants from a seed nucleotide sequence of influenza A virus using the codon variation parameters included in the SimFlu package. The SimFlu's library provides pre-calculated codon variation parameters for H1N1, H3N2 and H5N1 subtypes of influenza A virus isolated from 2000 to 2011. All the source sequences (56 328 sequences) of the SimFlu's library were collected from the Influenza Virus Resources at NCBI. The SimFlu supports 3 types of operating systems, including Windows, Linux, and Mac OS X, and it also provides a command option-based version to run on a Linux queuing system. SimFlu is publicly available at http://lcbb.snu.ac.kr/simflu. Moreover, we also developed an analytical tool for calculating the codon substitution patterns named SimFluVar to support the researchers who want to use their own variation parameters. SimFluVar provides precise patterns of co-don variations between 2 viral groups, especially for the influenza virus groups. SimFluVar also provides the useful functions, such as editing and visualization of the result matrix. SimFluVar is in C++, and Java RCP is used for distribution package. Documentation, examples, results and source code are available at http://lcbb.snu.ac.kr/simfluvar.

Conformational flexibility and domain binding interfaces in human tyrosyl-tRNA synthetase studied by molecular dynamics simulations

O. V. Savytskyi[1], S. O. Yesylevskyy[2], A. I. Kornelyuk[1]
[1]Department of Protein Engineering and Bioinformatics, Institute of Molecular Biology and Genetics, National Academy of Sciences of Ukraine, [2]Department of Physics of Biological Systems, Institute of Physics, National Academy of Sciences of Ukraine, Kyiv, Ukraine

Human tyrosyl-tRNA synthetase (*Hs*TyrRS) is a key enzyme of protein biosynthesis, which catalyzes the aminoacylation of cognate $tRNA^{Tyr}$ and also reveals non-canonical cytokine activities. After proteolytic cleavage *Hs*TyrRS reveals both IL8-like activity of its N-terminal catalytic module and EMAP II-like activity of non-catalytic C-terminal domain (Wakasugi and Schimmel, 1999; Kornelyuk et al., 1999). Earlier, it was found that the ELR-motif (E91, L92, R93) in *Hs*TyrRS is responsible for IL8-like cytokine activity (Wakasugi and Schimmel, 1999), but its structural state in full-length human TyrRS was unknown.

In this work we constructed the model of the full-length *Hs*TyrRS structure and studied its putative compactization by all-atom molecular dynamics simulations. All MD computations were performed using grid services of the MolDynGrid virtual laboratory (http://moldyngrid.org). 3D structure of *Hs*TyrRS was constructed in Modeller 9.7 using structure templates (1N3L, 1NTG, and 1OPL for interdomain linker). Six independent 100 ns MD trajectories of *Hs*TyrRS were computed using GROMACS 4.0.5 software in G43a1 force field. The Contacts Analyzer Script (CAS) and the tRMSF tool of the Pteros molecular modeling library (http://pteros.sourceforge.net) were used for MD simulation data analysis. The Distributed Analyzer Script was used for analytical tools automation (Savytskyi et al., 2011).

Our MD simulations revealed the strong binding energy of ~1000 kJ/mol for C-module binding to mini-TyrRS dimer. Antiparallel β-sheet formation at the Ala355-Val363 region of interdomain linker was observed at 3–100 ns time interval (~85% of time). Also, the β-turn formation at the Pro365-Arg367 region was revealed for 40–90 ns time interval (~50% of time).

During 100 ns MD simulations the H-bonds formation between R93 residue of ELR cytokine motif and A340 and E479 residues of C-module was observed. These findings support the idea that the full-length TyrRS lacks its cytokine activity due to the direct interactions between N-terminal and the C-terminal modules, which protect the ELR cytokine motif.

This work was partially supported by National Academy of Sciences of Ukraine. Cytostatic and proapoptotic effect of n-hydroxy-4-({[(e)-2-phenylethenyl]sulfonyl} amino) butanamide on tumor cells

O. Dzhus[1], L. Garmanchuk[1], T. Nikolaienko[1], V. Nikulina[1], V. Orysyk[2], Y. Zborovskii, M. Vovk[2]
[1]*Institute of Biology, Taras Shevchenko National University,*
[2]*Institute of Organic Chemistry NAS of Ukraine, Kyiv, Ukraine*

Hydroxamic acids possess high biological activity due to their ability to form stable complexes with metal ions which play an important role in the metabolic processes of living organisms. Polifunctional hydroxamic acids coordinating with enzyme protein fragmentare able to bind metal ions in their active site in complexes. Therefore, many hydroxamic acids are inhibitors of metal-containing enzymes. In particular, they can inhibit zinc-containing enzymes histone deacetylases and metalloproteases, thereby have a role in regulating gene expression, proliferation and cell migration, angiogenesis. Histone deacetylases inhibitors cause accumulation of acetylated forms of proteins which can alter their structure and function, induce different phenotypes in various transformed cells, including growth arrest, apoptosis and mitotic cell death. This mechanism of action of hydroxamic acids determines their high antitumor and antibacterial activity and the selectivity of the effect, because normal cells are resistant to the action of histone deacetylases inhibitors.

We found thatN-Hydroxy-4-({[(E)-2-phenylethenyl]sulfonyl} amino) butanamide (here in after compound 1) has cytostatic and apoptotic effect with respect to cells of the cervix carcinoma line Hela. The compound 1 at concentration 2.5 mkM-2.5 mM increased the number of apoptotic cells in 6 times, and shifted the distribution of cells in phases of the cell cycle. Last was manifested in the increase of cell percentage inG_0/G_1 phase in 1.2 times and reduction in S phase of the cell cycle in 2 times, compared with the control.

We have also identified changes in the morphology of the cell culture under the action of the compound 1. Hela cells acquire the phenotype of normal epithelium â�� polygonal shape with characteristic processus, elongated nucleus after co-culturing with the compound.

Thus, N-Hydroxy-4-({[(E)-2-phenylethenyl]sulfonyl}amino) butanamide can be a promising compound for cancer therapy.

Development of a double sandwich enzyme immunoassay for quantitation of Moroccan snakes venom after envenomation

F. E. Khaddach[1,2], B. Benaji[1], N. Ghalim[2]
[1]*Microbiology, Pharmacology, Biotechnology and Environment Laboratory, Faculty of science Ain chock Casablanca, Hassan II University, Casablanca,* [2]*Venoms and Toxins Laboratory, Pasteur Institute of Morocco, Casablanca, Morocco*

Snake envenomations remain an important yet neglected public health problem in tropical and subtropical countries. In morocco, viper species (*Cerastes cerastes* and *Macrovipera mauretanica*), and the Moroccan Cobra specie (*Naja haje legionis*) are among the common causes of severe snakebite accidents. In this work, a double sandwich enzyme-linked immunosorbent assay (ELISA) was developed for the first time in Morocco and validated to detect and to quantify snakes venom in biological samples.

The method proved to be simple, specific, reproducible, sensitive (detection limit = 0.5 ng/ml) and the calibration plot was based on linear regression analysis ($r^2 = 0.980$) between 0.9 and 1000 ng/ml of venom concentration, with a lower limit of quantification of 1.58 ng/ml. The intra- and interassay coefficient of variation ranged from 2.02 to 4.62% and 5.29 to 7.40%, respectively.

The specificity of the assay was tested using vipers, cobra and scorpion venom. This method detected venom from all viper species tested without significant cross reactivity with other venoms in the concentration range of 0.9–1000 ng/ml.

This ELISA may prove to be helpful to establish a rationale approach of specific antivenom therapy, as well as it is a promising test for identification of envenomations by species of vipers found in most of North Africa. It can also be used to study the toxicokinetics of the vipers venom in experimental envenomations.

Keywords: Moroccan snakes venom, Sandwich ELISA, validation.

Effect of charge-stabilized silver nanoparticles with various surface properties on physiological state of seedlings of *Triticum aestivum*

M. Ocwieja[1], A. Gorczyca[2], M. Niemiec[3], Z. Adamczyk[1], E. Pociecha[4]
[1]*Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences,* [2]*Department of Agricultural Environment Protection,* [3]*Department of Agricultural and Environmental Chemistry,* [4]*Department of Plant Physiology, University of Agriculture, Cracow, Poland*

The widespread use of silver nanoparticles causes that they can be transferred to the environment in an uncontrolled manner. This poses a serious problem because some studies show that silver nanoparticles can be toxic in environment. Although the mechanism of silver nanoparticle action is still not precisely elucidated, it is assumed that it can be affected by their surface properties, especially by stabilizing agents of nanoparticles which were used during the synthesis.

Therefore, the aim of this work was to determine the influence of charge-stabilized silver nanoparticles of similar size but various surface properties on *Triticum aestivum* seedlings. Three types of silver nanoparticles used in our experiments were synthesized using trisodium citrate, tannic acid and sodium hexametaphosphate as stabilizing agents.

The morphological changes in roots and shoots of *T. aestivum* treated by suspensions showed that the silver nanoparticles stabilized by sodium hexametaphosphate exhibit the most adverse action on seedlings whereas the influence of citrate-stabilized nanoparticles was rather indifferent. Moreover, taking into account that silver nanoparticles interact with the cellular components which results in the formation of reactive oxygen species (ROS), the changes in catalase (CAT) and superoxide dismutase (SOD) activity were examined. It was found that CAT activity increase significantly in roots of plants treated by tannic acid-stabilized nanoparticles. On the other hand, SOD activity increases for tannic-acid and phosphate-stabilized nanoparticles. The strongest impact on membrane permeability in both leaves and roots was caused by phosphate-stabilized nanoparticles and by silver nitrate. Additionally, it was shown that all suspensions as well as silver nitrate caused the increase of quantum efficiency of energy trapping in PS II reaction center compared to the control.

This results unequivocally shown that the surface properties of nanoparticles of similar size can affect wheat seedlings growth in various ways. The most profound effect is exerted by silver nanoparticles stabilized by sodium hexametaphosphate.

Effect of serotonin on membranes properties studied by molecular dynamics simulations

H. Santuz[1], S. Azouzi[1], P. Amireault[2], C. Etchebest[2,3]
[1]UMR-S1134, INSERM, University Paris-Diderot, [2]UMR-S1134 Inserm-University Paris Diderot, [3]INTS-GREX, Paris, France

Extending the life of transfused red blood cells (RBC) has major implications in the treatment of several diseases (anemia, sickle cell disease) that require repeated transfusions. Recently, it has been demonstrated that serotonin (5-hy- droxytryptamine), a monoamine neurotransmitter implicated in the central nervous system, has a protective role on red blood cells and is crucial to ensure normal erythropoiesis and red blood cells survival in mice. Without serotonin, the half-life of RBC is reduced both in vivo and in vitro. Among the mechanisms responsible for this effect, oxidation cascade plays a significant role. Serotonin could act as an antioxidant agent to prevent destabilization of the membrane and lipid peroxidation. Different hypotheses are advanced to investigate its protecting effect: How does serotonin prevent destabilization of membranes? What are the mechanisms in which serotonin interplays with lipid peroxidation?

We present results related to the first question, i.e. how does serotonin interact with membranes. We performed molecular dynamics simulations with a protonated serotonin molecule initially placed in the solvent compartment of a fully hydrated bilayer of POPC. We observed that serotonin rapidly locates at the membrane interface. The key interaction is a salt bridge between the amine group of serotonin and the phosphate group of lipids with the aromatic group of serotonin pointing inward the bilayer. Simulations with several serotonins show no aggregation of the latter at the interface. Examination of different membrane properties shows a slight increase of the order parameter for the unsaturated chain. Impact on membranes composed of lipids with different alkyl chain unsaturation is also examined. Analogs of serotonin molecules, which have increased or decreased protective effects compared to serotonin, are currently underway in similar conditions.

Keywords: insaturation, membrane, simulation.

Effect of vitrification on expression level of DNA methyltransferase genes

M. Koliforosh[1,2], M. Shahhosseini[1], R. Favaedi[1], B. Ebrahimi[3]
[1]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, [2]Department of Biology, Science and Research Branch, Islamic Azad University, [3]Department of Embryology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran

Background: Ovarian tissue cryopreservation is a feasible method to preserve female reproductive potential, especially in young patients with cancer or in women at risk of premature ovarian failure. Vitrification has recently emerged as a new trend for biological specimen preservation. However, this technique has not been optimized. On the other hand, gene expression changes during vitrification can influence oocyte maturation and need to be studied. Methylation of mammalian DNA is a major epigenetic regulatory mechanism that play a special role in the initiation of chromatin remodeling and gene expression regulation. The aim of the present study was to evaluate the effects of vitrification on mRNA expression levels of DNA methyltransferase (DNMTs) genes *Dnmt1, Dnmt2, Dnmt3a, Dnmt3b* and *Dnmt3 l*

Material &Method: Ovaries of 4- to 6-week old NMRI female mice were placed in two control and needle immersed (NIV) vitrification groups. In vitrification groups, ovaries were transferred in to equilibration and vitrification medium, then they immersed in liquid nitrogen after loading by acupuncture needle. Parallel to vitrification process, morphology of ovarian tissues in control and vitrification group were analyzed and compared by using hematoxylin & eosin staining. Then, the expression of *Dnmts* genes were investigated by real-time PCR.

Result: In morphological analysis, ovarian tissue integrity was well preserved in vitrification group and was similar to the control group. However the results of this study showed that the expression levels of all candidate genes in vitrification group were increased in comparison with control group; although this increase was only significant for *Dnmt1*, *Dnmt3b* and *Dnmt3 l* genes ($p < 0.05$).

In conclusion: In general we can conclude that despite normal morphology of ovarian tissue after vitrification, this process may induce changes at the genetic/epigenetic level of cryopreserved tissues.

Keywords: DNA methylation, ovary, Vitrification.

Free radical destruction of amine-containing biomolecules

A. Sladkova, A. Sosnovskaya, I. Edimecheva, G. Semenkova, O. Shadyro
Chemistry Department, Belarusian State University, Minsk, Belarus

Amine-containing compounds such as amino acids and amino sugars are of great biological importance. Serine (Ser) and threonine (Thr) are building blocks of proteins, being also essential parts of active sites of many important enzymes (serine proteases, serine integrases, cytochromes P450 etc.) and receptors (protein kinases substrates). Glucosamine (GlcN) and its derivatives are the monomeric units of mucopolysaccharides. It is also well known that reactive oxygen and chlorine species (ROS and RCS), in particular hydroxyl radicals (•OH) and hypochlorous acid (HOCl), generated in biosystems via various enzymatic and non-enzymatic pathways, can cause damage to biomolecules.

Using γ-irradiation model for •OH generation as well as chromatographic techniques coupled with UV-visible, fluorescence and mass spectrometry detectors, we have shown that GlcN, Ser, Thr, Thr-Val, Ser-Ala and similar dipeptides undergo •OH-induced carbon skeleton destruction in aqueous solutions. The free radical mechanism of the destruction has been proposed, which includes formation of N-centered radicals and their further fragmentation. It has been proven experimentally that the presence of 2-aminoethanol moiety as well as an unsubstituted and non-protonated amine-group in the biomolecules is necessary for the realization of this type of fragmentation. For instance, it was shown that in case of Ser homolog homoserine, which contains hydroxyl-group in γ- rather than in β-position to amine-group the proposed scheme of conversion was inhibited. It is interesting to note that the non-enzymatic free radical Ser conversion according to the proposed scheme, resulting in the formation of glycine and formaldehyde, is similar to the Ser bioconversion driven by serine hydroxymethyltransferase. This bioconversion has recently been revealed to be important for cancer metabolism [1]. Since cancer cells exhibit increased intrinsic ROS, the non-enzymatic Ser conversion can also be supposed.

© 2014 The Authors. FEBS Journal © 2014 FEBS

It is known that HOCl, formed in living organism mainly due to myeloperoxidase activity, reacts with a wide variety of biological molecules [2] and causes tissue damage. It was established that HOCl can initiate carbon skeleton destruction of Ser, Thr and GlcN according to the proposed scheme.

Therefore the discovered conversion mechanism is recommended to take into consideration during investigation of ROS/RCS-induced pathophysiological processes involving biomolecules with 2-aminoethanol moiety, such as Ser, Thr and the corresponding peptides as well as GlcN, and, possibly, their complex macromolecular derivatives.

Introduction: In AL amyloidosis, widespread deposition of immunoglobulin light chains (LCs) as amyloid fibrils translates into organ dysfunction. In vivo and in vitro evidence indicates that soluble amyloidogenic LCs possess intrinsic toxicity towards cells. The mechanisms of damage are not yet clarified and may involve abnormal interactions between toxic LCs and cell components. We developed a system to investigate LC-protein interactions in cardiac cells, potentially leading to functional perturbation and genesis of proteotoxicity.

Methods. Monoclonal LCs that are amyloidogenic and cardiotoxic in vivo, along with non-amyloidogenic ones (controls), were purified by chromatography from urines of clinically characterized patients (with AL cardiomyopathy and multiple myeloma, respectively), and assessed for purity and aggregation in vitro. Direct and inverse co-immunoprecipitation (co-IP) approaches, combined with mass spectrometry and immunoblotting, were used to identify and confirm the protein species interacting in vitro with each light chain. The lists of interactors were analyzed by bioinformatics. Selected interactions were validated by imaging approaches in cultured human cardiac cells.

Results. Our functional proteomics approach showed that the soluble LCs that are cardiotoxic for patients interact with a common subset of cellular proteins in vitro, mainly possessing mitochondrial localization and involved in key viability and metabolic functions. No evidence of in vitro formation of light chains amyloid fibrils was documented during the analysis time. Imaging studies, in human cardiac fibroblasts (hCF) and cardiomyocytes (hCMC), showed that LCs are internalized. Validation of proteomic data by co-localization analyses, in hCF, confirmed that LC-protein interactions, specific for the analyzed cardiotoxic LCs, occur within live cells.

Discussion. Our data indicate that toxic LCs establish interactions with intracellular species, affecting proteins involved in viability and metabolism. This study opens new perspectives on the mechanisms of LC proteotoxicity and AL cardiomyopathy and on potential therapeutic strategies.

While there is an urgent need to find new drugs that suppress aging and age-related diseases, in vivo studies evaluating drug efficiency in higher mammals may take decades. An intelligent process for predicting the activity and ranking the geroprotective activity of various factors and strengthening the prediction in rapid and cost-effective studies on cell cultures and model organisms may help increase the longevity dividend of these studies. We developed a method and a software package termed GeroScope for *in silico* screening and ranking of drugs and other factors that act on the many signaling pathways implicated in aging and longevity by calculating their ability to minimize the difference between signaling pathway activation patterns in cells of young and old patients. We applied GeroScope on publically available gene expression datasets, computed pathway activation profiles of various tissues and selected potential geroprotective drugs to be tested *in vivo* and *in vitro* to narrow down the list of preventative medicine choices for clinical trials.

HOCl-induced sphingolipid free radical destruction resulting in bioactive 2-hexadecenal

A. Lisovskaya, N. Amaegberi, G. Semenkova, I. Edimecheva, O. Shadyro
Chemistry Department, The Belarusian State University, Minsk, Belarus

It was found that the action of hypochloric acid (HOCl) on aqueous lysosphingolipids dispersions produces 2-hexadecenal. For the realization of such process, the presence of a free amino group in the sphingolipid molecule is required to ensure formation of N-centered radicals from the substrate on its interaction with reactive oxygen and chlorine species.

The obtained data allows to conclude that hypochlorous acid chlorinate amino group of sphingosine, sphingosine-1-phosphate, sphingosine-1-phosphocholine followed by rapid C–C bond rupture and accumulation of 2-hexadecenal.

Analysis of the effect of HOCl on transplantable rat glioma C6 cells indicates 2-hexadecenal to be formed. We developed method based on high performance liquid chromatography using fluorescence detection to quantify the sphingolipid destruction product 2-

© 2014 The Authors. FEBS Journal © 2014 FEBS

hexadecenal. The obtained results suggest the described mechanism of free radical fragmentation of sphingolipids may be implemented on cell culture under stress of reactive chlorinating species.

We demonstrated that 2-hexadecenal causes cytoskeletal reorganization during neutrophil adhesion which is revealed by increasing of both F-actin content and the cells' size. 2-Hexadecenal can regulate the redox state of neutrophils which stimulated by chemotactic peptide fMLP, redistributing contribution of myeloperoxidase, phospholipase A_2 and enzymes of arachidonic acid metabolism in the formation of reactive oxygen and halogen species.

These findings evidence the existence of non-enzymatic pathway of sphingolipid destruction leading to formation of 2-hexadecenal, which possesses a wide spectrum of biological activity. Therefore, any change in the sphingolipid/2-hexadecenal ratio in a cell should play an important role in the signaling way switch-over mechanisms and, as a consequence, in functioning of the cell. Hence, realization of non-enzymatic reactions leading to formation of 2-hexadecenal in living organisms may influence functions of the latter.

Keywords: 2-hexadecenal, reactive chlorinating species, sphingolipids.

How can we quantify ligand sensitivity for single-cell heterogenous dynamical responses?

T. Jetka, M. Komorowski

Institute of Fundamental Technological Research, Polish Academy of Science, Warsaw, Poland

All biological organisms need to sense and response to their environment. At the level of single cells, surface receptors convert extracellular cues into activation of transcription factors that control cellular decisions.

A considerable unresolved issue is how information about ligand binding is encoded into nuclear activity of the transcription factors. A growing number of studies supports the hypothesis that this is achieved by temporal regulation of their activities. The current challenge is to recognise the features of temporal activity profile that represent information about a given stimulus.

A natural strategy to decipher this temporal coding is to scan cellular responses across a range of considered stimuli and identify most sensitive features of temporal profiles. Methods however to quantify sensitivity at the single cell level, where stochastic effects play a major role, are virtually missing. We have developed a statistical framework to measure sensitivity of cellular outcomes from time-resolved, single cell, heterogeneous responses. The method allow us to quantify changes in response to stimuli despite substantial heterogeneity of single cell behaviours.

We use the method to analyse nuclear translocation of the NF-kB transcription factor upon TNF stimulation in mouse embryonic fibroblasts. We identified how the sensitivity the system changes with TNF concentration and indicate the essential features of the nuclear NF-kB temporal profile that are most sensitive to TNF changes. Our method provides essential methodological advancement needed to gain understanding how temporal activity profiles encode information about a given stimulus.

How do peptidic tree-like molecules fold?

L. Filipe[1], S. R. R. Campos[1], M. Machuqueiro[2], T. Darbre[3], A. M. Baptista[1]

[1]ITQB-UNL, Oeiras, [2]FCUL, Lisboa, Portugal, [3]University of Bern – DCB, Bern, Switzerland

Peptide dendrimers are tree-like molecules formed by alternating functional amino acids with branching diamino acids such as lysine [1]. Dendrimers of this kind have already rendered several models for different applications, such as vitamin B12 transporters, antimicrobial agents and catalytic systems.

Unfortunately these molecules have not yet yield to experimental structural characterization, hampering the possibility of constructing truly tailor-made peptide dendrimers and improve the existing ones. Computational methods seem to be an adequate tool to address these issues.

Herein we present a comprehensive set of computational studies using molecular dynamics simulation methods, including stochastic titration constant-pH simulations, to explore the conformational behavior of these molecules and the key determinants to such behavior [2,3].

Moreover, we unravel the first hints on the influence of pH in the folding of these molecules, and the role played by dendrimer-substrate interactions during dendrimer-catalyzed ester hydrolysis.

We used several conformational analysis procedures (clustering, energy landscapes and multivariate analysis) to analyze conformational changes that can be correlated with particular structural trends.

Our results show that peptide dendrimers exhibit a remarkable structural plasticity which is crucial for their activities.

This work provides new insights into the atomic-level structures of these systems and might, in a near future, contribute to the development of novel knowledge-based dendritic systems with enhanced functionalities.

IKKα regulates hair follicle morphogenesis and hair growth cycle

M. L. Casanova[1], A. Bravo[2], M. J. Fernandez-Aceñero[3], J. P. Alameda[1], Y. Jimenez[1], N. Junca[1], C. Suarez[1], F. Sanchez-Sierra[1], M. A. Page[1], M. Navarro[1], A. Ramirez[1]

[1]Basic Research, CIEMAT, Madrid, [2]Veterinary Clinical Sciences, University of Santiago de Compostela, Lugo, [3]Pathology, Fundacion Jimenez Diaz, Madrid, Spain

The IKKα protein is mainly known by its essential function in epithelial physiology. It is also recognized by its role in non-melanoma skin cancer (NMSC) tumor development. To gain insight into IKKα function in adult skin as well as in skin appendages such as hair follicles- considered the place of origin of NMSC-, we have generated IKKα-siRNA transgenic mice. Here, we compare the skin of these mice with that of IKKa+/- mice expressing reduced levels of IKKα.

Both types of transgenic mice show similar external phenotypic features consisting in scarce and ruffled hair. This hair coat phenotype was observed in the first hair growth cycle. After depilation, hair regrowth was delayed in IKKa-siRNA transgenic mice and

© 2014 The Authors. FEBS Journal © 2014 FEBS

there were apparent anomalies in the histology of the new hair follicles, consistent in distorted shapes and follicle degeneration, accompanied by dermal deposition of melanin and local infiltration of mononuclear cells around the follicular debris. In addition, transgenic mice presented morphologically distorted hair shafts, which did not correspond to any of the usual hair types found in control mice—guard, awl, auchene, and zig-zag hair. In aged IKK+/- mice, in addition to hair alterations, we have observed alopecia and histological alterations of the intrafollicular epidermis, including foci of parakeratosis, basal hyperplasia and atypia that occasionally lead to the development of spontaneous papillomas and *in situ* carcinomas. We have not analyzed aged IKKα-siRNA mice.

The study of the skin and hair follicles of both, IKKα-siRNA and IKKa+/- transgenic mice show that IKKα is required for the control of hair follicle homeostasis. The alterations of these appendices are similar in both types of mice. These results and previous work of our group suggest that the expression of IKKα must be strictly regulated since both the decreased and increased levels of IKKα lead to the predisposition to skin malignancy.

Ruthenium complexes are evaluated as prospective pharmaceutical agents and have emerged as promising alternatives to Platinum compounds for anticancer chemotherapy. Due to the large interest of this class of compounds for bioinorganic chemistry and biomedical applications, it is demanding to investigate their reactivity with proteins. The reaction between NAMI-A and AziRu, two structurally related Ru(III) compounds with antitumor activity, and the model proteins hen egg white lysozyme, HEWL, and bovine pancreatic ribonuclease, RNase A, was investigated through electrospray ionization mass spectrometry, Raman microscopy, UV-visible absorption spectroscopy and X-ray crystallography [1–3]. In all cases, formation of stable metal-protein adducts was unambiguously demonstrated. Similarly, the product of the reaction between the paddle-wheel tetrakis (acetato)chlorido diruthenium (II,III) complex, $[Ru_2(\mu\text{-}O_2CCH_3)_4Cl]$, and HEWL has been characterized [4]. Taken together, the results of these works suggest that the combined used of X-ray crystallography, Raman microspectroscopy and electrospray mass spectrometry is a valuable tool for examining in detail the protein metalation process.

Investigation of interactions between anti-tumor antibiotics and biomolecules by molecular modeling

E. Sahin[1], C. Selcuki[2]
[1]*Graduate School of Natural and Applied Sciences, Department of Biochemistry,* [2]*Department of Biochemistry, Ege University, İzmir, Turkey*

Objective: Chemotherapy is the treatment of cancer with natural or synthetic chemicals, biological agents and hormones which selectively kill especially, rapidly dividing cells as an important part of cancer therapy. A glycopeptide antibiotic bleomycin and an antracycline antibiotic doxorubicin with anti-tumor activity are produced by the bacterium Streptomyces verticillus and Streptomyces peucetius, respectively. These anti-tumor antibiotics targeted to DNA by intercalation. The structure of bleomycin is composed of mainly 4 domains; metal-binding domain, bithiazole tail (DNA-binding domain), linker region and carbohydrate domain. The spectroscopic studies and crystal structure models of bleomycin have been used to understand the function of metal binding domain of bleomycin. The modes of intercalation with DNA, minor groove binding, full or partial intercalations have been contraversial issues for both drugs. For this reason, we will study the interactions of bithiazole tail of bleomycin and doxorubicin with the DNA by using quantum mechanical methods.

Material and Methods: For this purpose, conformational analyses of bithiazole domain of bleomycin and doxorubicin were performed with Spartan 08 software. In order to identify the appropriate conformer of bithiazole domain and doxorubicin, optimizations were performed with Spartan 08 software. Geometry optimizations and frequency analyses were performed for each conformer using density functional theory (DFT), at B3LYP/6-31G (d,p) level using Gaussian 09 software.

Results: 798 conformers for bleomycin and 422 conformers for doxorubicin were determined by conformational analyses. In order to find the most stable structure (i.e. lowest-energy structure), geometry optimization was performed. After the frequency analyses the most stable structures for bithiazole domain of bleomycin and doxorubicin were determined.

Conclusion: In this study, it was shown that bithiazole domain of bleomycin molecule can be found in 798 different conformations and doxorubicin molecule can be found in 422 different conformations. The most stable structures of these conformers were determined by optimization analyses. In order to clarify the effects of these drugs on DNA,

these structures will be used to study interactions of bithiazole domain and doxorubicin with the DNA.

Keywords: Bleomycin, doxorubicine, molecular modeling.

Iron in *Mycobacterium smegmatis* Dps: defining its pathway, a role for flexible aspartate residues in its channeling and charge neutralization by chloride ions

S. M. Williams, D. Chatterji
Molecular Biophysics Unit, Indian Institute of Science, Bangalore, India

Iron plays a vital role in the biology of living organisms. It acts as a co-factor in many redox processes and is found in the active site of many enzymes. But the acquisition and storage of iron poses a problem for aerobic organisms as it is easily oxidised to its insoluble form Fe^{3+} which is non bioavailable. Free iron

© 2014 The Authors. FEBS Journal © 2014 FEBS

generates toxic byproducts through a process called Fenton reaction, harmful to organisms. Ferritins are a family of iron storage proteins present in vertebrates, invertebrates, plants and microorganisms, and has the function of storing iron as a non-toxic and bioavailable form in their hollow protein shell. The 12-meric compartments are called DNA binding proteins under starvation or miniferritins, since they protect DNA by direct binding, as well as indirectly from free-radicals by sequestering iron in the core. *Mycobacterium smegmatis* has two Dps proteins, namely the MsDps1 and MsDps2. MsDps1 was discovered in starved mycobacterial cultures, and MsDps2 based on a BLAST search from the TIGR database.

By studying the effect of substitutions at conserved sites near ferroxidation center, we attempt to arrive at a pathway which iron atoms take to reach ferroxidation site. This pathway is the shortest route for iron from the entry site, and is lined by negatively charged residues. The two regions, the ferroxidation and iron entry sites, which are highly electronegative are linked by Arg73 which is placed at the junction and extends a number of inter-subunit interactions. When Arg73 is substituted with a glutamate, we find that the dodecamer dissociates upon the addition of iron. This instability in the presence of iron suggests that there is a direct interaction of iron with the residues which are part of the cluster. Also, by crystallization of proteins loaded with varying amounts of iron, we tried to map the changes in the protein structure in the presence of it's ligand. The protein does not show any detectable iron clusters inside the dodecamer even on saturation conditions of iron. In the presence of iron a number of residues were found to exhibit alternate conformations. Iron was detected at the entry site of the protein, and the chloride ion present at the Dps-like trimeric interface was found to dissociate at high amounts of iron, suggesting an anion channel at this interface for MsDps2.

Live-cell measurements with fluorescence cross-correlation spectrometry reveal a potential role in competitive bindings for in vivo dissociation constants

W. Sadaie[1], M. Michiyuki[1,2], A. Kazuhiro[2]
[1]*Graduate School of Biostudies,* [2]*Graduate School of Medicine, Kyoto University, Kyoto, Japan*

The EGFR-Ras-ERK MAP kinase pathway plays a pleiotropic role in many cellular functions such as proliferation, differentiation, survival, and tumorigenesis. Computer-assisted simulation is a promising approach for clarifying such complicated signaling networks; however, this approach is currently limited by a deficiency of reliable kinetic parameters. Moreover, even when such parameters are available, they are often determined by in vitro experiments, which may not be applicable to computer simulation of intracellular signal transduction. To overcome this problem, we applied fluorescence correlation spectrometry (FCS) and fluorescence cross-correlation spectrometry (FCCS) to measure dissociation constants of signaling molecule complexes in living cells (*in vivo* K_d). Among several pairs of fluorescent molecules tested, that of mEGFP and HaloTag-tetramethylrhodamine was most suitable for the measurement of *in vivo* K_d by FCS and FCCS. Using this pair, we determined more than 20 *in vivo* K_d values of signaling molecule complexes comprising EGFR-Ras-ERK MAP kinase pathway. With these parameters, we developed a kinetic simulation model of the EGFR-Ras-ERK MAP kinase pathway, and revealed a potential role played by stoichiometry in Shc binding to pEGFR during the peak activations of Ras, MEK and ERK. This multiple binding o Shc proteins to pEGFR was validated by quantitative imaging, showing that approximately 3 Shc molecules associated with an pEGFR molecule. Intriguingly, most of the *in vivo* K_d values determined in this study were higher than the *in vitro* K_d values reported previously. This data implicated the importance of competitive bindings inside cells, but not macromolecular crowding, which reduced K_d values. These *in vivo* K_d values will provide an important basis for the quantitative understanding of signal transduction.

Keywords: dissociation constant, FCCS, live-cell measurements.

Low resolution structure of the pNth1:Bmh1 complex

M. Kopecka[1,2], Z. Kukacka[3], P. Man[3], V. Obsilova[1]
[1]*Institute of Physiology, Academy of Sciences of the Czech Republic, v.v.i.,* [2]*2nd Faculty of Medicine, Charles University in Prague,* [3]*Institute of Microbiology, Academy of Sciences of the Czech Republic, v.v.i., Prague, Czech Republic*

Neutral trehalase (Nth1, EC 3.2.1.28) from *Saccharomyces cerevisiae* hydrolyses disaccharide trehalose amassed by yeast as a storage carbohydrate and a universal stress protectant. Nth1 activation is mediated by PKA-phosphorylation, Ca^{2+} and the yeast 14-3-3 protein (Bmh1) binding [1, 2]. Bmh1 modulates the structure of both the catalytic domain of Nth1 and the region containing the EF-hand like motif which is conserved among many Ca^{2+} binding proteins [3]. The structure of the pNth1: Bmh1 complex and the importance of the EF-hand like motif were investigated using site-directed mutagenesis, enzyme kinetic measurements, hydrogen deuterium exchange coupled to mass spectrometry, chemical cross-linking and small angle X-ray scattering (SAXS) [4]. We proved that structural integrity of the EF-hand like motif is essential for the Bmh1 mediated activation of Nth1 and that Ca^{2+} binding facilitates this process by affecting Nth1 structure. The low resolution structural views of Nth1 alone and the pNth1:Bmh1 complex (see Fig.) show that the Bmh1 binding induces a significant structural rearrangement of the whole Nth1 molecule. We revealed that the EF-hand like motif-containing region forms a separate domain that interacts with both Bmh1 protein and the catalytic trehalase domain. Thus EF-hand like motif functions as the intermediary through which Bmh1 modulates the activity of Nth1. Our study is important not only for better understanding the mechanism of the yeast stress response and trehalose metabolism but also as an example of structural study of complex of 14-3-3 protein with fully active enzyme.

This work was supported by the Czech Science Foundation (Project P207/11/0455) and by Grant Agency of Charles University (Grant 644313).

Lysozyme adsorption at SiO2 and mica surfaces: atomistic molecular dynamics and experiments

M. Ćwięka[1,2], K. Kubiak-Ossowska[3], P. Mulheran[3], B. Jachimska[1]
[1]Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences, [2]Faculty of Chemistry, Jagiellonian University, Cracow, Poland, [3]Department of Chemical and Process Engineering, University of Strathclyde, Glasgow, UK

Lysozyme (LYS) is a model macromolecule in the study of protein adsorption on surfaces. We combine fully atomistic Molecular Dynamics (MD) simulations with experimental measurements to gain new insight into LYS adsorption at a silica surface. We describe the LYS adsorption mechanism at SiO_2 in detail: we elucidate the adsorption driving force, list the most important residues anchoring the protein at the surface, and describe the protein structure alteration required for the adsorption. Comparison of LYS adsorption at SiO_2 and a model mica surface reveals no substantial differences in the general adsorption mechanism.

Experimental work has shown that both the surface properties and the protein itself influence the effectiveness of adsorption. We performed analysis of conformational changes of proteins by quartz crystal microbalance (QCM-D) and surface plasmon resonance (MP-SPR). Furthermore, QCM-D can be used to study the adsorption behavior (kinetics, adsorbed amount and the thickness of protein film layer). Effect of solution concentration, pH and electrolyte type was studied to elucidate the nature of the association processes. Effect of contact time and applied load was related to the viscoelastic properties of the protein matrix on the surface, formed under different conditions. MP-SPR was used to study structural effects such as changes in the thickness/density of the protein layer. Such protein layer structures are expected to possess viscoelastic properties, giving information on molecular conformation, which can be confirmed by QCM-D.

The experimental methods give the average signal from the entire adsorption surface. In contrast, using MD we observe changes during adsorption of a single protein. From the atomistic resolution of the MD results on the one hand, and good agreement with experimental data on the other, the nature of the protein interactions with the solid surface can be understood in detail.

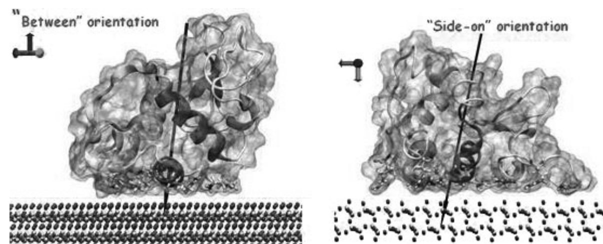

Fig. 1. Sample LSZ orientation at the SiO2 surface. The arrow shows the protein dipole moment. LSZ orientation can be "side-on" and "between".

Metabolic network reconstruction and modelling of nitrogen fixation in *Azotobacter paspali*

T. Ozer, I. Isildak
Bioengineering, Yildiz Technical University, Istanbul, Turkey

Azotobacter is an aerobic, free living N fixing bacterium. Most Azotobacter species can utilize nitrate as a nitrogen source by reduction to nitrite and then to ammonium. Azotobacteria is used on the behalf of studying nitrogen fixation and inoculation of plants because it has rapid growth and high level of nitrogen fixation (Jagnow, 1987; Gouri and Jagasnnatathan, 1995; Maltseva et al., 1995; Mrkovaki et al., 1996a). The nitrogen fixation bacterium *Azotobacter paspali* was first described by Dobereiner (1966) and has only been isolated from the rhizosphere of Paspalum notatum, a tetraploid subtropical grass widely distributed in South America (Dobereiner and Campelo, 1971).

Our strategy for bacterial nitrogen fixation consisted of three steps; metabolic reconstruction for *A.paspali*, *in silico* modelling of nitrogen fixation, and evaluation of computational predictions and experimental results. The microbial genome sequence was the first step to attain analysis of gene-protein associations and metabolic reconstruction in this systems biology research. The genome sequence of *Azotobacter vinelandi* was used for this process due to its phylogenetic similarity with *A.paspali*. Through an iterative reconstruction process, the metabolic network was constructed based on the genomic, biochemical and physiological information on *A.paspali*.

In this work we present a genome scale metabolic reconstruction for *A.paspali*, which includes 380 metabolic and transport reactions across 26 metabolic pathways. This model was used to analyze the physiological capabilities of *A. paspali* during stages of nitrogen fixation. To study the physiological capacities *in silico*, an objective function was determined to conduct simulations of nitrogen fixation. After flux balance analysis (FBA) performed, it was observed that predicted active metabolic pathways agreed with experimental data. In addition to being a useful guide for identification and filling of knowledge gaps, the reconstructed metabolic network will accelerate the research on this bacteria towards application of systems biology approaches and design of metabolic engineering strategies to enhance nitrogen fixation.

Keywords: Metabolism, Modelling metabolic reconstruction, Nitrogen fixation.

WED-039
Microtubule catastrophe as a multi-step sequence of reversible events

N. Gudimchuk[1,2], P. Zakharov[3], F. Ataullakhanov[2], E. L. Grishchuk[3]
[1]*Federal Research Center of Pediatric Hematology, Oncology and Immunology,* [2]*Center for Theoretical Problems of Physico-chemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation,* [3]*Physiology Department, University of Pennsylvania, Philadelphia, USA*

Microtubules are cytoskeletal filaments, essential for cellular structure, transport and motility. They are dynamically unstable, i.e. exhibit distinct phases of growth and shortening. Transitions between growth and shortening are called catastrophes. Catastrophes determine the lengths of microtubules in the cells and affect a variety of key cellular processes including cell division, cell migration and others. Experiments in vitro and in vivo have demonstrated that the frequency of microtubule catastrophes increases during microtubule polymerization, manifesting in "microtubule aging". The molecular nature of the "microtubule aging" and the mechanism of microtubule catastrophe remain unclear. Two recent models have been proposed to explain these phenomena. One model postulates that catastrophes result from irreversible accumulation of three catastrophe-promoting features in the microtubule lattice. Another model finds the origin of the "microtubule aging" in progressive tapering of the microtubule tip, leading to gradual microtubule destabilization. To examine these hypotheses, we have created a detailed model of the microtubule based on a combination of Brownian dynamics and kinetic approaches. This quantitative model successfully recapitulates available structural and kinetic data about microtubule dynamics, including the phenomenology of the "microtubule aging". The model however does not involve accumulation of irreversible catastrophe-promoting features nor does it show any gross changes in the tip structure during MT growth. Thus, we propose an alternative hypothesis to explain the "microtubule aging". We argue that the microtubule catastrophe is a statistical phenomenon that results from rare combinations of multiple short lived reversible molecular events taking place at the microtubule tip. Our data indicate that these reversible destabilizing molecular events likely represent a combination of stochastic GTP hydrolysis and formation of curved protofilaments. Altogether, our study provides novel insights into the microtubule catastrophe and offers important predictions about the mechanisms of action of proteins and drugs, regulating microtubule dynamics.
Keywords: catastrophe, microtubule, modeling.

Modelling of *Saccharomyces cerevisiae* K2 toxin entry and response of the host cell

E. Serviene[1], J. Lukša[1], M. Podoliankaite[1], I. Vepštaitė[1], D. L. Lafontaine[2], J. Urbonavicius[3]
[1]*Nature Research Centre, Vilnius, Lithuania,* [2]*Center for Microscopy and Molecular Imaging, Charleroi-Gosselies, Belgium,* [3]*Nature Research Centre, Vilnius University, Vilnius, Lithuania*

The production of antimycotic killer toxins (mycocins) has been detected in several yeast genera and has been proved to be a widely distributed phenomenon. The toxins of the yeast origin confer a growth advantage to their hosts by increasing survival in clinical, environmental, and industrial ecosystems. They find application in food protection from spoiling, wine production, phytopathogen control, creation of a new generation vaccines and antibiotics, development of antifungal immunotherapy. The characterization of such toxins has consistently provided significant insights into the basic mechanisms of self-defence, virus-host cell interactions and toxin entry into target cell.

In order to identify gene products modulating the sensitivity to K2 killer toxin, we performed high-throughput genome-wide screen in *S. cerevisiae* and identified 332 genes affecting resistance formation process. To get further insights into the cellular activities involved in the biology of K2 killer toxin, we analysed discovered effectors and calculated the enrichment of 'biological process' and 'cellular component' gene ontology (GO) terms associated with pronounced K2 resistant and sensitive phenotypes. We built interaction networks and demonstrated physical and functional interaction of such gene products inside the cell. Also, we assigned several unknown factors to cell wall biogenesis, mitochondrial function, and stress signalling pathways. Based on the established data, we performed the modelling of the entry of K2 toxin into the susceptible yeast cell and response of the target cell by activating cell wall integrity and high osmolarity glycerol pathways.
Keywords: host effectors, *Saccharomyces cerevisiae*, toxin.

WED-043
Molecular dynamics simulations of oncogenic mutations of the EGFR ectodomain reveal an unexpected activation intermediate

L. Orellana[1,2]
[1]*Joint IRB-BSC-CRG Program on Computational Biology, Institute for Research in Biomedicine Barcelona, Barcelona, Spain,* [2]*Theoretical and Computational Biophysics Group, Science for Life Laboratory, Solna, Sweden*

Conformational changes are central to protein function, but in spite of their robust character, they can be sensitive to perturbations at critical regions such as mutations. In particular, interdomain regions can be important to orchestrate large-scale rearrangements of multidomain structures. Here we analyze the role of interdomain interactions in the conformational dynamics of the extracellular domain of the Epidermal Growth Factor Receptor (EGFR). EGFR activation is triggered by a ligand-favored transition of the ectodomain from a closed, self-inhibited tethered monomer, to an open untethered state, which exposes a loop required for dimerization and activation. A preliminary coarse-grained analysis shows that cancer-mutations tend to cluster at conserved interdomain interfaces and loops important for large-scale movements. Molecular Dynamics simulations of two muta-tions targeting one of the detected hot spots reveals a dramatic conformational shift towards a transient untethered intermediate different from known crystal structures, but in agreement with several experimental evidences. The present findings point to the existence of conformational states other than the open and closed, and to differential processes driving ligand-dependent and independent untethering in EGFR. In a wider

context, our results suggest a novel oncogenic and evolutive mechanism based on the perturbation of the native motions at the interfaces of structural elements.

Keywords: EGFR, glioma mutations, molecular dynamics.

WED-044
Molecular mechanism of fibrosis – proteomic and transcriptomic analysis

K. Kusińska[1], R. Bednarek[1], J. Niewiarowska[2], C. S. Cierniewski[†,3], M. Stasiak[1]
[1]Cytobiology and Proteomics, [2]Molecular Cell Mechanisms, [3]Molecular and Medical Biophysics, Medical University of Lodz, Lodz, Poland

The epithelial-mesenchymal transition (EMT) plays a pivotal role in embryonic development, wound healing, tissue regeneration, organ fibrosis and cancer progression. This process is initiated by Transforming Growth Factor-β1 (TGF- β1) which induces potent stimulation of the expression of numerous genes participating in fibrosis.

Endothelial to mesenchymal transition (EndMT) might be an important source of the mesenchymal cells participating in the fibrotic process. To establish profiles of the endothelial cell genes involved in the early stages of fibrosis HMEC-1 cells (human microvascular endothelial cell-1) were stimulated with TGF- β1 at the concentration of 5 ng/ml for 48 h.

The treatment of HMEC-1 with TGF- β1 leads to increase in the level of Snail1, Vimentin and decrease in the level of Claudin1. Differential proteomics to perform a global quantitative comparison of two proteomes with Orbitrap Velos mass spectrometers and iTRAQ – a labeling method analysis of HMEC-1 displayed a total number of 5522 proteins among those only 17 were overexpressed and 27 were down-regulated. Transcriptomic analysis of 57716 genes demonstrated up-regulation of 264 genes and down-regulation of 211 genes. These small changes at the molecular level give rise to the formation of EndMT-dependent fibrosis.

Keywords: EndMT, fibrosis, TGF-β1.

WED-045
Mutations close to the central residues of the structural network of the beta glucosidase Sfbglu affect its thermostability

V. P. Souza, S. R. Marana
Biochemistry, Instituto De Química – Universidade De São Paulo, São Paulo, Brazil

The structure of proteins can be represented as a network in which the amino acids are the nodes and their non-covalent interactions are the connections. The presence of central nodes contributes to existence of shorter paths (sets of connections) between different nodes on the network. Thus, it has been suggested that central residues are determinant for several enzymatic properties, as stability, allostery and catalytic activity. Besides that it is proposed that mutations directed to the central residues or their proximity could be easily propagated and cause significant modifications in the protein structure. The goal of this project is to test this hypothesis, that is, to evaluate the relevance of the central residues in the propagation of mutational effects through the structural network of the beta-glucosidase of *Spodoptera frugiperda* (Sfbglu) changing its thermostability.

The mutant Sfbglu were produced as recombinant protein in *E. coli* BL21 gold (DE3) using the vector pET46. After that they were purified using affinity chromatography (Ni-NTA). The homogeneity of these samples was verified by SDSPAGE. To assess whether the mutants structures were properly folded, tryptophan fluorescence spectra were collected. The spectra of the mutants did not show any change with respect to the WT Sfbglu. Furthermore, experiments of tryptophan fluorescence suppression by acrylamide were performed. The K_{sv} parameters of the mutant Sfbglu were equal to the WT Sfbglu. Circular dichroism spectra were also collected for the mutant Sfbglu, of which only two, A264F and D84A, showed slight differences from the wild-type protein. So these experiments indicated that mutant Sfbglu were properly folded. To evaluate the thermal stability of the WT and mutant Sfbglu, T_m were calculated using two different techniques, circular dichroism and thermal shift assay. Mutations D260A, A263F, L335A, V336F and S337F, which were directed to close neighbors of the central residue F251, decreased the T_m from 45°C (WT Sfbglu) to values between 30 and 41°C. Moreover mutations A264F (connected with the central residue F251) and D84A (indirectly connected with central residue R97) abolished the thermal transition. Conversely mutations E261A, M262F and E265A at 3 distant neighbors of the residue F251 caused no change in the T_m. In agreement mutations V319A, L389A,Y390A and N391A, which are close to the non-central residue F280, caused no significant change of the T_m. Therefore the experimental data suggest that the propagation of the mutational effect altering the thermostability of Sfbglu correlates with the closeness between the mutated and the central residues.

WED-046
Neutral and anionic forms of aspartic and glutamic acids interacting with RNA and DNA nucleotides

P. Auffinger, L. D'Ascenzo
Architecture et Réactivité des ARN, IBMC/CNRS, Strasbourg, France

Asp and Glu amino acids are usually depicted under their negatively charged form involving a carboxylate group. In this respect, they form anion–nucleic acid interactions [1,2]. Yet, they might also interact with nucleic acids in their unfamiliar neutral form that involves a carboxyl group. We report here, along with a classification of regular Asp/Glu binding sites, several surprising instances of close contacts between Asp/Glu side chains and hydrogen bond acceptors in nucleic acid systems. Favored nucleobase binding sites emerged; more specifically, guanine Watson-Crick sites were observed to dominate over other possibilities without excluding less obvious interaction patterns and contacts with backbone phosphates. The adenine/glutamic acid pair that involves the neutral form of the amino acid illustrates this point (see figure). Such counterintuitive contacts involving Asp/Glu residues generally considered as negatively charged and nucleic acid electronegative atoms can only be understood by considering the neutral forms of these amino acids. To confirm that these interactions associated with neutral Asp and Glu forms are not anecdotal, a survey of the PDB was performed. This survey collected a large array of short hydrogen bond contacts between Asp and Glu residues with themselves and with other electronegative atoms, therefore stressing that their neutral interacting form is more frequent than previously thought.

The purpose of this study is to emphasize the implications of such unexpected hydrogen bond networks in our current understanding of protein/nucleic acid interactions. It is anticipated that the neutral Asp and Glu amino acids will have to be included into an expanded bestiary of interacting residues leading to novel recognition patterns. These interaction motifs will certainly have

New control mechanisms of water transport identified in AQP1 by combining molecular dynamics simulations and experiments

M. Ng Fuk Chong[1], P. Ripoche[1], S. Genetet[1], Y. Colin-Aronovicz[1], I. Mouro-Chanteloup[2], C. Etchebest[3]
[1]UMR-S1134, Inserm, University Paris-Diderot, INTS, GREX, [2]liations: UMR-S1134, Inserm, University Paris-Diderot, INTS, GREX, [3]UMR-S1134, Inserm, University Paris Diderot, INTS, GREX, PARIS, France

Aquaporin family gathers membrane proteins that are identified as selective water channels. The transport of water is bidirectional, extremely rapid and is driven by the osmotic pressure. High-resolution 3D structures have brought valuable information to characterize the translocation channel. However, a better understanding of the protein function requires a dynamic view of the transport process. Interestingly, the transport rate is compatible with current molecular dynamic (MD) simulations time-scale. Accordingly, they were extensively used to catch the details of the water transport mechanisms. In particular, simulations helped in identifying two filter regions, one located in the central part of the channel and the other facing the extracellular medium.

In the present work, we revisited the transport of water in AQP1 using long MD simulations. We characterize two new gates located on the extracellular and cytoplasmic sides respectively. Interestingly, the cytoplasmic exit is controlled by two conserved residues (H74 and E17), which are stabilized by hydrogen bonds. We tested different protonation states for these two residues and we showed how they influence the permeation events.

These results suggest that the intracellular pH (pHi) would play a role in the transport mechanisms. In order to confirm this hypothesis, we measured the Pf (osmotic permeability) at different pHs (pHi=pHe=6.5 or 7.2 or 8.0) by following the fluorescence quenching of the 5 (6) carboxyfluorescein. The low Pf at pH6.5, whatever the mannitol gradient, was increased at pH7.2 and pH8.0. When pHi was fixed to 7.2 but the extracellular pH (pHe) varied, Pf was unchanged.

These results clearly demonstrate the impact of pHi on transport and how combining theoretical studies and experiments help to enrich the spectrum of mechanisms that control AQP1 water transport.

Keywords: Aquaporin, permeability, pH.

New control mechanisms of water transport identified in AQP1 with molecular dynamics simulations

M. Ng Fuk Chong[1,2,3], C. Etchebest[4,5]
[1]INSERM,UMR-S1134, [2]University Paris Diderot, PARIS, [3]University St Denis La Réunion, St Denis La Réunion, [4]UMR-S1134 Inserm-University Paris Diderot, [5]INTS-GREX, PARIS, France

Aquaporin family gathers membrane proteins that are identified as selective water channels. The transport of water is bidirectional, extremely rapid (~3 billion water molecules per second), and is driven by the osmotic pressure. In addition, charged species are excluded from the transport. Aquaporins are present in all organisms and in mammalians, 13 homologous AQPs (AQP0 to AQP12) have been characterized. They also differ by their tissue distribution and the pathologies with which they are associated. High-resolution 3D structures have brought valuable information to identify translocation channel. However, a better understanding of the protein function requires a dynamic view of the transport process. Interestingly, the transport rate is compatible with current molecular dynamic (MD) simulations time-scale. Thus, MD simulations have been extensively used to catch the details of the water transport mechanisms. In particular, simulations helped in identifying two filter regions, the NPA (asparagine/proline/alanine) region located in the central part of the channel and the constricted ar/R (aromatic/arginine filter) region facing the extracellular medium.

In the present work, we revisited the transport of water in AQP1 using long MD simulations. We identified new gates located on the extracellular and cytoplasmic sides respectively. Interestingly, the cytoplasmic exit is controlled by two conserved residues (H74 and E17), which are stabilized by hydrogen bonds and seem sensitive to intracellular pH. We tested different protonation states for these two residues and we showed how they influenced the permeation events. These results, which were confirmed by different experiments, enrich the spectrum of mechanisms that control AQP1 water transport.

New in DEPPDB – a portal for electrostatic and other physical properties of genome DNA and its elements

A. A. Osypov[1], G. Krutinin[1,2], E. Krutinina[1], S. Kamzolova[1]
[1]Institute of cell biophysics of RAS, [2]DIAKON Ltd, Pushchino, Russian Federation

DNA is highly charged and its electrostatic and other physical properties define its shape in the functional space and influence its interactions with different proteins, esp. regulating transcription, in particular RNA-polymerases and transcription factors. DEPPDB was developed to hold and provide all available information on these properties of genome DNA combined with its sequence and annotation of biological and structural properties of genome elements and whole genomes, organized on a taxonomical basis.

The electrostatic potential around the double-helical DNA molecule was calculated by the original method [1] using a program package [2,3]. Calculations of other physical properties are based on the di- and trinucleotide content. Different cross-correlation analysis algorithms are applied.

DEPPDB (deppdb.psn.ru or electrodna.psn.ru) contains all completely sequenced bacterial, viral, mitochondrial, plastids and eukaryotic genomes according to current release of NCBI RefSeq

© 2014 The Authors. FEBS Journal © 2014 FEBS

[4]. Data for promoters, regulation sites, binding proteins etc. are incorporated from DBs and literature. All data are fully integrated, several tools are provided to support different forms of analysis. Calculation on the fly of the user-provided sequences is available.

DEPPDB can be considered as a portal or collection of databases on the electrostatic and other physical properties of whole genomes and different genome elements in different taxa and organisms: Promoter DB, Regulatory Sites (Transcription Factors, TF) DB, Gene Starts DB, Terminator DB, etc. as well as comprehensive analysis toolbox.

Acknowledgements: The authors are grateful to Saveljeva E. G. for technical support and the Institute of Mathematical Problems of Biology of RAS for hosting the Database.

New parameters for describing conformational rearrangements in G-quadruplexes

A. Varizhuk, V. Tsvetkov, G. Pozmogova
Institute for Physical-Chemical Medicine, Moscow, Russian Federation

Conformational changes in G-quadruplexes (GQs) are important issues for molecular biology considering the profound effects of GQs on genome function. Molecular modeling may complement NMR and XDR data on known GQ structures and is commonly used to get insight into GQ folding or to predict GQ unwinding. For quantitative description of GQ geometry, specific parameters are needed. Ideally, they should allow characterization of various types of GQ topologies in dynamics. Several attempts have been made to introduce such parameters, but no systematic studies have been reported so far.

Reshetnikov et al. used mean square deviations from the initial structure to characterize dynamics in models of the thrombin binding aptamer [Biochemistry (Moscow), 2010, 75(8); J. Chem. Theory Comput., 2010, 6(10)]. The distance between the centers of mass (COMs) of G-quartet guanines was used to monitor “in plane” GQ motions (fluctuations in a quartet plane), and the distance between COMs of the two tetragons (the outer one formed by the N9 atoms and the inner one formed by the O6 atoms) was used to monitor “from plane” GQ motions (the tendency of a quartet to form a tepee structure). Some additional characteristics have been proposed to illustrate GQ rigidity and twisting.

Although the aforementioned parameters seem applicable for assessing certain conformational changes (GQ disruption, ion capture, etc.), they are far from exclusive and may not be optimal in the case of some complex rearrangements related to the recently reported new types of GQs with defects (i.e. bulging of the mismatching nucleosides from G-quartets).

We present novel parameters that enable comprehensive and systematic description of GQ geometry in dynamics and compare them with the previously reported parameters. We used a telomeric GQ rearrangement to illustrate our approach to monitoring GQ topological changes. In this approach, G-quartet planarity is characterized by the angles between the normals to guanine planes. An alternative planarity-related parameter determined for each particular guanine in a quartet is N1 atom deviation from the plane created by other N1 atoms. The new parameters were shown to be more informative and representative than the “in plane” and “from plane” motion characteristics discussed above. Interestingly, quartet collapse upon GQ rearrangement or deviation (bulging) of a single nucleoside from the quartet is often followed by its stacking with a neighboring quartet. We used the distances between COMs of particular guanines and COMs of the neighboring quartets to monitor such a process in the telomeric GQ.

In conclusion, we developed a new set of GQ-characterizing parameters and demonstrated its usability for monitoring GQ dynamics.

This work was supported by RSF [14-25-00013].

WED-051
Nuclear EP2 receptor mediates the transactivation of epidermal growth factor receptor by PGE2

A. B. Fernández, J. Lucio-Cazaña
Universidad de Alcala, Alcala de Henares, Spain

The biological actions of PGE2 have been generally attributed to result from its interaction with four membrane G-protein coupled receptors designated EP1, EP2, EP3 and EP4. Our previous work in human renal proximal tubular HK2 cells showed that PGE2 increases the expression of hypoxia-inducible factor-1, a putative renoprotective factor. The mechanism, which also was shared by several cancer cell lines, involved EP receptor-dependent transactivation of epidermal growth factor receptor (EGFR) leading to increased expression of retinoic acid receptor-beta (RARB). PGE2-induced EGFR transactivation was prevented by inhibiting the prostaglandin uptake transporter and EP receptors were ubiquitously located in the cells. Therefore, intracellular EP receptors rather than cell membrane EP receptors seemed to be responsible for the transactivation of EGFR by PGE2. Given that the nucleus contains functional EP receptors, we hypothesized that nuclear EP activated a subset of EGFR which was also located in the nucleus. Here we aimed to confirm this hypothesis. We analyzed in nuclei isolated from HK2 cells: i) expression of EP receptors (immunofluorescence), ii) the effect of PGE2 on the phosphorylation of EGFR and c-src, which may mediate EP-dependent transactivation of EGFR (western-blot), iii) the EP subtype responsible for the PGE2 effects (specific EP agonists), and iv) the effect of PGE2 on the transcription of RARb (in vitro transcription assay).The results showed that PGE2 increased the phosphorylation of EGFR and c-src in the isolated nuclei through EP2 receptor, which resulted in increased expression of RARb mRNA. This is the first time in which has been provided a piece of evidence showing that transactivation of EGFR may proceed in the cell nucleus. The fact that EGFR transactivation was triggered by a nuclear subset of EP receptors,which has its major correlate in the transactivation of cell membrane-located EGFR by G-protein coupled EP receptors, suggests that there might be more cases in which nuclear transactivation of EGFR is induced by nuclear subsets of cell membrane receptors.

Oleuropein aglycone: a natural polyphenol with inhibitor effects on toxicity by *Transthyretin fibrillogenesis*

M. Leri[1], A. Natalello[2], D. Nosi[3], D. Ami[2], S. Rigacci[4], S. M. Doglia[2], M. Stefani[4], M. Bucciantini[4]
[1]*Department of Experimental and Clinical Biomedical Science, University of Florence, Florence,* [2]*Department of Biotechnology and Biosciences, University of Milano-Bicocca, Milan,* [3]*Department of Experimental and Clinical Medicine,* [4]*Department of Experimental and Clinical Biomedical Science, University of Florence, Florence, Italy*

Transthyretin (TTR) is a plasma protein secreted by hepatocytes into the blood and cerebrospinal fluid, where it transports thyroid hormones, thyroxine (T4) and triiodothyronine (T3) and cotrasport of vitamin A with Retinol Binding Protein (RBP). The TTR is an amyloidogenic protein implicated in diseases such as senile systemic amyloidosis (SSA) and familial amyloid polyneuropathy (FAP), both characterized by extracellular deposition of insoluble amyloid fibrils in heart, peripheral nerves and other organs. In particular, fibrils in FAP patients are composed of single-site mutant TTR and among the numerous pathogenic variants Leu55 → Pro55 (L55P) is the most amyloidogenic and it forms amyloid fibrils in vitro. It is suspected that the single-point mutations accelerate amyloidogenesis by destabilizing the monomeric partially unfolded amyloidogenic intermediate state rather than by altering the tetrameric native state.

TTR fibrils have been considered direct responsible of tissue impairment in FAP and SSA, but the unstable fibril precursors are increasingly considered the main responsible of cell suffering and tissue impairment in amyloid diseases. In particular, the early unstable oligomeric intermediates are highly toxic due to their ability to interact, disassemble and permeabilize cell membranes. Moreover, increasing information on polymorphism of pre-fibrillar and fibrillar assemblies has led to propose that apparently similar fibrils can display different stability and efficiency in generating toxic species. These data suggest the opportunity to search natural or synthetic molecules interfering with amyloid aggregation by stabilizing the TTR native state by hindering the appearance of toxic species, or by favoring the growth of less toxic assemblies. We have recently described a natural compound (oleuropein aglycone) which is protective in Tg animal models of Abeta deposition and cultured cells by stimulating cell autophagy and the endolysosomal path and by modifying the pattern of aggregation of amylin and Abeta peptides skipping the appearance of toxic oligomers and reducing plaque load. Our study is focused on the ability of oleuropein aglycone (the main phenolic component of Mediterranean extra virgin olive oil) to inhibit the toxic effects of both wild-type amyloid TTR and highly amyloidogenic L55P variant on HL-1 cells. Our data offer the possibility to validate and optimize the use of rationally designed and promising drugs that could enter in a clinical experimental phase.

Pericytes play key role in maintenance of vascular architecture in CADASIL

M. Ghosh[1], M. Balbi[1], U. Lindauer[2], N. Plesnila[1]
[1]*Institute for Stroke and Dementia Research, Munich,*
[2]*Neurosurgery, RWTH Aachen, Aachen, Germany*

Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL), one of the most common small vessel diseases, is a major contributor of vascular dementia in humans. Primarily, it is known to be caused by Notch3 mutation. Recently, ultra-structural changes in pericytes have been shown in CADASIL[1,2]. Pericytes are important component of neurovascular unit that contributes to the integrity of blood brain barrier (BBB). Presence and participation of pericytes in initiation and progression of CADASIL is unknown. In murine model of CADASIL (R169C; Tg88 by overexpression of mutated transgene) 3, we investigate the role of pericytes in neuro-vascular architecture maintenance and vasculopathy of CADASIL.

As previously reported, using *in vivo* immunostaining, we found abnormal Notch3 deposit associated with the brain vessels. Importantly, we found a significant age-dependent decrease in pericyte coverage of cortical micro vessels in CADASIL mice. The decrease in pericyte coverage also correlated with increased Notch3 aggregation and increased BBB permeability. We also addressed the role of neurovascular components such as astrocytes and gap junctions. Along with this functional changes such as cerebral blood flow and neurovascular coupling has been studied. Further, using intravital 2- photon microscopic imaging *in vivo* the pericytes morphology and density will be investigated.

The preliminary results suggest involvement of pericytes in fabricating the neuro vascular architecture in CADASIL.

Predicting protein function from sequence and co-expression: preliminary results for breast cancer molecular markers

B. Gemovic, V. Perovic, S. Glisic, N. Veljkovic
Centre for Multidisciplinary Research and Engineering, Vinca Institute of Nuclear Sciences, University of Belgrade, Belgrade, Serbia

The accurate annotation of protein functions improves understanding of biological processes, but the inherent difficulty and expense of their experimental characterization emphasizes the need for the computational annotation. Since the functional characterization of disease-related proteins can provide new perspective on the disease etiology and therapy, this study focuses on the molecular markers of breast cancer – BRCA1 and BRCA2. These genes are relatively new in evolution, with no orthologs in the yeast, fly or worm, which imply their fundamental role in mammals and specialized functions. These features also make the prediction of their functions difficult for evolutionary-based algorithms. So far, experimental analyses showed BRCA1 and BRCA2 involvement in preserving chromosome structure, DNA repair, recombination, cell cycle control and transcription.

Protein functions of BRCA1 and BRCA2 were predicted using a new algorithm with three steps: selection of similar proteins, co-expression and enrichment analysis, which resulted in the list of Gene Ontology (GO) terms (Fig. 1). The most critical is the

© 2014 The Authors. FEBS Journal © 2014 FEBS

first step, in which the evolution-independent Informational Spectrum Method (ISM) was used. ISM is the Fourier transform-based pattern recognition method for protein sequence analysis, previously shown to be able to identify proteins involved in the same or similar biological processes. Three ISM approaches were used, with different parameters, although in each of them protein selection was done based on the comparison of informational spectra of BRCA1 and BRCA2 and human proteins in the UniProt database. The final list of the GO terms contained only the terms that were identified in all three ISM approaches.

For BRCA1, 98 GO terms were identified, of which 73 (75%) are already in the BRCA1 GO tree of biological processes. The terms with which BRCA1 has not yet been associated can be clustered as: nucleoside metabolic processes and cytoskeleton and intracellular localization. For BRCA2, 88 GO terms were identified, of which 60 (68%) are associated with this protein in GO. Biological processes not in the BRCA2 GO tree cluster as: processes involved in immune response, response to chemical stimuli, signal transduction and regulation of molecules functions.

The new algorithm for protein function prediction showed precision of 70%, when compared with the known BRCA1 and BRCA2 GO functional annotations. It identified some biological processes in which the involvement of these two proteins should be further investigated. Additionally, this study raises the possibility for the use of the algorithm to guide future protein function experiments.

Production of human proteins using well-established and alternative recombinant expression hosts

J. Mrázková[1,2], G. Jančaříková[2,3], M. Pokorná[2,3], P. Kysel[2,3], M. Wimmerová[1,2,3]
[1]Department of Biochemistry, [2]Central European Institute of Technology, [3]National Centre for Biomolecular Research, Masaryk University, Brno, Czech Republic

A successful production of proteins of interest in a sufficient amount and a satisfactory quality is one of key steps for almost all life science branches, structural biology studies and biotechnology applications. Over the time, a lot of recombinant expression systems have been developed according to the diverse needs of use. In addition to the well-established systems such as *Escherichia coli* or mammalian cells routinely utilized in many laboratories, many alternative expression hosts have been discovered and engineered. And these unconventional systems proved to be often more suitable for protein-of-interest production from many various reasons [1].

In our paper, we demonstrate using several approaches of production of a difficult-obtainable human lectin. It has a low expression yields and it is prone to precipitation. For these reasons, a recombinant form of this protein was prepared and different expression systems were tested to obtain the active protein in a soluble form.

The first attempts were done using production of this protein using the E. coli expression host but this way failed because the protein is produced in the insoluble form only. Hence refolding, *in vitro* denaturation/renaturation and some solubility-enhancing tags were utilized to obtain protein in soluble form. The long-term optimization resulted in low yields of the active protein, which is rather unstable for longer period of time.

A generally better way for production of human proteins is using eukaryotic expression systems. In our case, we utilized the *Leishmania tarentolae* cells because of the combination of a fully eukaryotic protein expression machinery including post-translational modifications and easy *E. coli*-like handling. It appears that the *L. tarentolae* possibilities of the disulfide bond formation and the human-like glycosylation are crucial for a sufficient production of our target protein and it seems to be the very effective system for a routine production of human proteins in general.

PTM-SD: curation of posttranslational modified residues in protein structures

P. Craveur[1], J. Rebehmed[2], A. G.de Brevern[1]
[1]UMR-S 1134, DSIMB, INSERM, [2]IMPMC, UMR 7590, CNRS, PARIS, France

The residues in a protein can undergo covalent and chemical modifications that are usually called post-translational modifications (PTMs). The concept of PTMs encompasses different types of modifications from a simple addition of atoms group such as the phosphorylation, to the binding of important large groups, in the N-linked Glycosylation. PTMs play important roles in modulating various biological functions by altering the physical and chemical properties, the localization and activity of proteins. They are also associated to major human diseases such as cancer, diabetes, cardiovascular disorders and Alzheimer.

Recent studies have shown that PTMs have significant effects on the protein conformations and on their flexibility (Xin and Radivojac 2012). Current databases contain crucial sequence annotation but do not provide valuable resource on the 3D structure related to these PTMs.

Post-translational modification structural database (PTM-SD) (Craveur, Rebehmed et al. 2014) provides access to structurally solved modified residues which are experimentally annotated as PTMs. It combines different PTM information and annotation gathered from other databases, *e.g*., Protein DataBank (Berman, Westbrook et al. 2000) for the protein structures and dbPTM (Lu, Huang et al. 2013) and PTMCuration (Khoury, Baliban et al. 2011) for fine sequence annotation.

PTM-SD can be browsed by PDB id, UniProt accession number, organism and classic PTM annotation. Advanced queries can also be performed, *i.e*., detailed PTM annotations, amino acid type, secondary structure, SCOP class classification, PDB chain length, and number of PTMs by chain. Statistics and

© 2014 The Authors. FEBS Journal © 2014 FEBS

analyses can be computed on line on a selected dataset of PTMs. Each PTM entry is detailed in a dedicated page with information on the protein sequence, local conformation with secondary structure and Protein Blocks.

On June 2014, PTM-SD consisted of 10 628 entries. It corresponds to 842 Uniprot AC, 2986 PDB files and 5350 PDB chains containing at least one modified position. 21 different kinds of PTMs were detected, 11 with more than 50 occurrences. The most important one is glycosylation (60.09%), followed by phosphorylation (15.23%) and methylation (8.10%). 206 different organisms are present, with an over-representation of Human (44.27%), and other mammals, e.g., mouse (7.98%), bovine (7.79%), pig (1.64%) and rat (1.52%).

PTM-SD gives valuable information on observed PTMs in protein 3D structure, which are of great interest for studying sequence – structure – function relationships at the light of PTMs, and could provide insights for comparative modelling and PTM predictions protocols.

PTM-SD can be accessed at http://www.dsimb.inserm.fr/dsimb_tools/PTM-SD/.

Pupal weight as suitable indicator for monitoring dengue vectors

S. Banerjee, G. Aditya, G. K. Saha
Zoology, University of Calcutta, Kolkata, India

Entomological surveillance of mosquitoes is a prerequisite for prediction of population abundance and thus possibilities of mosquito-borne diseases. Current monitoring strategies for dengue and chikunguniya vectors employ various indices based on sampling of prospective larval habitats. Although these indices provide information sufficient to predict the probable population abundance, the fitness of individual mosquitoes remains obscured limiting projection about the disease transmission potential. The disease transmission potential of dengue vectors are linked to the life history traits, which are dependent on the resources acquired during larval development. Pupal weight provides key information about the probable state of nutrient reserves, adult body size, longevity and fecundity, thereby qualifying as a suitable indicator of fitness of mosquitoes. Based on this proposition, an appraisal of pupal weight as predictor of the life history features of the dengue vectors – *Aedes aegypti* and *Aedes albopictus* was made to validate its use entomological surveillance. Using laboratory reared 1200 F_2-individuals of each species, the correlations of life history traits were evaluated under varying temperature, food and rearing density. Although sexual dimorphism was prominent for each trait, the pupal weight of *Ae. aegypti* and *Ae. albopictus* were significantly correlated with larval development time, adult body weight, nutrient reserves, longevity and fecundity. The strength of correlations varied with the rearing density of larva, ambient temperature and amount of food, suggesting that pupal weight appropriately amplifies the habitat conditions of the developing larvae. Owing to sensitivity to larval habitat conditions, pupal weight qualifies as an indicator of the prospective adult life history traits. Therefore monitoring of larval habitats of dengue vectors should include pupal weight as a parameter to indicate the fitness levels of adult mosquito, thereby facilitating prediction of population characteristics of *Aedes* mosquitoes with higher precision.

Keywords: Life history traits, pupal weight, fitness.

Purification and characterization of pineapple (*Ananas comosus*) α-galactosidase by three-phase partitioning

H. Bayraktar[1], A. Kutlugun[2], S. Konan[2], S. Onal[2]
[1]*Biochemistry, Graduate School of Natural and Applied Sciences,*
[2]*Biochemistry, Ege University Faculty of Science, Izmir, Turkey*

α-Galactosidases (α-D-galactoside galactohydrolase, EC 3.2.1.22) are the exoglycosidase that catalyses the hydrolysis of α-1,6-galactose bonded D-galactosyl residues of basic and complex oligo- and polysaccharides (raffinose, stachyose, mellibiose, galactomannans). They have been purified with different techniques from plants, animals and various microorganisms. They have great importance in especially sugar industry, elucidation of the biological functions of complex carbohydrates, structural analysis, organic synthesis and medical purpose.

Three phase partitioning (TPP) is a simple and often one-step procedure successfully used for separation and purification of enzymes and proteins in recent years. It involves the addition of a salt to the aqueous solution containing proteins followed by the addition of a water miscible aliphatic alcohol. In less than an hour three phases are formed. The upper solvent phase containing pigments, lipids, hyrophobic materials is separated from lower aqueous phase containing proteins, saccharides and cell debris by an intermediate layer. This protein-rich middle layer generally contains desired enzymes or proteins. TPP process is also simple, inexpensive, scalable and rapid procedure that works at room temperature in comparison to conventional separation and purification processes.

In the present study, we have used three-phase partitioning for direct one-step purification of α-galactosidase from pineapple (*Ananas comosus*) fruit. α-D-galactosidase was first isolated from pineapple with conventional protein extraction methods and then concentrated and purified with TPP. TPP systems were prepared by using ammonium sulfate as a cosmotropic salt and t-butanol as organic solvent. Various system parameters (ammonium sulfate saturation, enzyme/t-butanol ratio and pH) required for the efficient purification of the enzyme were optimized to get highest purity fold and yield. The best α-galactosidase yield (100%) was obtained in the interphase of the TPP system, which consisted of the crude extract to t-butanol ratio of 1.0:0.50 in the presence of 65% (w/v) $(NH_4)_2SO_4$ at pH 6.5. The purified enzyme was also characterized. For this aim, different parameters (temperature, pH and substrat concentration) affecting to the enzyme activity and stability were investigated. Sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) analysis was also performed to determine the purity and molecular weight of the enzyme. The results showed that, with necessary optimization TPP is a simple, quick, economical and very attractive bioseperation technique for primary purication of α-galactosidases compared to conventional chromatographic protocols.

WED-061
Redox cellular signaling by thiol peroxidase: what are the molecular mechanisms of the specificity of the redox relay H2O2/Gpx3/Yap1 in *S. cerevisiae*?

A. Bersweiler, H. Mazon, A. Kriznik, G. Branlant, S. Rahuel-Clermont
UMR7365 CNRS-Université de Lorraine, Vandoeuvre lès Nancy, France

Thiol-peroxidases, initially identified as antioxidant enzymes, have been associated with peroxide-dependent cell signaling as sensors and relays of the H_2O_2 mediated signal (1). One of the best documented examples of such a mechanism is the activation of the transcription factor Yap1, a key regulator of the transcriptional peroxide stress response in *Saccharomyces cerevisiae*, which depends on the formation of intramolecular disulfide bonds catalyzed by the thiol peroxidase Gpx3 (2; 3). In this mechanism, it has been proposed that the relay occurs via the oxidation of Gpx3 peroxidasic Cys as a sulfenic acid intermediate (Figure 1: Model of the S. cerevisiae Orp1-Yap1 redox relay) (3). In addition, the Ybp1 protein has been identified as an essential partner for the activation of Yap1 by Gpx3 (4).

The intrinsic reactivity of the sulfenic acid could potentially result in reaction of this intermediate with other thiols in competition with the reaction of activation of Yap1, such as with the regeneration Cys of Gpx3 or with other cellular thiols. This raises the question of the specificity of Yap1 activation by Gpx3. To address this question, and to elucidate the role of Ybp1 in this mechanism, we have used an approach combining (i) the kinetic characterization of the two major reactions in competition: the peroxydasic cycle of Gpx3 and the signal transduction pathway; (ii) the study of the impact of Ybp1 on the evolution of the Gpx3-C_P-SOH intermediate by the two pathways in competition; and (iii) the characterization of the protein-protein interactions between the three partners by spectroscopic and biophysical methods. Our results show that Ybp1 and Yap1 associate and recruit Gpx3, and indicate that within the ternary complex, intramolecular disulfide formation within Gpx3 is slowed down, thus allowing the reaction with Yap1.

Regio- and stereospecificity of arachidonic acid oxygenation catalyzed by Leu597 mutants of rabbit 15-lipoxygenase. A quantum mechanics/molecular mechanics study

R. Suardiaz, L. Masgrau, J. M. lluch, À. González-Lafont
Department of Chemistry, Universitat Autònoma de Barcelona, Cerdanyola del Valles, Spain

Abstract 15-Lipoxygenases catalyze the peroxidation reaction of arachidonic acid (AA) in mammals with a high regio- and stereospecificity. It is known that Leu597 controls the shape and size of the substrate-binding cavity in the corresponding rabbit enzyme (15-rLO), which is the only mammalian 15-LO enzyme with a resolved crystallographic structure. In this paper we have combined quantum mechanics/molecular mechanics calculations with molecular dynamics simulations to show that Leu597 also plays a very important role in the regiospecificity and the stereospecificity of the reaction. We have studied the addition of molecular oxygen to the pentadienyl radical of AA catalyzed by the Leu597Val and Leu597Ala mutants of 15-rLO. In the Leu597Val mutant the O_2 addition to C_{15} of AA is still predominant, although the mutation of Leu597 to a residue with a shorter side chain like Val creates some extra space where the O_2 molecule can be accommodated to form a pre-reactive minimum and to approach easily to C_{11}, so reducing almost ten times the C_{15}/C_{11} product ratio with respect to the wild type. The reaction keeps its S stereochemistry. Very interestingly, mutation to Ala, a residue even shorter than Val, causes just the opposite effects: the regiospecificity favoring addition to C_{15} is somewhat sharper than in the wild type, but the stereochemistry is now R. This is because the extra space created by the mutation to Ala is now big enough for AA to move, so adopting an alternative binding mode, changing the interaction with the different residues and opening new feasible paths for the attack of O_2. So, we have shown that the Leu597Ala mutant 15r-LO works as an aspirin-acetylated cyclooxygenase-2 making 15-(R)-hydroperoxyeicosatetraenoic acid.

WED-063
Regulatory action of bile pigments in terms of the native and modified RNA bases interaction with drug carrier protein

A. V. Solomonov[1], E. V. Rumyantsev[1], B. A. Kochergin[1], M. K. Serebryakova[1], A. S. Timin[1], S. P. Ivanov[2]
[1]Inorganic Chemistry Department, Ivanovo State University of Chemistry and Technology, Ivanovo, [2]Institute of Organic Chemistry, Ufa Scientific Centre of Russian Academy of Sciences, Ufa, Russian Federation

Long period the main product of oxidation heme-containing proteins bile pigment bilirubin was considered to be only as ballast product of its metabolism and toxic agent. However, it was found that bilirubin is able to inhibit free radical reactions, but its regulatory function is still remains unknown. Regulatory function of bilirubin was limited only by a possible inhibition of sphingomyelinase and mediating during the expression activation of one of the cytochromes by ultrasound.

Recent investigations by Japanese researchers (Miyawaki et. al., Nature, 2013) revealed an unususal effect of bilirubin. When the pigment binds with novel expressed UnaG protein, the former is able to activate the latter light emission. Thereby, a new fluorescent protein from eel revolutionizes key clinical assay.

Previously [1], we have established the influence of bilirubin within protein matrix on interaction of meso-tetrakis-(p-sulfophenyl)porphin with albumin. Current investigations are devoted to establish regulatory action of bilirubin in terms of the native and modified RNA bases interaction with drug carrier protein. Several progresses in this field have already been reached [2]. Established, that 5-hydroxy-6-methyluracil more effectively binds with albumin and its complex with bilirubin compared to substituted uracil. Interesting effect is observed when replacing 5-I- to 5-Cl- and 5-F-uracils and thymine. Analysis of binding constant values indicates that practically in all cases bilirubin promotes binding of nucleic acid bases with protein.

Current investigations will help for understanding the pathogenesis of bile pigments and development of new therapeutic treatments for a number of common hyperbilirubinemia diseases.

Revealing of novel affine interactions of NBD-labeled fluorescent steroids with bacterial steroid-converting oxidoreductases using molecular docking

Y. Faletrov[1], E. Rudaya[1,2], H. Hlushko[2], I. Edimecheva[1,2], V. Shkumatov[1,2]
[1]Research Institute for Physical and Chemical Problems, [2]Chemistry Department, Belorussian State University, Minsk, Belarus

Previously we have shown that known 7-nitrobenz-2-oxa-1,3-diazol-4-yl (NBD)-labeled fluorescent 3β-hydroxy-5-en-steroids, trivially mentioned as 22-NBD-cholesterol and 25-NBD-cholesterol, can be converted into their 3-oxo-4-en-derivatives (22-NBD-one & 25-NBD-one, respectively) by bacterial cholesterol oxidase & cholesterol dehydrogenase [1–3]. To predict further metabolism of these compounds by some bacteria, series of rigid docking simulations have been performed using Autodock 4.2 & MGLTools 1.5.6 packages as well as 3D-structures of 3-ketosteroid-1-dehydrogenase (ksd1) from *Rhodococcus erythropolis* (PDB code: 4c3y) & cytochrome P450 CYP125 from *Mycobacterium tuberculosis* (PDB code: 2x5w). It has been shown that 22-NBD-one & 25-NBD-one can be bound affinely into the active site of the ksd1 in the substrate-like manners. The calculated binding energies values (BEs) for the interactions of 22-NBD-one, 25-NBD-one & androst-4-en-3,17-dione (a natural substrate) with the ksd1 have been estimated to be –13.9, –12.9 and –9.7 kcal/mol, respectively. Analogously, BEs for binding of 22-NBD-one, 25-NBD-one & cholest-4-en-3-one into the active site of the CYP125 have been estimated to be –14.7, –15.4 and –12.6 kcal/mol, respectively, however the obtained conformations do not allow to predict definitely if 22-NBD-one & 25-NBD-one can be hydroxylated by the enzyme. Thus, an alternative probable NBD-labeled steroidal substrate for CYP125 has been designed. 3β- as well as 3α-isomer of 3-((NBD)-amino)-cholestane have been computed to be able to bound affinely in the active site of CYP125 (BEs ~ –15 kcal/mol) in the manners, allowing C26 hydroxylation of the both isomers. These novel compounds have been synthesized from cholest-4-en-3-one (15% yield), the isomers have been separated chromatographically & then characterized using fluorimetry ($\lambda_{ex,max}$ 460 nm; $\lambda_{em,max}$ 540 nm) & mass-spectrometry ($[M\text{-}H]^-$ with m/z 549). Analogously, two isomers of 20-((NBD)-amino-pregn-5-en-3β-ol (20NBDP) have been synthesized, characterized ($[M\text{-}H]^-$ with m/z 479; $[M + H]^+$ with m/z 481) & evaluated to be new substrates for cholesterol oxidase (PDB code: 1coy). These findings reveal new perspectives for experimental studies of 22-NBD-one, 25-NBD-one, 20NBDP & 3-((NBD)-amino)-cholestane as novel fluorescent substrates for ksd1, CYP125 as well as related bacterial enzymes for biochemical/biophysical investigations and development of new antimicrobial drugs.

Revisiting demand rules for gene regulation

S. Saini, K. Jain, M. K. Prajapat, D. Choudhury
Chemical Engineering, Indian Institute of Technology Bombay, Mumbai, India

How do cells chose a particular mode of regulation over the other? Given different topologies to achieve the same task in the

© 2014 The Authors. FEBS Journal © 2014 FEBS

cell, what determines the choice of one topology over the other. Savageau and coworkers have proposed a set of demand rules that govern this decision – a gene whose product is required by the cell most of the time tends to be regulated positively. The rationale for this was provided by Alon and colleagues in terms of minimization of error in expression. Here, we revisit the question and analyze all transcription factor-target gene interactions in *E. coli*.

Our analysis from *E. coli* and simulation of network topologies suggests that there is a large deviation from the demand rule regarding distribution of regulatory arrangements in *E. coli*. Analysis of carbohydate metaboism genes and amino acid biosynthesis genes in the organism also dictate significant deviations from the demand rules. Combining our analysis and modeling, we propose additional parameters which might plan an important role in choice of regulatory arrangement between a transcription factor and target gene.

RING MD: gathering time into structures

A. Masiero[1], M. Giollo[2], G. Minervini[1], S. C. Tosatto[1], Biocomputing UP

[1]Department of Biomedical Sciences, University of Padua, Padova, Italy, [2]Department of Information Engineering, University of Padua, Padova, Italy

Several methods have been developed and tested for molecular dynamics (MD) simulations output analysis. Most of them focus only on Root Mean Square Deviation (RMSD) and Root Mean Square Fluctuation (RMSF). The aim of this work is to provide the scientific community a tool that directly analyses a MD simulation trajectory file, extending and simplifying this step. The tool provides per-residue calculation of H-bonds, salt bridges, disulphide bridges, π-π stacks, cation-π interactions, van der Waals contacts and a comprehensive interaction calculation of the frequencies of occurrence of these interactions. The tool is an extension of the already existing RING (1), which represents proteins and protein interactions as networks, including time as a new dimension. Once the trajectory file is cleaned from all non-protein molecules, the protein is centred on its centre of mass. Subsequently, a network is generated for every frame of the trajectory, and a frequency analysis of a minimal number of representative frames is carried out. The frame number is statistically determined in order to avoid information loosing. Finally, the user is provided of a PDB structure with residues coloured proportionally to the frequency of occurrence (0, no frame-1, all frames) of every type of RING computed interaction, and of a contact map highlighting the most important interactions responsible for protein structural maintenance and function. The submitted frames are then divided into clusters depending on network and structural changes, and a representative structure per cluster will be provided to allow structural analysis of the target. The novel capability of this tool is to depict in a structure the entire behaviour of a MD simulation. RING MD also provides RMSD and RMSF calculations. To validate the tool, three classical MD simulation targets were selected and analysed by means of classical MD analysis, and then compared to RING MD analysis. The targets were Ubiquitin (2), Glutaredoxin (3) and Lysozime (4), which were processed with 50 ns of classical MD simulation each. RING MD provides results that are coherent with classical analysis results.

RNA-Puzzles is a CASP-like collective blind experiment for the evaluation of RNA 3-dimensional structure prediction. The primary aims of *RNA-Puzzles* are to determine the capabilities and limitations of current methods of 3D RNA structure prediction based on sequence, to find whether and how progress has been made, and to illustrate whether there are specific bottlenecks that hold back the field. Ten puzzles have been set up and three assessments are published. Nine groups of modelers around the world participate in this collective effort. We now report a second round focusing on the prediction of two large riboswitches, the adenosylcobalamin and the T-box bound to a tRNA. No homologous structures existed in the databases at the time of the experiment. Although only two targets were selected, these targets provide a wealth of sub-domains (around 10), including both well-known modules like K-turns as well as new ones.

The 168nt adenosylcobalamin riboswitch consists of a ligand-bound structured core and a bent peripheral domain. Although the RMSDs of the prediction models range from 11.7 to 37.5 Å, the topology of the top ranked models are quite similar to the native structure. Top ranked models show much better scores in Deformation Index (DI) and non-Watson-Crick interaction network fidelity (nwc INF) than others, but surprisingly have worse clash scores.

The T-box and tRNA, 96 and 75nt in length respectively, form a large complex. The difficulty in prediction lies mainly in (i) the lack of homologous model for T-box and (ii) the interaction between T-box and tRNA. The RMSD range of the predictions is 6.8–17.4 Å and the top ranked models also have better DI score with worse clash scores.

The Das group performed best in both problems with their models ranked #1 at 14.5 and 7.6 Å, respectively. The Bujnicki group performed well in the second problem with the model

© 2014 The Authors. FEBS Journal © 2014 FEBS

ranked #1 at 10.2 Å and excellent clash scores with nwc INF around 0.5 like the models of the Das group. Further, the less well predicted models always had worse nwc INF score, demonstrating the importance of identifying non-Watson-Crick pairs and RNA modules.

Role of caveolin 1 in the sorting of sphingomyelin

A. Levy[1,2], C. Lamaze[2], P. Bassereau[1]

[1]*Institut Curie, Centre de Recherche, Laboratoire Physico-chimie Curie, CNRS UMR 168, 75231 Paris Cedex 5,* [2]*Institut Curie, Centre de Recherche, Laboratoire Trafic, signalisation et ciblage intracellulaires, CNRS UMR 144, 75248 Paris Cedex 5, France*

Sorting of lipids and proteins is a key process allowing eukaryotic cells to execute efficient and accurate intracellular transport and to maintain membrane homeostasis (Van Meer et al. 2008). In contrast to proteins, lipid sorting is still poorly understood.

Our group had previously proposed that if a protein has a high affinity for both curved membranes (such as small vesicles or tubules) and for specific lipids, it can lead to enrichment of these lipids in transport intermediates although they could be normally depleted for physical reasons in the absence of the protein (Safouane et al. 2010). Since caveolin 1 (CAV1) and sphingomyelin have similar trafficking pathways between the Golgi apparatus and the plasma membrane and since CAV1 has a high affinity for sphingomyelin (Haberkant et al. 2008), we hypothesize that sphingomyelin transport can be mediated by their interaction with CAV1.

To test this hypothesis, we use two complementary approaches.

First, we use a powerful in vitro system, the "giant unilamellar vesicles" (GUVs) which has been shown well suited to analyze the effect of a single protein type on the organization of lipid membranes (Sens et al. 2008). As a first step, we have developed an improved purification protocol of CAV1 in E Coli system (Coll.: Marjolaine Noirclerc-Savoye and Michel Thépaut, IBS, Grenoble) and we have reconstituted CAV1 in GUVs for the first time. This will allow us to study caveolin-mediated sphingomyelin sorting in curved structures by pulling membrane nanotubes of controlled diameter from these GUVs.

Secondly, in vivo studies are performed with mouse lung endothelial cells (MLEC) that express (WT) or not CAV1 (KO). We follow by confocal microscopy the distribution of BODIPY-ceramide, a fluorescent analogue of sphingomyelin precursor in order to study the intracellular trafficking of sphingomyelin as a function of the expression of CAV1. In a complementary manner, we quantify the level of sphingomyelin using mass spectrometry (Coll. Justine Bertrand-Michel, MetaToul-Lipodomique, Toulouse) in MLEC WT and KO.

Eventually, this study will contribute to elucidate mechanisms that govern the traffic of lipids in cells.

Scanning the role of conserved amino acid in ferritin nanocage

C. Bernacchioni, V. Ghini, P. Turano

Magnetic Resonance Center (CERM), University of Florence, Sesto Fiorentino, Italy

Ferritins are iron storage proteins composed of 24 subunits, each of one folded in a 4-helical bundle, that, in coming together, form an almost spherical protein shell with 4,3,2 point symmetry (Image). The main feature of the cage is a large cavity, designed to accommodate up to 4500 Fe atoms as iron(III)-oxobiomineral, which communicates with the bulk solvent via six hydrophilic channels at the C3 axes. Other channels lie along the C4 axes, but they are tight and hydrophobic and their function was unknown.

Each catalytically active subunit hosts a ferroxidase site where Fe(II) is oxidized to Fe(III) and then migrates to the biomineralization cavity. The biological significance of that process is related to the very high iron binding capacity of ferritin that concentrates iron in a compact and safe form which can be made readily available when needed. Moreover, the reaction sequesters Fe(II) from Fenton-like reactions in which the spontaneous oxidation to Fe(III) donates single electrons to generate highly toxic radicals.

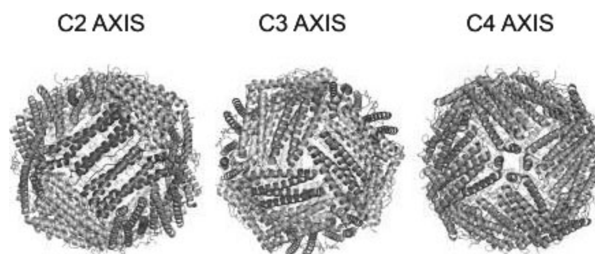

Fig. 1.

Here, we study $2Fe^{2+} + O_2$ protein catalysis and dissolution of ferritin biominerals in variants with altered subunit interfaces at C3 axes (E130I), C2 axes (E88A and D80K), and C4 axes (L165I and H169F). The results extend observations on the functional importance of C3 axes in iron uptake and unravel a functional role of C4 axes. Conserved amino acids localized at C4 axes facilitate dissolution of ferritin-protein-caged iron biominerals. Moreover multiple functions for amino acid along the C2 axis have been delineated; E88A substitution modulates ferritin catalytic activity in agreement with previous cross-linking studies, while a new role for cage self-assembly of some conserved amino acids forming salt bridges at the center of the C2 axis is identified.

Keywords: ferritin, function, mutagenesis.

Secondary DNA structures in G/C-rich microsatellites. Investigating the equilibrium between G-quadruplexes, I-motifs and duplexes

G. Pozmogova, V. Severov, A. Varizhuk, I. Smirnov, A. Sekridova, V. Tsvetkov

Institute for Physical-Chemical Medicine, Moscow, Russian Federation

The focus of this work is conformational dynamics in G/C-rich sequences, i.e. the equilibrium between B-DNA and noncanonical

© 2014 The Authors. FEBS Journal © 2014 FEBS

structures. Recent findings [Dhakal et al. Biophys J. 2012; 102 (11):2575] suggest that in sequences containing four G/C-runs coexistence of G-quadruplexes (GQs) and I-motifs and in unlikely, presumably due to steric hindrance, and GQs or I-motifs are instead opposed by single-stranded loops. We assumed that in the case of microsatellites and other sequences with multiple (>4) G/C-runs, simultaneous formation of GQs and I-motifs might be possible provided that they are mutually shifted, which excludes steric hindrance (Figure 1). To verify our hypothesis and to study the impact of pH and salt concentration on conformational rearrangements in such G/C-rich sequences, we studied a series of DNA fragments from the human genome (chr 18, +66294092 to +66294035): the GQ-forming strand with 6 G-runs $(G_3AT)_5G_3$, its I-motif-forming complement and their truncated analogs containing only 4 G/C runs. We also synthesized elongated oligonucleotides with non-G/C rich flanks to model secondary structures in duplex media and their non-GQ/non-I-motif mutants.

The formation of individual GQs and I-motifs was demonstrated by physicochemical methods (UV-melting and circular dichroism spectroscopy). Noncanonical structures in duplex media were additionally studied by FRET and by monitoring fluorescence intensity of EtBr intercalated in duplex. Fluorescence of EtBr intercalated in GQs/I-motifs or ss-DNA (loops) is insignificant. Thus, decreased fluorescence in the microsatellites concerned in comparison with control B-DNA under GQ/I-motif-favoring conditions may be regarded as an evidence for the existence of non-B secondary structures (pH and salt-dependence of EtBr fluorescence intensity was taken into account).

Our preliminary results confirm the formation of non-B-DNA (presumably I-motif or mutually shifted I-motif and GQ) in native microsatellites. The equilibrium between duplex, I-motif and GQ is highly salt-dependent and may be shifted by the addition of various ligands. Assessment of the duplex:I-motif:GQ: loop ratios under different conditions and visualization of the ‘shifted’ structures by atomic force microscopy is currently underway.

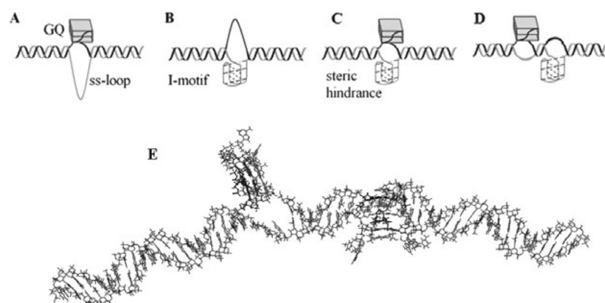

Fig. 1. GQs and I-motifs in duplex media. Possible variants of spatial organization.

Sensitisation in the IFN-α/β,IFN-γ crosstalk reveals mechanisms for enhanced information processing capacity of the STAT1,STAT2 signalling pathway

E. Glow, T. Jetka, M. Komorowski
Institute of Fundamental Technological Research, Polish Academy of Sciences, Warsaw, Poland

Signaling pathways are the main cellular mechanism to transmit information about extracellular cues to the decision-making machinery of posttranslational protein modifications and gene expression processes. In the mammalian immune system processing information about extracellular cytokine concentration is of crucial importance for the tight control of the immune response and efficiency of the defence mechanisms. Malfunction of the signal transduction is tightly related to a variety of disorders ranging from impaired immunity to autoimmune diseases and cancer. Among the most intensely studied pathway is the JAK – STAT mechanism that controls cellular response to the plethora of cytokines, particularly to Interferons α/β and γ. Although interferons have been characterised as having antiproliferatory and apoptotic effect their mechanism of action is significantly more subtle and is a subject of intense investigations. In our work we have theoretically and experimentally examined the crosstalk between IFN-α/β and IFN-γ. The experimental measurements of the STAT1 and STAT2 activation upon stimulation with various combinatorial protocols provided novel insight about the sensitising role of IFN- α/β for subsequent IFN- γ detection. To clarify experimental data we constructed a mathematical model that is capable to explain the sensitisation mechanism, and together with the employed information theoretic methodology explains that prestimulation can enhance information processing capacity of the Jak1/Stat1. Our results provide a detailed mechanistic insight and general design principle that enables information processing in the immune system to be a dynamic process. We explain how adaptation leads to selectivity of information transmission, which is known to be a crucial mechanism for tight control of the immune response.

Keywords: Interferon, Jak/Stat, Stimulation.

Stem cells: novel tool for treatment of human rare disoders. Computational modeling of adult stem cells

K. Simeonova
Institute of Mechanics, BAS, Sofia, Bulgaria

Stem cells (SCs) could be considered as relatively new living cells with perspective characteristics and properties. They are a good tool for transplantation, in vitro and in vivo manipulations too. In cancer (leukemia) SCs have been used for surviving of the human organism as well. The aim of the work presented could be formulated as follows: to give some important points omn experiments and theory of stem cells. Also to creat a new computational model based on classical mathematics and mechanics theories for adult stem cells at different environments conditions. Author’ s FORTRAN programs have been designed and used for numerical experiments.

Striatin/PP2A complex modulates microtubules dynamics via regulation of MAP2 phosphorylation

J. Kazmierczak-Baranska, M. Cieslak, M. Sobczak, B. Mikolajczyk, N. Barbara
Department of Bioorganic Chemistry, Centre of Molecular and Macromolecular Studies Polish Academy of Sciences, Lodz, Poland

Microtubules (MTs) are components of the eukaryotic cytoskeleton. These tubular polymers of tubulin are responsible for a wide variety of cellular processes including maintenance of the cell shape, motility and intracellular transport. Microtubules are also involved in the formation of mitotic spindle taking a part in a right segregation of chromosomes during the cell division. MTs are highly dynamic structures and their polymerization/depolymerization rate depends on a family of proteins called microtubule-association proteins (MAPs). Phosphorylation of MAPs is the major mechanism of their regulation. The PP2A protein is an enzyme responsible for dephosphorylation of MAP2, the process by which the MAP2-MTs binding is enhanced and, as the result, the MTs are stabilized (Gong Ch-X et al., 2000). PP2A is a serine/threonine phosphatase, composed of the catalytic (C), structural (A) and regulatory (B) subunits. Striatin (STRN), an ubiquitous protein expressed mainly in the central and peripheral nervous system, is one of the regulatory subunits of PP2A (Moreno et al., 2000). The exceptional feature of striatin is the presence of four protein-protein interaction domains. As a consequence, the modular structure of striatin is a molecular scaffold that organizes the large signaling complex (Hwang J. and Pallas D., 2013).

In the course of our studies on the function of striatin in a cell, using immunofluorescent imaging, we have shown that striatin and MTs co-localize in HEK293T cells. In the co-immunoprecipitation experiments we confirmed literature information on the formation of PP2A-STRN complex in HEK293T. Then, we asked a question whether the PP2A-striatin complex is involved in regulation of phosphorylation of MAP2, and thus controls the MTs stability. Co-immunoprecipitation experiments indicated that endogenous MAP2 and STRN form a complex in HEK293T. Subsequently, we found that silencing of striatin, via RNA interference, results in hiperphosphorylation of MAP2. In addition, the decrease in STRN expression caused a modest destabilization of MTs in HEK293T. Taking together all the results we hypothesize that the PP2A/striatin complex modulates the microtubules dynamics via regulation of MAP2 phosphorylation.

The project was financed by Young Researchers Programme for PhD Students of CMMS PAS in Lodz, Poland.

Structural basis of the sperm-specific glyceraldehyde-3-phosphate dehydrogenase stability: view from Molecular dynamics simulations

O. Makshakova
Kazan Institute of Biochemistry and Biophysics of Russian Academy of Science, Kazan, Russian Federation

D-Glyceraldehyde-3-phosphate dehydrodenase is an enzyme of glycolysis catalyzed oxidative phosphorylation of glyceraldehyde-3-phosphate to 1,3-diphosphoglycerate with reduction of NAD+ to NADH. GAPD is a multifunctional protein it can be directly involved in development of neurodegenerative diseases, apoptosis and many other cellular processes. In mammalian organisms somatic (GAPD) and sperm (GAPDS) enzymes are expressed that encoded by different genes. GAPD appears in all tissues of the organism and places in the cell cytoplasm whereas GAPDS is expressed only in sperms. However, in some cases of pathological disturbances of the cell's functioning, expression of GAPDS in somatic cells was detected.

Two type of the dehydrodenase are very homological but reviled some differences in their properties. In spite of numerous studies of functional and structural properties of GAPDs from different sources understanding of how the small differences in structure and dynamics of the GAPD homologous influence on their properties is still insufficient. In particular there is a lack of information about GAPDS. Here we study structural and dynamics aspects of GAPDS comparing to GAPD and their influence on stability of the tetramers based on MD simulations. Influence of individual amino acids on the stability and dynamics of tetramer is studied by the point mutation of several residues. We believe that detailed comparison of pair interaction energies in GAPD tetramers and elucidation of energetic impact of key residues onto the tetramer stability will provide new information for construction of mutagenic proteins with alternated properties and for development of new inhibitors with indirect influence on catalytic site.

Switching points in the CYP74 (P450) catalysis

Y. Toporkova[1], S. Gorina[2], V. Ermilova[2], Y. Gogolev[1], A. Grechkin[2]
[1]Laboratory of Molecular Biology, [2]Laboratory of Oxylipins, Kazan Institute of Biochemistry and Biophysics, Kazan, Russian Federation

Unlike most of the cytochromes P450 which are monooxygenases, enzymes of the CYP74 family do not require molecular oxygen nor any redox partners, but use their hydroperoxide substrates as sources for reducing equivalents and as oxygen donors. So their oxygen-binding domain is degenerate and substituted by I-helix central domain (IHCD) which participates in the CYP74 catalytic action. The CYP74 enzymes including allene oxide synthases (AOSs), hydroperoxide lyases (HPLs), divinyl ether synthases (DESs) and epoxy alcohol synthases (EASs) convert fatty acid hydroperoxides into structurally different products: allene oxides, divinyl ethers, hemiacetals and epoxy alcohols. Thus, AOSs and DESs function as dehydrases, whereas HPLs and EASs are isomerases.

Alignment of the CYP74s primary structures revealed several conservative domains; some of them fall into substrate-recognition sites which are typical for all P450s. Number of sites within these domains were chosen, and amino acids at those sites were substituted. The obtained data demonstrate the interconversions of the CYP74 enzymes as a result of site-directed mutagenesis. Three mutations led to complete conversions: AOS into HPL, DES into AOS and HPL into EAS. Some more mutations led to alterations of the CYP74s catalytic activities in different ratios: from partial to almost complete. Moreover, several mutants with dual and trial activities were obtained. On the other hand, no one case of the CYP74s regiospecificity change caused by site-directed mutagenesis was detected. Thus, the results of site-directed mutagenesis revealed primary determinants of the CYP74 catalysis.

The data demonstrate that the catalytic mechanisms of the CYP74 enzymes are closely related. The results of site-directed

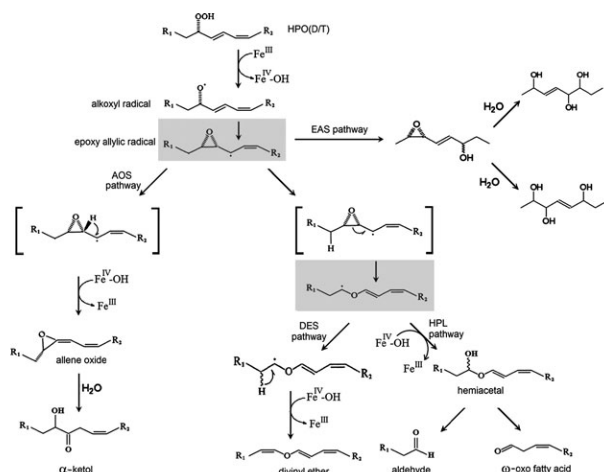

Fig. 1.

mutagenesis indicate that the epoxyallylic radical is the switching point of the CYP74 catalysis (Fig. 1). Depending on primary sequences of conservative domains, the epoxyallylic radical either undergoes the deprotonation to form the allene oxide (AOS pathway), or recombines with hydroxyl radical to form the epoxy alcohol (EAS pathway), or undergoes the rearrangement into the vinyl ether radical, which then is either recombined with hydroxyl radical to afford the hemiacetal (HPL pathway), or loses a hydrogen atom to afford divinyl ether (DES pathway).

Synergistic effect of minerals and low-intensity electromagnetic field on fibroblasts proliferation

R. Albulescu[1,2], A. Armatu[1], B. Vladila[3], G. Neagu[4], V. Vulturescu[4]
[1]Pharmaceutical Biotechnology, National Institute for Chemical Pharmaceutical R&D, [2]Biochemistry-Proteomics, Victor Babes Natl. Institute of Pathology, [3]SC Denticare SRL, [4]Pharmacology, National Institute for Chemical Pharmaceutical R&D, Bucharest, Romania

Background: The beneficial actions of warm crystals and low-intensity electromagnetic field (EMF) on human body are well known. A resonance environment that includes at least one mineral / crystal will support the transition of electromagnetic radiation in a favorable frequency range for repairing immediately adjacent tissue. Crystals can transmit vibrational energies that have biological effects. Such a device would be beneficial for facial skin (counteracting effect on wrinkles), creating stability for dental implants and generally by stimulating the regenerative capacity.

The aim of this study was to investigate the influence on cell proliferation of different mineral compositions (aragonite, topaz) placed at the interface between the EMF generating device and outside the culture dish. The beneficial effect is more remarkable as there is no direct contact with the target cells.

Method and results: The cellular model is based on human dermal fibroblasts Hs27; they are the predominant cells to synthesize extracellular matrix, with special importance both in the medical and cosmetic fields.

The electronic apparatus used is based on a device for generating a sinusoidal frequency with precision and stability.

In the action area of EMF, above and below the plate culture were applied various types of mineral powders (topaz and aragonite). On the same culture plate a "control" area was preserved, kept only under the influence of the electromagnetic field. Also, another control culture plate was prepared in the same conditions, but unexposed either to EMF or minerals influences. Fibroblasts were exposed to EMF and minerals for 3 days, 2 h per day. After this, the cells viability was measured using MTS assay. In the case of cells exposed both to minerals and EMF the proliferation rate was higher (7–12%) and extreme statistically significant than in the case of cells exposed only to EMF (5–10%), compared to unexposed control.

Conclusions: Although the beneficial effects of EMF and crystals are well known, official recognition and full acceptance requires more solid experimental data. The proposed method is non-invasive and risk-free because it stimulates the physiological mechanism of healing, opening opportunities for further exploitation in regenerative medicine.

TDP-43 inclusion bodies formed in bacteria are structurally amorphous, non-amyloid and inherently toxic to neuroblastoma cells

C. Capitini[1], S. Conti[2], M. Perni[2], F. Guidi[2], R. Cascella[2], A. De Poli[2], A. Penco[3], A. Relini[3], C. Cecchi[2], F. Chiti[2]
[1]Biomedical, Experimental and Clinical Sciences, [2]University of Florence, Florence, [3]University of Genova, Genova, Italy

Accumulation of ubiquitin-positive, tau- and a-synuclein-negative intracellular inclusions of TDP-43 in the central nervous system represents the major hallmark correlated to amyotrophic lateral sclerosis and frontotemporal lobar degeneration with ubiquitin-positive inclusions. Such inclusions have variably been described as amorphous aggregates or more structured deposits having an amyloid structure. Following the observations that bacterial inclusion bodies generally consist of amyloid aggregates, we have overexpressed full-length TDP-43 and C-terminal TDP-43 in *E. coli*, purified the resulting full-length and C-terminal TDP-43 containing inclusion bodies (FL and Ct TDP-43 IBs) and subjected them to biophysical analyses to assess their structure/morphology. We show that both FL and Ct TDP-43 aggregates contained in the bacterial IBs do not bind amyloid dyes such as thioflavin T and Congo red, possess a disordered secondary structure, as inferred using circular dichroism and infrared spectroscopies, and are susceptible to proteinase K digestion, thus possessing none of the hallmarks for amyloid. Moreover, atomic force microscopy revealed an irregular structure for both types of TDP-43 IBs and confirmed the absence of amyloid-like species after proteinase K treatment. Cell biology experiments showed that FL TDP-43 IBs were able to impair the viability of cultured neuroblastoma cells when added to their extracellular medium and, more markedly, when transfected into their cytosol, where they are at least in part ubiquitinated and phosphorylated. These data reveal an inherently high propensity of TDP-43 to form amorphous aggregates, which possess, however, an inherently high ability to cause cell dysfunction. This indicates that a gain of toxic function caused by TDP-43 deposits is effective in TDP-43 pathologies, in addition to possible loss of function mechanisms originating from the cellular mistrafficking of the protein.

The effect of low frequency electromagnetic field on apoptotic proccesses in rat thymocytes under peroxide induced damage

V. M. Sobko, V. S. Martynyuk
Biophysics, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Environmental exposure to electromagnetic fields of low frequency (EMF LF) has been steadily increasing, and in the modern world everyone is exposed to a complex mix of weak electric and magnetic fields. EMF LF are known to modulate cells functioning both in physiological and pathological conditions, we sought therefore to clarify the possibility of EMF LF to induce and modulate cell death. It was shown that the influence of EMF LF led to the increased number of apoptic cells. To elucidate the mechanisms of this effect we identified the level of the intracellular calcium concentration $[Ca^{2+}]_i$ in rat thymocytes. It is known that calcium (Ca^{2+}) is a secondary messenger and universal signaling ion that regulates diverse cellular functions and is one of the key elements of the apoptotic signaling pathways. To assess changes of intracellular calcium concentration $[Ca^{2+}]_i$ the dual-wavelength method for detecting changes of fluorescent Indo-1 was used. At early and late stages of apoptosis it was observed from the kinetic curves that the influence of low frequency magnetic fields on the rat thymocytes suspension caused the considerable increase of intracellular calcium concentration both in the presence of H_2O_2, that enhanced the effect, and in solution without H_2O_2. It should be noted that this effect caused by EMF LF could be observed with slight deviation in different pH, and the process of the intracellular calcium concentration augmentation occured with different dynamics. Thus, these data indicate that EMF LF causes an increase in intracellular calcium concentration, both independently and in combination with H_2O_2 (where the effect is greatly enhanced), which in turn can lead to activation of the important mediators of apoptotic processes such as CaMKII and JNK, and thus promotes apoptosis run. At the same time, using the reliable and sensitive method of comet assay the nucleuses DNA damages were studied in the suspension of isolated rat thymocytes after three hour incubation with hydrogen peroxide and exposure to electromagnetic fields, considering both individual and combined effects. We have shown that significant augmentation of DNA damages was observed under the action of hydrogen peroxide, and the effect was enhanced by the EMF LF.

The effect of *Montivipera raddei* viper venom on human red cell membrane ATPase activites

G. Kirakosyan, T. Hasmik, N. Ghazaryan, A. Kishmiryan, N. Ayvazyan
L. Orbeli Institute of Physiology, NAS Armenia, Yerevan, Armenia

We have studied the influence of *Montivipera raddei* venom (MR) (Latoxan, France) on the activity of ATPases. We also have studied influence of MR venom on the erythrocyte ghosts by the fluorescent microscopy. The lyophilized toxin of MR was dissolved in Tris-HCl buffer (pH 7.4); final concentration $3*10^{-5}$ M, 1.1 ml of this solution was added to the sample during ghost visualization. We have shown that in presence MR venom erythrocyte ghosts were shrinking during 58 s.

The addition of MR venom into assay mixture with low, sublethal (0.35 mg/kg approx. 0.5 LD 50 for rat) and lethal concentrations in accordance with LD50, increased Na^+/K^+ ATPase activity in erythrocytes membranes (low concentaraton ~5.28 times, sub –lethal concentration ~ 4.5 times and lethal concentrations ~2.93 times respectively). Under these conditions Ca^{2+} ATPase activity increased at low concentaration ~1.59 times, then decreased at sub –lethal concentration ~2.87 and lethal concentrations ~4.41 times respectively. Mg^{2+} ATPase activity also increased (low concentaration ~12.1 times, sub –lethal concentration ~ 5.98 times and lethal concentrations ~3.05 times respectively).

These results suggest that ATPase activity is very sensitive to venom components and venom influence leads to possible conformation changes in ATPases.

Acknowledgments: Research was performed in the frames of ANSEF project # chemen- 3575.

The effect of soloxolone methyl on gene expression profile and its biological activity *in vitro*

E. Logashenko[1], A. Markov[1], A. Kel[2], O. Kel-Margoulis[2], O. Salomatina[3], N. Salakhutdinov[3], M. Zenkova[1]
[1]*Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation,* [2]*GeneXplain GmbH, Wolfenbüttel, Germany,* [3]*Novosibirsk Institute of Organic Chemistry SB RAS, Novosibirsk, Russian Federation*

In attempt to find more potent analog of glycyrrhetinic acid we synthesized soloxolone methyl (SM) (2-cyano-3,12-dioxo-11-deoxo-18βH-glycyrrhet-1(2),9(11)-dienoate) [doi: 10.1002/cbic.201000618].

To find the molecular targets of SM we investigated its effect on gene expression profile of KB-3-1 human carcinoma cells using HumanHT-12 v4 Expression BeadChip (Illumina, USA). Incubation of KB-3-1 cells with 1 μM SM significantly alters the expression of 311 genes (Log_2(Fold Change)>1, $p < 0.001$). Gene ontology and promoter analysis was performed using the geneXplain platform. Data show that SM inhibits cell growth and promotes death of cancer cells through the modulation of multiple signaling pathways. Expression of many genes related to apoptosis and cell death, cell cycle and cell proliferation, angiogenesis, metastasis and differentiation is significantly altered upon SM treatment. Master regulator search in TRANSPATH database (BIOBASE GmbH, Germany) let us to identify potential early molecular targets of SM, which are bst2, CEPT1, CRMP2, cxcr4, DDB1, elongin C, FGF-BP, hBre1, insig-1, LAMA5, LT-betaR, Mi2-Beta, MO25, p18INK4c, p22phox, p70S6K2, pkmyt1, SRXN1, SVIL, TMP21, TfR1, UBE2Q2.

Evaluation of biological action of Soloxolone methyl (SM) *in vitro* showed that this compound induces the death of cancer cells by triggering of mitochondrial pathway of apoptosis that confirms obtained bioinformatic data.

We found that SM possesses anti-influenza A activity, causing 10-fold decrease of virus titer relative to control in infected MDCK cells. Time-of-addition studies demonstrated that SM is likely to affect virus penetration into the cell and the early stages of virus replication. It was also shown that SM exhibits the anti-inflammatory activity reducing the IL-6 level upon viral infection.

Additionally, the anti-inflammatory potential of SM was demonstrated in the murine peritoneal macrophages model: SM caused significant reduction of NO production in LPS-activated macrophages.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Our results show that SM is multifunctional compound with pronounced anticancer, anti-influenza and anti-inflammatory activities.

The effect of substitutions at several sites on the functioning of two CYP74 enzymes (P450 superfamily)

S. Gorina[1], Y. Toporkova[2], L. Mukhtarova[1], Y. Gogolev[2], A. Grechkin[1]
[1]Laboratory of Oxylipins, [2]Laboratory of Molecular Biology, Kazan Institute of Biochemistry and Biophysics, Kazan, Russian Federation

Oxylipins (fatty acid hydroperoxides, hydroxy-, oxo-, or keto-fatty acids, divinyl ethers, volatile aldehydes, or jasmonic acid) play important roles in plant cell signalling and defense. The key role in biosynthesis of oxylipins belongs to the CYP74 enzymes that are nonclassical cytochromes P450: allene oxide synthases (AOS), hydroperoxide lyases (HPL), divinyl ether synthases (DES). DESs are less characterized than AOSs and HPLs. Earlier we cloned and characterized new member of the CYP74 family from flax (*Linum usitatissimum* L.) – divinyl ether synthase LuDES (GenBank HQ286277.1). It possessed high homology with sequences of the CYP74B enzymes – 13-HPLs. We obtained mutant forms of LuDES and HPL of *Medicago truncatula* (MtHPL) for identifying determinants of the CYP74 catalysis. We substitute two amino acids in the I-helix central domain (IHCD) corresponding to the oxygen-binding domain of classical P450 monooxygenases by site-directed mutagenesis and obtained mutant forms LuDES E292G, A287G and MtHPL G288E. The mutant form LuDES E292G possessed the catalytic activity of 13-AOS, while the DES activity was not detectable. The substitution A287G in LuDES sequence resulted in regiospecificity loss. This mutant produced several isomers of etherolenic acid. The mutant form MtHPL G288E catalyzed conversion of substrate into corresponding epoxy alcohol.This work is partly supported by Russian Foundation of Basic Research (13-04-40103-H, 14-04-01532-a, 12-04-97087-r, 12-04-97059-r), MK-4886.2013.4 and SS-1890.2014.4.
Keywords: divinyl ether synthase, hydroperoxide lyase, site-directed mutagenesis.

The molecular dynamics simulation and experimental evaluation of carbon nanotubes – Congo red drug delivery system into cancer cells

A. E. Jagusiak[1], B. Piekarska[1], T. Pańczyk[2], P. Laidler[1]
[1]Chair of Medical Biochemistry, Jagiellonian University Medical College, [2]Institute of Catalysis and Surface Chemistry, Polish Academy of Science, Kraków, Poland

Most of the present anti-cancer drugs have low specificity and devastating side effects. Thus drug delivery systems that combine targeted delivery and controlled release without damaging the healthy tissue are widely investigated. The carrier is expected to have high drug loading capacity and drug release, low toxicity and ensure the effective transport of the carried drugs. The model drug used in this study is doxorubicin (DOX). Single walled carbon nanotubes (SWNTs) are studied as potential transporters of drugs absorbed to their surface. The supramolecular ribbon-like assemblies created by the dyes of the Congo red (CR) type can incorporate by intercalation certain drugs (especially polycyclic, planar molecules like DOX) and thus can also be considered as potential drug carriers. The combination of both systems appears to be promising solution.

The aim of the study is to determine whether it is possible to use CR-functionalized carbon nanotubes for drug delivery into cells and whether CR improves drug-loading properties of SWNTs. Parallel analysis of this drug transporting system was carried out by the molecular dynamics simulation.

Microscopic analysis (AFM, TEM) of the SWNTs-CR complexes showed the increase in the diameter of the SWNTs and change the mechanical properties, suggesting that the CR binds the SWNTs in its supramolecular form. The quantitative analysis of the amount of CR complexed to SWNTs and the release of DOX from these complexes in different pH conditions was studied. The highest rate of DOX release was observed in acidic solutions. Studies concerning the cytotoxicity of the system were conducted using the human glioblastoma U87MG and human fibroblast Hs27 cell lines. The addition of the SWNTs-CR-DOX led to the inhibition of cell proliferation, while cells treated with carriers free of DOX (CR, SWNTs-CR) showed the proliferation at the control level.

The molecular dynamic simulation confirmed the ribbon-like structure of CR micelle and interaction of CR with SWNTs. Using the method of umbrella sampling and weighted histogram analysis of the free energy profiles established that the SWNTs-CR systems are thermodynamically stable.

The results indicate that this type of carrier can potentially improve the pharmacological efficacy and reduce side effects.

gous for the disrupted *Gle1* allele from E8, and our examination of E5.5 embryos and E 3.5 blastocyst cultures suggest that embryonic lethality occurs between E3.5 and E6. X-Gal staining of mouse embryos hemizygous for the disrupted allele showed regionally restricted expression in the brain and other organs. Notably, X-Gal staining was prominent in developing joint cartilages, consistent with the multiple joint contractures seen in LCCS1. X-Gal expression was low or absent in the spinal cord, though prominent in the dorsal root ganglia, suggesting that its role in motor neuron survival may be non-cell autonomous.

The quest for the dynamic fingerprint of photo-switching in GFPs: a comparative molecular dynamics study

D. Smyrnova[1], S. Michielssens[1], B. Moeyaert[2], P. Dedecker[2], A. Ceulemans[1], J. Hofkens[2]

[1]Quantum Chemistry and Physical Chemistry Section, [2]Molecular Imaging and Photonics, KU Leuven, Leuven, Belgium

Green Fluorescent Proteins (GFPs) are well know for their valuable properties for high-resolution microscopy. In most cases the GFPs used for cell labeling are not the wild type proteins, but mutants which enable faster or slower photo-switching (ps) and thus higher resolution and conditions which are more suitable to follow the process under the investigation.

To understand how the photo-switching is “turned on” we should also understand how it is “turned off”[1]. Rational design of a non-photoswithcing (non-ps) mutant of Dronpa would provide us with new insight on the photo-switching mechanism. Following previous studies on various GFPs it can be concluded that the flexibility of this protein plays an important role into its' behaviour [2]. A detailed analysis of the flexibility of a set of similar proteins with different properties (ps and non-ps) could reveal the nature of the difference.

To analyze how the flexibility of the GFP beta-barrel influences the photo-switching properties we have conducted an MD study for a set of 6 proteins: EosFp – IrisFP (97%), mAG – Dronpa (73%), EGFP – rsEGFP (96%). Those couples of proteins differ by a minimum set of mutations (sequence similarity is indicated in the brackets), however one of them is photo-switching and the other is not. Primary backbone flexibility analysis was based on a RMSF vs. residue comparison. Partial-least square (PLS) analysis was performed to detect the differences in the ensemble of the non-ps and ps GFPs.

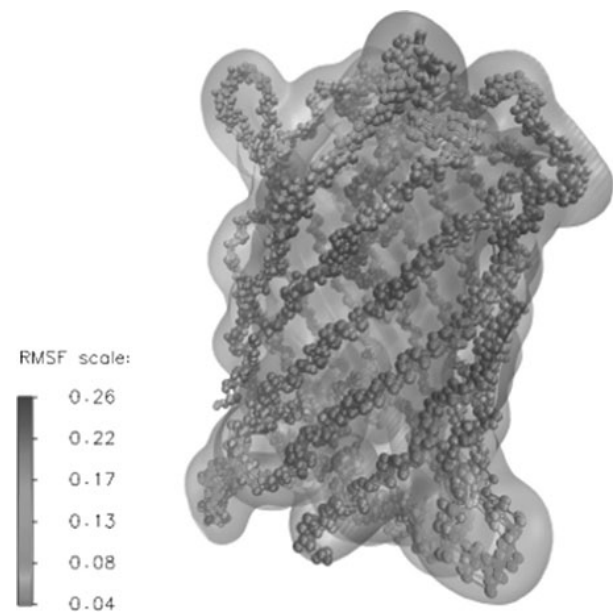

Fig. 1.

The analysis has clearly indicated that the average flexibility of the proteins does not determine the photo-switching properties, while it is the local flexibility which distinguishes the psGFP and non-psGFP (see the picture, which is the superposition of 4x2 proteins. Regions with the lowest RMSF are indicated in red.). The results also indicate the regions as well as the single aminoacids responsible for the photo-switching properties. To test the conclusions mutations were made to psGFP Dronpa which would render it non-ps. The obtained results have confirmed the protocol and can provide insight into the photo-switching mechanism of Dronpa.

The role of dynamic β-hairpin structures in the catalytic loop of *Mycobacterium tuberculosis* tyrosyl-tRNA synthetase

V. Mykuliak[1,2], A. I. Dragan[1,2], A. I. Kornelyuk[1,2]

[1]Institute of High Technologies, Taras Shevchenko National University of Kyiv, [2]Department of Protein Engineering and Bioinformatics, Institute of Molecular Biology and Genetics, NASU, Kyiv, Ukraine

Tyrosyl-tRNA synthetase from *M. tuberculosis* (*Mt*TyrRS) is an enzyme that belongs to Class I of aminoacyl-tRNA synthetases, that catalyze the attachment of tyrosine to its cognate $tRNA^{Tyr}$ at the preribosomal protein synthesis step. *Mt*TyrRS is incapable of cross-recognition and aminoacylation of human cytoplasmic $tRNA^{Tyr}$, so this enzyme is a promising target for development of novel selective inhibitors as new antituberculosis drugs. *Mt*TyrRS has the HIGH-like and KFGKS motifs that catalyze the amino acid activation with ATP. We have investigated the dynamic properties of *Mt*TyrRS catalytic loop (-KFGKS-) using molecular dynamics (MD) simulations in solution within a long time interval of 100 ns. In our previous studies we have shown that the catalytic loop can form two dynamic β-strands in its flanking regions. In this study special attention has been given to the role of the β-hairpins in structural dynamics of the catalytic loop.

The crystalline *Mt*TyrRS dimer structure was used as an initial structure (PDB code 2JAN). All-atom MD simulations were performed using the GROMACS 4.5 package with the Amber ff99SB-ILDN force field. The *Mt*TyrRS in solution was simulated for 100 ns at 310 K temperature and 150 mM NaCl salt concentration. To study the influence of the β-sheets on the catalytic loop dynamics and structural-functional state we designed a variant of the *Mt*TyrRS loop with proline substitutions (proline residues effectively break the β-sheets) at sites involved in β-hairpin formation. All MD simulations were calculated using the MolDynGrid virtual laboratory services (http://moldyngrid.org).

© 2014 The Authors. FEBS Journal © 2014 FEBS

For the wild type TyrRS the catalytic loop has M-like structure, the central part of which points to the active center of the enzyme. We hypothesize that flanking β-hairpins in the catalytic loop keep it in the closed functional M-like state, which directs the catalytic KFGKS motif toward the active center cavity. To verify this, we made a mutant *Mt*TyrRS by substituting residues that are involved in β-sheet formation with proline: T225P, A226P, T230P, K231P, K234P, S235P, and S240P. Remarkably, the catalytic loop starts to move out of the active site cavity from the very beginning of MD simulation. The M-shape of the loop (initial structure) rapidly changes (in a 20 ns time interval) to an "open" ring-like structure (O-structure) that is fully exposed to the solvent. This result elucidates the important role of β-hairpin structures in maintaining the active M-state structure of the catalytic KFGKS loop inside the enzyme active center.

Keywords: Molecular Dynamics simulations, tyrosyl-tRNA synthetase, β-strands.

The use of human digestive juices and commercial enzymes preparations for evaluation of biological activities of carp protein hydrolysates

M. Darewicz[1], J. Borawska[1], P. Minkiewicz[1], V. E. Gerd[1,2], A. Iwaniak[1]

[1]Chair of Food Biochemistry, University of Warmia and Mazury, Olsztyn, Poland, [2]Department of Chemistry, Biotechnology and Food Science, University of Life Sciences, Aas, Norway

Fish proteins are considered as an interesting source of peptides with biological activity, including angiotensin converting enzyme (ACE) inhibitory and antioxidant peptides. Carp (*Cyprinus carpio*) is one of the most popular fish in Poland with high digestibility of proteins exceeding 98%, so it may be the source of bioactive peptides in the human diet. The aim of this study was to identify ACE inhibitory, antioxidant peptides and antimicrobial peptides in hydrolysates of carp myofibrillar and sarcoplasmic proteins, obtained *via* different ways of human digestive tract conditions simulation.

The study covered the *in silico* part – with the use of UniProt and BIOPEP databases as well as tools available within, Fragment Ion Calculator and Sequence Specific Retention Calculator application. The next step of analysis was *in vitro* hydrolysis – with the use of commercial enzyme preparations, and *ex vivo* digestion – with the use of human digestive juices isolated from individuals. The method was developed using carp muscle tissue. *In vitro* hydrolysis of protein extracts was carried out using a commercial enzyme preparations such as pepsin and Corolase PP. Bioactive peptides in the obtained hydrolysates were identified using RP-HPLC with MS detector based on the expected retention times.

Peptide sequences, which from the theoretical point of view should be released during the hydrolysis of carp proteins, were selected from the results of the *in silico* part of study. The identification of bioactive peptides in hydrolysates of carp protein isolates was possible *via* the expected retention times for each of the selected sequence calculation. The comparison of theoretical and experimental retention times of searched peptides was the basis for identification and analysis. For example the predicted retention time of peptide FIKK was 19.15 min and the retention time observed during the study was 19.56 min and 19.57 min for *in vitro* and *ex vivo* samples, respectively. ACE inhibitory peptides ALPHA, MNPPK, VKAGF, IVY, GL, HL and antioxidative peptides FIKK, PW, HL were identified in both kinds of hydrolysates but TVY and IW peptides (ACE inhibitors) were presented only in *ex vivo* and *in vitro* hydrolysates respectively. It was proved that during *in vitro* and *ex vivo* digestion different products were released. It was impossible to identify antimicrobial peptides in hydrolysates that were studied. It was concluded that carp proteins can be the source of antihypertensive and antioxidant peptides.

Keywords: bioactive peptides, carp proteins, hydrolysis.

Towards to mechanism of uptake bilitranslocase transporter. NMR study of TM2: TM3 assembly and modelling simulations in micellar environment

I. Zhukov[1,2], A. R. Choudhury[3], E. Sikorska[4], S. Zuperl[3], L. Popenda[1], K. Szutkowski[1], M. Novic[3], S. Jurga[1]

[1]NanoBioMedical Centre, Adam Mickiewicz University, Poznan, [2]Institute of Biochemistry and Biophysics, Warsaw, Poland, [3]National Institute of Chemistry, Ljubljana, Slovenia, [4]Faculty of Chemistry, Universoty of Gdansk, Gdansk, Poland

Using a combination of genomic and post-genomic approaches is rapidly altering the number of identified human influx carriers. A transmembrane protein bilitranslocase (BTL) is involved in transport of bilirubin and several other organic anions from blood to liver cells. Moreover, the BTL has been identified as a potential target for cellular uptake of several drugs. The drug delivery task requested to knowledge about high-reslution 3D structure and mechanism of functioning of transmembrane channel. Previously, the chemometrics model have been developed in our group on base of the counter-propagation neural network (CPNN). As result of our studies, we possible to predict four transmembrane (TM) regions in BTL protein. To the time being, the 3D structures of TM2 and TM3 BTL fragments in SDS micelle are available [1,2]. According these data, both TM segments – TM2 (^{73}Ser.Leu^{99}) and TM3 (^{220}Ser.Thr^{237}) – are folded as a helix – loop – helix motifs with a kink around the central proline residues (Pro85, Pro231). Very recently, the structure of two TM2 and TM3 transmembrane fragments, dissolved together in SDS lipid media was evaluated on base NMR data [3]. The detail analysis reveal significant alteration of TM2 and TM3 peptides in assebly compare to the previously reported structural data. In addition, the experimental values of ^{15}N R_1, R_2 relaxation rates and ^{1}H-^{15}N *NOE* obtained for ^{15}N-labeled alanines incorporated in both regions reveals existence conformational exchange motions. The efects of such processes more pronounced for alanines located close to central prolines. Finally, taking into account the side chains orientation in hydrophobic and hydrophilic residues we conclude that TM2: TM3 assemble of BTL fragments possible to facilitate formation of a BTL transmembrane anion channel with uptake mechanism based on *cis*/*trans* isomerization.

Understanding the mechanism of ASK1 regulation by thioredoxin using biophysical characterization of their complexes

S. Kylarova[1,2], D. Kosek[1,2], K. Psenakova[2], L. Rezabkova[1,2], P. Herman[3], J. Vecer[3], V. Obsilova[1], T. Obsil[1,2]
[1]Institute of Physiology AS CR, 142 20 Prague, [2]Faculty of Science, Charles University in Prague, 128 43 Prague, [3]Faculty of Mathematics and Physics, Charles University in Prague, 121 16 Prague, Czech Republic

Apoptosis signal-regulating kinase 1 (ASK1) is a member of the mitogen-activated protein kinase kinase kinase (MAP3K) family that activates c-Jun N-terminal kinase and p38 MAP kinase pathways in response to various stress stimuli, including oxidative stress, endoplasmic reticulum stress, and calcium ion influx. The function of ASK1 is associated with the activation of apoptosis in various cells and plays a key role in the pathogenesis of multiple diseases including cancer, neurodegeneration and cardiovascular diseases. The kinase activity of ASK1 is regulated by many factors, including binding of thioredoxin (Trx) and the 14-3-3 protein that both function as inhibitors of ASK1 [1]. However, the mechanisms by which these binding interactions inhibit ASK1 are still unclear.

To better understand the role of Trx binding in the inhibition of ASK1, we prepared the isolated Trx-binding region of ASK1 (ASK1-TBD), performed its structural and biophysical characterization and studied its interaction with Trx under both reducing and oxidative conditions. Data obtained from analytical ultracentrifugation, time-resolved fluorescence anisotropy measurements, circular dichroism and small-angle X-ray scattering suggest that: (1) ASK1-TBD is a compact monomeric and rigid domain that under reducing conditions forms with Trx a stable and well defined complex with 1:1 molar stoichiometry; (2) the structural integrity of the catalytic Trp-Cys-Gly-Pro-Cys motif of Trx is essential for its binding to ASK1-TBD; (3) Trx interacts with the region of ASK1-TBD located in the vicinity of Cys250; and (4) Trx binding does not induce significant structural change of ASK1-TBD. In addition, it seems that the interaction between ASK1-TBD and Trx does not involve the disulfide bond formation, as has been suggested in the literature [2,3].

Urea-unfolded ubiquitin: from NMR to MD simulation

M. Candotti, Molecular Modelling and Bioinformatics, Bioinformatics
IRB Barcelona, Barcelona, Spain

The delicate equilibrium between the folded and functional structure of a protein and its unfolded state is highly dependent on environmental variables such as the solvent. For example the co-solvent urea is a well-known protein denaturant that displaces the equilibrium towards unstructured and non- functional conformations of proteins. However the molecular mechanism behind its ability remains an enigma and the interpretation of the experimental data is still ambiguous. In this work we present the characterization of the structural, dynamics, and energetics of properties of the urea-denatured state of ubiquitin, a small prototypical soluble protein. By combining molecular dynamics simulations with nuclear magnetic resonance and small-angle X-ray scattering data, we were able to: (*i*) define the unfolded state ensemble, (*ii*) understand the energetics stabilizing unfolded structures in urea, (*iii*) describe the differential nature of the interactions of the fully unfolded proteins with urea and water, and (*iv*) characterize the early stages of protein refolding when chemically denatured proteins are transferred to native conditions. The results provide a new picture of the chemically unfolded state of proteins and contribute to deciphering the mechanisms that stabilize the native state of proteins, as well as those that maintain them unfolded in the presence of urea.

Utilizing reprogramming technologies to study neurodegeneration: a case study in ALS

E. Kiskinis[1], B. Wainger[2], J. Sandoe[1], L. Williams[3], C. Woolf[2], K. Eggan[3]
[1]Stem Cell and Regenerative Biology, Harvard University, Howard Hughes Medical Institute, Cambridge, [2]Neurobiology, Childrens Hospital, Harvard Medical School, [3]Stem Cell and Regenerative Biology, Harvard University, Howard Hughes Medical Institute, Boston, USA

Although many distinct mutations in a variety of genes are known to cause Amyotrophic Lateral Sclerosis (ALS), it remains poorly understood how they selectively impact motor neuron biology and whether they converge on common pathways to cause neural degeneration. We have combined reprogramming and stem cell differentiation approaches with genome engineering and RNA sequencing to define the transcriptional and functional changes that are induced in human motor neurons by mutant SOD1. Mutant SOD1 protein induced a transcriptional signature indicative of increased oxidative stress, reduced mitochondrial function, altered sub-cellular transport, electro-physiological excitability as well as activation of the ER stress and unfolded protein response pathways. Functional studies demonstrated that perturbations in these pathways were indeed the source of altered transcript levels. Importantly, we used a genetic targeting approach to demonstrate that these phenotypes are reversed by genetic correction of the SOD1 mutation.

Utilizing this patient-specific induced pluripotent stem cell (iPSC) approach we next addressed two important, outstanding questions in the field. Why are motor neurons selectively lost in ALS? And are there common molecular pathways between distinct ALS-causing mutations? We found that motor neurons exhibit inherent ER stress that is related to their physiological properties and renders them vulnerable to disease. Finally, inter-

© 2014 The Authors. FEBS Journal © 2014 FEBS

rogation of stem cell-derived motor neurons produced from ALS patients harboring a repeat expansion in C9orf72 and FUS mutations identified electro-physiological excitability as a major feature of distinct types of ALS. These results provide an insight to the common functional defects that physiological levels of mutant proteins may lead to, in patient motor neurons. More broadly our studies demonstrates that iPSC technology can be used to probe an adult-onset neurological disease such as ALS.

Valorization of agricultural residues for Compactin production by *Aspergillus terreus* MTCC 279 in mixed substrate solid state fermentation

M. B. Syed, Dr. T. Viruthagiri
Chemical Engineering, Annamalai University, Chidambaram, India

The present study was aimed to enhance the production of compactin by *Aspergillus terreus* MTCC 279 in mixed substrate solid state fermentation using various solid substrates. Twenty solid substrates including agricultural residues and other solid substrates were tested for the compactin production by *Aspergillus terreus*. Among the twenty substrates tested, the three substrates which gave maximum compactin production was taken for further optimization in mixed substrate solid state fermentation in various combinations using response surface methodology. Green peas, millet and ragi were found to be suitable substrates which produced maximum compactin production in SSF. The combinations of the substrates with 1.5 g of green peas, 1.5 g of millet and 1.5 g of ragi gave maximum production of 389.34 mg/gds compactin. Response surface methodology was used to determine the optimal combination of each substrate. To the best of our knowledge this is the first report on enhancing compactin production in mixed substrate solid state fermentation.

Keywords: Compactin; mixed substrate solid state fermentation; Optimization; Response Surface Methodology; Aspergillus terreus.

A kinetic approach for immobilization of NAD+/NADH on magnetic solid support and its regeneration for enzymatic biosynthesis

S. Tural, M. S. Ece, E. Ertaş, B. Tural
Chemistry, Dicle Univ., Diyarbakir, Turkey

β-nicotinamide adenine dinucleotide (β-NAD) is one of the most important electron carriers in all living cells and used various scientific and technologic fields such as biofuel cell, sensor technology, and hydrogen production. Therefore, the immobilization of β-NAD is of great importance. For this purpose, 3-aminophenyboronic acid (APBA) functionalized Fe_3O_4 nanoparticles were prepared as a magnetic solid support for the purification of β-nicotinamide adenine dinucleotide (β-NAD). The condensation product of 3-aminophenyboronic acid (APBA) was attached on the synthesized magnetite nanoparticles. X-ray diffraction, fourier transform infrared spectroscopy, vibrating sample magnetometer and transmission electron micrograph methods were used to characterize the surface modified magnetic nanoparticles. The reversible immobilization behavior of β-NAD was investigated using the APBA functionalized magnetic particles in batch-fashion. Loading capacity of 3-aminophenyboronic acid (APBA) functionalized Fe_3O_4 nanoparticles for β-NAD adsorption was 13.0 μmol/g. Immobilizaton kinetic and isotherm studies, respectively, showed that the immobilization process followed a pseudo-second-order kinetic model and the Langmuir isotherm model which agrees with experimental data better than the Freundlich isotherm model.

3-aminophenyboronic acid (APBA) functionalized Fe_3O_4 nanoparticles were proposed as alternative support for the β-NAD immobilization. The results elucidated the significance of magnetic separation as a fast, relatively simple and low-cost technique.

Keywords: Magnetic solid support; Immobilization; Elution; Re-usability; cofactor.

A lithotrophic microbial fuel cell operated with iron-oxidizing bacteria enriched at the anode

H. T. Pham
Department of Microbiology, Vietnam National University – University of Science, Hanoi, Viet Nam

In this study, we attempted to enrich neutrophilic iron bacteria in a microbial fuel cell (MFC) in order to develop a lithotrophic MFC system that can utilize ferrous iron as an inorganic electron donor and operate at neutral pHs. Electrical currents were steadily generated at an average level of 0.6 mA in MFC reactors initially inoculated with microbial sources and operated with 20 mM Fe^{2+} as the sole electron donor; whereas in an uninoculated control reactor, the average current level only reached 0.2 mA. The MFC inoculated with a natural microbial source (MFC 2) appeared to generate a higher and more stabile current, in comparison with the MFC inoculated with a previously enriched iron-oxidizing culture. Cultivation-based and DGGE analyses both show the dominance of *Pseudomonas* species in the anode communities of the MFC reactors. On the other hand, fluorescent in situ hybridization results revealed significant increases in the quantity of neutrophilic iron-oxidizing bacteria in the anode community of MFC 2. The results, altogether, prove the successful development of a lithotrophic MFC with iron bacteria enriched at its anode and suggest a special metabolic cooperation of the anodic bacteria in such a system. This MFC system might offer unique potential applications.

Keywords: iron bacteria, iron oxidation, lithotrophic microbial fuel cell.

WED-097
A novel mycovirus in the human pathogenic fungus *Aspergillus fumigatus* and its application as a virus-induced gene silencing (VIGS) vector

L. Kanhayuwa, R. Coutts, P. Spanu
Department of Life Sciences, Imperial College London, London, UK

A novel mycovirus named *Aspergillus fumigatus* tetramycovirus (AfuTmV-1) was discovered in the human pathogenic fungus, *Aspergillus fumigatus* clinical isolate. AfuTmV-1 is a capsid-less, double-stranded (ds) RNA mycovirus comprised of four genomic segments, ranging in size from 1.1 to 2.4 kbp. Each component (dsRNA1-4) has a high GC content and contains a single open reading frame (ORF) flanked by 5′- and 3′- untranslated regions with strictly conserved termini. The largest component encodes a putative viral RNA-dependent RNA polymerase (RdRP) where the sequence of the most highly conserved motif changes from GDDX to GDNQ. Proteins predicted from the dsRNA 2–4 share similarity with respectively serine proteases, highly basic APC proteins and proline-alanine-serine rich proteins which might be associated with scaffolding functions in cells. The virus causes latent infection with no phenotypic alterations to the fungal host and appears to be a unique dsRNA mycovirus which is still unassigned to a known virus family. The AfuTmV-1 sequence information together with its unique features was exploited to develop a potential tool for silencing genes in *A. fumigatus*. A truncated AfuTmV-1 based vector was successfully constructed and used as a prototype vector for generating a recombinant virus-induced gene silencing (VIGS) vector. Silencing vector was engineered to carry host endogenous gene fragment corresponding to the *ALB1/PKSP* gene responsible for conidia pigmentation and subsequently introduced into the wild type fungal protoplasts. Silencing efficiency and stability of the vector to silence gene in *A. fumigatus* are being investigated using quantitative RT-PCR to investigate the expression of the *ALB1/PKSP* gene. Also, the accumulation of the small interfering (si) RNAs derived from the *ALB1/PKSP* fragment will be determined. We anticipate that the development will provide a powerful reverse genetic tool for functional genomics studies to identify key elements involved in fungal pathogenicity and also provide a medical benefit in exploiting mycovirus as a future therapeutic agent against fungal infections.

Keywords: *Aspergillus fumigatus*, Gene silencing, Mycovirus.

Analysis of lipids of probiotic bacteria

A. Sidarenka[1], M. Pasciak[2], G. Novik[3], A. Gamian[2]
[1]Belarus Collection of Non-Pathogenic Microorganisms, Belarus Academy of Sciences, Institute of Microbiology, Minsk, Belarus, [2]Institute of Immunology and Experimental Therapy, Wroclaw, Poland, [3]Belarus Academy of Sciences, Institute of Microbiology, Minsk, Belarus

Lipids are important constituents of bacterial cells, served as structural components of membranes, energy sources, signaling molecules. Characterization of lipidome in bacteria plays a crucial role for taxonomic identification, understanding of metabolic processes, selection of valuable strains for biotechnology.

The lipidomes of three industrial probiotic bacteria *Bifidobacterium longum*, *Lactobacillus paracasei*, *Enterococcus faecium* were studied by means of thin layer chromatography (TLC) and matrix assisted laser-desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) analysis of the total lipid extracts. Analysis of lipid extracts of probiotic bacteria by one- and two-dimensional TLC demonstrated the presence of major phospholipids (PLs), glycolipids (GLs) and lipids with free aminogroups (ALs) with different chromatographic mobility (R_f). The major lipids of *B. longum* were PLs (R_f=0.25, R_f=0.35, R_f=0.40, R_f=0.45), GLs (R_f=0.14, R_f=0.22, R_f=0.25, R_f=0.35, R_f=0.40, R_f=0.8), AL (R_f=0.40); *L. paracasei* – PL (R_f=0.45), GLs (R_f=0.15, R_f=0.31, R_f=0.36, R_f=0.59, R_f=0.73), ALs (R_f=0.24, R_f=0.49); *E. faecium* – PL (R_f=0.45) and GLs (R_f=0.25, R_f=0.72). Comparative analysis of lipid extracts and PL standards – diphosphatidylglycerol (DPG), phosphatidylglycerol (PG), phosphatidylinositol (PI), phosphatidylethanolamine (PE), phosphatidylcholine (PC), phosphatidylserine (PS), phosphatidic acid (PA) revieled that PG (R_f=0.45) is major PL in *L. paracasei, E. faecium*, and one of the dominat PLs in *B. longum*. Other PLs of *B. longum* were not similar to PL standards in their chromatograthic mobility. Analysis of lipid extracts of probiotic bacteria by MALDI-TOF MS showed characteristic peaks with *m/z* 478.7, 780.6, 1459.5, 1573.4, 1601.3, 1613.9, 1628.6, 1669.9 for lipid components of *B. longum*, *m/z* 478.7, 808.4, 850.5, 914.7, 982.7, 1118.9 – of *L. paracasei*; *m/z* 478.7, 780.3, 834.4, 954.6, 1110.8, 1196.9, 1238.9, 1325.1, 1425.2 – of *E. faecium*. Significant differences were observed among MALDI-TOF mass spectra of lipid extracts of probiotic bacteria, and they can be easily distinguished by lipid mass peak profiles. The fatty acid (FA) composition of lipids of probiotic bacteria was determined using gas-liquid chromatography/mass spectrometry. Normal saturated, unsaturated and cyclopropane FA were detected in analized bacteria. Major FA of *B. longum* were $C_{14:0}$ (14%), $C_{16:0}$ (50%), $C_{18:0}$ (9%), $C_{16:1}$ (5%), $C_{18:1}$ (8%), *cyc*-C_{19} (10%) acids, *L. paracasei* – $C_{16:0}$ (19%), $C_{18:0}$ (13%), $C_{16:1}$ (6%), $C_{18:1}$ (35%), *cyc*-C_{19} (20%) acids, *E. faecium* – $C_{14:0}$ (3%), $C_{16:0}$ (17%), $C_{18:0}$ (12%), $C_{16:1}$ (10%), $C_{18:1}$ (14%) and *cyc*-C_{19} (30%) acids. Further studies of the lipid extracts of probiotic bacteria will be performed to determine their biological activity.

Analysis of structure, purity and activity of recombinant human growth hormone produced in *Escherichia coli*

Z. Levarski, J. Krahulec, A. Soltysova, K. Jirickova, D. Hopkova, S. Stuchlik, J. Turna
Department of Molecular Biology, Comenius University in Bratislava, Bratislava, Slovakia

Human growth hormone (hGH) was one of the first recombinant proteins approved for the treatment of human growth disorders. Its small size (191 amino acids), possession of only 2 disulphide bonds and absence of posttranslational modifications make *Escherichia coli* the host of choice for its production on any scale. Previously, we have presented s novel *E. coli* based expression system capable of producing high quantities of soluble recombinant hGH. In this work, we have analyzed amino acid sequence of hGH using the in-source decay and peptide mapping mass spectrometry. Further, we have determined purity using reverse-phased HPLC, size-exclusion HPLC and endotoxin concentration assay (LAL assay). Secondary structure has been determined by the circular dichroism measurements and the activity of the recombinant hGH has been tested by Nb2 cell line proliferation assay. Results show that recombinant hGH produced in *E. coli* has the structure and activity indistinguishable from the native product, while the purity after three steps of chromatography purification reaches level of more than 99%. This data supports the claim that our system for the production of high levels of soluble recombinant hGH represents a viable production process adaptable to large scale.

This contribution is the result of the projects implementation: "Centre of Competence of Comenius University in Bratislava for R&D in molecular medicine" (ITMS 26240220071) and "University Science Park of Comenius University in Bratislava" (ITMS 26240220086) supported by the Research & Development operation Programme funded by ERDF

Antibacterial mechanism for the apoptosis-like response in *Escherichia coli* induced by silver nanoparticles

W. Lee, D. G. Lee
School of Life Sciences, College of Natural Sciences, Kyungpook National University, Daegu, Korea

Silver nanoparticles are known to have antimicrobial properties and have been used extensively in medicine, although the mechanism(s) of action have not yet been clearly established. In the present study, the findings suggest a novel mechanism for the antibacterial effect of silver nanoparticles on *Escherichia coli*, namely, the induction of a bacterial apoptosis-like response. We propose a possible mechanism for the bacterial apoptosis-like response that includes the following: accumulation of reactive oxygen species (ROS), in particular hydroxyl radicals (·OH) (detected with HPF staining), increased intracellular calcium levels (detected with Fura-2 AM), phosphatidylserine exposure in the outer membrane (detected with Annexin V) which is the hallmarks of early apoptosis, disruption of the membrane potential (detected with $DiBAC_4(3)$), activation of a bacterial caspase-like protein (detected by FITC-VAD-FMK staining) and DNA degradation (detected with TUNEL assay) which is the hallmarks of late apoptosis in bacterial cells treated with silver nanoparticles. We also performed RecA expression assay with western blotting and observed activation of SOS response to repair the damaged DNA. To summarize, silver nanoparticles are involved in the apoptosis-like response in *E. coli* and the novel mechanisms which were identified in this study, suggest that silver nanoparticles may be an effective antimicrobial agent with far lower propensity for inducing microbial resistance than antibiotics.

Keywords: Antibacterial effect, Apoptosis-like response, Silver nanoparticle.

Antifungal activity of lactic acid bacteria isolated from Armenian dairy products

I. Bazukyan, L. Matevosyan
Faculty of Biology, Department of Microbiology, Plant and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia

Food and feed spoiled by moulds and yeasts cause great economic losses worldwide. Furthermore, the presence of moulds with the concomitant production of allergenic spores and possibly mycotoxins makes them serious potential health hazards. The reduction of mould and yeast growth in food and feed production and storage is primarily important. The development of efficient and safe strategies for solution of this purpose attaches attention. In this context, the application of bio-preservation, i.e. control of one organism by another, has got much interest in recent years. The natural origin and good study of producers, isolated from wild nature, are the primary demands. The best candidates suitable for these demands are lactic acid bacteria (LAB)

The aim of this study was to reveal the antifungal activity of lactic acid bacteria isolated from dairy products of Armenia different regions. The temperature and pH stability, as well as the effects of elicitation on synthesis of antifungal components were studied too.

Primary screening of LAB revealed the antifungal activity of *Lactobacillus delbrueckii* subsp. bulgaricus RIN-2003-Ls, *L. delbrueckii* subsp. bulgaricus INRA-2010-4.2, *L. rhamnosus* R-2002, *L. cryspatus* INRA-2010-5.2 against *Fusarium oxysporum* CB1853, *Cladosporium herbarium, Mucor plumbeus, Penicillum aurantio-violaceum, Debaromyces hansenii.* The ability of LAB inhibited the growth of 10^4 spores of moulds was used as the minimal inhibitory activity. The synthesis of antifungal agents started only after 48 h of LAB cultivation. The effects of different temperature on the antifungal activity revealed a high sensibility of components. The treatment at 45°C leaded to inhibition of antifungal activity of *L. rhamnosus* R-2002 against *M. plumbeus,* while treatment at 55°C inhibited activity against *Penicillum aurantio-violaceum*. The effects of different pH on the antifungal activity determined a high stability of antifungal substances. *L. rhamnosus* R-2002 showed the antifungal activity in broad spectra of pH from 2 to 10. The cell free supernatant (without concentration, as well as 10 or 22.5× concentrated) did not show antifungal activity. Moulds' autolysates which were used as elicitors during the cultivation of LAB did not increase the antifungal activity. The association of antifungal components with cell wall was determined.

All studied strains are suggested to be able to be used as starters for production of functional food, as well as preserving strain–producers.

The work was supported by grant from the Armenian National Science and Education Fund (ANSEF) based in New York, USA.
Keywords: antifungal activity, lactic acid bacteria.

WED-103
Antimicrobial activity of samarium doped hydroxyapaptite prepared by co-precipitation method

C. S. Ciobanu, C. L. Popa, S. L. Iconaru, D. Predoi
National Institute of Materials Physics, Magurele, Romania

This research focuses on understanding the antimicrobial activity of samarium doped hydroxyapatite (Sm:HAp). Samarium doped hydroxyapatite, $Ca_{10-x}Sm_x(PO_4)_6(OH)_2$ with $x_{Sm} = 0.7$ were developed by coprecipitation method. The bactericidal effect against common Gram-positive bacteria and fungus has been also investigated. Elemental maps for the samples prepared with $x_{Sm} = 0.7$ are also shown. The spectrum and images confirmed the presence of samarium in the samples. The EDAX spectrum of Sm:HAp confirms the presence of calcium (Ca), phosphor (P), oxygen (O), and samarium (Sm). They show that a substantial Sm content has been enrobed in the hydroxyapatite. The XPS spectra revealed the presence of a material composed mainly of phosphate, calcium, oxygen, hydrogen and samarium.

This study showed that Sm:Hap with $x_{Sm} = 0.7$ presented a good antimicrobial activity against *Bacillus Subtilis* and *Candida Albincas*. The antimicrobial activity of Sm:HAp was tested using the standard microdilution method. *Bacillus Subtilis* and *Candida Albincas* were grown on LB agar broth with Sm:HAp ($x_{Sm} = 0.7$). Yeast extract agar plates were incubated for 24 h at 37°C and the obtained colony forming units (CFU) were visually counted. The Sm:HAp ($x_{Sm} = 0.7$) show strong antibacterial activity.

The results of this study clearly showed that the Sm:HAp with $x_{Sm} = 0.7$ inhibited the growth and multiplication of the *Bacillus Subtilis* (gram-positive) and *Candida Albicans*. These data suggest that development of novel Sm:HAp is a promising material with the antimicrobial properties that may be used for covering the various surfaces of ambulatory and other medical devices.

Keywords: samarium, hydroxyapatite, antimicrobial activity.

Anti-microbial compounds targeting the alternative thymidylate synthase ThyX

H. Myllykallio, K. Djaout, S. Skouloubris, U. Liebl
Laboratory of Optics and Biosciences, Ecole polytechnique, Palaiseau, France

The growing problem of antibiotic-resistant bacteria in clinical settings points to a need for new anti-infective therapies to address global health problems. However, the rate of new antimicrobial compounds to be developed by the pharmaceutical industry alone will not be sufficient to meet the expected need for the foreseeable future.

We have exploited the alternative thymidylate synthase ThyX proteins discovered in the laboratory as a new target for antimicrobial compounds. This is highly justified as ThyX enzymes are essential, present in many pathogenic bacteria (e.g. *Helicobacter*, *Mycobacteria*, *Chlamydia*, *Rickettsia* and *Clostridium* species, 30% of completed bacterial genomes carry *thyX*), but absent in humans. The active site configurations and catalytic reaction mechanisms differ drastically between human thymidylate synthase and ThyX proteins, thus further facilitating conception of ThyX-specific inhibitors. Moreover, recent genome-wide sequencing studies have established ThyX proteins as a virulence factor in *Leptospira* and revealed that overexpression of *thyX* is associated with resistance to the first- and second-line tuberculosis drugs.

We describe how the use of medium-throughput robotized tests for detecting ThyX activity led to the discovery of specific ThyX inhibitors that do not act on human thymidylate synthase. The most interesting ThyX inhibitors inhibit ThyX in genetically modified bacterial strains and show bactericidal activity in the micromolar range against laboratory and clinical strains of *Helicobacter* and *Mycobacteria* species. These inhibitors bind in the vicinity of the redox active co-factor flavin adenine nucleotide, in unexpected configuration.

Our molecules are the first non-substrate based ThyX inhibitors with activity against whole cells. Our biochemical, biophysical and structural studies provide means for development of more potent ThyX inhibitors in order to the fight the problem of antibiotics resistance.

Changes of catalase, superoxide dismutase and peroxidases activities after UV-C exposure of *Pseudomonas aeruginosa*

S. Kloula Ben Ghorbal[1], L. Maalej[2], K. Chourabi[3], I. Cherif[4], A. Chatti[5]
[1]Technopole of Borj Cedria, Hammam lif, [2]Technopole of Borj Cedria, Sfax, [3]Technopole of Borj Cedria, Soliman, [4]Faculté des sciences de Tunis, Tunis, [5]Technopole of Borj Cedria, Mahdia, Tunisia

Ultraviolet (UV) light is the most commonly technology used in wastewater disinfection. However, bacteria have evolved several strategies to counteract oxidative stress generated by UV-C rays. As a first line of defense against potentially toxic levels of endogenous superoxide, *Pseudomonas aeruginosa* possesses superoxide dismutase (SOD), catalase (CAT) and peroxidases (POX) enzymes that are involved in the detoxification of O^{-}_2 and H_2O_2.

In the present study, we investigate the expression of CAT, POX and SOD enzymes of *P. aeruginosa* after exposure to UV-C radiations. Furthermore, different SOD isozymes were separated by a non-denaturating polyacrylamide gel and MDA content was determined for the same UV-C exposure times.

Our results showed that CAT and POX activities exhibited a gradual increase after 5 and 15 min. These variations were concomitant with SOD activity peak at 15 min. For shorter exposure time, SOD activity was inactivated by MDA products, highly generated under UV-C short exposure time. Furthermore, gel activity staining assay detected the presence of three differentially regulated SOD isozymes with an important role of iron-cofactored isoform in response to UV-C stress.

In conclusion, the results of these studies suggest that antioxidant enzymes act in a coordinated manner to counteract stress generated by UV-C. Moreover, we suppose that CAT and POX enzymes have the same importance in scavenging H_2O_2 at shorter and longer exposure times and this may confer additional protection to SOD from damage that is mediated by MDA products.

Keywords: antioxidant enzymes, P. aeruginosa, UV-C.

WED-107
Characterization of DnaB-like proteins in *Acetobacter pasteurianus*

V. Cimová[1], M. Babič[1], J. Bugala[1], P. Grones[2], J. Grones[1]
[1]Department of Molecular Biology, Comenius University in Bratislava, Bratislava, Slovakia, [2]Department of Plant Systems Biology, Gent University, Gent, Belgium

The DnaB protein is an essential replication protein in *Escherichia coli* which is involved in both the initiation and elongation stages of DNA replication. The protein is the *E. coli* primary replicative helicase, the factor responsible for unwinding the duplex DNA in front of the replication fork. Studies *in vitro* have shown that the DnaB protein elicits multiple activities: 1) binding of rNTPs and dNTPs; 2) ATPase and ribonucleotide triphosphatase activities; 3) binding to single- and double-stranded DNAs; 4) interactions with DnaC protein and primase (DnaG protein); and 5) helicase activity. These multiple activities reflect the essential role of the DnaB protein in *E. coli* cell's DNA metabolism and involvement in crucial interactions in the primosome as well as in the protein-nucleic acid complexes formed at the origins of DNA replication. The protein has been studied intensively in *E. coli* strains. In this presented work we focused on the study of the DnaB-like proteins which are encoded by the chromosome of *Acetobacer pasteurianus*. Based on the nucleotide sequence of the genome of *A. pasteurianus* IFO 3281-01, we designed PCR primers to amplify *dnaB-like* genes from chromosome of the bacterial strains *A. pasteurianus* LMG 1513 and *A. pasteurianus* CCM 3610. We cloned the PCR products into cloning vector pGEM^{R}-T Easy and we used these prepared constructs for sequencig analysis. We compared the primary nucleotide and amino acid sequences of the *dnaB-like* genes to each other, as well as to the sequences of *dnaB* gene from *E. coli* strains in BLAST database. Bioinformatic analysis showed sequence similarity between both *Acetobacter* strains but low sequence similarity between the compared *Acetobacter* and *E. coli* strains. Based on the primary amino acid sequences and by using the PSIPRED program we predicted the secondary structure of both DnaB-like proteins from *Acetobacter* strains. We recloned the targeted *dnaB-like* genes from vektor pGEM^{R}-T Easy into expression vector pET30a+. We transformed the competent cells *E. coli* BL21 (DE3) with this newly prepared constructs that carried *dnaB-like* genes. We optimalized the overexpression of our targeted proteins that were in fusion with a hexahistidine sequence and then we purified them by afinity chromatography. We measured the ATPase and helicase activity of the purified proteins and compared them with enzymatic activity of DnaB protein from *E. coli* K12.

Keywords: Acetobacter, DnaB protein, enzymatic activities.

Characterization of the genomic island harboring the gene cluster for production of the antibacterial peptide microcin E492

A. Marcoleta, G. Nuñez, O. Monasterio, R. Lagos
Laboratorio de Biología Estructural y Molecular BEM, Facultad de Ciencias, Universidad de Chile, Santiago, Chile

Microcin E492 (MccE492) is a peptide produced and secreted by *Klebsiella pneumoniae* RYC492 (*Kp*RYC492), which has antibacterial effects against *Enterobacteriaciae*, antitumoral effects over some human cell lines, and forms amyloid fibers modulating their activity. Genetic determinants for the MccE492 production are encoded in a gene cluster that has been cloned and studied in *E. coli*. However, genomic context of the cluster in the former strain has not been explored. Analysis of *Kp*RYC492 genome revealed a sequence context suggesting that MccE492 cluster is allocated in a putative ~23 kbp genomic island named *Kp*GI-E492. In this work we show that *Kp*GI-E492 is an unstable mobile element, unveiling their structural features, and evaluating factors influencing their excision from their host chromosome.

Keywords: antibacterial peptide, Genomic Island, microcin e492.

Chemical composition and antimicrobial activity of *Artemisia annua* essential oil

M. Ioana Cristina[1], C. Carmen[1], O. Eliza[2], B. Mihaela[3], L. Veronica[1]
[1]*Microbiology and Immunology, Faculty of Biology, University of Bucharest,* [2]*Organic Chemistry, Biochemistry and Catalysis,* [3]*Department of Analitic Chemistry, Faculty of Chemistry, University of Bucharest, Bucharest, Romania*

Artemisia annua, a native species of East Asia, due to its high degree of morphological and reproductive plasticity and massive seed production become widespread in temperate regions, including Europe. In Romania this species is included in the invasive plants category.

Considering the fact that the eradicating methods are extremely costly and furthermore not ecological, therefore, in the desire to offer a viable alternative for the approach of this phenomenon, our objective was to study the chemical composition and the antimicrobial properties of the *A. annua* essential oil extracted from leaves.

The volatile constituents of *A. annua* L. have been analyzed using GC/MS. The qualitative screening of *Staphylococcus aureus*, *Bacillus subtilis, Enterococcus fecalis, Klebsiella pneumoniae*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Acinetobacter baumanii* and *Candida* sp. (clinical and reference strains) susceptibility to the *A. annua* essential oil was performed using Kirby-Bauer diffusion method. The quantitative analysis of the antimicrobial activity was performed by using binary serial microdilution method in liquid medium. Positive and negative controls for microbial growth, as well as for the antimicrobial activity of the solvent were used. The influence of the obtained plant extracts on the microbial adherence capacity on the inert substratum was studied using the biofilm microtiter method.

The extract yields of essential oil were 0.783%. A total of compounds were identified by GC/MS was 91.7%, the main components were α-pinene, camphene and eucalyptol. The tested microbial strains proved to be susceptible to the essential oil of *A. annua*, including those clinical strains resistant to antibiotics. The minimum inhibitory concentrations of stock solutions from *A. annua* essential oil solubilized in DMSO (1:2) ranged from 0.51 to 16.33 mg/ml. The tested essential oil showed good antibiofilm activity, inhibiting the initial stage of formation of the microbial cells adhesion to the inert substratum, but was also active against the mature, pre-formed bilofilms.

Our results demonstrated that among other biological activities, the essential oil of *A. annua* contains antimicrobial active compounds with selective activity on Gram-positive, Gram- negative bacterial and yeasts species and interfere with the microbial adhesion and biofilm development.

Keywords: antimicrobial activity, essential oil, GC-MS.

Chitinolytic enzymes from *Clostridium paraputrificum* for biomedical applications

P. Kolenko[1], J. Dušková[2], G. T. Tiščenko[1], T. Koval'[1], K. Fejfarová[1], J. Šimůnek[3], J. Hašek[1,2], J. Dohnálek[1,2]
[1]*Institute of Macromolecular Chemistry AS CR, v.v.i., Prague 6,* [2]*Institute of Biotechnology AS CR, v.v.i.,* [3]*Institute of Animal Physiology and Genetics AS CR, v.v.i., Prague 4, Czech Republic*

Gastrointestinal tract with its microflora remains an interesting target for search for new biomedical applications. Presence of chitin degrading enzymes in human colon can play an important role in defense against fungal invasions. We have isolated and characterized bacterium *Clostridium paraputrificum* strain J4 (CpJ4) that is able to degrade chitin using wide range of extracellularly produced chitinolytic enzymes.

We have characterized the expression spectrum of CpJ4 and cultivated sufficient amount of CpJ4 for DNA isolation and consequential whole genome sequencing. We have developed several procedures to isolate three major chitinases naturally produced by CpJ4 grown in colloidal chitin containing medium. Furthermore, we have identified the three chitinases in the genome of CpJ4 and cloned them for production in *E. coli*. Two of the chitinases (chitinase B and chitinase Chit62J4) have been already recombinantly produced. We have performed comparative analysis of natural and recombinant proteins with focus on their activity towards chitin-derived substrates. We have observed remarkable differences between the proteins. *E.g.* in the case of chitinase Chit62J4, both forms exhibit almost identical characteristics in activity studies. Surprisingly, differences in potency to inhibit or enhance the activity of natural and recombinant protein have been observed for several compounds used in our analysis.

Our results show that there are significant differences between the natural and the recombinant proteins as for their activity profiles. Design of purification techniques for chitinolytic enzymes produced in natural source organism remains important for intended biomedical applications.

Combined use of genetics and metabolomics to study the biosynthesis and function of small antioxidative metabolites in *S. pombe*

T. Pluskal, M. Yanagida
G0 Cell Unit, Okinawa Institute of Science and Technology (OIST), Onna, Japan

Our laboratory studies basic mechanisms that control the transition between cell division and quiescence in response to nutritional conditions. We use fission yeast *Schizosaccharomyces pombe* as a model. Since our recent results suggest that oxidative stress plays a significant role in the regulation of cell division and quiescence, we are interested in the biosynthetic pathways of small antioxidative metabolites. We employ genetic and metabolomic approaches to obtain detailed, quantitative data on the function of the biosynthetic enzymes. Recently, we characterized the two-step (Egt1 and Egt2) biosynthetic pathway of a proposed antioxidant ergothioneine, and its selenium-containing derivative, selenoneine (Pluskal et al, 2014). Currently, we focus on the biosynthetic pathway of a major antioxidant, glutathione, consisting of Gcs1 (glutamate cysteine ligase) and Gsa1 (glutathione synthetase) enzymes in *S. pombe*. The same pathway is reportedly used to synthesize ophthalmic acid, the function of which is completely unknown. In addition, glutathione can be polymerized by Pcs2 enzyme into phytochelatin, a compound required for protection from heavy metal stress. We found that deletion mutant Δ*gsa1* fails to grow in a synthetic minimal medium (EMM2). This defect can be rescued by supplementation with a tiny amount (5 μg/ml) of glutathione, but not by other antioxidants such as

© 2014 The Authors. FEBS Journal © 2014 FEBS

N-acetylcysteine or ascorbate. Interestingly, deletion mutants of other oxidative-stress related genes, such as *sod1*$^{+}$ (superoxide dismutase) or *trx1*$^{+}$ (thioredoxin), also show growth defects in the synthetic medium, suggesting a common underlying mechanism. In spot test experiments, the Δ*gsa1* mutant was highly sensitive to copper and cadmium, presumably due to the lack of phytochelatin. Metabolomic analysis of the Δ*gsa1* mutant has shown a complete absence of glutathione and increase in γ-glutamylcysteine, its precursor. In addition, we found an accumulation of thiamine disulfide, suggesting that thiamine might complement the antioxidative function of glutathione in Δ*gsa1* mutant. As ophthalmic acid was also absent in this mutant, we are interested to study the function of this poorly understood compound using the combined genetic/metabolomic system.

Comparative assessment of poly-β-hydroxybutyrates synthesis in bacteria and yeasts

R. Carpa, I. Lupan
Department of Molecular Biology and Biotechnology, Babes-Bolyai University, Cluj-Napoca, Romania

Poly-β-hydroxybutyrates are biodegradable polymers which accumulate intracellularly as storage granules in bacteria. They can be obtain from renewable sources and have important medical and environmental advantages.

Colony PCR techniques were used for screening poly-β-hydroxybutyrates (PHB) producers isolated from different soils from Transylvania, Romania (soils from alpine meadow, karstic zone with limestone meadow, hill zone with xeric meadow, flood plain). The primers used in colony PCR were used in order to detect *phbC* synthase gene. *Azotobacter vinelandii* 720 DSMZ, Germany, was used as control strain.

A recombinant plasmid was constructed using *phb* gene (1704 pb, NC_012560.1) and *pJET1.2* vector, which codifies *phbC* synthase gene from *Azotobacter vinelandii.* This construct was chemically transformed and introduced in competent cells of *Escherichia coli* strain XL1 Blue. Then it was trasfered in *Saccharomyces cerevisiae* by lithium acetate transformation. The transformed groups were recovered on leucine deficient medium.

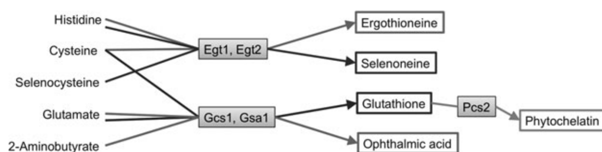

Fig. 1.

Comparative assessing of PHB synthesis in bacteria and yeasts in different experimental conditions led to the conclusion that the synthesis reached the maximum to the *Azotobacter* strains on YE medium with mannitol and tryptone. The highest PHB contents were found to the standard strain *Azotobacter vinelandii 720* (3.65 μgPHB/mg pellet) and to the *Azotobacter* strain from alpine meadow (1.96 μgPHB/mg pellet).

Keywords: bacteria, poly-β-hydroxybutyrates, yeast.

Comparison of activity of immobilized and free recombinant formate dehydrogenase expressed in *Escherichia coli*

S. Stuchlík[1], L. Hason[1], Z. Levarski[1], L. Bocánová[1], K. Jiríčková[1], D. Hopková[1], P. Koiš[2], J. Turna[1]
[1]Department of Molecular Biology, [2]Department of Organic Chemistry, Comenius Univ in Bratislava, Bratislava, Slovakia

The enzymatic bioconversion of aromatic compounds in food and cosmetic industry is often accompanied by the limitation in terms of co-factor depletion or its insufficient regeneration. To address this issue, we have constructed an efficient *E coli* based expression systems capable of producing functional yeast formate dehydrogenase (FDH) and alcohol dehydrogenase (ADH), enzymes used in conversion of trans-2-hexenal to trans-2-hexenol. To further improve this reaction, we have immobilized FDH onto magnetic Fe_3O_4 nano-particles and tested the ability of produced enzyme to improve activity of ADH by NAD+/NADH conversion. The activity of FDH has been tested by applying various physical and chemical condition changes, such as buffer pH and reaction temperature. The results show that although the activity of the immobilized FDH decreased compared to the one of free enzyme, the stability increased significantly allowing prolonged incubations or repeated use of a single batch.

This work was supported by the Slovak Research and Development Agency grant APVV-0061-11 and is also result of the "Competence centre for R&D in molecular medicine" (ITMS 26240220071) project implementation supported by the Research and Development Operational Program funded by the ERDF.
Keywords: formate dehydrogenase, immobilization.

Copper (II) complexes with Schiff base from methionine and o-vaniline as antimicrobials – synthesis and characterization

F. Eliza Catalina[1,2], R. Tudor[2], D. Lia Mara[1], C. Carmen[1]
[1]Microbiology, Faculty of Biology, [2]Inorganic Chemistry, Faculty of Chemistry, University of Bucharest, Bucharest, Romania

In the last decade, interest in copper (II) complexes has been increasing because of their potential use as antiviral, anti-inflammatory, antipyretic or enzyme inhibitors.

A new Schiff base derived from methionine and o-vaniline has been synthesized. The structures assigned to Schiff base are supported by elemental analysis, IR, H^1-NMR, C^{13}-NMR and UV-Vis spectra.

A number of six complexes with this Schiff base and copper salts (chloride, bromide, sulphate, nitrate, perchlorate and acetate) have been also synthesized through the reaction of the Schiff base with copper (II) salt. The structures assigned to complexes are supported by elemental analysis, thermal studies, IR, UV-Vis and RPE spectra.

All compounds have been assayed to demonstrate the changes in biological activity due to the coordination of Schiff base to Cu (II) comparing with the Schiff base and for complexes on copper salt changing.

The antimicrobial activity was tested against reference and clinically isolated resistant strains of Gram-positive bacteria (*B. subtilis*, *S. aureus*), Gram-negative bacteria (*E. coli*, *P. aeruginosa*) and fungal strains (*C. albicans*) using the screening disk dif-

© 2014 The Authors. FEBS Journal © 2014 FEBS

fusion method and the quantitative, serial microdilution method for establishing the minimal inhibitory concentration values (MIC) for each compound.

The antimicrobial activity assayed by *in vitro* qualitative and quantitative methods showed that the complexes exhibited an improved antimicrobial activity as compared to non-coordinating Schiff base. The best activity was obtained for the complexes with copper chloride, sulphate and nitrate on *B. subtillis* and for the one with copper sulphate on *C. albicans*.

The compounds that exhibited the best antimicrobial activity were tested for the influence on the bacterial adhesion to HT-29 eukaryotic cell (Human colon adenocarcinoma grade II) and HEp-2 cell (human epithelial carcinoma) lines, using Cravioto method, and for the biofilm development on inert substratum.

Through their microbicidal, anti-biofilm and anti-pathogenic features, the obtained complexes open new perspectives for the development of the novel anti-infective strategies.

Keywords: antimicrobial activity, copper complexes, Schiff base.

WED-116
De novo evolution of kin discrimination in a social bacterium

O. Rendueles, G. J. Velicer
Institut of Integrative Biology, ETH Zürich, Zürich, Switzerland

The capacity to distinguish self from non-self, or kin from non-kin, critically determines if and how cooperative behavior evolves across the biological spectrum, from complex vertebrates to microbes. Kin discrimination favors high genetic relatedness amongst interacting individuals and can hinder the spread of "cheaters", or non-cooperative organisms that exploit cooperative individuals and take advantage of public goods. Various forms of microbial kin discrimination have been reported, including colony-merger incompatibilities in the model cooperative bacterium *Myxococcus xanthus,* in which swarming groups of distinct genotypes fail to merge during group swarming on agar medium. Most natural isolates of *M. xanthus* cooperate well with clonemates but display a high degree of social incompatibility with distinct natural genotypes. Such incompatibilities during swarming appear to be relevant for understanding the social structure of natural populations, as they were found to limit co-aggregation during multicellular fruiting body development among very similar natural strains that had diverged recently in sympatry.

We examined experimentally evolved populations of *M. xanthus* to investigate the evolutionary and molecular origins of microbial kin discrimination. More than 120 populations that evolved independently across a variety of selective environments were screened and swarming colonies from ~60% of these populations failed to merge freely with colonies of their ancestor on agar medium, whereas control swarms of the same genotype always merged. A similar proportion of evolved populations failed to merge with other independently evolved populations. Thus, kin discrimination – broadly defined as reduced cooperation toward less related genotypes – was found to have pervasively evolved as a by-product of adaptation to a variety of selective conditions.

Kin discrimination phenotypes appeared either abruptly as single-step phenotypic jumps to the full incompatibility phenotype or gradually as continuous increases over evolutionary time, with roughly equal numbers of populations showing each pattern. Whole-genome sequencing (WGS) of evolved lineages indeed revealed that each temporal pattern of phenotypic change correlates with point mutations in two different genes. Additionally, WGS revealed strong links between the origin of kin discrimination and CRISPR immunity pathways.

Keywords: evolution of cooperation, kin discrimination.

Development of genetic engineering systems in *Actinomyces* spp.

C. Mashimo, T. Nambu, H. Maruyama, T. Yamanaka, H. Fukushima
Bacteriology, Osaka Dental University, Osaka, Japan

Background: Recent studies have revealed that oral *Actinomyces* spp. plays an important role as an initial colonizer in dental plaque formation. However, only a few systems for genetic engineering is available for this species. Here, we constructed new pJRD215-based plasmids with the high efficiency for cloning We also established an inducible expression system using a P_{BAD}/*araC* system.OBSERVATIONS: pJRD215 is the only plasmid that can replicate in some *Actinomyces* spp. We determined the whole sequences to elucidate the genetic background of this plasmid. Then we reconstructed smaller plasmids, pCMDk (KmR) and pCMDs (SmR), by eliminating non-essential regions, and evaluated their transformation efficiency in *A. oris* strain MG-1. Both plasmids resulted in a 100-fold increase in the transformation efficiencies compared to those of pJRD215. Furthermore, to demonstrate the utility of *Actinomyces* b -galactosidase gene (gene locus: ANA1492) as reporter, we made an in-frame deletion mutant of ANA1492 (*A.oris* DANA1492) by a two-steps allelic exchange method using *galK* (coding for galactokinase) as a counter-selectable marker. We also constructed the plasmid expressing ANA1492 for complementation (pCMDk::ANA1492). We transformed DANA1492 with pCMDk::ANA1492, then detected that transformant has a strong b-galactosidase activity compared to *A.oris* DANA1492 on HIA plate containing X-gal chromogenically. Finally, we constructed a new expression vector containing the P_{BAD}/*araC* system by subcloning the relevant portion of pBAD/HisA (Invitrogen) into a pCMDk, resulting in pCMiex1. The Reporter gene constructed in pCMiex1 was successfully used to provide b -galactosidase (ANA1492) in *E.coli*.

Conclusions: We constructed pJRD215-based new plasmids with higher transformation efficiencies (pCMDk and pCMDs), and confirmed pCMiex1 as an inducible expression vector.

Keywords: oral bacteria Actinomyces pJRD215.

WED-119
Differentiation of bacilli on genera level based on tRNA modification profiles

H. Panosyan[1,2], M. Wagner[2], C. Brandmayr[2], T. Carell[2]
[1]*Microbiology and Plant and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia,* [2]*Center for Integrated Protein Science, Department of Chemistry, Ludwig Maximilian University Munich, Munich, Germany*

Transfer RNAs (tRNAs) are widely speculated to be among the most ancient RNA molecules, present at the dawn of life in the last universal common ancestor. Recently by using a parallel systems-type approach it was shown that the collective set of modified bases is highly species-specific and linked to phylogeny.

The aim of this study was to characterize of aerobic bacilli isolated from Armenian geothermal springs based on tRNA modification profiles. The objects for investigation were 14 aerobic bacilli strains including thermophilic (*Anoxybacillus, Geobacillus*) and mesophilic (*Bacillus, Brevibacillus, Ureibacillus*, *Paenibacillus*) representatives isolated from Armenian geothermal mineral springs. LC-MS was applied for the quantification of modified nucleosides by using isotopically labeled standards. 16 tRNA modifications (m^1A, m^6A, Am, t^6A, i^6A, ms^2i^6A, Q, m^1G, $m^6{}_2A$, m^2G, $m^2{}_2G$, Gm, m^2A, m^7G, m^5C, Cm) in both their natural and isotopically labeled forms were synthesized for the parallel quantification.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Results obtained were confirmed presence of m^6A, i^6A, $m^6{}_2A$ and Cm modifications at low levels in all the species studied. In contrast m^2A and m^7G modifications were present at high levels in all species indicating their oldest origin, which likely contributed to the very early development of bacilli. Relatively high level of i^6A modification was observed in *Paenibacillus*. The lowest level of Cm modification was found in *Bacillus*. The highest level of m^5C modification was presented in *Ureibacillus*. The ms^2i^6A modification was found in all bacteria except *Ureibacillus*. On the other hand, only in *Ureibacillus* was observed modifications Am and $m^2{}_2G$. In *Brevibacillus* was absent m^1G modification. While both thermophilic and mesophilic species contains Gm, m^1G and ms^2i^6A modifications, large quantities of them (especially ms^2i^6A and Gm modification) were detected only in thermophilic ones (representatives of genera *Geobacillus* and *Anoxybacillus*). The high resolution of the analysis indicated that quantification of tRNA modifications could be applicable for use in reliably distinguishing thermophilic bacilli from related mesophilic species. The presented results offer a deeper insight into the evolution of tRNA modifications, and shows that they characterize species at a very fine level and are linked to phylogenetic variation of endospore-forming bacteria.

Composting operation systems are a wide source of microorganisms and enzymes produced by them. Among these enzymes, proteases, besides their role during the composting process as appropriate indicators of organic matter decomposition, are also important in industry, accounting for about 35% of microbial enzymes. In this study, we assessed the diversity of cultivable bacteria and extracellular proteases produced by some selected species from the facility inside the São Paulo Zoo Park (SPZPF) in Brazil, the biggest zoo in Latin America. Three hundred bacterial isolates were obtained and identified through 16S rRNA sequencing as belonging to 13 different genera. The predominant genus prospected was *Bacillus* (67%), which encompasses potential new species. Some of these strains showed high proteolytic activity. We biochemically characterized the secreted proteases of the potential new species of *Bacillus sp* through different techniques such as Fluorescence resonance energy transfer (FRET) peptides and gelatin zymography and found a repertoire of serine and metallo proteases with different molecular weight; among them, we are interested in some low molecular weight proteases (<15 kDa) that are related with sporulation. This general screening can be geared toward prospection of proteases with distinct properties.

Down-stream processing for bioethanol production and high-added value products

R. Papi[1], A. Moschona[2], D. A. Kyriakidis[1],
M. Liakopoulou - Kyriakides[2]
[1]*Chemistry*, [2]*Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Wine industries produce a vast amount of wastes such as grape pomace, lees and tartar. Their organic content consists of dissolved sugars, alcohol, acids, polyphenols, tannins and lignins. The need for specific winery waste management plans for production of added value products has been widely understood. Red and white grape pomaces from Gerovassiliou wine industry (Thessaloniki, Greece) were used in this study. Extraction of main constituents, polyphenols and sugars, was performed using chromatographic or/and selective biosorption techniques. Fractions enriched in sugars after removing the majority polyphenols, were fermented for ethanol production. Pretreatment of samples with cellulases (in suspension or immobilized in calcium alginate beads) was also performed prior to fermentations. *Saccharomyces cerevisiae* and a mutant strain of *Zymomonas mobilis* CP4, tolerant to sucrose up to 40% (w/v), were used to produce ethanol from the wine wastes supplemented with different salts. Results revealed that ethanol production from wine wastes fractions was promising with possible commercial interest.

Keywords: bioethanol, down-stream processing.

Dynamic processes in the heme-based transcription factors CooA and DNR

U. Liebl[1], L. Bouzhir-Sima[1], L. Lobato[1], J.-C. Lambry[1], M. H. Vos[1]
[1]*Laboratory of Optics and Biosciences, INSERM U696-CNRS UMR 7645, Ecole Polytechnique, Palaiseau, France*

A group of transcription factors is specifically activated by the binding of diatomic signaling molecules like carbon monoxide (CO), nitric oxide (NO) or dioxygen (O_2). These small gaseous ligands are selectively bound to a single heme-cofactor in a protein sensor domain. The presence or absence of the effector gas triggers a conformational change by which the protein passes from an inactive to an active state, ultimately leading to binding to target DNA and regulatory events. The bacterial transcription factors CooA[1] and DNR[2] are members of the CRP/FNR family. Both proteins contain a six-coordinate heme and are thought to undergo large and delocalized conformational changes upon binding of their physiological ligand. Purple bacterial CooA initiates the CO-dependent transcription of genes encoding the CO oxidation system, whereas the dissimilative nitrate respiration regulator DNR mediates NO-dependent induction of denitrification in the opportunistic pathogen *Pseudomonas aeruginosa*. We used biochemical approaches and advanced optical spectroscopy to investigate the mechanism and molecular pathways of the activation and deactivation of these gas-sensing transcription factors. Binding of CooA and DNR to their respective target DNA was studied by fluorescence anisotropy measurements and demonstrated that activation is highly specific for the physiological ligand. FRET measurements allowed direct determination of the distance between target DNA and the native heme, opening up the perspective of mapping out global protein conformational changes using time-resolved FRET techniques. Primary mechanistic processes in heme-based sensor proteins are initialized by ligand binding and dissociation from the heme[3]. Our ultrafast studies of ligand dynamics in the heme environment of wild type and mutant CooA proteins, combined with molecular modeling

© 2014 The Authors. FEBS Journal © 2014 FEBS

approaches, suggest a large conformational change of the protein backbone upon CO binding, involving a dramatic move of one heme-ligand. In DNR, NO recombination is very fast and nearly complete, revealing “NO-trapping” properties similar to what has been observed in other heme-based NO sensors and possibly providing means to control the effects of fast environmental fluctuations. The energetic barriers involved in CO migration have been determined in both transcription factors by temperature-dependence studies and compared to the five-coordinate heme sensor protein DosT and the electron transfer protein cytochrome *c*. The results will be discussed in the light of a general mechanism for ligand dynamics in heme-based sensor proteins.

Enzymatic dipeptide synthesis

T. Abe[1,2], Y. Hashimoto[2], Y. Zhuang[2], Y. Ge[2], T. Kumano[2], M. Kobayashi[2]
[1]*Division of Life Science and Engineering, School of Science and Engineering, Tokyo Denki University, Hatoyama,* [2]*Institute of Applied Biochemistry, and Graduate School of Life and Environmental Sciences, The University of Tsukuba, Tsukuba, Japan*

We previously reported an acyl-CoA synthetase, AcsA, which plays an essential role in acid utilization in the nitrile-degrative pathway of Pseudomonas chlororaphis B23 [1]. Acyl-CoA synthetase, which is one of the acid-thiol ligases, catalyzes the ligation of an acid with CoA in the presence of ATP and Mg^{2+}. The reaction mechanism and structures of acyl-CoA synthetase have been extensively investigated. During studies on the characterization of AcsA, however, we discovered a new reaction. When L-cysteine was used as the substrate instead of CoA, *N*-isobutyryl-L-cysteine was surprisingly detected as the reaction product [2]. This finding demonstrated that the enzyme formed a carbon-nitrogen bond involving the carboxyl group of the acid and the amino group of the L-cysteine, although the enzyme essentially catalyzes the formation of a carbon-sulfur bond. Furthermore, this unexpected enzyme activity was also observed for acetyl-CoA synthetase and firefly luciferase, both of which belong to the same superfamily of adenylate-forming enzymes. Therefore, all enzymes in this superfamily of adenylate-forming enzymes are likely to synthesize *N*-acyl-L-cysteine when L-cysteine is used as one of the substrates.

An adenylation domain of nonribosomal peptide synthetase (NRPS) also belongs to this superfamily of adenylate-forming enzymes. This domain is known to be responsible for the selective substrate recognition and formation of acyl-AMP as an intermediate under ATP consumption. Here, we found that N-aminoacyl-L-cysteine (dipeptide) was synthesized by a bacterial enzyme, which is homologous to the adenylation domain of NRPS. When the reaction mixture including the enzyme, ATP, an amino acid, and L-cysteine were analyzed by HPLC, a significant increase in AMP was observed. The increase in the amount of AMP with consumption of the amount of ATP indicates that the reaction proceeds. In addition, a new product peak other than that of AMP was detected by HPLC analysis. No other new peaks were detected. Without the enzyme, the peaks due to the new product and AMP were not detected. So, we purified and identified the product by LC-MS/MS and NMR analyses. The results of these analyses showed that the new product is not *S*-aminoacyl-L-cysteine but *N*-aminoacyl-L-cysteine (namely, dipeptide).

Expression and purification of proteoglycan-like domain of carbonic anhydrase IX in *Escherichia coli*

S. Stuchlík[1], Z. Levarski[1], V. Borčinová[1], I. Vidličková[1], J. Krahulec[1], J. Turna[1]
[1]*Department of Molecular Biology, Comenius Univ in Bratislava, Bratislava, Slovakia*

Carbonic anhydrase IX (CAIX) is a transmembrane enzyme expressed in some types of tumors. It is commonly used as a marker or a target for potential therapy using monoclonal antibodies, generated using intact enzyme, but recognizing the epitope located in the extracellular proteoglycan-like (PG) domain. Therefore, isolation of only this part of the enzyme could potentially increase the efficiency of production and improve properties of monoclonal antibodies against CAIX. In this work, we present the construction of an efficient *E.coli* based expression system capable of producing high levels of PG-domain fused to thioredoxin (Trx-PG) and its purification using affinity chromatography. The product was expressed in soluble form at levels reaching 25% of total cell proteins. Using two steps of affinity chromatography and enterokinase cleavage we have gained recombinant PG domain with sufficient purity for generation of monoclonal antibodies against CAIX.

This publication is the result of the projects implementation: “Centre of competence of R&D in molecular medicine” (ITMS 26240220071) and “University Science Park of Comenius Univ. in Bratislava” (ITMS 26240220086) supported by the Research and Development Operational Program funded by the ERDF.

Expression, localization and killing mode of yeast K2 toxin

J. Luksa[1], M. Podoliankaite[1], J. Urbonavicius[2], A. Sasnauskiene[2], S. Serva[2], E. Serviene[1]
[1]*Nature Research Centre,* [2]*Vilnius University, Vilnius, Lithuania*

Budding yeast produces four types of dsRNA virus-encoded killer toxins (K1, K2, K28, and Klus) capable of killing non-killer yeast as well as killer yeast of the different types. Despite some similarities in their mode of production, killer toxins have different biochemical properties and profoundly distinct modes of action. While K28 toxin primarily acts in the nucleus of the host cell interfering with gene expression, K1 and K2 are active at the cell wall where they ultimately disrupt the structural and/or functional integrity of the plasma membrane. Mode of action of the Klus toxin is not completely understood.

In this work we demonstrated that K2 killer toxin, when expressed either from dsRNA or cDNA, is found in secretion vesicles of yeast cells and in extracellular medium. We have shown that K2 cDNA containing yeast exhibited lower toxin expression level even under inducing conditions comparing to the

© 2014 The Authors. FEBS Journal © 2014 FEBS

dsRNA-conditioned synthesis. Based on *in vivo* analysis of toxin activity and detection of the K2 protein by the Western blot, we discovered that killer protein is secreted when the yeast were grown at different pH values, even non-permissive for toxin activity. By modifying the pH of the growth medium, we showed possibility to revert the compromised activity. In order to explore the killing mode of K2 toxin, we investigated the dynamics of K2 protein binding to the cell wall-localized receptors, evaluated the dependence of K2 binding and killing activities on the presence of different glucans *in vitro* and *in vivo*. We established that cytotoxic effect of the K2 toxin on the *S. cerevisiae* cells assert very quickly, when fast decline of living cell population occurs due to the toxin-induced damages.

Extracellular vesicles and development of resistance to fluoroquinolones in *Acholeplasma laidlawii*

E. S. Medvedeva[1], N. B. Baranova[1], T. Y. Grigoreva[1], A. A. Mouzykantov[1], M. N. Davydova[1], O. A. Chernova[1], V. M. Chernov[1]

[1]*Kazan Institute of Biochemistry and Biophysics, KazSC, RAS, Kazan, Russian Federation*

Acholeplasma laidlawii (class Mollicutes) is an ubiquitous mycoplasma found in the tissues of humans, animals and plants, the causative agent of phytomycoplasmoses and the major contaminant of cell cultures. Mycoplasmas quickly become resistant to antibiotics. Despite its low efficiency, antibiotic therapy remains the primary tool used for the treatment of mycoplasma infections and decontamination of cell cultures. The elucidation of the mechanisms of the rapid development of antibiotic resistance and solving the problem of control of mycoplasma infections are connected with the investigation of molecular-genetic mechanisms of mycoplasma adaptation to stress. In our studies the stress-reactive proteins and genes of *A. laidlawii* PG8 were first identified, and it was shown that adaptation of the mycoplasma to environment was associated with the secretion of extracellular vesicles. Recent studies suggest the possible involvement of vesicles in the development of resistance to antibiotics in bacteria, however, similar studies in mycoplasmas have not been conducted yet. Characterization of extracellular vesicles and elucidation of the possibility for its participation in the development of resistance to fluoroquinolones (ciprofloxacin) in *A. laidlawii* was the purpose of our work.

In our studies it was shown that the level of secretion of vesicles in strain *A. laidlawii* with higher level of resistance to ciprofloxacin was found to be significantly more than that in the original parent strain. The cells and vesicles of this strain contained mutant nucleotide sequences of the target gene of ciprofloxacin (*parC*), exported the antibiotic from cells and displayed bacteriostatic effect toward the ciprofloxacin-sensitive bacteria strain. As a result of a global proteome profiling of *A. laidlawii*-derived vesicles it was revealed that vesicles from the mycoplasma were enriched in virulence factors. Thus our study allow to conclude that development of resistance to ciprofloxacin in mycoplasmas turns out to be related to mutation in gene of DNA-gyrase, the secretion of extracellular vesicles which mediate export of DNA sequences coding the protein-target for antibiotics and the traffic of ciprofloxacin. The vesicle mediated export of DNA sequences coding the proteins-targets for ciprofloxacin may promote the distribution (in bacterial populations) mutant versions of the respective genes via lateral transfer. The obtained data may facilitate the development of effective approaches to control mycoplasma infections and the contamination of cell cultures.

Formation of chromosome in bacteria

B. Lafay[1], **O. Poirion**[2]

[1]*UMR5005-Laboratoire Ampère, CNRS,* [2]*CNRS UMR5005-Laboratoire Ampère, École Centrale de Lyon, Écully, France*

The genome of bacteria is classically separated into the essential, stable and slow evolving chromosomes and the accessory, mobile and rapidly evolving plasmids. This paradigm is being questioned since the discovery of extra-chromosomal essential replicons (EER), be they called "megaplasmids", "secondary chromosomes" or "chromids". These genomic elements are thought to be indispensable based on their having a GC content identical to that of the chromosome and harboring essential genes, but plasmidic in origin because of the structure of their replication origin. However, none of these criteria are universally applicable and the true nature of these replicons is yet to be formally determined. Here, we explore the relationships of chromosomes and plasmids with reference to their genetic information inheritance systems (GIIS), under the assumption that the inheritance of EERs is integrated to the cell cycle and highly constrained in contrast to that of standard plasmids.

We performed a global comparative genomic analysis including all bacterial complete genome sequences available in NCBI RefSeq. Using ACLAME and KEGG GIIS-related proteins as input, we first identified GIIS functional homologs from all bacterial genomes. These homologs were then clustered according to function and sequences homology. The relationships between all bacterial replicons were then investigated using the GIIS clusters as parameters and unsupervised analyses (projections and graphs, and clustering. Finally, identification of putative EERs and of trends in GIIS usage were performed using supervised analyses (classification, regression).

This strategy clearly discriminated between chromosomes and plasmids with respect to their GIIS usage, and revealed another class of genomic elements that corresponds to EER-annotated replicons. They are characterized by a specific GIIS usage that testifies of the continuity of the genomic material in bacteria. Furthermore, whereas some are plasmidic in origin, others derive from the cleavage of an ancestral chromosome. Our study provides insights into the formation of "neo-chromosomes" and the

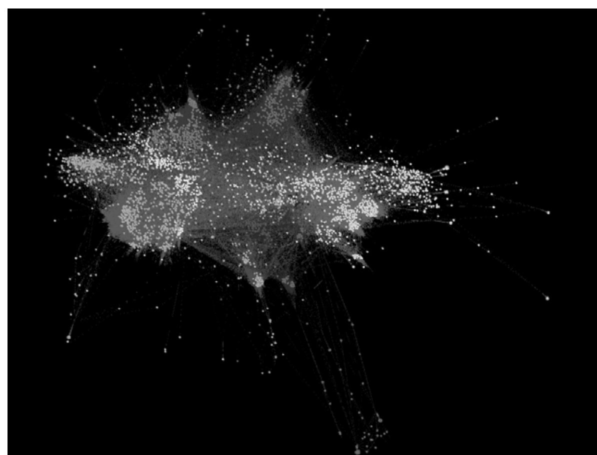

Fig. 1.

Functional characterization of *Zymomonas mobilis* polyphosphate kinase 2 (PPK2); implications for polyphosphate and nucleotide metabolism

B. Lu[1], M. Kotaka[2], R. Watt[1]
[1]*Oral Biosciences, The University of Hong Kong,* [2]*School of Life Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Inorganic polyphosphate (poly-P) is a linear biopolymer comprised of tens to hundreds of phosphate monomers. Poly-P plays a variety of important physiological roles in all living organisms; for example, helping microbial cells survive and adapt to external stresses. Type 2 polyphosphate kinase (PPK2) enzymes are encoded in a wide variety of bacterial organisms. General consensus is the primary function of PPK2 proteins is to catalyze the phosphorylation of nucleotide monophosphate (NMP) or nucleotide diphosphate (NDP) substrates using polyphosphate as the phosphate donor. However, PPK2 proteins are diverse, and their full range of functions remains to be determined. Here, we report the biochemical characterization of the PPK2 homologue encoded by the ethanol-producing bacterium *Zymomonas mobilis* (ZM-PPK2). The ZZ6_0566 gene from *Zymomonas mobilis* subsp. *mobilis* ATCC 29191, which encodes a putative one-domain PPK2 protein of 261 amino acids, was cloned and overexpressed in *Escherichia coli*. Size exclusion chromatography indicated that the purified recombinant ZM-PPK2 protein adopts a stable tetrameric arrangement in solution. Its substrate range and biochemical activities were determined by analyzing reaction mixtures containing different nucleotide substrates using chromatography and gel-based approaches; in conjunction with fluorometric and spectrophotometric assays. Results indicated that purine 5′-monophosphates, e.g. AMP and GMP were efficiently phosphorylated to the corresponding 5′-diphosphates using poly-P as the phosphate donor. Pyrimidine 5′-monophosphates e.g. UMP were not utilized. To a lesser extent, ZM-PPK2 also catalyzed the transfer of phosphate units from poly-P to GDP to form GTP; but did not utilize ADP. Medium and long chain length poly-P substrates were utilized more effectively than short chain lengths, and the reverse reactions (i.e. polyphosphate synthesis) were not catalyzed to notable levels. Mg(II) or Mn(II) ions were essentially required and the activity of ZM-PPK2 displayed a broad pH optimum (pH 6.8 to 8.8). Studies are ongoing to establish its biological functions. In conclusion, our preliminary results suggest that the primary function of ZM-PPK2 is to utilize medium to long chain polyphosphate for the synthesis of GDP and ADP nucleotides.

WED-131
Functional gene responses in a perfect world – can we trust quantification of transcripts in soil in response to manmade chemicals?

C. S. Jacobsen[1], J. Bælum[2]
[1]*Geochemistry, Geological Survey of Denmark and Greenland, Copenhagen,* [2]*Technical University of Denmark, Lyngby, Denmark*

Analyzing environmental relevant microbial processes in situ is extremely challenging. Nucleic acid based studies are becoming more and more popular, but pitfalls exist and should be taken into account. In a perfect world we would know the genes involved, we would know the expression pattern, we would know the mRNA degradation rate, we would know the nucleic acid extraction biases, we would trust our DNase treatment, reverse transcriptase reaction and the quantitative PCR. Does the perfect world exist?

In a less perfect world the functional genes might not be known – or at least only some of them are known. Such a scenario might be when searching for *tfd*A degradation genes for modern herbicides in a soil originating from below a burial mound that has been isolated from the surrounding environment for more than 5000 year.

Another less perfect world would be RNA/DNA extraction from inorganic clay sediments – in this scenario the problem is that when cells are lysed in the nucleic acid extraction procedure the nucleic acids sticks to the clay due to the phosphate backbone. However, using an optimized RNA/DNA extraction protocol including the patented G2 blocking solution, we were able to obtain high-resolution expression profiles of the functional reductive dehalogenase genes *bvcA* and *vcrA* during two consecutive dechlorination events of trichlorethene (TCE), *cis*-dichlorethene (*cis*-DCE) and vinyl chloride (VC) in a clay subsurface environment. Up-regulation of the *bvcA* (for the biostimulated microcosms) and *vcrA* (for the bioaugmented microcosms) gene expression fitted well with high rates of dechlorination of VC, while no known transcripts could be measured during TCE and *cis*-DCE dechlorination. But is this trustable?

What is needed to further establish quantitative transcript based analysis of functional genes in environmental samples? – will we be able to adapt rules for gene expression as used in mammalian cells? Should a housekeeping gene be used for validation? – if so which?

Gene analysis of all two-component systems of *Thermus thermophilus* HB8 and their molecular cross-talk

P. Resvani[1], M. Zisi[1], L. Vasilikos[1], S. Theofanous[1], R. Papi[1], D. A. Kyriakidis[1]
[1]*Chemistry, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Bacterial proliferation and adaptation are governed by sophisticated signal transduction networks, including the versatile two-component systems (TCSs) that comprise sensor histidine kinases and response regulators and rely on phosphotransfer to exert their molecular function. Based on the comparative study of several databases involving genome and protein family domain annotations and that the complete genome of *Thermus thermophilus* HB8 has been sequenced, 11 HKs and 14 RRs were identified. The genes of all TCSs are located on the bacterial chromosome except for a cognate pair that is found on the pTT27 megaplasmid. For the functional characterization of all TCSs *in vitro* and the related phosphatases, the full-length coding sequences of the 14 RRs, 11 HKs and 2 protein phosphatases near to the TCSs, were amplified. Each amplified sequence was cloned into pET-29c vector and the overexpressed proteins were purified by affinity metal chromatography. Results from *in vitro* phosphorylation assays revealed the communication of the cognate pairs, as well as other intense interactions indicating the cross-talk between the non-cognate components. The biochemical and molecular exploration or new cellular functions in *T. thermophilus,* in which the TCSs participate to the bacterial signaling or to other mechanisms, remains to be elucidated.

Keywords: cell signaling, thermophiles,, two component systems.

Genetic variability of *Listeria monocytogenes* strains persisting in food processing plants

H. Drahovska[1], J. Minarovicova[2], A. Veghova[2], E. Kaclikova[2]
[1]Molecular Biology, Comenius University, [2]Microbiology and Molecular Biology, Food Research Institute, Bratislava, Slovakia

Listeria monocytogenes is opportunistic foodborne bacterial pathogen that represents an important hazard to human health because it is capable of causing listeriosis mainly in newborns, elderly, immuno-compromised individuals, and pregnant women. Contamination of food products could be the be the result of *L. monocytogenes* persistence in the food processing plant.

In the present study, genetic variability of *L. monocytogenes* strains from meat processing plant were studied. Total amount of 33 *L. monocytogenes* strains were isolated from different places of food production plant, from food contact and non-food contact surfaces as well as raw materials, semiproducts and final products, during half-year sampling in years 2011–2014.

Identity of isolates was analyzed by PFGE, PCR-serotyping and MLST. Seven different PFGE profiles and three different serovars were distinguished, with preference contribution to PFGE profile 2 (21 %) and profile 9 (21 %) and serovar 1/2a (34 %), followed by serovar 1/2c (21 %) and 4b (21 %). While *L. monocytogenes* PFGE profile 2 strains were obtained regularly during whole sampling period, strains with profile 9 were isolated only since 2013 and repeatedly from three subsequent samplings. Our results emphasize the importance of environmental monitoring to identify potential contamination sources and transmission routes, particularly of *L. monocytogenes* persistent strains in food production chain.

Keywords: bacteria, Listeria, pathogen

Genomic footprints of domestication in cheese-making fungi

R. C. Rodríguez de la Vega[1,2], J. Ropars[1,2], J. Gouzy[3,4], A. Branca[1,2], T. Giraud[1,2]
[1]Genetique et Ecologie Evolutives, ESE, Universite Paris-Sud, [2]UMR8079, CNRS, Orsay, [3]LIPM UMR441, INRA, [4]LIPM UMR2594, CNRS, Castanet-Tolosan, France

Domestication is an evolutionary process studied since Darwin times as a model of rapid selection and diversification. Much insight has been gained from the study of domesticated plants and animals, both on the type of genes under selection during phenotypic and molecular evolution, and on the genomic architecture of adaptation. The process of domestication has been much less studied in eukaryote microorganisms than in plants or animals. Domesticated fungi, such as the ones used for cheese production, represent ideal eukaryote models for studying the evolutionary processes involved in domestication. The bacteria and fungi used for producing cheese are amongst the earliest human domesticated micro-organisms, their evolutionary histories have been shaped by the strong selection imposed by growing in a nutrient-rich media. This selection implies some adaptation of cheese-making fungi to a novel, human-made, environment with many potential competitors, thus providing a good model for studying several aspects of rapid eukaryotic evolution. In this study, we compared the whole genome sequences of two fungal species widely used for the production of mold-ripened cheeses (*Penicillium roqueforti* and *P. camemberti*), with those of other three publicly available (*P. chrysogenum*, *P. rubens* and *P. digitatum*) plus five newly sequenced non cheese-making species from the same genus (*P. nalgiovense*, *P. biforme*, *P. fuscoglaucum*, *P. paneum* and *P. carneum*). Seven of these species are known to occur in the cheese environment, either as desired or contaminant species. We compared the whole genomes of the ten species in order to elucidate the genomic processes involved in the domestication of the cheese-making Penicillium and in the adaptation to the cheese substrate. For this goal, we looked for gene gains and gene losses, gene family expansions and genes showing cheese-making specific selection regimes. We also investigated the content and insertion sites of Transposable Elements (TE). In the end, we revealed that TE-mediated genomic events and gene family expansions have been crucial processes of adaptation as mechanisms allowing rapid acquisitions of novel functions while fine tuning of preexisting functions also occurred via amino-acid substitutions.

Growth inhibition of Cronobacter in reconstituted infant milk formula using cocktail of T4-like and T7-like bacteriophages and antimicrobial human cathelicidin LL-37

M. Kajsík[1], L. Oslanecová[1], C. Toth[1], J. Krahulec[1], S. Stuchlik[1], J. Turna[1], H. Drahovska[1]
[1]Department of Molecular biology, Comenius University in Bratislava, Bratislava, Slovakia

Cronobacter is a foodborne pathogen responsible for infections in neonates. Powered infant milk formula has been implicated as the vehicle of transmission. Bacteriophages can be used as perspective biocontrol agents against food contamination by these pathogens. The human antimicrobial peptide LL-37 of the cathelicidin family is a host defense molecule and a potent killer of different microorganisms. The aim of the present study was to determine efficiency of *Cronobacter* inactivation in reconstituted infant milk formula by new isolated bacteriophages and to observe synergism between bacteriophages and the antimicrobial peptide. Phage and cathelicidin inhibition of bacterial growth was measured in LB medium and in reconstituted infant milk formula. Different strains belonging to *C. sakazakii, C. turicensis* and *C. dublinensis* were used. Bacterial lysis in LB was measured by spectrophotometry, growth of bacteria in reconstituted milk was determined by colony counting. Bacteriophages used in experiments were isolated from waste water. According to the genome sequences they belonged to T4-like group of *Myoviridae* (Dev-CS-701 and Pet1) and to T7-like and KMV-like groups of *Autographivirinae* (Dev2, Dev-CD-23823 and Dev-CT-57). We observed that application of individual phages decreased numbers of *Cronobacter* cells in reconstituted infant formula and the highest reduction was obtained with Dev-CS-701 and Dev-CT-57 phages. By using high initial phage concentrations (10^8 PFU/ml) numbers of *Cronobacter* strains decreased under detection limit after 4–6 hours of cultivation. However, lowering phage concentration to 10^4 PFU/ml caused overgrowth of resistant bacteria in later periods of time. Application of mixture consisting of all phages showed the highest efficiency as it eliminated bacteria in both high and low phage concentrations. In further experiments the recombinant cathelicidin LL-37 expressed in *E. coli* system was employed to enhance the inhibition effect of phages. Cathelicidin LL-37 alone caused inhibition on bacterial growth in first two hours, but regrowth of the culture occurred after prolonged cultivation. Addition of LL-37 to phage treatment further decreased bacterial numbers in the range 1–2 log comparing to

the phage alone experiment. Synergic effect of phages and antimicrobial peptides could be therefore used in food protection measurements.

Keywords: bacteriophage, food safety

Gut microbiome in inflammatory bowel disease patients with and without arthropathy

J. Kabeerdoss[1], S. Pugazhendhi, A. Balekuderu, D. Prabavathi, R. Goel, D. Danda, B. S. Ramakrishna
[1]*Department of Clinical Immunology and Rheumatology, Christian Medical College, Vellore, India*

Introduction: Inflammatory bowel disease (IBD) is considered to result from an abnormal innate immune response elicited by components of the gut microbiota in genetically predisposed individuals. The gut microbiota shows alterations (dysbiosis) in IBD. Joint disease or arthropathy occurs in IBD. We hypothesized that the gut microbial alterations in IBD patients would be different in those with arthropathy compared to those without arthropathy.
Objective: To compare gut microbial phylotypes in IBD patients with and without arthropathy.
Methods: IBD patients were recruited from outpatient departments of Christian Medical College from January 2007 to March 2009. Clinical details, laboratory results, and severity of joint involvement (by rheumatologist, RG & DD) were entered into structured forms. Patients who had received antibiotics in the 60 days prior to study were excluded. This study was approved by Institutional research board. Fresh samples of stool were collected, DNA extracted and DNA libraries prepared using primers targeting hypervariable regions (HVR) 3 and 4 of the 16S rRNA gene using multiplex identifier sequence tags. The DNA libraries were sequenced in a 454 sequencing platform. The metagenomic diversity and phylogenetic analysis was assessed using the MG-RAST pipeline. Taxonomic comparison of bacteria between the groups was performed using Kruskal-Wallis test and pairwise Wilcoxon test in linear discriminate analysis effect size (LEfSe) program.

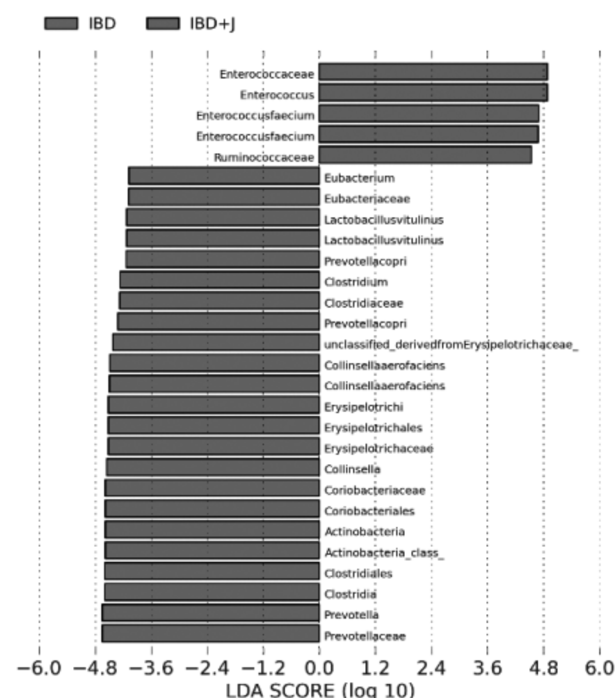

Fig. 1.

Results: Twenty four IBD patients (12 with and 12 without arthropathy) were recruited for study. Arthropathy patients included five each with isolated axial and peripheral and 2 with mixed type of joint involvement. A total of 800,968 reads were generated for the current study. The median read count of the samples was 24,884 (range 17,774–48,477). Alpha (Shannon) diversity index was significantly different between the groups (21.7 ± 4.4 Vs 38.41 ± 4.1; $p < 0.05$) with significantly higher diversity in IBD with arthropathy. The taxonomic comparison between the groups revealed that statistically significant differences in the microbial phylotypes were noted from Class to Strain levels. The important observation noted in the study that *Enterococcaceae, Enterococcus* and *Enterococcus faecium* were increased in IBD with arthropathy compared to IBD without arthropathy (Figure).
Conclusion: An increase in the abundance of *Enterococcus* and its species in the faeces differentiated IBD patients with arthropathy from those without arthropathy. Enterococcus may be relevant to the pathogenesis of arthropathy in IBD.

HicA3-HicB3, a novel toxin-antitoxin system of *Yersinia pestis*

S. Bibi-Triki[1,2,3,4,5], I. Li de la Sierra-Gallay[6], N. Lazar[6], A. Leroy[7], H. Van Tilbeurgh[6], F. Sebbane[1,2,3,4,5], E. Pradel[1,2,3,4,5]
[1]*Equipe Peste et Yersinia pestis, INSERM U1019,* [2]*CNRS UMR 8204,* [3]*Centre d'Infection et d'Immunité de Lille, Institut Pasteur de Lille,* [4]*Université Lille Nord de France,* [5]*Université Droit et Santé, Lille,* [6]*Equipe Fonction et Architecture des Assemblages MacroMoléculaires, CNRS UMR 8619, Orsay,* [7]*EA 4529, Châtenay-Malabry, France*

Toxin-antitoxin systems (TASs) are widespread in bacteria. They are encoded by bicistronic operons born on plasmids or on the chromosome. In type II TASs, the toxin and antitoxin are both small cytoplasmic proteins. The toxin is usually stable and targets essential cellular processes such as replication, translation and cell division. The antitoxin is unstable and has a double function: it represses the TA operon promoter and neutralizes the toxin by direct binding. Under normal growth conditions, the level of expression of a TA operon is low due to autorepression by the antitoxin or the TA complex. Under stress conditions, the antitoxin is degraded by cellular proteases, the TA promoter is derepressed, and the toxin is then free to poison the cell. TASs have multiple roles including stabilization of mobile elements, biofilm formation, bacterial persistence or virulence.

In previous research, we found that a *Yersinia pestis* mutant lacking the HicB3 protein was attenuated for virulence in a murine model of bubonic plague. It had been suggested that HicB3 was an orphan antitoxin. Here, using biochemical and mutagenesis-based approaches, we identified the partner of the HicB3 antitoxin that we called HicA3. We demonstrated that the HicA3 toxin is an RNase with a catalytic histidine residue and that HicB3 neutralizes HicA3. In addition, HicB3 binds to two operators in the *hicA3B3* promoter region to repress the transcription of the *hicA3B3* operon. Thus, HicA3-HicB3 constitutes a new functional TAS of *Y. pestis*. We solved the X-ray structures of the HicB3 antitoxin and of the HicA3-HicB3 complex. HicB3 forms tetramers which can bind two HicA3 toxin molecules. The HicA3 RNase is monomeric and folds as a double-stranded RNA-binding domain. HicB3 occludes the HicA3 active site via its N-terminal domain, while its C-terminal domain folds as a Ribbon-Helix-Helix (RHH) DNA binding motif.

Identification and characterization of plant cell wall degrading enzymes from analyses of genomic libraries of *Bjerkandera* adusta

R. A. Batista Garcia[1], L. I. Cuervo Soto[1], C. Martínez Anaya[2], J. L. Folch Mallol[3]
[1]Faculty of Science, Autonomous University State Morelos (Mexico), [2]Biotechnology Institute, Nacional Autonomous University of Mexico, [3]Biotechnology Research Center, Autonomous University State Morelos (Mexico), Cuernavaca, Mexico

The use of lignocellulosic biomass as raw material in various industrial processes, has received much interest. Among the enzymes that degrade biomass, which are produced by different organisms, carbohydrate esterases (CE) and xilanases (Xil) are required for complete degradation of plant material. Hemicellulose shows modifications (presence of acetyl groups) that may be eliminated by the CE. In addition, Xil catalyse the depolymerisation of hemicellulose, being this an essential step for the conversion of lignocellulosic biomass. *Bjerkandera* is a genus that groups several Bacidiomycetes causing white rot of wood, and their enzymes have great potential for biotechnology applications. Performing an analysis of sequences from a cDNA library of *Bjerkandera* grown in the presence of crude oil, sequences with similarity to CE and Xil were found. Knowing the roles of these proteins, it will be interesting to characterize and express these genes in a heterologous system, allowing us to characterize biochemically. To predict the size of the transcript, Northern blot was performed, and full genomic and cDNA sequences were obtained using G.Walker and RLM-RACE kit, respectively. The cDNA was cloned into the pPICZ-αA vector, for expression in *P. pastoris* and the transformant strains was analysed. The complete gene for CE has an ORF of 470 aa and high identity with family 4 CE. The protein was partially characterized and shows a temperature and a pH optimum of 28°C and 6.0 respectively, and the substrate specificity was better for the 2-naphthyl acetate and 4-ethyl-p-Nitrophenol as compared to other substrates tested. Acetic acid release was measured from natural substrates, confirming the activity of deacetylase. These results correlate with the possible function of the protein predicted by in silico analysis. On the other hand, characterization of a Xyl gene demonstrated that this sequence was incomplete. Genome Walker and 5′RACE allowed progress in sequence from genomic DNA and cDNA. The sequence of the gene from genomic DNA is comprised of 1500 bp. Blastx with this sequence showed homology with fungal glycosyl hydrolases. Currently, we are working on the cloning and expression of this gene in *P. pastoris*, for the subsequent functional characterization of the enzyme. This study demonstrates that the application of genomic tools for characterization of new genes is a novel approach to study the physiology of poorly characterized organisms.

Improved baculovirus vector as high-productive expression system for developing a subunit vaccine against influenza

E. Guijarro-Pardo[1], S. Gómez-Sebastián[2], M.-P. Susana[2], E. Jose M[1]
[1]Biotechnology, INIA, [2]I+D, ALGENEX S.L., MADRID, Spain

Influeza virus causes morbility and mortality every year due to its high rate of mutation capacity. Production systems currently used for egg-based vaccines are time-consuming and expensive; thus, they would not be the best option neither in a possible pandemic situation nor in a seasonal-repetitive campaign of vaccination. So that, developing a fast, reliable and low-cost production system for facing this economical important disease has a high relevance. Recombinant vaccines are good candidates, moreover when these are producing using cost-cutting technologies such as baculovirus expression system (BEVS). Lately, this system has risen up as a trustable and quick approach to produce high yield of recombinant proteins. However, the lytic nature of this system implies baculoviral-infected cells undergoing to a severe cytopathic effect that usually ends in degradation of the expressed protein, interfering in its quantity as well as its quality. A recently described improved baculovirus expression vector (TOPBAC®) is characterized in this work as an alternative to overcome this bottleneck to produce the globular domains (aa 18-529) of hemagglutinin (HA) protein from mouse-adapted H1N1/PR/8/34/Pto Rico influenza virus. This vector has been previously described in our laboratory as a new vector that is able to minimize cytopathic effect and improve recombinant protein production rates. In the present research, we have compared the expression levels of this protein using the TOPBAC ® or a conventional expression vector in *Sf*9-suspension culture assays. Moreover, we have used two approaches for the improvement of the protein's folding pattern: the use of the signal peptide melittin (Mel), which facilitated an efficient secretory pathway in insects, or the endoplasmic reticulum retention signal (KDEL), that had been used before in other productive models to increase recombinant protein production. The results have shown a reduced cytopathic effect in TOPBAC® infected suspension cultures compared to those infected with the conventional vector and an improvement of the secreted protein yield: considering the best production conditions, increments of 1.2 times (in the case of the melittin version) and up to 4.5 times (in the case of KDEL option) have been achieved in supernatant fractions when TOPBAC® vector was used. Also, increments of around 2 times were observed in total protein production (supernatant plus intracellular fractions yields) in the case of KDEL signaling. In conclusion, this alternative system would allow a fast production of more vaccine doses at lower costs, giving an attractive and feasible technology to fight seasonal and, even, a pandemic, influenza attack.

Lactococcus lactis, a new bacterial factory for functional expression of membrane proteins

S. Bakari[1], D. Seigneurin-Berny[2], F. André[1], M. Delaforge[1], D. Werck-Reichhart[3], N. Rolland[2], A. Frelet-Barrand[1]
[1]SB2SM UMR 8221 CNRS/LSOD, CEA SACLAY/IBITEC-S, Gif sur Yvette, [2]CNRS, Laboratoire de Physiologie Cellulaire et Végétale, UMR5168, Grenoble, [3]Institut de Biologie Moléculaire des Plantes, UPR 2357 du CNRS, IBMP, Strasbourg, France

In spite of the functional and biotechnological importance of membrane proteins, their study remains difficult due to their hydrophobicity and relatively low abundance in the cells. Moreover, in the well-known heterologous systems, these proteins are often produced at very low rates, often toxic and/or not correctly folded. In the last decade, *Lactococcus lactis*, a Gram-positive lactic bacterium, proved to be a valuable alternative system for functional expression of MPs. This bacterium, traditionally used in food fermentation, is now largely used in biotechnology for large-scale production of functional prokaryotic and eukaryotic MPs from diverse origins and functions. Initially, several yeast mitochondrial carriers were successfully expressed in a functional

© 2014 The Authors. FEBS Journal © 2014 FEBS

state. Then, both prokaryotic and eukaryotic ABC transporters could be expressed and characterized in their structural and functional manner. More recently, four chloroplast MPs of *Arabidopsis thaliana* tested could be produced at levels compatible with further biochemical analyses (1,2). Processes of solubilization and purification could also be developed and several proteins were active (1,3). Interestingly, few human proteins were expressed in active forms in this system (4, unpublished data). These recent data suggest that *L. lactis* can be an attractive system for effective and functional production of difficult membrane proteins.

LC-MS analysis of antimicrobial peptides from *Lactobacillus plantarum* 8PA-3

A. V. Soboleva[1], A. Kolobov[1], L. Leonova[1], T. Grishina[1]
[1]*Faculty of Biology, department of Biochemistry, Saint-Petersburg State University, Saint-Petersburg, Russian Federation*

Fighting against pathogenic microorganisms is very essential nowadays. Bacreriocins – bacterial antimicrobial proteins and peptides can be considered as potential antimicrobial and antifungal agents which regulate bacterial population growth and provide colonization stability of human body. Sequencing of genome of commercial probiotic strain *Lactobacillus plantarum* 8PA-3 found a locus that can be responsible for synthesis of two bacteriocins EF and NC8.

The mostly potent against standard test-cultures strain L. plantarum 8PA-3 was chosen for purification and characterization of antimicrobial peptides. Peptides were extracted from culture using 5% acetic acid and afterwards were ultrafiltrated through 10 kDa and 1 kDa membranes. Fractionation of peptides were performed using cation-exchnge chromatography on CM-sephadex G25 column and RP-HPLC on Discovery HS C18 column on ÄKTAexplorer 10S instrument. For testing antimicrobial activity of peptide fractions were used radial diffusion and overlay methods. Molecular weights of fraction's components were calculated using LC-Q-TOF instrument Agilent Tehnologies (LC-1260, MS-6538 UHD Accurate-Mass Q-TOF).

During LC-MS analysis of mostly active fraction of peptides (molecular weights 1 - 10 kDa) were found a lot of single-charged components of culture medium MRS (m/z 300n - 750) and some peptides with MW: 2946,7 Da; 3784,2 Da; 3883,9 Da; 3896,2 Da; 3900,0 Da; 4611,1 Da; 5454,9 Da and 6280,4 Da.

Despite of strong antimicrobial activity of low molecular weight peptides fraction from Lactobacillus plantarum 8PA-3 MW of characterized using LS-MS peptides don't mach to MW of predicted bacteriocins.

Work was made within the terms of SRW (scientific research work) SPbSU Ф-№0.37.123.2011 "Morphophysiological and biochemical aspects of bacteriocins antimicrobial action".

Keywords: bacteriocins, Lactobacillus plantarum, antimicrobial peptides.

[2]*Biochemistry and Molecular Biology, University of Goiás, Goiania, Brazil*

Acid phosphatase (ACP) is a hydrolase that converts organic phosphate into a soluble inorganic form by monoester phosphate hydrolysis and transphosphorylation reactions. It has been found in seeds and roots of the plants; kidneys, prostate, bones; in mycelia and secretions of microorganisms, presenting different physiological activities. These enzymes have been applied in clinical diagnostic and remediation processes recycling organic phosphate. *Trichoderma harzianum* is a saprophytic fungus worldwide known as a biological control agent, able to produce hydrolytic enzymes of economic interest. In this work we purified, sequenced and identified a new acid phosphatase from *T. harzianum*. The PCR and RT-PCR assays was done and the genomic DNA was analyzed (gene and Open Reading Frame) by Sanger sequencing. The crude extract was obtained from culture of spores previously inoculated in minimum medium 1.5% glucose and 20-fold concentrated by ultrafiltration. The protein was purified by molecular exclusion chromatography on a Superdex 200 column using FPLC facility (GE Healthcare) in 0.15 M sodium acetate pH 4.8. The identification of the enzyme was carried out based on amino acid sequence of seven peptides, obtained from the protein hydrolyzed with trypsin, using MALDI-TOF/TOF spectrometry and compared to those sequences from GenBank. Enzyme production was 11.33 ± 0.10 U/mg and molecular weight of 95 kDa. A broad substrate specificity was observed for this enzyme, specifically glucose 1-phosphate, phenylphosphate and phytic acid. The optimum pH and temperature were estimated in 3.8 and 65°C, respectively, using pNP-P substrate. The peptides sequences are similar to phytase of *T. harzianum*, histidine acid phytase of *T. pleuroticola* and a protein of *T. virens*. The RT-PCR assays revealed high expression in medium containing only glucose as a carbon source. Semi-quantitative PCR fragments were amplified containing gene with five introns and ORF with signal peptide of 21 amino acids. Genomic DNA was sequenced and compared with those described in JGI. It presented some differences considering the *T. harzianum* strain. Taken together, the sequence analysis of peptides and biochemical features and sequencing genes allow to conclude that the purified protein is a bifunctional enzyme belonging to the acid phosphatase and phytase families.

demic is still a crucial problem of the society. In spite of the fact, that chemotherapeutic approaches have already been known for 50 years, one third of population carries tuberculosis infection in a latent state, being in a constant risk of transformation of the latent disease into the active form. Few years ago in our lab a protein Rpf (Resuscitation promoting factor), that stimulates reactivation of the "non-culturable" mycobacteria (incl. *M. tuberculosis*) into the active state was discovered. It had been proven, that Rpf possess enzymatic activity, namely – peptidoglycanhydrolase. But then the question arises how both activities - resuscitation and enzymatic are bound together. We supposed first, that low-molecular weight metabolites oligosaccharide-oligopeptides might be released in milieu as a result of peptidoglycan Rpf hydrolysis. These products presumably could serve as a signal directly toward the cell and the other surrounding cells. Though, it is still unclear, which compounds are being released under peptidoglycan Rpf treatment and which of them directly induce reactivation. In the current study we demonstrated the ability of Rpf to hydrolyze mycobacterial cell wall peptidoglycan, and it has been shown that, as low molecular weight as well as high molecular weight products were able to stimulate resuscitation of the dormant mycobacteria. High molecular weight products, as a matter of fact, served as a substrate for Rpf, with subsequent release of the products with the lower molecular mass. We identified, that the end product of mycobacterial PG joint degradation by Rpf with endopeptidase RipA (resuscitation promoting factor interacting protein) is N-acetylglucosaminyl – (ß1→4)-N-glycolyl-1,6-anhydromuramyl-L-alanyl-D-glutamin. Comparison of the resuscitation activity of some synthetic muropeptide-derivates allowed us to suggest, that disaccharide-dipeptide is a key molecule, triggering resuscitation process.

Mycobacterial cell wall components – oligosaccharide-oligopeptides – are resuscitation inducers of the dormant mycobacteria

Nanoparticle-based paper biosensors for visual detection of infectious diseases pathogens

D. Toubanaki[1], M. Margaroni[1], E. Athanasiou[1], E. Karagouni[1]
[1]Microbiology, Hellenic Pasteur Institute, Athens, Greece

Paper-based sensing has emerged as an attractive analytical platform for pathogen diagnostics. Lateral flow paper biosensors (LFB) are optimal for accurate, rapid and sensitive analysis in research laboratory setups, but they have the potential to be used for field analysis. Especially the use of functionalized nanoparticles, as recognition labels has accelerated nucleic acids/ proteins sensing by LFBs, by increasing their sensitivity and specificity. LFBs are important for diagnostic purposes, such as to ascertain presence of infectious diseases, contamination with pathogens including biowarfare agents and presence of toxic compounds in food or the environment. Aim of the present study was to develop novel LFBs utilizing Au nanoparticles conjugated with specific antibodies or oligonucleotides for virus or parasite detection. Since aquaculture is one of the most important sectors of Greek and European economies with great environmental implications, we focused on viral nervous necrosis virus (VNNV) or Nodavirus; however adaptation of the proposed LFB for other viruses is feasible. In brief, Nodavirus particles were isolated from infected fish samples and applied on the LFB or mixed with specific polyclonal anti-Nodavirus antibodies before application. Specific anti-Nodavirus monoclonal or polyclonal antibodies were immobilized on the LFBs membrane, where antibody-conjugated Au NPs were also deposited. A red test line was formed when Nodavirus particles were present. The visual detection was completed within 30 min. In parallel, a lateral flow biosensor was developed for the parasite Leishmania detection. Infectious diseases caused by Leishmania affect humans with high killing rates in developing countries, but they also affect dogs, which are their main animal reservoirs. In this case, total DNA, isolated from canine samples was subjected to PCR amplification. The PCR products were mixed with specific oligonucleotide probe and applied next to oligonucleotide or antibody conjugated Au NPs. A red test line was formed when Leishmania product was present. The visual detection was completed within 20 min. Apart contributions on basic research, the proposed biosensors offer great potential for commercial kit development. This fact will have great impact on environmental safety and disease monitoring without time consuming and costly procedures.

Novel nano-coating surfaces based on hydrophobic polymers and phytostructures prepared by MAPLE with increased resistance to microbial colonization

A. M. Grumezescu[1], E. Andronescu[1], V. Grumezescu[1], A. Ficai[1], G. Socol[2], F. Iordache[3], A. M. Holban[4]

[1]Department of Science and Engineering of Oxide Materials and Nanomaterials, Faculty of Applied Chemistry and Materials Science, Politehnica University of Bucharest, Bucharest, [2]Lasers Department, National Institute for Lasers, Plasma & Radiation Physics, Magurele, [3]Department of Fetal and Adult Stem Cell Therapy, Institute of Cellular Biology and Pathology of Romanian Academy, "Nicolae Simionescu", [4]Microbiology Immunology Department, Faculty of Biology, University of Bucharest, Bucharest, Romania

In recent years antibiotic resistant infections emerged and many Gram-positive and Gram-negative bacterial strains represents one of the major health and survival threats for hospital environment. This study reports novel surfaces based on hydrophobic polymers e.g. poly(lactic-co-glycolic acid), poly(lactic acid) and essential oils/phytostructures prepared by matrix assisted pulsed laser evaporation (MAPLE), to be used as anti-adherent coating for medical surfaces, in order to improve their resistance to microbial colonization and biofilm formation. The prepared surfaces were characterized by Transmision Electron Microscopy (TEM), Scanning Electron Microscopy (SEM), X-Ray Diffraction (XRD), Differential Thermal Analysis (DTA) and Infrared Microscopy (IRM). Microbial biofilms developed by the tested Gram-positive (*Staphylococcus aureus*) and Gram-negative (*Escherichia coli*) microbial strains were analyzed using SEM and culture-based assays for up to 3 days of incubation at 37°C, in order to establish the biofilm dynamic in different experimental conditions. *In vitro* citotoxicity was evaluated by the qualitative and quantitative analysis of the phenotypic changes of the treated eukaryotic cells up to 5 days, using flow cytomertry and MTT assay. *In vivo* biocompatibility was established by using a balb C mouse model, treated for up to 14 days with standardized suspensions of the tested bioactive nanostructures. SEM micrographs revealed uniform morphologies of the prepared coatings, while IRM proved the functional groups integrity and the homogeneity of the thin coatings. Microbiology results showed that the obtained thin coatings efficiently inhibited bacteria tested strains adherence and biofilm formation at different time points, in a strain and coating material type manner. These results, along with the great biocompatibility of the tested materials recommend the functionalized surfaces with hydrophobic polymers and essential oils/phytostructures prepared by MAPLE to be successfully used in the development of improved medical surfaces, resistant to microbial colonization.

Keywords: anti-biofilm surface, MAPLE deposited bioactive thin films, nano-coating.

Photophysical properties of porphyrins as a selection criterion of porphyrins for study of their effectiveness against microorganisms

A. G. Gyulkhandanyan[1], E. S. Tuchina[2], R. K. Ghazaryan[3], M. H. Paronyan[4], B. M. Dzhagarov[5], G. V. Gyulkhandanyana[1], V. V. Tuchin[2]

[1]Pathological Biochemistry, Institute of Biochemistry of National Academy of Sciences of Armenia, Yerevan, Armenia, [2]N.G. Chernyshevsky Saratov State University, Saratov, Russian Federation, [3]Yerevan State Medical University, [4]Science and Production Center "Armbiotechnology" NAS of Armenia, Yerevan, Armenia, [5]Institute of Physics NAS of Belarus, Minsk, Belarus

One of the most promising directions of destruction of antibiotic-resistant microorganisms is photodynamic inactivation (PDI) of microorganisms by photosensitizers (basically porphyrins). Currently it is generally accepted that singlet oxygen is the main cytotoxic agent in phototherapy of cancer tissues and in PDI. Among the characteristics of photosensitizers the generation of singlet oxygen is the determining criterion to ensure the effective action of porphyrins. We studied photophysical properties of 16 new porphyrins and metalloporphyrins and has been shown that Zn-containing metalloporphyrins have higher values of quantum yields of singlet oxygen generation than the metal-free porphyrins (85–97% and 77–79%, respectively). The efficacy of these compounds was tested on a number of Gram (+) and Gram (-) microorganisms. Among the Gram (+) microorganisms one of the most dangerous is an antibiotic-resistant strain of the microorganism *Staphylococcus aureus* (*St. aureus*). In the U.S., the number of deaths due to methicillin-resistant strain *St. aureus* is equivalent to the total number of deaths from AIDS, tuberculosis and viral hepatitis. The objects of our study were the strain *St. aureus* 209 P and the strain *St. aureus*, methicillin-resistant. Using the criterion of the quantum yield of singlet oxygen generation we studied the effectiveness of four types of porphyrins: meso-tetra [4-N-(2′-oxyethtyl) pyridyl] porphyrin (TOEt4PyP)-(I); Zn-TOE4PyP-(II); Zn-meso-tetra [4-N-butyl pyridyl] porphyrin (Zn-TBut4PyP)-(III) and Zn-TBut3PyP-(IV). It was found that against both strains of *St. aureus* the highest activity has metalloporphyrin (IV) when the concentration of metalloporphyrins was 0.01 μg/ml, which correlates with the values of the quantum yields of singlet oxygen (97% for compounds III and IV). Destruction efficiency of microorganism *St. aureus* 209 P by compound (IV) in comparison with compound (I) was higher more than 8 times that would be expected from the values of quantum yield of singlet oxygen generation (for the compound (I) is 77%). Close results were also obtained for methicillin-resistant strain of *St. aureus*: in the same conditions, the highest efficiency was of the compound (IV) - 2.5 times higher than for the compound (I). Considering that the compounds (III) and (IV) are practically non-toxic, these compounds were recommended for studies *in vivo*.

Keywords: microorganisms, porphyrins, singlet oxygen.

Poly (amidoamine) (PAMAM) dendrimers: physicochemical characterization for multifunctional applications

K. Bieda[1], B. Jachimska[2]

[1]Department of Chemistry, Jagiellonian University, [2]Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences, Cracow, Poland

In this work, we used dynamic laser scattering (DLS) and viscosity measurements to characterize in detail the properties of G6 PAMAM dendrimers in electrolyte solutions. These measure-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ments were supplemented by electrophoretic mobility measurements, which allowed us to determine the isoelectric point and the uncompensated (electrokinetic) charge of the dendrimers. These results provide insight into the dynamic structure of PAMAM dendrimers in solutions.

The adsorption of PAMAM dendrimers onto silica surface was studied with quartz crystal microbalance (QCM-D) and surface plasmon resonance (MP-SPR) measurements. These measurements allowed the determination of both the kinetics of adsorption and the maximum coverage of PAMAM. We found that the thickness of the PAMAM films depends strongly on the pH and ionic strength of the solution that influences swelling of the PAMAM films. Our results supply the first compelling experimental evidence for significant swelling of G6 PAMAM dendrimer upon its protonation at the solid/solution interface. This phenomenon is a consequence of spatial relocation of the dendrimer amide groups due to the interactions of the positively charged amines with the oppositely charged condensed counterions and the penetrating water molecules. Insight into the interfacial phenomena is essential for designing materials dedicated to biological applications.

Our results have also a practical merit, because, they indicate that dendrimers may be used as stimulus-responsive drug delivery carriers, which can release a trapped drug upon a conformational transition induced in the dendrimer molecule by change in pH or the ionic strength.

Polyamines upregulate the formation of *E. coli* persister cells through the modulation of rpoS expression

A. Tkachenko[1], N. Kashevarova[1], M. Shumkov[2], E. Karavaeva[1]
[1]*Laboratory of Microbial Adaptation, Institute of Ecology and Genetics of Microorganisms RAS, Perm,* [2]*Laboratory of Biochemistry of Stresses in Microorganisms, Bach Institute of Biochemistry RAS, Moscow, Russian Federation*

Background: Transition of a bacterial culture to stationary phase is accompanied by an increase in the number of persister cells - quasi-dormant variants of regular cells that are highly tolerant to antibiotics. This property of persister cells establishes requirements for the development of technologies and drugs targeted to their killing. Our previous investigations exhibited that a decrease in cell antibiotic tolerance can be achieved through the inhibition of key enzymes for the polyamine synthesis.
Objectives: In this work we therefore tried to discern if polyamines could promote the persister cell formation, which is one of cell strategies for the survival at lethal antibiotic impacts.
Methods: HPLC fluorescent method was used for determination of cell polyamines. In order to obtain the pure RpoS protein in the level enough for Western blot analysis, the overexpressing *E. coli* strain BL21DE3 pET19b rpoS was constructed. Western blot was used for assessment of cell RpoS protein. *rpoS::lacZ* operon fusion was transferred to *E. coli* HT306 with λRZ5. Gene expression was determined by β-galactosidase activity.
Conclusions: Data obtained in our experiments with the polyamine-deficient *E.coli* strain revealed that the formation of persisters tolerant to netilmicin was highly upregulated by polyamines in a concentration-dependent manner when the cells entered the stationary phase. Furthermore, the more tolerant persister fractions were formed on the later stages of stationary phase. We investigated dependence of persister formation on the expression of *rpoS*. It was shown that polyamine-dependent upregulation of *rpoS* expression reinforced persister cell formation during cell transition to stationary phase. These data were obtained with three independent experimental approaches: polyamine supplementation of polyamine-deficient mutant harboring *rpoS::lacZ* fusion, an ectopic expression of *rpoS* overexpressing plasmid and reciprocal experiments with the pair of isogenic *E. coli* K12 *rpoS*⁻ and *rpoS*⁺ strains. The latter approach enabled us also to assess quantitatively a contribution to persister cell formation of each of two players implicated in this process – RpoS and putrescine. Their complementary activity resulted in almost 1000-fold positive effect on persister cell formation.

This work was supported by the Program of Presidium RAS “Molecular and cellular biology” (project #12-П-4-1047) and grant from the Russian Foundation for Basic Research #13-04-96002.

Preparation of an iutA/pVax DNA cassette as a DNA vaccine candidate against urinary tract infection

R. Bakhtiari[1], S. Ahmadian[1], J. Fallah Mehrabadi[2], B. Chehri Cham Chamali[3]
[1]*Department of Biochemistry, Institute of Biochemistry and Biophysics, University of Tehran, Iran,* [2]*Department of Microbiology,* [3]*Department of bioinformatic, The Lister Institute of Microbiology, Tehran, Islamic Republic of Iran*

Urinary Tract Infection (UTI) is one of the most infectious diseases in human and Uropathogenic Escherichia coli (UPEC) strains are major agent of UTI. These strains colonize in bladder tissue and cause cystitis. Moreover, they could cause pyelonephritis if they get to kidneys. IutA protein has a major role during UPEC pathogenesis and consequently infection. In this study, IutA selected as a candidate immunogen. Genomic DNA was extracted from E.coli 35218 and *iutA* gene amplified by PCR. The amplicon was cloned to pBluescript vector and confirmed by sequencing. Subsequently, inserted to pVax expression vector and final pVax/iutA clone was verified by sequencing and transferred to COS7 cell line. Efficiency of pVax/ iutA expression in COS7 verified by RT-PCR. Mouse model divided to three groups and they injected with pVax vector, PBS and pVax/iutA cassette respectively in two stage (Days 1 and 14). One week after the second injection, bleeding from immunized mouse was performed and IgG, IgG1 and IgG2a sub classes were measured. Potency of Immunization was more in mouse that received DNA vaccine and shows higher cellular immune response. It signifies that houmoral immune response has a main role in prevention of bacterial colonization on bladder and cellular immune response could be efficient in preventing of recurrent infection. So, the current DNA cassette will be valuable for more trying to prepare a new vaccine against UTI.

Thrombin is a key enzyme of blood coagulation and its recombinant form is often used in pharmaceutical industry as a topical

© 2014 The Authors. FEBS Journal © 2014 FEBS

hemostatic reagent. *Escherichia coli*-based expression system is one of the most commonly used expression systems for heterologous expression of industrially important recombinant proteins. This expression system is characteristic of its simplicity and efficiency. In this work prethrombin-2, the smallest thrombin precursor, was used. Prethrombin-2 forms inactive intracellular inclusion bodies during the expression, therefore the refolding process to obtain an active conformation is necessary. Since refolding often does not lead to the desired yields of biologically active recombinant protein, the optimizing of protein expression is the first and key step. Here we demonstrate preparation of suitable medium composition for optimal cell growth in high cell density during the batch fermentation in bioreactor, which is crucially related to obtaining high yield of target protein. In this work a new optimized complex medium for batch fermentation was developed. Medium creation was based on the observation that the medium should not only contain essential ingredients, but it is also necessary to find a suitable concentration of the each component. Our results showed that addition of nutrients like a yeast extract and enzymatic casein hydrolysate to the defined medium components further supplemented with 4% glycerol had positive impact on protein expression. Using this medium, the amount of the target protein reached almost 50% of total cellular proteins

This work is result of project implementation: "Production of biologically active agents based on recombinant proteins" (ITMS 26240220048) supported by the Research and Development Operational Program funded by the ERDF.

Production and characterization of exopolysaccharides synthesized by geobacilli isolated from an Armenian geothermal spring

H. Panosyan[1,2], G. Anzelmo[1], B. Nicolaus[1]
[1]*Institute of Biomolecular Chemistry, C.N.R., Pozzuoli, Naples, Italy,* [2]*Microbiology and Plant and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia*

Exopolysaccharides (EPS) produced by microbes have found a wide range of applications in the food industry, medicine, agriculture, and wastewater treatment. During last decade a new approach to encountering EPS with novel properties is investigating different extreme environments, including thermal habitats. Among the various thermal ecosystems geothermal springs are proving to be a precious source of thermophiles that are able to produce EPS with unique characteristics.

The aim of this study was to determine composition and chemical-physical properties of EPSs produced by two geobacilli strains isolated from Arzakan, Armenia (located 40°26.902′N, 44°36.508′E, 44°C, pH 7.3) geothermal spring.

The phylogenetic analysis of 16S rRNA gene sequence of EPS producing isolates, designated as ArzA-6 and ArzA-8, referred them to *Geobacillus thermodenitrificans* (98% similarity) and *G. toebii* (98% similarity), respectively. The EPS yields using different carbohydrates (glucose, fructose and saccharose), added in the medium at the optimal growth temperature (65°C), were analyzed. Fructose displayed to be the most appropriate carbon source for EPS production. Maximum EPS production was reached in the stationary phase of growth. Indeed, the highest concentration of EPSs harvested after 48 h of culture were approximately 270 mg/g dry cells and 220 mg/g dry cells for *G. thermodenitrificans* ArzA-6 and *G. toebii* ArzA-8, respectively. Purified EPSs displayed a high molecular weight: 5×10^5 Da for *G. thermodenitrificans* ArzA-6 and and 6×10^5 Da for *G. toebii* ArzA-8. Chemical composition of the biopolymers, determined by using a high pressure anion exchange-pulsed amperometric detector (HPAE-PAD), showed the presence of Man/Gal/Ara/Fru/Glu/Sac in a relative proportion of 1/0,13/0,1/0,06/0,05/trace for the *G. thermodenitrificans* ArzA-6 and Man/Gal/Glu/Ara in relative proportion of 1/0,5/0,2/0,05 for the *G. toebii* ArzA-8. Optical rotation values $[a]_D^{25°C}$ (2 mg ml^{-1} H_2O) of EPSs were -142,135 and -128,645 for *G. thermodenitrificans* ArzA-6 and *G. toebii* ArzA-8, respectively.

Production of deleted form of human enterokinase light chain in *Pichia pastoris*

K. Jirickova[1], J. Krahulec[1], Z. Levarski[1], D. Hopkova[1], S. Stuchlik[1], J. Turna[1]
[1]*Department of Molecular Biology, Comenius University, Faculty of Natural Science, Bratislava, Slovakia*

Enterokinase, serin protease, highly efficiently catalyzes the hydrolysis of the polypeptide chain downstream of the N-terminal recognition sequence $(Asp)_4Lys$. Its high specific enzymatic activity and its tolerance to a wide range of reaction condition are the main characteristic features that make enterokinase a useful tool for an *in vitro* cleavage of various fusion proteins. The light chain represents catalytic domain of serin protease. Disadvantage of this enzyme is ability to cleavage besides canonical sequence. For increasing efficiency of enzymatic digestion is necessary eliminate unspecific proteolytic activity. This could be achieved by creating form with shorter amino acid sequence coding enterokinase light chain. In our work, light chain of enterokinase with deleted N-terminal and C-terminal end was developed. This modified form of enterokinase was produced in methylotrophic yeast *Pichia pastoris* in shake-flask. Subsequently, enzymatic activity of these two mutated form were compared with unmodified enterokinase light chain by digestion dermcidin 1 fused with thioredoxin. However, both of these mutated enzyme forms showed no activity in cleavage this fusion protein.

This publication is the result of the project implementation: "Competence center for research and development in molecular medicine" (ITMS 26240220071) supported by the Research and Development Operational Program funded by the ERDF.
Keywords: heterologous expression, human enterokinase light chain, Pichia pastoris.

WED-153
Production of recombinant human growth hormone in *Pichia pastoris* under constitutive promoter

D. Hopkova[1], K. Jirickova[1], Z. Levarski[1], J. Krahulec[1], S. Stuchlik[1], J. Turna[1]
[1]*Department of molecular biology, Comenius University Bratislava, Bratislava, Slovakia*

The growth deficiency in children is usually cured with a recombinant human growth hormone (rhGH) intravenous application. The hormone improves patient's condition in case of the Turner′s syndrome or cachexia associated with AIDS also. It was one of the first recombinant proteins approved for the usage in pharmaceutical industry. To this day, rhGH has been produced in different host organisms as *Escherichia coli, Bacillus subtilis, Saccharomyces cerevisiae* etc. The rhGH was successfully prepared in yeast *Pichia pastoris* under the strong inducible AOX promoter lately. In our study, the expression system in *P. pastoris*

© 2014 The Authors. FEBS Journal © 2014 FEBS

for the production of rhGH under a constitutive promoter was designed and implemented. The rhGH gene was integrated into genome of *P. pastoris*, in order to produce native rhGH into the extracellular media. The genome integration was validated through a PCR and expression in flasks. The SDS-PAGE results were confronted with a Western blot analyses. rhGH was then successfully produced in 1L fermenter and partially purified using anion-exchange chromatography. *P. pastoris* was chosen as the host organism because of its ability to grow to high cell densities and its strong promoters capable of the production of high yields of a recombinant protein. The system combines both, advantages of prokaryotes – high expression, simple scale-up, cheap production media; and advantages of eukaryotes – ability to perform various post-translation modifications.

This publication is the result of the project implementation: "Competence center for research and development in molecular medicine" (ITMS 26240220071) supported by the Research and Development Operational Program funded by the ERDF.
Keywords: constitutive promoter, human growth hormone, Pichia pastoris.

WED-154
Production of thermostable lipases by thermophilic bacilli

G. Shahinyan[1], H. Panosyan[1], A. Trchounian[1]
[1]Department of Microbiology, Plants and Microbes Biotechnology, Yerevan State University, Yerevan, Armenia

Thermophilic microbes, thrived in the extreme environments, are interesting sources for the thermozymes. Particularly thermostabile hydrolases, including lipases are known as one of the most imperative biocatalysts in today's epoch. Thermostabile lipases were purified and characterized from thermophilic isolates mainly belonging to genus Bacillus and related genera, which nowadays are used in industry.

The present study was aimed to isolate extracellular thermostable lipase producing bacilli and to optimize their growth conditions affecting the lipase production and activity. Two bacilli strains namely Bacillus licheniformis Akhourik 106 and B. aestuarii Akhourik 107 isolated from geothermal spring of Akhourik (Armenia) served as subjects of study. The thermostable lipase was estimated by qualitative and quantitative analysis. The enzyme production was investigated in inducing medium containing Tween 40, 60, 80 (1%) and/or olive oil (1%), CaCl2x2H2O (0.05%), which visualize a halo close around the colonies. The lipase activity was measured by alkalimetric titration method at temperature range of 25°C–65°C and pH range of 5–10.

The temperature of 56°C, 0.5% salinity level and pH 6.5–7 were defined to be the optimal conditions for lipase activity. Maximal activity level was determined on the late stages of bacterial exponential growth. The activity values were 0.03 U ml-1 min-1 and 0.027 U ml-1 min-1 for B. licheniformis Akhourik 106 and B. aestuarii Akhourik 107, respectively. The thermal stability in aqueous solution of the crude enzymes was also assayed.

The work was partially supported by MES of RA and ANSEF-2011 Microbio-2493.
Keywords: lipase activity optimization, thermophilic bacilli, thermostable lipases.

WED-155
Protein-protein and protein-DNA interactions during replication proces of plasmid DNA

M. Babič[1], V. Cimová[1], J. Bugala[1], M. Lukáčová[1], P. Grones[2], J. Grones[1]
[1]Department of Molecular biology, Comenius University in Bratislava, Bratislava, Slovakia, [2]Department of Plant Systems biology, Gent University, Gent, Belgium

Many plasmids are able to replicate in their original host and related species, and some of them have an extended host range which allows their establishment in several different bacterial species. At least two essential processes contribute to the host range phenotype: replication and partition Theplasmids became more interesting when scientist discovered that many plasmids contain genes responsible for antibiotic resistance and are responsible for the spread of antibiotic resistance among pathogen bacteria. Plasmids can give its host other kinds of resistance e.g. against heavy metals, bacteriocins, radiation and toxic anions. In this situation, the parasite host relation is more symbiotic, since the host gain some benefits. Many plasmids today are very important tools in gene technology and science e.g., as cloning vectors and expression vectors. In the previously isolated pAG20 plasmid from the Acetobacter aceti CCM 3620 strain, the Rep20 protein was characterized as a main replication initiator. The pAG20 plasmid origin was localized in the vicinity of the rep20 gene and contained two 21-nucleotide-long iteron sequences, two 13-nucleotide-long direct repeats, and a DnaA-binding site. Electrophoretic mobility shift assay and nonradioactive fragment analysis confirmed that the Rep20 protein interacted with two direct repeats (5′ TCCAAATTTGGAT 3′) and their requirement during plasmid replication was verified by mutagenesis. 9 amino acids of the third a-helix (between 58 and 66 amino acids) play a key role in the Rep20-specific binding to theoriregulation region. Similarly, the region (9 amino acids between 49 and 57 amino acids) in the middle of the second and the third α-helices, containing the β-sheet structure, appeared to be also important for DNA binding. Targeted mutagenesis of the Rep20 protein revealed the importance of the third a-helix and $_{63}$Lys, specifically during DNA binding.The second, closely adjacentb-sheet also took part in this process in which $_{52}$Asn played a significant role to binding Rep20 to DNA.

WED-156
Protonophores affecting *Rhodobacter sphaeroides* growth and hydrogen photo-production

H. Sargsyan[1], L. Gabrielyan[2], A. Trchounian[1]
[1]Department of Microbiology & Plants and Microbes Biotechnology, [2]Department of Biophysics, Yerevan State University, Yerevan, Armenia

Purple non-sulfur bacteria has been established to produce hydrogen (H_2) under anaerobic conditions upon illumination that is mediated by nitrogenase catalyzing conversion of protons to H_2 by using energy from ATP [1]. It was shown that cyanide m-chlorophenylhydrazone (CCCP), a protonophore, which dissipates the proton gradient and inhibits the synthesis of ATP, suppressed nitrogenase activity in the other bacteria – cyanobacteria [2]. But effects of protonophores on purple bacteria are not known yet. In this study the comparative analysis of the effects of different protonophores such as CCCP and 2,4-dinitrophenol (DNF) on growth and H_2 production by *Rhodobacter sphaeroides* MDC6521 from Arzni mineral springs in Armenia was done.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Both uncouplers affected the bacterial growth rate. *R. sphaeroides* was unable to grow in medium with CCCP and DNF, and addition of protonophores after 24 h growth of bacteria inhibited growth. The medium pH and redox potential are considered as the important factors evaluating bacterial growth under various conditions [1]. During the *R. sphaeroides* growth up to 24 h, pH of medium increased from 7.5 (initial pH) to ~8.0. By addition of CCCP (0.5–2 mM) pH decreased to ~7.4 during the growth up to 72 h. However, different kinetics of pH was observed after addition of DNF (5–50 mM): pH increased to ~9.0. Redox potential of *R. sphaeroides* control cells decreased down to -690 mV during the growth up to 72 h. CCCP (2 mM) delayed drop in redox potential, which was decreased to -135 mV. In the presence of 5 mM DNF redox potential dropped to -660 mV; whereas with 50 mM DNF potential drop was to -170 mV only. Both uncouplers inhibited H_2 production: H_2 yield lowered ~1.2-fold in the medium with 5 mM DNF, and was not observed in the presence of CCCP and 10–50 mM DNF. It is suggested that protonophores can decrease H_2 production by suppressing nitrogenase or proton-translocating ATPase activity. This study would be helpful for understanding the mechanisms of protonophores effect on H_2 production by purple bacteria and its application in H_2 biotechnology.

Real-time PCR optimization to identify *Mycobacterium tuberculosis* complex strains in clinical samples

R. Sanjuan-Jimenez[1], J. D. D. Colmenero[2], P. Morata[1], Infectious Diseases
[1]Biochemistry, Molecular Biology and Immunology, University of Málaga, [2]Infectious Diseases Service, Carlos Haya University Hospital, Malaga, Spain

During recent years several molecular techniques have become available for *Mycobacterium tuberculosis* complex (MTC) detection, both for clinical samples and for isolates. One of the techniques more widely used is real time PCR in combination with nucleic acid amplification protocols. There are numerous studies based on PCR for the diagnosis of tuberculosis although the different protocols and primers used in the laboratory, together with the variability in the diagnostic performance of the methods tested, require that a comparative study be performed. Furthermore, the fact that the detection from clinical samples requires using highly sensitive targets suggests that this type of study should include multicopy targets to compare their efficiency with respect to the single copy. Our aim was to identify the members of the MTC using real-time PCR assays based on SYBR Green, among a large panel of isolated bacterial strains and clinical samples. We chose three targets (IS6110, senx3-regx3 and cfp32) and the optimal values for each PCR assay were empirically defined by testing in triplicate different concentrations of $MgCl_2$ and primer sets and different annealing temperatures. These conditions were determined based on the specific amplification reactions that showed a lower Ct value, higher fluorescence and absence of non-specific PCR products. The analytical sensitivity was evaluated by ten-fold serial dilutions of DNA from MTC and the specificity was tested by 62 different microorganisms, including bacteria related with the MTC. The diagnostic yield was evaluated in 66 specimens from patients with suspected tuberculosis; 30 had tuberculosis and 36 (control group) had different diseases. Under the conditions that resulted in optimization, standard curves showed that senx3-regx3 assay was the most efficient, followed by IS6110 and cfp32. However, the detection of bacterial DNA was faster with the repetitive element IS6110, with Ct values of up to 3 and 9 cycles of difference with respect to senx3-regx3 and cfp32. The analytical specificity, done only with the senx3-regx3 and IS6110 targets, was in the order of 100 and 93.5%, since IS6110 amplified various non-tuberculous micobacteria. For all the clinical samples studied, the sensitivity of both assays was identical (93.3%) but the specificity of senx3-regx3 (100%) was higher than that of IS6110 (94.7%). In conclusion, real time PCR assay-SYBR Green based on the targets senx3-regx3 is highly reproducible and more sensitive and specific than the assays based on IS6110 or cfp32. The protocol developed in this study provides an appropriate and rapid tool to identify the strains of MTC in different clinical isolates and specimens.

Regulation of flagellar motility by the PTS in *Vibrio vulnificus*

S. Park[1], C.-R. Lee[2], Y.-R. Kim[3], Y.-J. Seok[1,3]
[1]Department of Biophysics and Chemical Biology, Seoul National University, Seoul, [2]Department of Biological Sciences, Myongji University, Yongin, [3]Department of Biological Sciences and Institute of Microbiology, Seoul National University, Seoul, Republic of Korea

Vibrio vulnificus is an opportunistic human pathogen that causes food-borne diseases such as gastroenteritis and primary septicemia, and its single polar flagellum-based motility is one of the potential virulence factors. Notably, it has been reported that glucose prevents the synthesis of flagella and hence swimming motility in some bacteria. Glucose is transported through the phosphoenolpyruvate: sugar phosphotransferase system (PTS) in most bacteria. The components of the PTS have multiple physiological roles as well as catalysis of the transport and accompanying phosphorylation of numerous PTS sugars. Here, we show that the dephosphorylated form of enzyme IIA of the glucose PTS, but not its phospho-form, interacts with a hypothetical protein (henceforth called Protein X) in *V. vulnificus*. A deletion mutation in the *protein X* gene resulted in loss of flagellum synthesis and reduced the expression of several flagellar genes, indicating that Protein X is essential for the flagellar motility. Taken together, we suggest that the interaction between enzyme IIA^{Glc} and Protein X regulates the flagellar motility by sensing glucose in *V. vulnificus*.

Keywords: Phosphotransferase system (PTS), Protein - protein interactions, vibrio vulnificus.

Secondary metabolism of the cyanobacterium Oscillatoria sp. PCC 6506: from genome sequencing to cyanotoxin and metabolite biosyntheses

O. Ploux[1,2], A. Méjean[1], V. Gautier[1], G. Paci[1]
[1]LIED UMR CNRS 8236, University Paris Diderot, [2]Chimie ParisTech ENSCP, Paris, France

Cyanobacteria are photosynthetic prokaryotes that are extremely diverse and certain species produce a wide range of secondary metabolites including potent toxins for animals and humans[1].

© 2014 The Authors. FEBS Journal © 2014 FEBS

Cases of animal death, due to cyanobacterial toxin exposure, are regularly reported worldwide. For instance, anatoxin-a and homoanatoxin-a, two cyanobacterial neurotoxins provoke the rapid death of animals by acute asphyxia on ingestion, because these alkaloids are potent agonists of the nicotinic acetylcholine receptor[2].

We have sequenced the genome of *Oscillatoria* sp. PCC 6506 which produces anatoxin-a and homoanatoxin-a and identified at least seven clusters of genes likely implicated in the biosynthesis of secondary metabolites, either polyketides, non-ribosomal peptides, or ribosomal peptides[3].

We have identified the *ana* cluster of genes that is responsible for the biosynthesis of anatoxin-a and homoanatoxin-a, and proposed an original biosynthesis for these neurotoxins involving polyketide synthases[4]. We have reconstituted in vitro this biosynthesis and solved the three dimentional strucutre of one of key enzyme of this pathway[5,6].

We have also identified the *cyr* cluster of gene responsible for the biosynthesis of cylindrospermopsin, a cytotoxin and showed that *Oscillatoria* sp. PCC 6506 produces cylindrospermopsin and 7-epi-cylindrospermospsin[7]. We have characterized CyrI a 2-oxoglutarate-dependent iron oxygenase that catalyzes the last step of this biosynthesis.

The characterization of the other clusters of genes involved in the secondary metabolism of *Oscillatoria* sp. PCC 6506 is under investigation, and so far we have identified a cluster responsible for the production of new cyanobactins, cyclic ribosomal peptides.

Structures of cell-wall glycopolymers of bifidobacteria

G. Novik[1], E. Kolomiets[1], O. Valueva[2], Y. Knirel[2]
[1] *Institute of Microbiology Belarus Academy of Sciences, Minsk, Belarus,* [2] *N.D. Zelinsky Institute of Organic Chemistry Russian Academy of Sciences, Moscow, Russian Federation*

Belarusian collection of non-pathogenic microorganisms (acronym BIM, WDCM 909) is authorized to deposit microbial strains for subsequent patenting procedure. Probiotic strains deposited at Belarusian collection are used in pilot plant production of probiotics, preventive – therapeutic veterinary compositions, bioactive supplements and substances. Bifidobacteria are thought to be important for health and their participation in the functions of the intestine, taxonomy and ecology has been reviewed. Several reports concerned the composition of the bifidobacterial cell wall and the structure of cell wall glycopolymers. It was shown that the cell wall glycopolymers of bifidobacteria possess anti-tumour

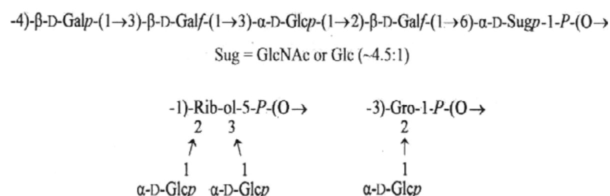

Fig. 1.

and immunopotentiating activities. A glycopolymers with oligosaccharyl phosphate repeats of two types and ribitol and glycerol teichoic acids were isolated from cell wall of *Bifidobacterium longum* BIM B-476 D (the patent application 20111815 BY) by stepwise extraction with 10% CCl_3CO_2H. The structures of the glycopolymers were established by sugar analysis, selective cleavage with aq 2% HOAc, dephosphorylation with 48 % HF, 2D NMR spectroscopy, and high-resolution ESI MS. The main chain of the ribitol teichoic acid is terminated with d-alanine.

Keywords: glycopolymer, structure, bifidobacteria.

Substrate specificity in peptide synthetic reaction

Y. Hashimoto[1], T. Abe[2], Y. Zhuang[1], Y. Ge[1], T. Kumano[1], M. Kobayashi[1]
[1] *Institute of Applied Biochemistry, and Graduate School of Life and Environmental Sciences, The University of Tsukuba, Tsukuba,* [2] *Division of Life Science and Engineering, School of Science and Engineering, Tokyo Denki University, Saitama, Japan*

We previously reported that an amide bond is unexpectedly formed [1] by an acyl-CoA synthetase, AcsA, which plays an essential role in acid utilization in the nitrile-degrative pathway of *Pseudomonas chlororaphis* B23 [2]. Although AcsA essentially catalyzes the formation of a carbon-sulfur bond (the ligation of an acid with CoA), it surprisingly synthesized *N*-acyl-l-cysteine when a suitable acid and l-cysteine are used as substrates. Furthermore, this unexpected enzyme activity was also observed for acetyl-CoA synthetase and firefly luciferase, both of which belong to the same superfamily of adenylate-forming enzymes. Therefore, all enzymes in this superfamily of adenylate-forming enzymes are likely to synthesize *N*-acyl-l-cysteine when l-cysteine is used as one of the substrates.

Here, we succeeded in the synthesis of dipeptides (*N*-aminoacyl-l-cysteine) using a bacterial enzyme, which belongs to the same superfamily of adenylate-forming enzymes like acyl-CoA synthetases. In addition, we discovered that some amino acids and l-cysteine were also active as the substrates of the enzyme. These results suggest that the corresponding dipeptides would be produced. The structures of the products were determined by LC-MS/MS. Each fragmentation pattern showed that these products are *N*-aminoacyl-l-cysteine but not *S*-aminoacyl-l-cysteine, demonstrating that various dipeptides were formed as the reaction product. Furthermore, we calculated kinetic values for the synthesis of each peptide, because we found that peptides are synthesized along with the consumption of the amount of ATP and the increase in the amount of AMP. According to the catalytic efficiencies (k_{cat}/K_m), substrate specificity in peptide synthetic reaction of the enzyme was clarified.

Swings in cell morphology, and expression of genes essential to cell adhesion, secretion, iron-chelation and transport, multi-drug resistance, and two-component signal transduction mechanism, from copiotrophic to oligotrophic lifestyle in a model strain, Klebsiella pneumoniae PB12

R. Chakraborty[1], A. K. Mandal[1], S. Mandal[2], O. Franco[3]
[1]Biotechnology, University of North Bengal, Siliguri, [2]Central Research Facility, Indian Institute of Technology, Kharagpur, India, [3]Pos-Graduacao em Ciencias Genomicas e Biotechnologia, Universidade Catolica de Brasilia, Brasilia, Brazil

Klebsiella pneumoniae although being a respiratory pathogen, the other sites of infection reported include urinary tract, digestive tract, surgical wound sites etc. The invasiveness of infection takes place generally via contaminated respiratory support equipment and urinary catheters or via other surgical/non surgical equipments. Interestingly, they are omnipresent. The model strain K. pneumoniae PB12, described in this study, isolated from river water possessing oligotrophic characteristics, was resistant to multiple antibiotics as well as resistant to human serum. PB12 can grow in an environment without nutrient-luxury. Whole genome transcriptomic responses of PB 12 to high and low nutrient medium was compared to reveal the regulation of gene expressions in relation to surface attachment, secretion, iron-chelation and transport, multidrug resistance, and two-component signaling system that might influence their adaptability to colonize diverse infection sites. The most highly up-regulated iron-transport genes in oligotrophic condition were afeABCD. Significant downregulation of dhaR, uhpA, evgS, basR, zraR, cusR, barA, sdiA, uvrY, and phoQ genes; and upregulation of six novel genes of two-component signal transduction system (phosho-relay) were observed under oligotrophic condition. Flow cytometric analysis has provided an understanding of the behavior of PB12 cells (and the presence of subpopulations) grown in oligotrophic medium enabling further insight into the phenotypic manifestation.
Keywords: Klebsiella pneumoniae, oligotrophy, whole genome transcriptomics.

The allelic variant ctxB7 of cholera toxin is a wide spread challenge

P. Kumar[1], S. K. Bhuyan[1], P. K. Yadava[1]
[1]School of Life Sciences, Jawaharlal Nehru University, New Delhi, India

Vibrio cholerae the causative agent of cholera keep changing in biotype and antibiotic resistance pattern for better survival and infection. In 2007, a novel allelic variant of cholera toxin (ctxB7) was noticed in Orissa, India. The sequencing of *ctxB* revealed His20 to Asn mutation in signal peptide at -2 position of signal peptidase cleavage site. Later it rose in fame with Haitian ctxB (HCT) after causing a devastating epidemic in Haiti. The HCT producing strains were also reported from recent large cholera epidemics in Western Africa. In 2012-13, we have also noticed cholera outbreaks caused by HCT harbouring *V. cholerae* O1 El Tor strains in India. All the epidemics or outbreaks were associated with severe diarrhea and enhanced rate of mortality. An increased level of MIC for ciprofloxacin or reduced susceptibility for the drug was observed in recent strains. The use of doxycycline in moderate to severe cases of cholera for the management of outbreak like situation was found effective. Emergence of variant strains hampers the cholera control policies which can be a serious concern. There is pressing need to formulate and implement integrated multidisciplinary guidelines at national as well as at international level to combat the dissemination of novel variant strains.
Keywords: Cholera toxin, ctxB7/Haitian CT and epidemics.

WED-165

The comparison of macromolecular changes in different acinetobacter isolates upon neomycin exposure

T. Kanat[1], A. G. Gozen[1], F. Severcan[1]
[1]Biology, METU, Ankara, Turkey

Species of *Acinetobacter* are ubiquitous in nature. Due to their versatile nature, *Acinetobacter* sp. has attracted considerable attention by many researchers. Bacteria of the genus *Acinetobacter* represent a group of opportunistic pathogens. They are of increasing importance because of their ability to rapidly develop resistance to the major groups of antibiotics. In this study, an environmental *Acinetobacter* isolate coming from a freshwater lake was compared to *Acinetobacter haemolyticus* ATCC 19002 in terms of neomycin resistance pattern. Also their whole cell alterations after sub-inhibitory concentration (<MIC) of neomycin exposure were examined with the help of attenuated total reflection Fourier transform infrared (ATR-FTIR) spectroscopy. Firstly minimum inhibitory concentration (MIC) values of neomycin were determined for both bacteria. Then these isolates were grown in nutrient broth medium with and without sub-inhibitory concentrations (<MIC) of neomycin. To take ATR-FTIR spectroscopy measurements the independent replicates for each of the *Acinetobacter* isolate neomycin treated groups and their controls were used. The results show that there were statistically significant changes on conformation of cell proteins and drastic changes in capsule and wall dynamics in both *Acinetobacter* isolates. The production of structurally different form of polyesters such as Polyhydroxybutyrate (PHB), which are induced under stress, was also shown in both bacteria. In addition, the significant alterations in lipid ordering of the membrane, in the amount of cell carbohydrates, the backbone of nucleic acids, and ribosomes were also shown for the environmental isolate. In conclusion, our results demonstrated that the metabolic responses of environmental *Acinetobacter* isolate differ from *Acinetobacter haemolyticus* even in the case of exposure to the same antibiotic.
Keywords: Acinetobacter, ATR-FTIR spectroscopy, neomycin.

WED-166

The large scale antimicrobial efficiency of a new multicomponent preparation for skin diseases treatment

M. Ginovyan[1], P. Ghazaryan[2], I. Bazukyan[1], A. Trchounian[1]
[1]Department of Microbiology, Plants and Microbe Biotechnology, Faculty of Biology, [2]Department of Pharmaceutical Chemistry, Faculty of Chemistry, Yerevan State University, Yerevan, Armenia

Human and animal skin diseases of bacterial, fungal and viral nature and their complications are widespread and cause serious trouble. The prevalence of these diseases is increasing continuously mainly due to acquired drug resistance phenomenon. Consequently, demand has increased for new antimicrobial drugs, which also could be less toxic, possess a wider spectrum of action and, on the other hand, would be economically more beneficial.

The goal of the study was to investigate antibacterial, antifungal and anti-bacteriophage activity of Petamcyn-A, new multicomponent preparation containing acetic acid, hexamethylenetetramine, phosphatidylcholine, tocopheryl acetate and glycerol [1].

© 2014 The Authors. FEBS Journal © 2014 FEBS

The investigations were performed using 9 bacterial, 3 yeast and 5 mould strains as test-organisms. T4 phage of *Escherichia coli* C-T4 was used to test the anti-bacteriophage activity. Nystatin (antifungal drug), Hexiloc (antiseptic drug) and 12% acetic acid (one of the active compounds of Petamcyn-A) were used as control agents for comparative analysis of Petamcyn-A activity.

The results have shown that Petamcyn-A has high activity against all used test strains. It has broader range of activity than control compounds. We found out that Petamcyn-A is more effective against tested gram-positive bacteria compared with gram-negative bacteria. Moreover, it has been demonstrated that Petamcyn-A has bactericidal activity against all used test strains. Minimal inhibitory, minimal bactericidal and minimal fungicidal concentrations of Petamcyn-A against different test strains were determined. MIC of Petamcyn-A was 14 μl/ml for *Staphylococcus aureus* WDCM 5233, 18 μl/ml for *E. coli* and 25 μl/ml for *Debaryomyces hansenii*. Both Petamcyn-A and 12% acetic acid inhibited the germination of tested fungal spores. Further determination of MIC showed that 12% acetic acid lost its activity at 20 μl/ml concentration, but Petamcyn-A was active till 15 μl/ml concentration against *Trichoderma viride* spores. In addition, the preparation demonstrated high activity against T4 phage of *E. coli* C-T4 completely inhibiting its growth. 1/5 dilution of the preparation also exhibited considerable activity reducing phage concentration by 2.6 Log10.

Thus, Petamcyn-A has the large scale of antibacterial, antifungal and anti-phage efficiency and is suggested to develop its production for skin diseases treatment. It is possible additional application of Petamcyn-A as disinfectant.

Keywords: Petamcin-A, skin infectious disease, antimicrobial activity.

The study of interaction's effect between genes associated to drug resistance in *Mycobacterium tuberculosis* complex

R. Ludannyy[1], M. Alvarez Figueroa[1], A. Prokopenko[1]
[1]*Molecular diagnostics, Federal Budget Institute of Science "Central Research Institute for Epidemiology" of Federal Service on Consumers' Rights protection and human Well-Being Surveillance, Moscow, Russian Federation*

The key role of *M. tuberculosis* complex (MTBC) resistance formation is played by the SNPs in genes: *pncA* (Pyrazinamide, Z), *inhA, katG, oxyR-ahpC* (Isoniazide, H), *rpoCAB* operon (Rifampicin, R), *embCAB operon* (Ethambutol, E) and cluster of ribosomal genes *rrs, rpsL* and *gidB, tlyA, eis* (Streptomycin, S). The distribution and genetic frequency of mutations strongly depend on origin and geographical localization of isolates. Although, the harboring genetic processes might be affect on manifestation (e.g. epistastatic interaction, compensatory mutations).

The molecular genetics techniques and bioinformatical analysis were applied for detailed investigation in genes associated with phenomenon of resistance (*inhA, katG, oxyR-ahpC, ndh, rpoB, pncA, embB, rrs, rpsL, tlyA, gidB* and *eis*–promoter) from collection of 155 clinical phenotypic characterized MTBC isolates from Moscow region (Russia).

More over 5000 sequences have been revealed of 108 different SNPs in 13 genes, associated with loss of susceptible in MTBC, exc. *oxyR*, *ahpC*, *tlyA* genes and *eis*–promoter, where the mutations were not found. The significances of genetic variability ((Nm) from 0.75% to 27.7%) and genetic diversity ((h) from 3.7% to 73.1%) showed absolutely heterogeneity and were not correlated between themselves. This fact that may indicates on spontaneous character of mutagenesis. The concordance score between phenotypic and genetic data were varied from 89 to 100% for all drugs without ethambutol (CS = 43.2%). By the principal component analysis all genes were classified into four groups: *katG*, *rpoB* and *pncA* separately and other genes were united in distant group that correlated with comparability of genetic changes, which has been described in multidrug-resistance strains. The interaction between genomic replacements were reconstructed and visualized by Circos plot (Figure 1). The three general combinations of *embB-rpoB-pncA* (35%), *embB-rpsL-rpoB* (37%) and *embB-rrs-rpoB* (24%) were detected, where the central role of interaction has been belonged to *embB* gene. The two hypotheses could be discussed. On the one hand, the epistatic effect might be playing a general role as reflection on the central position of *embB* gene in the combination of rearrangements in extensively drug-resistance strains. However, the discordance results (according to publications) and specific metabolic pathway are closely related to barrier function in cell, might be induce the appearance of replacements in *embB* gene as response on other drugs action (H, R, Z and S), that appeared as complementarity and may not be related to ethambutol resistance.

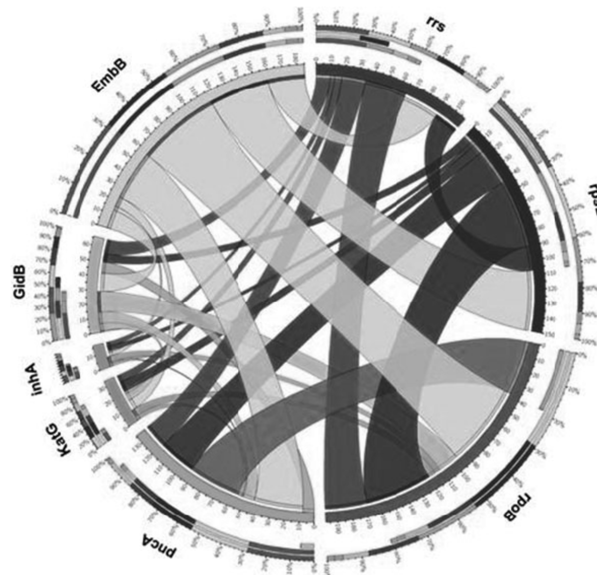

Fig. 1. Tlie reconstruction of interaction between genomic replacements in genes (*embB, rrs, rpsL, rpoB, pncA, katG, inhA* and *gidB*) associated to anti-tuberculosis drug resistance by Circos plot

Thermo-resistant microalgae for biodiesel production

M. Onay[1], C. Sonmez[2], H. A. Oktem[3], M. Yucel[3]
[1]*Department of Biochemistry,* [2]*Department of Biology,*
[3]*Department of Biotechnology, Middle East Technical University, Ankara, Turkey*

The rapid depletion of petroleum-derived fuels makes renewable energy sources more attractive in the world. Bio-diesel is a renewable fuel that is produced dominantly from agricultural waste, vegetable oils and animal fats. Moreover, biofuel is an alternative to diesel fuel, which is produced from oils via transesterification. Microalgae can be an attractive for biodiesel production because of its some properties such as growth rate, lipid content and bio-

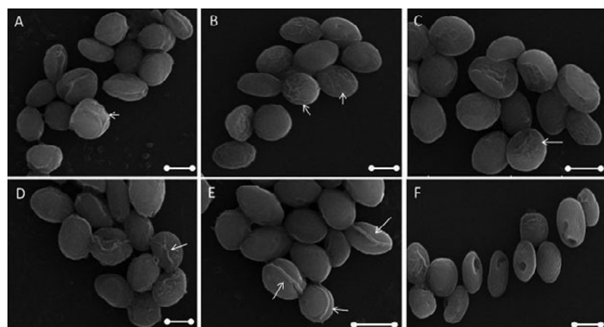

Fig. 1.

dieisel productivity. In this study, Samples were collected from three different hot spring locations from geothermal flora of Central Anatolia and we isolated microalgae by means of serial streaking cells across agar plate and dilution techniques. Then, we made their morphological and moleculer characterization via scanning electron microscopy (SEM) and sequencing 18S ribosomal RNA gene internal transcribed sequence 2 (ITS2)-rDNA of isolated samples, respectively. Scanning electron micrographs of the cells of microalgal isolates were given in Figure 1. ITS2 sequences of all isolates were analyzed and assembled using ContigExpress software of Vector NTI (Invitrogen). ITS2 secondary structure prediction of the consensus sequences of the isolates was done using the prediction algorithm implemented in the ITS2 database with the parameters of $E < 1e\text{-}16$ and minimum helical transfer of 75%. Next, we carried out lipid, carbohydrate and protein concentrations of isolated microalgae via hexane extraction method, anthrone method with minor modifications and Bradford method, respectively. One of our isolates identified as *Micractinium sp* displayed suitable properties for biodiesel production such as high photosynthetic rate, chlorophyll content, high growth rates and adaptibility to different temperatures, high biomass accumulation, desirable fatty acis methyl ester (FAME) profile and high biodiesel productivity. *Micractinium sp* has high growth rate, biomass concentration and biomass productivity as 5.2 ± 0.04, 0.76 ± 0.03 g.L^{-1} $^{\text{and } 0.17\pm0.007 \text{ g.L}-1}$. day^{-1}, respectively. In addition to this, *Micractinium sp* has high biodiesel production as $89 \pm 3.1\%$ and high amounts of oleic acid methyl esters (18:1), linoleic acid (18:2), palmitic acid methyl esters (16:0) for biodiesel production. In conclusion, *Micractinium sp* is a suitable candidate for biodiesel production and can further be improved for different industrial applications via genetic and metabolic engineering strategies.

Keywords: Biodiesel production, Micractinium sp., Microalgae.

Thermostable α-amylase produced by *Anoxibacillus flavitermus* K103 isolated from an Armenian geothermal spring

H. Panosyan[1,2], A. Margaryan[1], N.-K. Birkeland[2]
[1]*Microbiology and Plant and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia,* [2]*Department of Biology and Centre for Geobiology, University of Bergen, Bergen, Norway*

Thermozymes produced by thermophilic microbes have been of great scientific interest for the last decades and have found a number of commercial applications due to good correlation between their inherent stability and harsh industrial processes conditions. Thermostable starch-degrading enzymes are important for the production of glucose from starch and are widely used in food, feed, pharmaceutical and chemical industries. Thermostable α-amylases, mainly produced by thermophilic bacilli, have found a number of applications due to their overall inherent stability. Therefore, the isolation of novel thermostable amylase producers from natural sources is a priority research field.

The aim of this study was to isolate active producers of thermostable amylases from hot and warm mineral springs in Armenia and to select prospective producers of thermostable amylases and optimize the conditions for enzyme production. More than 160 thermophilic bacilli strains were isolated and 12 isolates with high amylase activity were selected. 16S rRNA genes analyses revealed affiliations to the genera *Geobacillus, Anoxibacillus* and *Brevibacillus*. The most active strain, designated *Anoxibacillus flavitermus* strain K103, was able to grow and produce amylase in the 50°C - 80°C temperature range and at pH 5.5 – 8.5, and showed maximum production of amylase at its optimum growth temperature (65°C) and pH 7. Amylase production started in early log phase and reached a maximum in late exponential phase with an activity of 205 U ml^{-1}. The enzyme fraction was subjected to zymographic analysis which revealed a single protein band. The molecular mass of the amylase was determined to 75 Kd by SDS-PAGE. The enzyme was stable at temperatures from 40 to 100°C and at a pH range from 5 to 10. It was stimulated by Ca^{2+} and Mn^{2+}, whereas inhibited by Cu^{2+}, Zn^{2+} and EDTA, suggesting metal dependence. High production rate, and activity and stability of the enzyme at high temperature indicate a strong industrial potential for *A. flavitermus* K103 and its amylase.

The work was supported by the CPEA-2011/10081 grant from the Norwegian Cooperation Programme in Higher Education with Eurasia and by a grant from the Armenian National Science and Education Fund ANSEF-2011 Microbio-2493 based in New York, USA.

Keywords: Anoxibacillus flavitermus, thermophilic bacilli, thermostable α-amylases.

WED-171
Transition to NC state is accompanied by increase of vapC toxin expression level

A. Goncharenko[1], O. Demidenok[1]
[1]*A.N.BACH Institute of Biochemistry RAS, Moscow, Russian Federation*

Toxin-antitoxin (TA) loci are widely spread in bacterial plasmids and chromosomes. Toxins affect such important functions of bacterial cells as translation, replication and cell wall synthesis, whereas antitoxins are toxin inhibitors. Participation in formation of the dormant state in bacteria is also suggested to be a possible function of toxins.

To validate the role of VapBC TA in dormancy formation, we used a model of dormant, «non-culturable» (NC) *Mycobacterium smegmatis* cells obtained in potassium limited conditions. Under such conditions *M. smegmatis* cells lose their culturability on solid medium transiting into the NC dormant (but reversible) state. Early we have found that overexpression of VapB antitoxin prevented transition to dormancy in these conditions [Demidenok et al., 2014]. In this work, we demonstrated that transition to NC state is accompanied by increase of vapC toxin transcription level.

Alteration of *vapC* expression level in *M. smegmatis* cells during transition to NC state was examined with qRT-PCR. It was revealed that the *vapC* transcription level was increased (ca. 20 times) before formation of NC state. Detected level of *vapC* expression in NC cells was decreased (ca. 6 times) in comparison with active cells. The lower level of *vapC* expression in NC dormant cells is obviously due to their low metabolic level [Shleeva et al., 2004].

© 2014 The Authors. FEBS Journal © 2014 FEBS

In summary, these findings point to involvement of a VapBC TA system in the development of dormant state.

Keywords: dormant state, toxin-antitoxin function.

WED-172
Trends in next generation bioactive lead compounds from microbes

R. N. Kumavath[1], S. S.V[1]
[1]*Genomic Science, Central University of Kerala, kasaragod, India*

Microbes are the large repositories of bioactive compounds with different structural and functional forms viz. sugars, acids, esters, ethers, terpenoids, peptides, proteins and nucleo peptides. Which are meant for the immense applications in the treatment of the wide range of disease types, such as anticancer, anti-inflammatory, antimicrobial, antiviral and antifungal etc., As long as the microorganisms are treated with the classical antibiotics they are supposed to be developing the nature of resistance to the specific disease types. Now it is time to prepare the new drugs and makes to modify in the structural characteristic for the target based drug design for the specific disease.

A significant number of interesting natural novel biomolecules have been reported from the microbial source like, Rhodethrin, Rubrivivaxin, Sphestrin and Rhodophestrol (Ranjith et al). These compounds exhibit HTP activities such as antimicrobial, anticancer, anti inflammatory, COX-I & II inhibition, cytotoxic and phytohormonal activities.

The utilization of these vast resources is poorly understood in microorganisms. However, the microbial screening provides an opportunity to manipulate new generation drugs for efficient therapeutic approach.

WED-173
Unravelling the molecular structure and function of VirB4-like ATPases in nucleoprotein import and export

V. K. Hunsur Rajendra[1], C. Gruber[2], E. M. Schrank[3], K. Zangger[3], E. L. Zechner[4]
[1]*Institute of Molecular Biosciences,* [2]*Institute of Plant Sciences,* [3]*Institute of Chemistry,* [4]*Institute of Molecular Biosciences, University of Graz, Graz, Austria*

Bacterial type IV secretion systems (T4SS) transfer macromolecules like nucleic acids and proteins from bacteria to eukaryotes or between bacterial cells. VirB4-like proteins are associated with all T4SSs described to date. These signature ATPases function in assembly of the T4SS channel and biogenesis of extracellular pili in Gram-negative systems. They are also required for translocation of secretion substrates and nucleoprotein uptake during pilus-mediated phage infection. Very little is known about the regulation of VirB4-like ATPases in protein trafficking. It is also not known whether these proteins are involved in recognition of substrates destined for secretion. Our paradigm to study control of VirB4-like ATPases is TraC of the F-like conjugative plasmid RI.

TraC was modified with a strep-tag and its function verified by complementation of conjugative transfer of a *DtraC* derivative of R1. However, purified strep-TraC did not exhibit ATPase activity in vitro. One possible explanation may be that ATPase activity is controlled by oligomeric state. Hexamers of VirB4-like protein TrwK hydrolyze ATP in vitro and ATP binding forces the formation of hexamers. Strep-TraC was incubated with a 20-fold molar excess of non-hydrolysable ATP and analyzed by gel filtration. The chromatograms indicate that strep-TraC behaves as a monomer in solution with and without ATP. The ATPase activity might be controlled by interaction(s) of TraC with other relaxosome proteins. Possible interaction partners are currently under investigation.

Enzymatic activity of VirB4-like ATPases can also be controlled intra-molecularly. The C-terminus of the VirB4-like protein TrwK possesses alpha helices, which were shown to have an auto-inhibitory activity. Secondary structure prediction of TraC shows four conserved alpha helices. The significance of these alpha helices for enzyme regulation is under investigation. Interestingly, truncated versions of TraC, lacking individual alpha helices are unable to complement the function of wild type *traC* in conjugative transfer.

To test the hypotheses that TraC is subject to auto-inhibition and that the alpha helices mediate protein-protein interactions, truncated versions of TraC will be purified. The ability of truncated TraC to hydrolyze ATP will be tested with and without other potential binding partners. Also, the purified truncated versions of TraC will be used in protein-protein interaction studies with other relaxosome proteins. Furthermore, these TraC truncated variants are used in phage-infection assays to study nucleoprotein uptake by T4SS.

Vibrio vulnificus HPr stimulates pyruvate kinase A activity to protect cells against H_2O_2 stress

H. M. Kim[1], Y.-H. Park[1], Y.-R. Kim[1], Y.-J. Seok[1,2]
[1]*Deparment of Biological Sciences and Institute of Microbiology,* [2]*Department of Biophysics and Chemical Biology, Seoul National University, Seoul, Republic of Korea*

The bacterial phosphoenolpyruvate (PEP):sugar phosphotransferase system (PTS) consists of two general energy-coupling proteins (enzyme I and HPr) and several sugar-specific enzyme IIs. In addition to the phosphorylation-coupled transport of sugars, the PTS components participate in many physiological processes. In this study, we have identified pyruvate kinase A (PykA) as a binding partner of HPr in *V. vulnificus*, which is an opportunistic human pathogen. The interaction between HPr and PykA was dependent on the presence of inorganic phosphate and only unphosphorylated HPr interacted with PykA. Domain swapping experiments between PykA and its *E. coli* ortholog revealed a requirement of the C-terminal domain of *V. vulnificus* PykA for specific interaction with *V. vulnificus* HPr. Unphosphorylated, but not phosphorylated, HPr decreased the Km of PykA for PEP about 4 fold without affecting Vmax. A *pykA* mutant became more susceptible to H_2O_2 than wild-type *V. vulnificus* and this sensitivity was completely rescued by the addition of pyruvate to the culture medium. Based on these data, we suggest that PykA plays an important role in H_2O_2 stress response in the presence of PTS sugars.

Keywords: Hydrogen peroxide, Phosphotransferase system (PTS), Pyruvate kinase.

Role of vitamin E on PPARgamma and Nrf2 related signalling pathways in in vivo model of atherosclerosis

P. Bozaykut[1], B. Karademir[1], B. Yazgan[1], E. Sozen[1], R. Siow[2], G. E. Mann[2], N. K. Ozer[1]
[1]Deparment of Biochemistry, Medicine Faculty, Marmara University, Istanbul, Turkey, [2]Cardiovascular Division, School of Medicine, King's College, London, UK

Increased serum cholesterol and oxLDL are implicated in the pathogenesis of atherosclerosis. We have previously reported a significant increase in mRNA levels of the scavenger receptor CD36 in aortas of cholesterol fed rabbits and shown that vitamin E treatment attenuated increased CD36 expression (1). In the present study, we investigated redox signaling pathways involved in the cellular defence against cholesterol diet induced atherogenesis and the effects of vitamin E on related signaling pathways in in vivo model of atherosclerotic rabbits. Male albino rabbits were assigned randomly to three groups fed: (i) vitamin E deficient diet, (ii) vitamin E deficient diet containing 2% cholesterol, and (iii) vitamin E deficient diet containing 2% cholesterol with daily intramuscular injections of vitamin E (50 mg/kg). After four weeks, supplementation with cholesterol resulted in ~30-fold increase of plasma cholesterol while vitamin E treatment increased serum vitamin E levels 11-fold (mean ± SD, $n = 7$, $p < 0.001$). When ROS generation was detected by lucigenin chemiluminescence, a significant increase in cholesterol group determined and vitamin E treatment inhibited cholesterol-mediated increase in ROS generation. (mean ± SEM, $n = 3$, $p < 0.001$). The effects of vitamin E supplementation on altered cellular signaling events in aortae were further examined by determining peroxisome proliferator-activated receptor gama (PPARγ), ATP-binding cassette transporter A1 (ABCA1), and matrix metalloproteinase-1 (MMP-1) mRNA levels (n = 5 per each group) by quantitative RT-PCR and protein levels of MMP-1, nuclear factor-erythroid 2-related factor 2 (Nrf2), and glutathione S-transferase α (GSTα) (n = 3 per each group) by immunoblotting. Increased MMP-1 and, decreased GSTα expession demonstrated that a cholesterol-rich diet contributes to the development of atherosclerosis, whereas vitamin E treatment affords protection by decreasing MMP-1 and increasing PPARγ, GSTα and ABCA1 levels in aortae from rabbits fed a cholesterol-rich diet for 4 weeks. Notably, Nrf2 protein expression was increased in both the cholesterol fed and vitamin E supplemented group. Although Nrf2 activation can promote CD36-mediated cholesterol uptake by macrophages, the increased induction of Nrf2-mediated antioxidant genes is likely to contribute to decreased lesion progression. Thus, our study demonstrates that Nrf2 can mediate both pro- and anti-atherosclerotic effects.

(Mis)regulation of nuclear import of disordered proteins in neurodegenerative disease and cancer

T. Madl[1]
[1]Chemistry/Structural Biology, Technische Universität and Helmholtz Zentrum München, Garching, Germany

"Function requires structure" – this is a common statement throughout structural biology. Indeed, most proteins need to adopt a defined 3D structure to carry out their function. However, recent studies have indicated that a large fraction of the genome of any organism encodes proteins that do not adopt a defined 3D structure but are nevertheless essential for cellular function: the so-called intrinsically disordered proteins/regions (IDP/Rs). IDP/Rs are highly abundant in nature and their functional repertoire complements the function of ordered proteins. Here, I will present our recent published and unpublished results on the molecular mechanism of (mis)regulation of nuclear import involving IDP/Rs, their essential role in signal transduction, as well as their link to ageing and age-related diseases such as cancer, diabetes, and neurodegeneration [1–3].

One prominent example of a largely disordered class of proteins are transcription factors. The *bona fide* tumor suppressor Forkhead box O transcription factors (FOXO) are of vital importance in cell-cycle control, oxidative stress resistance, tumor suppression, and organismal lifespan. FOXO activity and cellular localization are regulated through an intricate code of post-translational modifications (PTMs). However, how FOXOs re-localize to the nucleus as response to oxidative stress remains enigmatic. Using a combination of structural and *in vivo* techniques we have discovered a novel mechanism of oxidative stress-mediated nuclear import involving the formation of an inter-molecular disulfide bond between the disordered region of FOXO and the nuclear import factor transportin-1 [2]. This highly conserved mechanism not only connects redox signaling directly to the longevity and tumor suppressor protein FOXO but provides first evidence for a novel nuclear import mechanism specific for redox proteins.

Furthermore, I will present our recent results for the molecular mechanisms of (mis)regulation of the protein Fused-in-Sarcoma (FUS) and Tau involved in the neurodegenerative diseases amyotrophic lateral sclerosis (ALS)[3], and Alzheimer's [1], respectively.

Summarizing, our recent results demonstrate the key role of IDP/Rs in transcription factors (FOXO), RNA-binding proteins (FUS), and other disordered proteins (Tau). We find that these IDP/Rs are essential for regulation in signaling – they act as interaction hubs for a plethora of co-factors and platforms for an intricate code of PTMs. Given that misregulation linked to these regions is the cause of a plethora of diseases, our structural and functional studies provide the first insight into the underlying molecular mechanisms.

WED-177
A functional analysis of regulatory regions that differ between Neandertals and present-day humans

S. Weyer[1], S. Pääbo[1]
[1]*Department of Evolutionary Genetics, Max Planck Instiute for Evolutionary Anthropology, Leipzig, Germany*

The closest evolutionary relatives of present-day humans are the Neandertals and their Asian sister group, Denisovans. They share a common ancestral population with modern humans about 553,000 and 589,000 years ago. Because high-quality genomes from a Neandertal and a Denisovan individual are available, it is possible to identify changes in the genome that are present in all or almost all present-day humans but where the Neandertal and Denisovan genomes carry the ancestral, ape-like variants. This is an interesting class of changes since some of them may be of relevance for functional traits where modern humans differ not only from the great apes but also from extinct earlier forms of humans.

In order to begin to investigate such genetic changes that may be of regulatory significance, we focus on well-described transcription factor binding sites that are conserved among primates, Neandertals, and Denisovans yet changed in modern humans. We have cloned the ancestral and derived variants of 25 such binding sites into vectors containing a minimal promoter. After transfection into several cell lines we use the amounts of transcripts produced to assess the activity of the two variants. A number of constructs show transcriptional activity above background and differences in activity between the ancestral, Neandertal-like variant and the variant specific to present-day humans. The results will be presented and discussed.

Keywords: enhancer, human evolution, transcriptional regulation.

A new flexible approach to model the structure of large macromolecular assemblies with cross-linking data. Application to RNA polymerase III

M. Ferber[1], J. Kosinski[2], M. Beck[2], C. Mueller[2], M. Nilges[1]
[1]*Institut Pasteur, Paris, France,* [2]*European Molecular Biology Laboratory, Heidelberg, Germany*

Cross-linking/mass spectrometry has been recently demonstrated to allow modeling of large macromolecular assemblies based on structures of individual subunits. Although modeling methods based on cross-links have been proposed, the current methods do not deal well with conflicting cross-links. Moreover, current methods usually do not allow using cross-links that link regions missing in the starting structures, thus excluding many potentially useful modeling restraints. Here, we propose a novel semi-automated computational method to model the structure of large protein assemblies based on cross-links. To automatically deal with conflicting cross-links, we use a log-normal distance potential and a re-weighting scheme inspired by methods for structure determination from NMR data. Furthermore, the method allows modeling subunit structures as flexible molecules and including missing regions of the starting structures explicitly. To demonstrate the method, we performed cross-linking of 17-subunit yeast RNA Polymerase III (Pol III) and built its atomic model. The model agrees with published cryo-electron microscopy reconstruction and previously published cross-links not used in the modeling.

Keywords: Molecular modeling, MS cross-linking data, RNA polymerase III.

WED-179
Archaeal protein aFib and Nop5p heterodimer methylates 16S rRNA site-specifically, independently of C/D guide RNA

J. Ličytė[1], M. Tomkuvienė[1], B. Clouet-d'Orval[2], S. Klimašauskas[1]
[1]*Department of Biological DNA Modification, Vilnius University, Institute of Biotechnology, Vilnius, Lithuania,* [2]*Laboratory of Microbiology and Molecular Genetics, CNRS-UMR 5100, Université Paul Sabatier, Toulouse, France*

Archaeal fibrillarin (aFib) is a well-characterized RNA 2′-O-methyltransferase that acts in C/D RNP complexes. It has been established that the methylation target is selected via base-pairing of the guide RNA of the complex and aFib finds it only by interactions with the other proteins of the complex: L7Ae and, especially, Nop5p (1). Nevertheless, we investigated functions of C/D RNP components and showed that *Pyrococcus abyssi* aFib in a heterodimer with Nop5p, and without other components of a C/D RNP, effectively methylates 16S rRNA site-specifically *in vitro*. We further identified methylated positions using tritium-methyl incorporation into RNA assay, mass spectrometry, reverse transcription stop analysis, alkaline hydrolysis. This aFib-Nop5p heterodimer activity could be an example of proteins that evolved from stand-alone enzymes to C/D RNP components acting in RNA-guided manner.

Keywords: C/D RNP, Fibrillarin, RNA 2′-O-methylation.

WED-180
Asn53Ser SNP alters human RNase κ enzymatic activity

I. K. Kokkinopoulou[1], E. D. Karousis[1], **D. Sideris**[1]
[1]*Biochemistry and Molecular Biology, University of Athens, Athens, Greece*

Single nucleotide polymorphisms are single base changes found in both coding and noncoding regions of the genome. They represent the most frequent type of DNA variation throughout the human population. It is thought that non-synonymous coding SNPs along with SNPs in regulatory regions have high impact on phenotype. RNase κ belongs to a recently identified highly conserved in all metazoans protein family whose biological role is currently under investigation. Human RNase κ is a novel endoribonuclease expressed in all developmental stages of normal and malignant tissues [1].

In this report, we present data on the biochemical and enzymatic characterization of the single nucleotide polymorphism Asn53Ser of human RNase κ. This polymorphism is the only one found within the coding region of the gene that is identified exclusively in heterozygotes. Site directed mutagenesis was employed for the construction of the mutant Asn53Ser RNase κ. The recombinant mutant enzyme was expressed in the *Pichia pastoris* eukaryotic expression system and the secreted heterologous protein was partially purified using an anion exchange chromatography. Focusing on the study of the ribonucleolytic activity of the mutant molecule, a fluorescent substrate was used. The rate of ApG bond hydrolysis was compared with the ribonucleolytic activity of the wild type enzyme. Our data indicated that the mutant RNase κ exhibited a significantly lower activity towards the synthetic substrate used for both molecules. The obtained results could partially explain the presence of the Asn53Ser polymorphism only in heterozygotes.

CAT3 gene expression profiles in response to copper stress in tolerant and non-tolerant *Brassica nigra* ecotypes

Y. Tuna[1], B. C. Keskin[1], G. C. ÖZ[2], A. R. Memon[3]
[1]*GEBI, TUBITAK Marmara Research Center, KOCAELI, Turkey,* [2]*Department of Botany, İstanbul University, Faculty of Science, Istanbul, Turkey,* [3]*Deptartment of Genetics and Biooengineering, International University of Sarajevo, Sarajevo, Bosnia and Herzegovina*

Phytoremediation is being offered as an environmentally friendly and cost-effective means of reducing metal contaminated soil and other substrates worldwide. Illumination of the defense mechanism in response to heavy metal stress in plants is essential for convenient phytoremediation approach. Our knowledge about transcriptome response to heavy metal stress is limited. The purpose of this study is to evaluate the potential of *Brassica nigra* (Black mustard) for phytoremediation of Cu from contaminated soils. The majority of differentially induced genes in our Affymetrix ATH1 microarray experiments were functionally related to metal transport, accumulation and osmotic stress response mechanism. One of these genes the Catalase (CAT3), an important enzyme of antioxidant system, was investigated for the potential role in preventing the plant from Cu-induced oxidative stress caused by reactive oxygen species. RT-PCR approach was used in order to determine the variety of expression levels of CAT3 gene in different tissues of Cu-tolerant and non-tolerant *B. nigra* ecotypes. We showed different CAT3 regulatory mechanism in response to copper stress. qPCR experiments showed that CAT3 expression level increased by copper in leaf tissue of tolerant ecotype and decreasing expression pattern by Cu was shown in shoot tissue. Conversely, in non-tolerant ecotype, maximum expression level was observed in 25 μM Cu treated shoot tissue and increasing CAT3 expression level by Cu concentration was detected in leaf tissue. CAT3 was down regulated in root tissue. All our findings strongly support that overexpressing CAT3 in black mustard could enhance the tolerance under Cu stress.

Keywords: *Brassica nigra*, CAT3, Phytoremediation.

Characterisation of microRNA promoters in the murine genome

T. Leonardi[1,2,3], N. Iraci[2,3], A. J. Enright[1], S. Pluchino[2,3]
[1]*EMBL-EBI, Hinxton,* [2]*John van Geest Centre for Brain Repair,* [3]*Wellcome Trust-Medical Research Council Stem Cell Institute, University of Cambridge, Cambridge, UK*

The promoter of protein coding genes is conventionally considered to be located a few kilobases around their transcriptional start site (TSS). However – given the short half-life of miRNA primary transcripts (pri-miRNAs) – the TSS of miRNA is in most cases not annotated, therefore the position of the promoter is usually not know and potentially located tens or hundreds of kilobases upstream of the annotated miRNA gene (pre-miRNA). Several attempts have been made to identify miRNA TSSs and promoters in human, mouse, worm and plants. Nevertheless, to our knowledge, most of the studies in mouse only made use of a limited number of experimental techniques and/or sources of information available at the time of publication. To overcome these limitations we implemented an integrative approach based on computational predictions, sequence annotations and high-throughput chromatin modification data generated by the ENCODE project to produce an accurate and comprehensive annotation of miRNA promoters in the mouse genome.

For each murine miRNA annotated in miRbase version 18 we scanned a genomic region of 100 kb upstream of it looking for features indicative of promoters. We found on average 15.7 candidate promoters for each miRNA with a mean size of ~1.4 kb in accordance with the typical size of known promoters. We also found that they were typically located 5 kb upstream of the miRNA, supporting the validity of our approach and in accordance with previous reports. When we inspected what chromatin modifications supported each of the candidate promoters we found that nearly all of them have a DNase Hypersensitivity Site (DHS), more than 50% have both a DHS and H3K4 trimethylation (H3K4me3), and more than 30% have a DHS mark, an H3K4me3 mark and a CpG island. We also found that the highest scoring promoters are on average more conserved than all other promoters and more conserved than random genomic locations of the same size, strongly supporting the validity of our approach. Finally, by chromatin immunoprecipitation assay (ChIP) and methyl-CpG immunoprecipitation (mCIP) we validated H3K4me3 and CpG methylation of the predicted promoters of selected miRNAs, confirming the validity of our approach. Taken together, these results provide a valuable resource that will help to shed light on the transcriptional regulation of miRNAs in the murine genome.

Characterisation of the human URG-4 (Up-Regulated Gene 4) gene promoter

F. Kockar[1], E. Tokay[1]
[1]*Balikesir University, Faculty of Science and Literature, Balikesir, Turkey*

Upregulated gene 4 (URG4), a novel gene located on 7 chromosome (7p13), was firstly found as natural effector of HBxAg protein. It is reported that, this gene contributed to hepatocarcinogenesis regulating the expression of cyclin D1 protein, associated with the onset of tumorigenesis and cell cycle regulation. Due to the proliferative activity of URG4 in osteosarcoma cells, URG4 may be a valuable prognostic marker for certain types of human cancer. Also, there is no information about transcriptional activity of this gene. In this study, promoter activity and relation with transcription factors of URG-4 promoter site was clarified.

Initially, URG-4 promoter site was detected by bioinformatically and amplified based on PCR strategy. *In silico* analysis of URG-4 promoter site was showed that, it has 80% GC content and secondary structure. Therefore, different PCR strategies such as enhancers (Ethylen glycol, DMSO, Betain and 7-DeazaGTP), $MgCl_2$ and gDNA concentration gradients were tried. 5′truncated promoter fragments of URG-4 (-109/+63, -344/+63, -261/+63 and -109/+63) were cloned into pMetLuc Luciferase Reporter vector to detect core promotor activity by using transient transfection assay. Lusiferase activity of promoter fragments were measured by utilizing luminometer with Reporter Assay kit. Transient transfection analysis indicates -109/+63 promoter fragment is sufficient to drive transcriptional activity. In addition, expression plasmids containing SP1, USF and C/EBP transcription factors were cotransfected with URG-4 promoter fragments. Cotransfec-

Characterization of ARF1 paralogs in the nodular structure formation of *Medicago truncatula*

E. Yüzbaşıoğlu[1], B. Yüksel[2], E. Dalyan[1]

[1]Faculty of Science, Department of Biology, Istanbul University, Istanbul, [2]Plant Molecular Biology Laboratory, Advanced Genomics and Bioinformatics Research Group, TUBİTAK,Genetic Engineering and Biotechnology Institute, Kocaeli, Turkey

ADP-ribosylation factors (Arf), a family of small GTP-binding proteins, have been shown to be important for housekeeping functions; e.g., basic cellular trafficking in yeast, mammalian, and plant systems. Although these genes are very well conserved both functionally and sequentially throughout Eukaryotae, some members of these genes have been reported to be sub-or neofunctionalized in plant kingdom. In this study, we investigated the possible lineage-specific functional evolvement of four *Arf1* paralogous genes in the development and maintenance of nodular structures of *Medicago truncatula*. Even though all of *Arf1* paralogs expressed in every tissue of *M. truncatula,* but the expression level of them was higher in nodular tissues. Also, we further investigated the temporal expression profile of *MtArf1* paralog genes by looking into the expression at early stages of after the infection of the roots with *S. melliloti*. The previously identified gene, *Mtr13597775,*solely expressed at 72 hpi (hour post inoculation) and *Mtr27524313* significantly expressed at 6 dpi (day post inoculation), We further confirmed the temporal expressional characteristics of Arf paralogs at protein level by Western blot analyses. That is, Arf1 protein expression level was much higher in the infected roots and nodules in comparison to shoots. The findings in this study could suggest that Arf genes likely play an important role in the nodule formation of *M. truncatula*.

Keywords: ADP-ribosylation factors, medicago, nodule.

WED-185

Characterization of group I introns in bacterial flagellin gene and homing endonuclease from thermophilic *Bacillus* sp. Kps3

M. Ishizuka[1], W. Umano[1], N. Ishibashi[1], J. Hayakawa[1], G. Akanuma[1]

[1]Department of Applied Chemistry, Faculty of Science and Engineering, Chuo University, Tokyo, Japan

Bacterial flagellum is a rotary motility device that consists of three parts: a basal body, a hook, and a long helical filament. The flagellar filament is composed of a single protein subunit, flagellin, which is abundantly, expressed when flagellar filament is elongated. The self-splicing group I introns were identified in flagellin genes of thermophilic *Bacillus* species, which interrupt highly conserved 3′ region. These group I introns can be spliced at wide range temperature. *In vitro* splicing efficiency was increased with temperature, and the most efficient splicing was observed around the optimal growth condition of these thermophiles, 60–70°C.[1,2)]

We demonstrated the presence of two introns in the gene encoded flagellin in thermophilic *Bacillus* sp. Kps3. In addition, free-standing homing endonuclease gene (HEG) was found in downstream of the flagellin gene. Homing endonuclease (HEase) is a restriction enzyme which recognizes non-palindromic DNA sequence (14–40 bp). HEG is usually encoded within their group I or group II introns, and rarely located at the outside of the introns as an independent open reading frames (free-standing). HEG play an important role in the beginning of the intron transition (intron homing). It is known that many of the introns are found in archaea and eukaryotes. However bacterial introns are mostly found in non-protein coding genes, such as tRNA or rRNA. We analyzed the HEase to elucidate the function in detail. We found that the HEase catalyzes double-strand break of the gene encoded flagellin whose two introns were eliminated. Furthermore, we revealed that cleavage site of the HEase is 5′-GGCTCAAGC↓CAACC-3′ which located downstream of the insertion site of intron II.

Immunity against viruses and plasmids provided by CRISPR-Cas systems relies on a ribonucleoprotein effector complex that triggers the degradation of invasive nucleic acids. Effector complexes of Type I (Cascade) and Type II (Cas9-dual RNA) target foreign DNA. Intriguingly, the current knowledge regarding Type III systems maintains that Csm (III-A) complexes target DNA, whereas Cmr (III-B) complexes target RNA. Here we aimed to investigate nucleic acid targets and their degradation by the *Streptococcus thermophilus* (St) Csm (Type III-A) complex. We expressed the Type III-A St CRISPR-Cas locus in *Escherichia coli*, isolated the Csm effector complex and characterized its activity *in vitro*. Further, we demonstrated that Csm complex may be reprogrammed to cleave the NA substrate of interest. This work was funded by the Research Council of Lithuania (grant MIP-40/2013 to G.T.).

Keywords: CRISPR-Cas, Csm, effector complex.

Characterization of the mechanisms of transcription termination by the helicase Sen1p

Z. Han[1], D. Libri[1], O. Porrua[1]

[1]Institut Jacques Monod, paris, France

Pervasive or hidden transcription is widespread in eukaryotes and needs to be controlled in order to avoid interferences with gene expression. A key actor in controlling pervasive transcription in *Saccharomyces cerevisiae* is the Nrd1-Nab3-Sen1 (NNS) complex, which elicits early termination of non-coding RNAs and targets them for degradation/processing by the nuclear exosome. Nrd1p and Nab3p are RNA binding proteins that interact with specific sequences on the nascent transcript while Sen1p is a putative RNA and DNA helicase. We have recently developed a

© 2014 The Authors. FEBS Journal © 2014 FEBS

transcription termination *in vitro* assay using purified RNA polymerase II and NNS components to dissect the mechanism of termination. We have shown that the helicase Sen1p alone can elicit dissociation of elongation complexes *in vitro*. In addition, we have found that, akin to the bacterial terminator factor Rho, Sen1p interacts with the nascent RNA and hydrolyses ATP to provoke transcription termination.

In this work, we have pursued the study of the mechanisms of action of Sen1p. We have first performed a biochemical characterization of Sen1p activities to explore its capacity to bind several types of nucleic acids, as well as to unwind RNA-DNA and DNA-DNA duplexes. Finally we have also performed a functional dissection of Sen1 protein to identify the minimal regions that are required for ATP hydrolysis and for transcription termination. Our results provide important insights into the function of Sen1.

Keywords: Sen1p helicase, transcription termination.

Deciphering the cellular role of HelD, a helicase-like protein associated with bacterial RNA polymerase

P. Sudzinová[1], J. Wiedermannová[1], T. Koval' [2], J. Dohnálek[2], O. Delumeau[3], P. Noirot[3], L. Krásný[1]
[1]*Institute of Microbiology,* [2]*Institute of Biotechnology, Academy of Sciences of Czech Republic, Prague, Czech Republic,* [3]*INRA, Jouy-en-Josas, France*

Bacterial RNA polymerase (RNAP) is a central enzyme of gene expression. The activity of RNAP can be affected by a number of factors. We identified a new interaction partner of RNAP in *Bacillus subtilis*, a helicase-like protein termed HelD. Recently, we showed that HelD binds to RNAP and stimulates its activity in an ATP-dependent manner. Here, we will present data addressing the global effect of HelD on the transcriptome, a structural/functional analysis of HelD domains, and molecular details of HelD interaction with RNAP. A model of HelD's functioning will be presented and its cellular role(s) will be discussed.

Deletion of the maltase gene regulatory regions in yeast *Candida utilis*

J. Krahulec[1], H. Boňková[1], V. Lišková[1], M. Osadská[1], S. Stuchlík[1], J. Turna[1]
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Bratislava, Slovakia*

Candida utilis is an important organism with a significant potential in pharmaceutical and biotechnology applications. In the last few years it has been demonstrated that the yeast system *Candida utilis* represents a promising expression host, generating relatively high levels of recombinant proteins. However a basic knowledge of regulation of gene expression, which is needed for more extensive use of this organism, is lacking. We have successfully adapted the Cre-*loxP* system for the use in *C. utilis* and applied it to obtain a null mutant of the maltase gene by multiple gene disruptions. The first step was to introduce a mutagenesis cassette harboring a marker gene between two *loxP* sites into the target cells. By disruption of maltase gene and regulatory regions, we managed to prepare mutants without marker gene. After the disruption procedure both native and mutated alleles still existed even at high concentration of selective antibiotic. The deletion mutants exhibited a reduced level of α-glucosidase activity. When tandemous mutagenesis procedure was used on clone with reduced α-glucosidase activity, the clone with no detectable α-glucosidase activity and only with mutated allele was obtained.

This work is result of project implementation: "Production of biologically active agents based on recombinant proteins" (ITMS 26240220048) supported by the Research and Development Operational Program funded by the ERDF.
Keywords: candida, deletion, glucosidase.

Desulfovibrio gigas HcpR is required for growth under nitrosative stress conditions

S. M. da Silva[1], C. Amaral[1], C. Pimentel[1], S. S. Neves[1], C. Rodrigues-Pousada[1]
[1]*Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal*

Desulfovibrio gigas is an anaerobic microorganism that belongs to the group of sulfate reducing bacteria (SRB). SRB are metabolic versatile microorganisms widespread in nature as well as in the human gastrointestinal tract. The byproduct of sulfate respiration, hydrogen sulfide gas, is highly toxic and corrosive and thus has a major negative impact in economy and health. In their natural environments, SRB are often exposed to reactive nitrogen species (RNS), produced by other bacteria or by the human innate immune system. RNS interact with several cellular targets causing great damage to microbial cells. In order to overcome those deleterious effects microorganisms have developed several mechanisms that protect them against nitrosative stress. Although *Desulfovibrio* is the most studied genus of SRB, the mechanisms and regulatory elements involved in this protection are still poorly understood. Using *D. gigas* as a model organism we addressed the importance of HcpR, a transcriptional regulator belonging to the family of FNR/CRP regulators, in nitrosative stress response. We found that the growth of a mutant lacking HcpR is severely impaired under nitrosative stress conditions. An *in silico* search in *D. gigas* genome revealed several putative targets of HcpR whose dependence on this transcriptional regulator was experimentally validated by quantitative real-time PCR. Furthermore, we showed for the first time in *Desulfovibrio* spp. that recombinant HcpR is able to bind the consensus sequence present in the promoter region of *hcp* gene. We also found that *D. gigas* genome contains a related HcpR regulator, HcpR-like, that has orthologs in several other *Desulfovibrio* spp.

Keywords: Desulfovibrio gigas, HcpR, Nitrosative stress.

RNA decay is usually mediated by protein complexes and can occur in specific foci like P-bodies in the cytoplasm of eukaryotes. In human mitochondria little is known about the spatial organization of the RNA decay machinery and the ribonuclease responsible for RNA degradation was searched for many years. We demonstrated that silencing of human polynucleotide phos-

© 2014 The Authors. FEBS Journal © 2014 FEBS

phorylase (PNPase) causes accumulation of RNA decay intermediates and increases the half-life of mitochondrial mRNA. A combination of fluorescence lifetime imaging microscopy with Förster resonance energy transfer (FLIM-FRET) and bimolecular fluorescence complementation (BiFC) experiments proved that PNPase and hSuv3 helicase form a complex in vivo. This complex, referred to as the degradosome, is formed only in specific foci (named D-foci) which co-localize with mitochondrial RNA and nucleoids. Notably, interaction between PNPase and hSuv3 is essential for efficient mitochondrial RNA degradation. This provides indirect evidence that mitochondrial RNA decay takes place in foci present in the mitochondrial matrix. We present results showing that D-foci are sites for RNA decay in human mitochondria.

Keywords: mitochondrial RNA, RNA degradation, spatial organisation of RNA transactions.

DNA electrostatics: its role in transcription regulation in prokaryotes, a new natural selection factor, and a base for DNA phenotype and biophysical bioinformatics

A. A. Osypov[1]
[1] *Institute of cell biophysics of RAS, Pushchino, Russian Federation*

Genome DNA physical properties (PP) define its shape in the functional space and influence its interactions with proteins, esp. for transcription regulation (TR). DNA is highly charged and electrostatics (E.) contributes greatly to the subject. DEPPDB was developed to provide all available information on these properties of genome DNA combined with its sequence and annotation of biological and structural properties of genome elements and whole genomes, organized on a taxonomical basis.

DEPPDB and its tools [1,2] (deppdb.psn.ru or electrodna.psn.ru) were used to carry out the analysis.

E. potential (EP) is distributed non-uniformly along DNA molecule and correlates, though not corresponds exactly, with GC content, strongly depending on the sequence arrangement and its context (flanking regions). Binding frequency of RNA polymerase to DNA along the genome, measured in direct experiment, correlates to the calculated EP.

TR areas have EP and other PP peculiarities. Binding sites of transcription factors of different protein families in different taxa are located in long areas of high EP. Promoters in average have high value and heterogeneity of EP profile. The transcription starting sites of prokaryotic genomes are characterized by extensive (hundreds of bp) zone of high EP and some peculiarities directly around TSS. This is associated with protein binding and formation of PP due to transcription machinery. Specific details of the TSS EP architecture are similar in related taxa. Promoters up-element demonstrates electrostatic nature.

E. effects on genome functioning interact with other PP of DNA, in particular - bending, thermal stability, supercoiling. They may interact with E. in both, formation, and TR.

E. plays important and universal role in TR in prokaryotes, affecting proteins binding probability and positioning accuracy. It may influence horizontal gene transfer, TR systems evolution and contribute to genome regulatory regions high AT content.

PP formation principles affect such fundamental problems as Chargaff's II rule, redundancy of the genetic code, neutrality of synonymous substitutions; and justify the fundamental idea of DNA phenotype, defining the new principle of biophysical bioinformatics.

Domain organisation and functional analysis of small RNA methyltransferase HEN1

S. Baranauske[1], M. Mickutė[1], S. Klimašauskas[1], G. Vilkaitis[1]
[1] *Vilnius University Institute of Biotechnology, Vilnius, Lithuania*

Small, 21-33-nucleotide RNA molecules are essential for post-transcriptional gene regulation in eukaryotic organisms including humans. All types of small interfering RNAs (siRNAs) and microRNAs (miRNAs) in plants, piwi-interacting RNAs (piRNAs) in animals require 2′-O-methylation on the 3′-terminal nucleotide for their stabilization, preventing them from a 3′-end uridylation and degradation. This specific modification is carried out by the S-adenosyl-L-methionine–dependent small RNA 2′-O-methyltransferases, which are also found in metazoan, fungal, and bacterial proteomes. The best studied representative of them is *Arabidopsis thaliana* HEN1.

Analysis of tertiary protein structure revealed that *Arabidopsis* small RNAs methyltransferase consists of five domains. To elucidate experimentally the function of each domain, miRNA/miRNA* and siRNA/siRNA* binding analysis, steady-state and pre-steady-state kinetic studies of truncated variants of methyltransferase and HEN1 mutants with point mutations were done. The obtained data indicate that: the methyltransferase domain of HEN1 is important for methyl group transfer; the first double-stranded RNA-binding domain is required for substrate recognition and its tight binding; the second dsRNA-binding domain as well as the extra loop between beta sheets β1 and β2 in R1 (residues 31 to 49), which communicates with methyltransferase domain, are the essential factors decelerating the decay of ternary complexes after methylation reaction. Similar binding and methylation parameters observed with siRNA and miRNA substrates suggest that the HEN1 does not encompass any domain necessary for distinguishing two types of small non-coding RNAs *in vitro*. As the central part of HEN1 is not responsible for the interaction with substrates, it was supposed that this part can be important for binding others biogenesis proteins in plants. This hypothesis was confirmed by data obtained using electrophoretic mobility shift assay, yeast two-hybrid system and pull-down method. The obtained results provide valuable insights into the enzymatic mechanism and biological role of an abundant class of small RNA 2′-O-methyltransferases, which share similar catalytic domains, and are widely distributed in all biological kingdoms except archea.

Keywords: Methyltransferase, HEN1, microRNA biogenesis.

Drought stress alleviate boron toxicity by enhancing stress related gene expressions

M. S. Aydın[1]
[1]*Biology, Fatih University, Istanbul, Turkey*

Boron (B) is an essential micronutrient for plant growth and it is toxic in high concentrations. Also, drought is an important abiotic factor effects plant growth and development. To understand plant stress responses in high B condition with drought, we focused on transcript accumulation of three stresses related genes: *GR1*, *MT2*, and *Hsp90*. Quantitative real-time PCR technique was used to determine stress responses of these genes in B and drought stressed tomato leaves. Also, MDA content of plants were detected to observe stress level. Results showed that the genes were over-expressed upon B and drought-stressed induction. The highest relative fold change value was measured on *GR1* transcript (7–8 times comparing with control), indicating the activation of oxidative stress enzyme to tolerate B and drought stresses. Also, *Hsp90* transcript was over-expressed. However, *MT2* expression was not significantly changed. The results showed that the stresses were not enough to trigger the stress responsive genes alone. Dual effect, B with drought stress, can cause to activation of those genes. Hence, we proposed that drought stress may alleviate the B-toxicity by activating the stress-related genes in tomato.

Electrostatic properties of bacteriophage lambda genome and its elements

A. A. Osypov[1], G. Krutinin[1,2], E. Krutinina[1], S. Kamzolova[1]
[1]*Institute of cell biophysics of RAS,* [2]*DIAKON Ltd, Pushchino, Russian Federation*

Bacteriophage lambda (L.) is a classical model object and its genome is extensively studied. However, little is known about physical properties of its genome and its elements. Here for the first time we study their electrostatic potential (EP) properties.

Methods and Algorithms: DEPPDB and its tools [1,2] were used to carry out the analysis.

EP global distribution along L. genome corresponds to the localization of its main regulatory elements in the restricted area with high negative EP. Binding frequency of RNA polymerase to DNA along the genome, measured in direct experiment [3], correlates to the calculated EP. Strong lambda phage promoters have pronounced up-element compared to the absence of it in weak promoters. Promoters with intermediate strength possess weak up-element. Lambda-like phages strong pL promoters possess strong electrostatic up-elements, the sequence texts of which are quite different. As shown earlier [1], strong early T7-like and E.coli ribosomal promoters with pronounced up-element have high levels of the EP within it. Strong E.coli promoters such as rrnB with eliminated up-element (and thus greatly reduced strength) do not have pronounced EP valleys in the corresponding area. Mutated up-elements with enhanced promoter strength exhibit deep EP valleys and peculiarities of some other physical properties. This may indicate the direct role of EP in promoters functioning. Attachment sites of L. and E.coli have high EP for integrase recognition. Rho independent lambda and E.coli terminators have the same M-like EP profile, reflecting their palindrome nature, with the same EP scale in three-fold different annotated palindrome length. Rho dependent terminators have no common EP.

Almost all lambda genome elements exhibit E. peculiarities of different kind, that reflect their structural properties and may play role in their biological functioning. Overall genome EP reflects its transcription and host-integration regulation architecture.

Electrostatic properties of natural DNA palindromes – transcription factors binding sites and terminators

A. A. Osypov[1], G. Krutinin[1,2], E. Krutinina[1], S. Kamzolova[1]
[1]*Institute of cell biophysics of RAS,* [2]*DIAKON Ltd, Pushchino, Russian Federation*

Electrostatic properties of genome DNA are important to its interactions with different proteins, in particular those related to transcription - RNA polymerase and transcription factors.

During our studies of electrostatic properties of bacteriophage lambda (a classical model object), binding sites of different families of transcription factors and transcription start sites in different prokaryotic taxa, we revealed some common properties of the electrostatic potential distribution around the natural DNA palindromes, such as transcription factors binding sites and terminators, as well as around transcription start sites.

Rho independent lambda and E.coli terminators have the same M-like EP profile, reflecting their palindrome nature, with the same EP scale in three-fold different annotated palindrome length. Rho dependent terminators have no common EP.

The averaged profiles of the binding sites centers exhibit the pronounced rise in the negative potential value with the characteristic symmetrical profile in the consensus area. The same overall properties, though vary in particular details, are typical to binding sites of other families of transcription factors in a diverged range of bacterial taxa. The same pronounced rise in the negative potential value characterize TSS, that have M-like profile, although it is not symmetrical.

Although they share the same main property – symmetry, that reflects the palindrome nature of DNA, they may differ in the details due to different underlying sequences, that carry out their biological functions. Interestingly, terminators also have the base surrounding electrostatic potential valley, as the TFBS and TSS.

DEPPDB and its tools [1,2] were used to carry out the analysis.

Electrostatics of prokaryotic transcription factors match that of their binding sites

E. Krutinina[1], G. Krutinin[1,2], S. Kamzolova[1], A. A. Osypov[1]
[1]*Institute of cell biophysics of RAS,* [2]*DIAKON Ltd, Pushchino, Russian Federation*

Transcription regulation is well known to be influenced by physical properties of genome DNA, especially by its electrostatic interactions with different regulative proteins. We studied different families of transcription factors in different prokaryotic taxa together with their binding sites to reveal the role of these properties in the transcription regulation proteins binding.

DEPPDB and its tools [1,2] were used to carry out the analysis.

Electrostatics (E) distribution on TF surface reflects the DNA E of their binding sites. The averaged profiles of the DNA E potential aligned around the binding sites centers exhibit the pronounced rise in the negative potential value with the characteristic profile in the consensus area (often being a palindrome). The extensive (around 100–300 bp long), symmetrical overall potential rise can not be explained by the influence of the consensus alone and reflects the sequence organization of the flanking regions, contributing to the high potential area formation. Apparently this sequence organization was selected evolutionary to support the binding site recognition by the regulation protein molecule and its retention. TF have strong electropositive patch at the DNA binding area, that is surrounded by mostly electronegative or neutral surface. This may lead to proper orientation of TF molecule and facilitate DNA TF site recognition and binding.

The high potential area is relatively AT-enriched, which is reflected in that different other physical properties, especially energy-related, exhibit similar behavior, though the size and parameters of peculiarities are different. This may facilitate binding and accompanying DNA bending. The same overall properties, though vary in particular details, are typical to binding sites of other families of transcription factors in a diverged range of bacterial taxa.

The role of electrostatics in the regulations of cell genome functioning and evolution is significant and universal. This may facilitate the horizontal gene transfer and adaptation of new regulatory circuits for the pan-genome evolution.

Expression analysis of putative small GTPase in *Medicago truncatula*

E. Yüzbaşıoğlu[1], B. Yüksel[2], E. Dalyan[1], B. C. Keskin[3]
[1]*Faculty of Science, Department of Biology, Istanbul University,* [2]*Advanced Genomics and Bioinformatics Research Group, The Scientific and Technological Research Council of Turkey, Marmara Research Center,Genetic Engineering and Biotechnology Institute, Istanbul,* [3]*Plant Molecular Biology Laboratory, TUBITAK, The Scientific and Technological Research Council of Turkey, Marmara Research Center,Genetic Engineering and Biotechnology Institute, Kocaeli, Turkey*

The recent studies on genomes of *Medicago truncatula* and symbiont nitrogen fixing bacterium, i.e., *Sinorhizobium meliloti*, have contributed to the better elucidation of the symbiotic associations between rhizobial bacteria and leguminous plants at molecular level. Even though many genes have been reported to be evolved at Fabaceae lineage, possibly playing role in the development and function of the nodular structures, the nodulation has not been yet fully illuminated at molecular level. Small GTP-binding proteins purported to be involved mainly in basic cellular functions such as molecular switches in signal transduction, cell proliferation, cytoskeletal organization, and intracellular membrane trafficking. It is very likely that these genes could have been subfunctionalized in legume-specific manner to regulate processes related to nodulation. To assess the validity of this assumption, we have investigated the spatiotemporal expressional characteristics of the previously identified (*Yüksel and Memon, 2008) small GTP-binding genes, namely, Arf (*MtrGB13780538*, *MtrIMGAAC144806_7.1*), Rab (*MtrGB13781173*, *MtrGB13781681*, *MtrPUT45174*, *MtrPUT18368*, *MtrPUT155272*, *MtrIMGAAC1221648.2*), Rob (*MtrIMGAAC140545-16.1*). In brief, the quantitative reverse transcription PCR analyses indicated that these putative small GTPase genes have different expression profiles in different plant tissues of *Medicago truncatula*. All genes had significant level of expression in the root, nodules, petioles, stems, and leaves. However, the expression level of particular putative nodule-specific gene, i.e., *MtrPUT45174, MtrGB13781681, MtrPUT155272, MtrIMGAAC1221648.2 MtrPUT18368* were noticeably higher a in the infected roots and nodular structures. To further more detailed experiments will be needed to better assess the possible key role of these genes in the establishment and maintenance of nodular structures.

Expression patterns of catalase genes in maize plants colonized with the bird cherry-oat aphid (*Rhopalosiphum padi* L.)

H. Sytykiewicz[1], P. Czerniewicz[1], I. Sprawka[1], B. Leszczyński[1], C. Sempruch[1], A. Urbańska[1], A. Klewek[1], A. Skwarek[1]
[1]*Department of Biochemistry and Molecular Biology, Siedlce University of Natural Sciences and Humanities, Siedlce, Poland*

The purpose of this study was to investigate impact of *Rhopalosiphum padi* L. (bird cherry-oat aphid) colonization on relative expression of *cat1* and *cat2* genes encoding the relevant catalase isoforms in tissues of maize (*Zea mays* L.) plants. The biotests were accomplished on 14-d-old seedlings of Zota Karowa (aphid-susceptible) and Waza (aphid-relatively resistant) genotypes. Four levels of insect infestation were tested: 5, 10, 20 and 40 wingless parthenogenetic females per plant. Transcriptional activity of the two catalase genes was analysed after 1, 2, 4, 8, 24, and 48 h post-initial aphid infestation (hpi). Real-time qRT-PCR was applied to quantify the amount of *cat1* and *cat2* transcripts, and the data were normalized to glyceraldehyde 3-phosphate dehydrogenase (*gapdh*) gene. The insect attack led to profound alternations in gene expression levels compared to the non-treated controls. The highest transcriptional reprogramming of both examined genes in seedlings of investigated maize plants was evidenced after 24 and 48 hours of the aphid feeding. Importantly, it was demonstrated significant intervarietal differences in the scale of insect-elicited modulations in expression of the targeted catalase genes. The obtained results suggest a pivotal role of catalase isozymes in counteracting the redox imbalance occurring within *R. padi*-attacked maize plants.

Keywords: Catalase genes, Maize genotypes, Rhopalosiphum padi.

Functional analysis of a gene encoding a protein of Spen type, in *Arabidopsis thaliana* L. (Magnoliophyta: Brassicaceae)

M. Martinez-Trujillo[1], G. Solis-Guzman[1], Y. Carreon-Abud[1]
[1]*Biologia, Universidad Michoacana, Morelia, Mexico*

The family of Spen proteins (split ends) greatly varies in size (90–600 kD). These proteins are characterized by the presence of at least one RRM domain (RNA recognition motif) that allows them to bind to RNA, and a SPOC domain that allows them to interact with other proteins. RRM domain contains 90 amino-acid residues and it is found in a variety of hnRNPs proteins (heterogeneous nuclear ribonucleoproteins) which are implicated in the RNA alternative splicing, and in components of snRNPs proteins (small nuclear ribonucleoproteins). SPOC domain contains approximately 165 amino-acid residues and it is implicated in signaling pathways in development, facilitating protein-protein interaction. Spen proteins are involved in different biological processes (1).

The At4g12640 gene encodes a 823 aa putative protein containing two RRM motifs (25–92 aa 152–220 aa) and a SPOC domain (471-567 aa). We generated gene constructs in which a segment of 1000 base pairs of the promoter was fused to the marker gene *uidA::GFP* using the Gateway® technology, *A. thaliana* plants were transformed by the modified floral dip method (2), using *A. tumefaciens* strain pGV2260. Expression associated to the vascular tissue was observed in the transformed plants in the following structures: root, cotyledon leaf, true leaf and stamens. In the gynoecium the expression was detected in the developing embryos.

The second gene that encodes a protein of type spen, in Arabidopsis is *FPA*, which participates in the regulation of the autonomous pathway of flowering (3). However, the expression patterns of both genes are different, so we consider that At4g12640 participates in the development of the embryo and in vascular tissue. Moreover, inactivation and overexpression of the gene in the phenotype of *A. thaliana plants* are being analyzed to infer aspects of its biological function, which will be discussed in more detail.

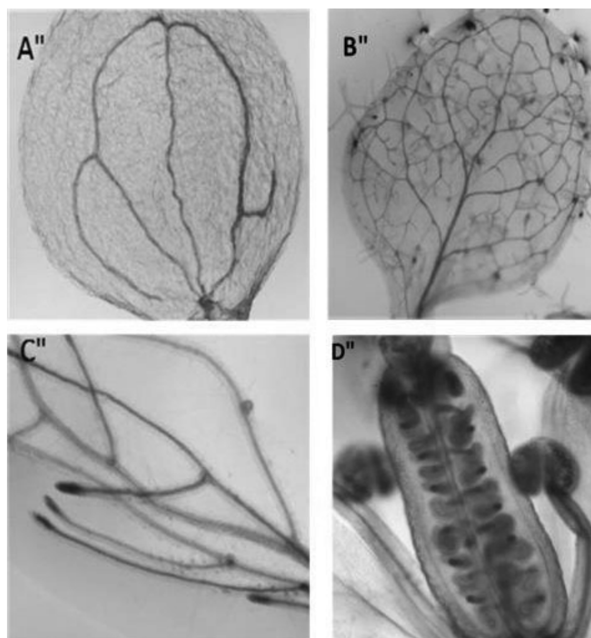

Fig. 1. Expression conferred by the promoter of the At4g12640 gene in transformed plants of *Arabidopsis thaliana*. (A) cotyledon leaf, (B) true leaf, (C) Roots, (D) Gynoecium with developing embryos.

Functional promoter analysis of the developmentally regulated A/B.L9 chorion gene pair in *Bombyx mori*

S. P. Tsatsarounos[1], G. C. Rodakis[1], R. Lecanidou[1]
[1]*Faculty of Biology, National & Kapodistrian University of Athens, Athens, Greece*

In the silkmoth *Bombyx mori*, chorion genes of the same developmental specificity are organized in divergently transcribed α/β gene pairs which share a common 5′ flanking promoter region. To date, the suggested model describing the developmental regulation of these genes implicates both *cis*-elements, harbored in their bidirectional promoters and their corresponding transcription factors (BmC/EBP, BmHMGA, BmCHD1, BmGATAβ).

In order to investigate the *A/B.L9* promoter (pL9) architecture (figure 1) and its contribution to temporal gene specificity, several pL9 constructs, bearing different *cis*-element mutations, were cloned upstream of the *lac*Z reporter gene in both orientations, so that the *lac*Z gene stood in for either the α- or the β- chorion gene. These were used in an electroporation-based transient

© 2014 The Authors. FEBS Journal © 2014 FEBS

expression method for *ex vivo* developing follicles. Constructs containing the complete promoter were used as control.

Mutation of the HMGA recognition site rendered pL9 completely inactive as expected, since HMGA is responsible for recruitment of transcription factors on the promoter. Promoter constructs with functional only one of the C/EBP1, C/EBP3 or C/EBP4 sites were not capable of initiating transcription in both directions. However, the pL9 construct with functional only the C/EBP2 site could initiate transcription in both directions, while mutation of the C/EBP2 binding site resulted in complete inactivation of pL9. Thus, the C/EBP2 site was required for promoter activation. The promoter construct with functional only the C/EBP3 site made pL9 completely inactive while mutation of the C/EBP3 binding site did not change the expression pattern in either orientation compared to the control. Therefore, the C/EBP3 binding site appeared to be "neutral". On the other hand, expression patterns produced from other constructs revealed the importance of the C/EBP4 binding site for fine tuning of *A/B.L9* gene expression. Finally, mutation of the GATA recognition site shifted the expression pattern to earlier stages - compared to the control - regardless of promoter orientation, confirming that BmGATAβ acts as an early repressor on the expression of middle specificity L9 chorion genes.

Combining the data described above and previous data from our lab we propose a more detailed model describing the events which control the developmentally accurate *A/B*.L9 gene pair expression.

Research Funding Program: Heracleitus II, co-financed by the European Union (ESF) and Greek national funds (Operational Program "Education and Lifelong Learning" of the NSRF).

Functional studies of CrNIP7 from *Chlamydomonas reinhardtii*: a protein involved in the ribosome biogenesis

R. F. Gutierrez[1], J. S. Avaca-Crusca[1], A. P. U. de Araújo[1]
[1]*Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, Brazil*

Ribosome biogenesis is a complex and highly regulated process, in which a primary transcript is processed to form mature ribosomal RNAs. This process is best characterized in yeast, interestingly several factors which were first described in *Saccharomyces cerevisiae* have shown divergent functions in humans. One of these divergent factors is NIP7, a highly conserved protein encoded by the essential single-copy *nip7* gene, that acts in the formation of 60S and 40S ribosomal subunits in yeast and human, respectively. To advance our understanding of ribosome biogenesis in other eukaryote models, we have performed some functional analysis of NIP7 ortholog from the algae *Chlamydomonas reinhardtii*, an ancestor organism to plants. In this context, the *CrNip7* gene was amplified by PCR from total cDNA and subcloned in plasmids for functional complementation assays, using three different strains of *S. cerevisiae*. Our results revealed that CrNIP7 complements the function of yeast Nip7p, since the expression of CrNIP7 in a temperature-sensitive mutant (DG130) strain and in the *nip7Δ* strain (DG442) recovered the growth of both strains, similarly to the positive control strain. Furthermore, yeast two hybrid assays were also performed in order to identify potential protein interactions of CrNIP7. Some potential protein partners were identified, including a protein with a G-path domain, and these interactions are currently under validation. Taken together, our results will contribute to clarify the role that CrNIP7 plays in the ribosome biogenesis of *Chlamydomonas reinhardtii* in comparison with other eukaryote models.

Keywords: Chlamydomonas reinhardtii, ribosome biogenesis, yeast complementation assay.

Genome wide identification of natural antisense transcripts in *Plasmodium falciparum* clinical isolates

A. K. Subudhi[1], A. P. Boopathi[1], S. Garg[1], S. Middha[2], J. Acharya[2], D. Pakalapati[1], V. Saxena[1], M. Aiyaz[3], H. B. Oreknondy[3], R. C. Mugasimangalam[3], P. Sirohi[2], S. K. Kochar[2], D. K. Kochar[4], A. K. Das[1]
[1]*Department of Biological Sciences, Birla Institute of Technology and Science, Pilani,* [2]*Department of Medicine, S.P. Medical College, Bikaner,* [3]*Genomics Group, Genotypic Technology Pvt Ltd, Bangalore,* [4]*Rajasthan University of Health Sciences, Jaipur, India*

Antisense transcription is pervasive among all kingdoms of life. Natural Antisense Transcripts (NATS) are transcribed from the strand opposite to that of the sense transcript of either protein-coding or non-protein coding genes. Initially, it was considered by many as the product of transcriptional noise but now it has taken its position as an important regulator of gene expression. In an organism, diverse species of NATs may exist in different developmental and environmental conditions and their level of expression may also change in response to various environmental cues. As the role of NATs in modulation of gene expression is becoming evident day by day, it is crucial to identify NATs in organisms like *Plasmodium falciparum*, where the understanding of genome regulation is limited. Although, NATs have been identified in different intra erythrocytic developmental cycle stages and gametocyte stages of *P. falciparum* in culture condition, its diversity in natural parasite population has not been documented.

We report here the diversity of NATs in this parasite, using isolates taken directly from patients with differing clinical symptoms caused by malaria infection. Using a custom designed strand specific 244K Agilent microarray, a total of 797 NATs targeted against annotated loci have been detected. These were compared with preciously reported studies from cultured parasites. Out of these, 545 NATs are unique to this study. The majority of NATs were positively correlated with the expression pattern of the sense transcript. The antisense transcripts map to a broad range of biochemical/ metabolic pathways. Importantly, NATs from 91 annotated gene loci were found to be differentially regulated in complicated malaria (n = 9) compared to uncomplicated malaria (n = 2). Detection of antisense transcripts and their differential expression for selected number of genes (n =6) was further validated using strand specific reverse transcriptase and quantitative real-time PCR experimentations. Moreover, position wise genome wide scanning and experimental studies were carried out to under-

© 2014 The Authors. FEBS Journal © 2014 FEBS

stand the possible mechanisms of antisense production. The results detailed here call for studies to deduce the possible mechanism of action of NATs, which would further help in understanding the *in vivo* pathological adaptations of these parasites.

Keywords: Complicated malaria, Natural antisense transcripts, Plasmodium falciparum.

Global transcriptional profiles of the copper responses in the cyanobacterium *Synechocystis* sp. PCC 6803

J. Giner[1], L. López Maury[1], on behalf of 2, F. J. Florencio Bellido[1]
[1]Instituto de Bioquímica Vegetal y Fotosíntesis, Universidad Sevilla-CSIC, Américo Vespucio 49, E-41092 Sevilla, Spain

Copper is an essential element implicated in fundamental processes like respiration and photosynthesis. However, it becomes toxic when is present in excess, which has forced organisms to control its cellular concentration. With the exception of the photosynthetic cyanobacteria, which contain an intracellular organelle called thylakoid which hosts the Cu-requiring process, photosynthesis, there are no known bacterial species that have intracellular copper-containing enzymes. All known copper-containing proteins in gram-negative bacteria are either periplasmic enzymes or located in the cytoplasmic membranes, making cyanobacteria in an important bacteria group to study copper metabolism. Copper resistance in the photosynthetic cyanobacterium *Synechocystis* is mediated by the CopRS (hik31-rre34) two-component system. This two-component regulates its own expression and expression of a RND metal transport system (CopBAC) in response to copper in the media [1]. The system is also able to respond to changes in internal copper pools when plastocyanin is degraded in response to photosynthetic electron transport block [1]. Furthermore CopS is able to bind copper directly with high affinity and is partially localized to thylakoid membranes where it could detect copper released from plastocyanin. Here we have used microarrays to interrogate the global responses to copper additions at non-toxic (0.3 μM) and toxic concentrations (3 μM) of copper in WT and in the copper sensitive *copR* mutant strain. Addition of the non-toxic copper concentration stimulated the metabolism and induced the switch in the use from cytochrome c_6 to plastocyanin. In contrast, toxic copper catalyse the formation of ROS, lead to a general stress response and induced expression of Fe-S cluster biogenesis. According to this, a *copR-sufR* mutant strain, that expresses constitutively the *sufBCDS* operon, tolerated higher copper concentration than the *copR* mutant strain, suggesting that Fe-S clusters are direct targets of copper toxicity in *Synechocystis*. Finally, global gene expression analysis of the copR mutant strain revealed that CopRS only controls the expression of *copMRS* and *copBAC* operons in response to copper.

Identification of RNA editing targets using NGS data

E. S. Gerasimov[1]
[1]Molecular Biology, Lomonosov Moscow State University, Москва, Russian Federation

RNA editing was first discovered in 1984 by Benne et al in trypanosomatid mitochondria. Since this time different types of RNA editing were discovered in many phylogenetically distant groups of organisms (plants, animals, dinoflagellates, myxomycetes).

In trypanosomatid mitochondria U are extensively inserted in or deleted from primary transcript by editosome – large multienzyme complex. Editing results in formation of functional ORF, including creation of start codon.

Out lab focuses on evolution of edited genes structure and function. Recently we began to use NGS approach to obtain and analyze full transcriptome from trypanosomatid's mitochondria. But still discovery of edited sites remains a challenging task. As example, ND8 edited transcript has length about 450 nucleotides and ND8 pre-edited mRNA has only about 250 nucleotides. So about 200 Us are inserted in the process of editing. Surely, it is not possible to map a read corresponding to edited from of RNA using the existing software.

We have modified Bowtie2 short read mapper to suite RNA edited reads mapping task and tested it on our data. The modified Bowtie2 version successfully maps even extensively edited reads on reference genome and produces correct high-quality alignment.

We think our approach can be used to identify new targets of RNA editing of different types not only in trypanosomatids, but in other organisms too. Furthermore we think that such search of new targets of RNA editing is an important step in understanding gene expression and regulation and especially nowadays when huge amounts of RNAseq data are generated in many labs.

Keywords: mitochondria, NGS, RNA editing.

WED-208
Investigating RNA editing in the pathogenesis of amyotrophic lateral sclerosis

K. Y. Alsomali[1], J. Simpson[1], P. R. Heath[1]
[1]Neuroscience, Sheffield University, Sheffield, UK

The susceptibility of motor neurons to injury in amyotrophic lateral sclerosis (ALS) may result from excitotoxicity and subsequent dysregulation of intracellular calcium homeostasis. Post-transcriptional editing of the AMPA glutamate receptor (GluR) subunit(s) may alter the calcium ion permeability of the receptor pore, leading to neurodegeneration.

Objectives: The aims of the study are (i) to investigate GluR RNA editing in ALS compared to non-neurological controls, and (ii) to characterise TDP43 and p62 expression in ALS.

Methodology: RNA extraction and cDNA preparation followed by amplification of cDNA by PCR was used to generate amplified $GluR_2$, $GluR_5$ and $GluR_6$. These products were digested to produce cuts in the internal site of GluR mRNA and differentiate edited from non- edited GluR, and analysed by agarose gel electrophoresis and using the Agilent Bioanalyser. TDP-43 and p62 expression was assessed by immunohistochemistry.

Results: $GluR_2$ was fully edited in all motor cortex of ALS cases and controls. $GluR_5$ was 83% edited in motor cortex of ALS cases and 82% edited in controls. Whereas, $GluR_6$ editing in motor cortex was 88% and 91% in the ALS cases compared to 75% and 62% in controls, respectively. $GluR_2$ was 100% edited in the motor neurons isolated by LCM.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Phosphorylated TDP-43^{+} and p62^{+} skein-like bodies and compact inclusions were detected in C9ORF72/ALS positive cases and C9ORF72/ALS negative cases whereas no immunoreactivity was detected in the control healthy subjects.

Conclusions: Our data on whole tissue sections suggests that $GluR_2$ receptor of motor cortex in both sALS and control individuals is fully edited whereas partial editing has been identified in $GluR_5$ and $GluR_6$ receptors. Full editing of $GluR_2$ in dissected motor neurons isolated by LCM was confirmed.

Motor neurons in ALS cases, both C9ORF72^{+} and C9ORF72^{-} expressed pathogenic inclusions of phosphorylated TDP-43 and p62, which are a hallmark for ALS

Keywords: ALS, RNA editing.

Ki-1/57 and CGI-55 ectopic expression impact cellular pathways involved in proliferation and stress response regulation

F. Costa[1], A. Saito[1], K. A. Gonçalves[1], P. M. Vidigal[2], G. V. Meirelles[1], G. C. Bressan[3], J. Kobarg[1]

[1]Brazilian Bioscience National Laboratory, Brazilian Center for Research in Energy and Materials, Campinas, [2]Instituto de Biotecnologia Aplicada à Agropecuária, [3]Departamento de Bioquímica e Biologia Molecular, Universidade Federal de Viçosa, Viçosa, Brazil

Ki-1/57 (HABP4) and CGI-55 (PAIRBP1) are regulatory proteins and paralogs with 40.7% amino acid sequence identity and 67.4% similarity. Functionally they have been implicated in the regulation of gene expression on both the transcriptional and mRNA metabolism levels. Both localize to the cytoplasm but also shuttle to the nucleus and are modified by several post-translational modifications. However, to date there is no knowledge on the target genes, which expression may be regulated by Ki-1/57 and CGI-55 and detailed insight in their possible cellular function is missing. Here, we were interested in characterizing the alterations of the global transcriptome profile after Ki-1/57 or CGI-55 over-expression in HEK293 cells by DNA microchip technology in order to obtain further insights in these proteins functions. We were able to identified 363 or 190 down-regulated and 50 or 27 up-regulated genes for Ki-1/57 and CGI-55, respectively, of which 20 were shared. The great majority of the genes with altered expression are associated to proliferation, apoptosis and cell cycle control processes, prompting us to further explore these contexts experimentally. We observed that over-expression of Ki-1/57 and CGI-55 results in reduced cell proliferation, mainly due to a G1 phase arrest. In case of Ki-1/57 over-expression we found protection from apoptosis after treatment with the ER-stress inducer thapsigargin. Furthermore, we found that CGI-55 and Ki-1/57 co-localize with cytoplasmic stress granules under different stress conditions. Our global transcriptome analysis after Ki-1/57 and CGI-55 over-expression, together with a correlation of the published protein interactome data suggest that both proteins act mainly as repressors that affect the expression of genes that are involved in proliferation and cell cycle as well as apoptosis regulation. Protein interactome data and additional experimental data confirmed these functional contexts and further established a link with stress responses, in which both proteins tend to localize to cytoplasmic stress granules.

Licensing mRNP for nuclear export: a role for chromatin remodelers

A. Babour[1], J. Dos Santos[1], C. Dargemont[1]

[1]Laboratory of Pathology and Molecular Virology, INSERM-CNRS, Hopital St Louis, Paris, France

The harmonious production of export competent messenger ribonucleoparticles (mRNP) is linked to the tightly orchestrated transcription. Indeed, RNA polymerase II coordinates the ordered recruitment of mRNA processing and export factors resulting in the assembly and release of 5′capped, spliced and polyadenylated mRNPs. In yeast, the conserved mRNA export receptor Mex67 mediates nuclear exit of fully mature mRNPs through sequential interactions with nuclear pore complex (NPC) proteins lining the pore. The nuclear export machinery already associates with nascent transcripts during the transcription and maturation steps and insure the tight connection between mRNA biogenesis and transport. Owing to its complexity, mRNA biogenesis is error prone and mistakes taking place at any step of the biogenesis process lead to nuclear accumulation and degradation of "faulty" mRNPs. This is the consequence of quality control systems that combat the nuclear exit of aberrant mRNPs, which may be harmful if translated into defective proteins. The accuracy of eukaryotic gene expression relies on the balance of mRNPs assembly and surveillance. This competition therefore implies the existence of nuclear export "checkpoints" to prevent futile synthesis/degradation cycles.

Intriguingly, our recent results evidence a central role for a conserved ATP-dependent chromatin remodeling complex in licensing nuclear mRNPs for export. Indeed we found that inactivation of this complex was able to partially suppress the growth and mRNA export defects of a certain category of mRNA export mutants. Chromatin remodelers have the faculty to slide, eject or reposition nucleosomes thereby providing the transcription and replication machineries with dynamic access to the genome. However, the complex we identified was reported to have very little influence, if any, on the transcription process per se. In this context, our identification of strong genetic, physical and functional interactions between the mRNP biogenesis machinery and a chromatin remodeler might well be key to unravel its previously unsuspected role in gene expression. Our working hypothesis is that this chromatin remodeler would exert a nuclear export licensing function already at the transcription site.

We are currently attempting to decipher the molecular mechanism this complex to the licensing of newly synthetized mRNPs for nuclear export. Whereas the dynamics of chromatin structure is increasingly recognized as playing an essential role in the control of DNA-associated processes (transcription, replication, repair), our present findings open up the possibility that chromatin remodelers might also influence the fate of newly synthesized transcripts.

siae with cycloheximide leads to inhibition of translation elongation and a decrease in rRNA levels. Interestingly, we and others found that under amino acid starvation the presence of cycloheximide can stimulate tRNA synthesis. Analysis of tRNAs by Northern blotting indicates that cycloheximide treatment augments the level of tRNA precursors, which suggests enhanced activity of the Pol III machinery. Activity of Pol III is known to be controlled by a set of factors, including a negative regulator Maf1. We showed that cycloheximide treatment of amino acid-starved cells partially suppressed Pol III repression by Maf1. In contrast to the previously observed dephosphorylation and nuclear localization of Maf1 under stress conditions, we observed that in cycloheximide-treated starved cells a fraction of Maf1 is in the cytoplasm. Moreover, cycloheximide treatment resulted in the increase of phosphorylated Maf1 fraction. Finally, a decreased interaction of Maf1 and Pol III was shown by co-immunoprecipitation. A possible mechanism controlling tRNA synthesis in conditions which repress translation elongation will be discussed.

Keywords: cycloheximide, Maf1, RNA polymerase III.

Modulation of HIV-1 gene expression by binding of UHM-containing splicing factors to a ULM motif in the Rev protein

L. Corsini[1,2], M. Pabis[1,2], M. Vincendeau[3], K. Tripsianes[1,2], T. Güttler[4], T. Gibson[5], R. Brack-Werner[3], M. Sattler[1,2]
[1]Institute of Structural Biology, Helmholtz Zentrum Munchen, Neuherberg, [2]Center for Integrated Protein Science Munich and Chair of Biomolecular NMR, TU München, Garching, [3]Institute of Virology, Helmholtz Zentrum Munchen, Neuherberg, [4]MPI for Biophysical Chemistry, Gottingen, [5]EMBL, Heidelberg, Germany

Human immunodeficiency virus type 1 (HIV-1) is a lentivirus encoding the Gag, Pol and Env proteins common to all retroviruses and several specific regulatory proteins. The HIV-1 regulatory protein Rev is essential for virus replication and ensures the expression of partially spliced and unspliced transcripts. Rev binds to the Rev-responsive element (RRE) in viral mRNAs in the nucleus and recruits factors required for the export of these viral mRNAs to the cytoplasm. Additional functions have been shown for Rev, among them the regulation of viral transcript splicing.

We identified a ULM-like motif in the RRE-binding region of the Rev protein. ULMs (UHM ligand motifs) mediate protein-protein interactions and modulate spliceosome assembly through their binding to UHMs (U2AF homology motifs). We therefore investigated whether the Rev ULM can interact with UHMs present in host splicing factors. Isothermal titration calorimetry and NMR titration experiments showed that Rev ULM binds to the UHMs of SPF45 and U2AF65, alternative and constitutive splicing factors, respectively. The crystal structure of the SPF45-UHM bound to the Rev ULM reveals that the Rev ULM adopts an extended conformation upon binding to SFP45. Structural analysis and biochemical experiments demonstrate that the highly conserved W45 in the Rev ULM is crucial for Rev-UHM interactions. Moreover, Rev coprecipitates with U2AF65 in human cells. Finally, we show, that W45 in Rev ULM is important for proper processing of HIV transcripts and Rev-mediated increase of unspliced RRE-containing RNA transcribed from a HIV-derived reporter plasmid (pDM128).

We propose that Rev-ULM interactions with UHM-containing splicing factors contribute to the regulation of HIV-1 transcript processing, possibly at the level of splicing.

NMR conformational dynamics of La and RRM1 motifs of La protein

D. Vourtsis[1], M. Apostolidi[2], A. Argyriou[1], C. Chasapis[1], P. Konstantinidou[2], D. Drainas[2], D. Bentrop[3], S. Constantinos[2], **G. A. Spyroulias**[1]
[1]Department of Biochemistry, School of Medicine, University of Patras, GR-26504, Patras, Greece, [2]Department of Pharmacy, University of Patras, GR-26504, Patras, Greece, [3]Institute of Physiology II, University of Freiburg, D-79104 Freiburg, Germany

La/SSB protein serves as an important mediator of RNA polymerase III transcripts folding. It has been well established that guides accurate 5′ end maturation of pre-tRNAs by RNase P, while protecting at the same time their 3′ ends from degradation. La/SSB is found in abundance within nuclei, and studies have shown that is up-regulated during oncogenesis, a cellular perturbation which requires elevated protein synthesis rates. Originally discovered in patients with systemic lupus erythematosus and Sjögren's syndrome, it contains a characteristic conserved, predominantly helical structure, termed "La motif" and two RNA binding motifs (RRM1 and RRM2). So far, the structure of full-length La protein remains elusive. Scattered structural data of the La and the RRM motifs from few eukaryotes (including human) with synthetic oligoribonucleotides bound provide only limited information on the possible roles of the La/SSB protein as a whole, in a more dynamic tRNA-dependent cellular network. In the present study we initiated an extensive structural and functional characterization of a "domain library" of La/SSB which includes several domains of different length and structural signature. Here, we present the NMR-derived structure of La and RRM1 motifs. Both motifs were found to be well-folded in "winged-helix" and classical RRM structures, respectively, as revealed by high resolution NMR spectroscopy. In addition, the RNA binding properties of the La motif were investigated and the interaction interface was identified through chemical shift perturbation of amide groups in ^{1}H-^{15}N HSQC spectra. Interestingly, both NMR analysis and biochemical experiments indicate that La motif alone can mediate interaction with pre-tRNAs, an observation which raises questions on the actual role of La motif in combination with the RRM motifs, during tRNA biogenesis.

On the track of novel mechanisms controlling iron storage in yeast

C. Pimentel[1], C. Santos[1], C. Vicente[1], S. M. Caetano[1], C. Rodrigues-Pousada[1]
[1]ITQB-António Xavier, Oeiras, Portugal

Disruption of iron homeostasis originates significant damage in cells. Organisms have evolved sophisticated mechanisms that, on one hand avoid the drastic consequences of iron scarcity and, on the other hand circumvent the toxic effects of iron overload. The budding yeast *Saccharomyces cerevisiae* is able to grow under a wide magnitude of Fe accessible environments and can survive large fluctuations in Fe bioavailability. Unlike vertebrates, but similar to plants, the yeast cell vacuoles function as iron reser-

© 2014 The Authors. FEBS Journal © 2014 FEBS

voirs. Ccc1 is the vacuolar transporter that mediates iron storage in yeast. In a high-Fe milieu, *CCC1* deletion is lethal and Yap5 - one of the eight members of the Yeast AP-1 like proteins (Yap) family - regulates its expression. We have previously shown that besides the iron vacuolar transporter *CCC1*, Yap5 also directly controls the expression of glutaredoxin *GRX4,* known to be involved in the regulation of the nuclear localization of Aft1 (the major transcriptional activator in Fe deficiency)[1]. Consistently, we showed that in the absence of Yap5, Aft1 nuclear exclusion is slightly impaired. In addition, we demonstrated that Yap5-mediated regulation of *CCC1* is not essential for cells to overcome iron overload. This new finding brings forward the hypothesis that another yet unidentified factor is regulating iron storage in yeast. This hypothesis is further corroborated by the unexpected observation that Yap5 is degraded in the presence of iron. Interestingly, the removal of *CCC1* 3′ untranslated region (3′UTR) renders yeast cells more sensitive to growth under Fe overload, suggesting that *CCC1* is also post-transcriptionally regulated. Overall, this work provides further evidence that cells avoid iron overload by using multiple pathways.

Regulation of EhTMKB1-9 gene is through lipid (s) via PI3 kinase signaling pathway in protozoan parasite *Entamoeba histolytica*

A. Saha[1], S. Shrimal[1], A. Bhattacharya[1]
[1]*School of Life Sciences, Jawaharlal Nehru University, New Delhi, India*

Amebiasis is a major health problem in developing countries and the third leading cause of death due to parasitic diseases. It is mainly spread through contaminated food and water. The protist parasite *Entamoeba histolytica* is the causative agent of amoebiasis. More than 90% of the infected individuals do not display symptoms of invasive disease (intestinal and extraintestinal) and under certain hitherto unknown conditions it invades tissues. It is believed that amoeba needs appropriate signal to turn from non virulent to virulent form. Our laboratory has been investigating different signaling pathways of this pathogen in order to understand mechanisms of this transition from a commensal to a pathogen. In this study we describe a signaling pathway initiated by an unsaturated fatty acid that is involved in regulating expression of a trans membrane kinase that may participate in proliferation of this parasite. Transmembrane kinases of *E. histolytica* are known to have diverse roles ranging from virulence, phagocytosis and stress response. Transmembrane kinase EhTMKB1-9 is one of the early response genes and is regulated by bovine serum, one of the components necessary for cellular proliferation *in vitro*. In our attempt to understand the nature of the signal given by serum, we tested different components of serum and found that bovine serum albumin can replace serum in stimulating EhTMKB1-9 expression in serum starved cells. Further analysis, showed that unsaturated fatty acid, such as oleic acid can replace bovine serum albumin in stimulating expression of EhTMKB1-9. Promoter element of EhTMKB1-9 was identified and found to be between -817 to -768. Both BSA and oleic acid stimulated EhTMKB1-9 expression through activation of the promoter as observed for whole serum suggesting that the activation is through transcriptional activation of promoter due to binding of specific factors. Inhibitors that block different signaling pathways were tested and the results showed that activation is through PI3 kinase mediated pathway. Inhibitor studies also indicated that Class I PI3 kinases are involved in the regulation of this gene. Our results also show that actin dynamics is not involved in this activation suggesting that uptake of lipids may not be linked to activation. Dietary fats are known to influence fate of infection and our results provide a possible explanation for this.

Keywords: cell proliferation, PI 3 kinase signaling, transcription regulation.

Regulation of slamf1 gene encoding co-stimulatory receptor CD150 in human B cell lines

L. Putlyaeva[1], A. M. Schwartz[1], K. Korneev[1], M. Covic[1], D. Kuprash[1]
[1]*Engelhardt Institute of Molecular Biology RAS, Moscow, Russian Federation*

SLAMF1 (CD150) receptor serves as co-activator molecule expressed on a variety of hematopoietic cells, controlling innate and adaptive immune responses. This receptor is a type I transmembrane glycoprotein of the CD2 family and immunoglobulin (Ig) superfamily. Disorders in regulation of SLAMF1 expression have been identified as important factors for development of autoimmune diseases. Expression of CD150 is low in naive human B cells and becomes upregulated after B cell activation via BCR, CD40, CD180 and signaling after LPS and IL-4 treatment.

In our study we investigated the expression of the gene slamf1 (CD150) in human B - lymphoblastoid cell lines. We found that there are two main mRNA isoforms in these cells, one of which contains a number of short upstream open reading frames (uORF) in its 5′- untranslated region (5′UTR) impeding effective translation. It was established that B-cell lines with high expression levels of CD150 protein (MP-1 line) preferably synthesized the short mRNA isoform containing no short uORF, whereas the long mRNA isoform is mainly expressed in the cell line with a relatively low expression level of CD150 (Blin-1 line).

The promoter of slamf1 gene was also studied. Using deletion analysis, we showed that the most significant area for CD150 promoter activity is 220 nucleotides upstream of the transcription start point of the short mRNA isoform. This sequence contains binding sites for transcription factors PU.1, IRF4, AP- 1, Oct2, EBF1, NfkB, SP1. Mutation of EBF1 binding site has reduced promoter activity by 80%; mutations of several other binding sites (PU.1, IRF4, NfkB, SP1 binding sites) also had significant effects on the promoter activity. Additionally, four putative enhancer sequences that can enhance the activity of the putative slamf1 gene promoter were found and functionally tested.

Keywords: gene expression, promoter analysis, slamf1.

Role of AhR in the myelination of the central nervous system

L. Juricek[1], C. Tomkiewicz-Raulet[1], R. Barouki[1], X. Coumoul[1]
[1]*INSERM UMR-S1124 Pharmacology, toxicology and cell signalling, Paris, France*

The aryl hydrocarbon receptor (AhR) is a transcription factor known to mediate most of the toxic effects of widely persistant organic pollutants such as dioxin (TCDD). This receptor belongs to the basic helix-loop-helix Per/ARNT/Sim family whose members are involved in physiological processes such as circadian cycle, neurogenesis and organs development. Historically, the AhR has been described as a xenobiotic-activated transcription

© 2014 The Authors. FEBS Journal © 2014 FEBS

factor, which promotes the elimination of xenobiotics through the regulation of the expression of genes involved in xenobiotic metabolism. Recently, studies conducted in invertebrates have demonstrated that this receptor played a role in the development and homeostasis of the nervous system regardless of exposure to xenobiotics. However, the physiological roles of AhR in mammals remain unclear. A behavioral study conducted in our laboratory showed that AhR knockout mice had eye instability named horizontal pendular nystagmus. Our goal is to identify and characterize the biological mechanisms involved in the development of this phenotype. Nystagmus is often associated with myelin disorders. In this context, we conducted experiments with TCDD, an AhR ligand and siRNA targeting this receptor used independently to block its physiological functions, and demonstrated in a murine oligodendrocyte lineage, that both protocols changed the expression of Wnt/ ß-catenin target genes coding for myelin or cell cycle proteins. Meanwhile, a real-time cell analysis (Xcelligence®) showed that treatments with AhR agonist or pharmacological antagonists altered the cell index values suggesting changes of cell morphology, alterations of the cell adhesion and/ or proliferation. Cytoskeleton labelling by immunofluorescence showed that these treatments produced early morphological changes.

Roles of nElavl in Kif2a pre-mRNA splicing and functional roles of KIF2A protein isoforms

Ç. Akkaya[1], E. Bayam[1], G. Guner[1], G. Ince Dunn[1]
[1]Molecular Biology and Genetics, KOC University, Istanbul, Turkey

RNA binding proteins (RNABP) are cytoplasmic and nuclear proteins that contain RNA recognition motifs (RRM) which binds to either single or double-stranded RNAs and form a ribonucleoprotein complex. *Elavl2*, *Elavl3* and *Elavl4* are family members of highly abundant nElavl (neuronal Embryonic lethal abnormal vision-like) RNABP proteins. nElavl proteins were discovered as autoantigens in a multisystem neurologic disorder termed paraneoplastic encephalomyelopathy and are exclusively expressed in neurons. Previously, it has been found that nElavl proteins regulate alternative splicing of numerous neuronal pre-mRNAs, by binding to specific intronic sequences. One of the targets of nElavl is *Kinesin superfamily protein 2a (Kif2a)* pre-mRNA, encoded by a gene with roles in axonal branching, pruning and cortical development. It has been shown that deletion of Elavl3 and 4 affect *Kif2a* alternative splicing at exon 18 and consequently isoform abundance. Our results demonstrate that nElavl proteins bind directly to intronic elements in the intronic regions flanking the *Kif2a* alternative exon 18. Moreover, it has been previously shown that KIF2A represses axon branching and elongation, such that deletion of *Kif2a* in neurons causes ectopic axonal branching and extra synapses at target regions. Currently, our understanding of the functional roles of different KIF2A isoforms is completely unknown. Our results demonstrate that exon 18 alternative splicing does not regulate the subcellular localization of the different Kif2a protein isoforms. Our efforts continue to focus on identifying different functional roles for Kif2a protein isoforms.

SCL and RUNX1 regulate RUNX1 gene expression by association to RUNX1-P1 promoter

S. Gutierrez[1], M. Martinez[1]
[1]Bioquímica y Biología Molecular, Universidad de Concepción, Concepción, Chile

RUNX1 is a transcription factor essential to hematopoiesis process. Its gene is located in chromosome 21 and two promoters, P1 and P2, regulate its transcription. Analysis of P1 promoter's sequence identified several consensus sites for different hematopoietic transcription factors include SCL, RUNX, and others, suggesting a possible role in transcriptional regulation of RUNX1 gene. Moreover several report have shown that these two transcription factors are associated to regulate target genes. To test if P1 promoter is regulated by SCL and RUNX1 we cloned P1 in a luciferase-reporter vector, and we measured reporter activity to SCL response. We observed increased reporter activity in a doses-dependent manner. To determinate association of SCL to P1 promoter we performed chromatin immunoprecipitation (ChIP) in hematopoietic cells (HL-60 and Jurkat cells), our results show that SCL binds to SCL site. Interestingly, we also detect SCL enrichment in RUNX sites present in P1 promoter. Using ReChIP assays we demonstrate that RUNX1 and SCL simultaneously associate to P1 promoter through RUNX binding sites. Taken together our results demonstrate that in HL-60 and Jurkat cells SCL regulate P1 promoter activity and associates to RUNX1 protein.

SREBP-1 is a transcriptional regulator of secreted frizzled-related protein 2 in chondrogenic cells

S.-Y. Park[1]
[1]Department of Biochemistry, Dongguk University, School of Medicine, Gyeongju, Republic of Korea

Secreted frizzled-related protein 2 (Sfrp2) is highly expressed in developing limbs and is associated with skeletal malformation such as Syndactyly and Brachydactyly. However, the molecular mechanism underlying the transcriptional regulation of Sfrp2 in chondrogenic cells is largely unknown. In this study, we demonstrated the mechanism of transcriptional activation of the Sfrp2 gene in chondrogenic cells. We found that overexpression of SREBP-1 led to stimulation of Sfrp2 promoter activity and increase of Sfrp2 mRNA in chondrogenic ATDC5 cells. Results of reporter gene assays using deleted Sfrp2 promoter constructs showed that the SREBP-1-responsive region is localized at the position between -1150 and -840 and is responsible for transcriptional activation of the Sfrp2 gene. Mutation of a SREBP-1-binding site in this region resulted in elimination of SREBP-1-mediated Sfrp2 promoter activity. Results of promoter enzyme immunoassay and chromatin immunoprecipitation assay showed that SREBP-1 binds directly to the SREBP-1-binding site at region -935/-926 of the mouse Sfrp2 promoter. Collectively, these results demonstrated that SREBP-1 is a positive regulator of Sfrp2 regulation in chondrogenic cells.

The effects of rotenone on ischemia-reperfusion injury in rat testis

A. Kucuk[1], M. Yucel[2], M. Tosun[3], A. Bayraktar[4], N. Erkasap[5], M. Kavutçu[4]
[1]Physiology Department, [2]Urology Department, Dumlupinar University, Medical Faculty, Kutahya, [3]Histology-embriology Department, Afyon Kocatepe University, Afyon, [4]Biochemistry Department, Gazi University, Ankara, [5]Physiology Department, Osmangazi University, Eskişehir, Turkey

Introduction: Testis is sensitive to ischemia-reperfusion injury, therefore, ischemia and consecutive reperfusion cause an enhanced formation of reactive oxygen species that result in testicular cell damage and apoptosis. The aim of this study is to investigate the effects of rotenone on testicular tissue.
Methods: 24 rats were randomly divided into3 groups: control, sham (I/R) and testis torsion+Rotenone group. Testicular ischemia caused by spermatic cord torsion of 720°. 1 h torsion and 2 h detorsion of the testis were performed. 10 µg/kg Rotenone (i.p) was administered to the I/R+rotenone group 30 minutes after ischemia.
Results: Thiobarbituric acid reactive substances (TBARS), superoxide dismutase (SOD), catalaz (CAT) and Glutatyon S-transferaz (GST) activities were evaluated. Data were analyzed with SPSS test, One way ANOVA was used. TBARS and SOD levels are significantly different, but CAT levels are not significantly different between groups. For immunohistochemistry p53, Bax, NfKB and E2F primary antibodies were used. While HRP detection kit was used for secondary antibodies, AEC was used for chromogen and Mayers Hematoxylin for counter staining. Immunopositive cells were counted under NIS Elements Image Analysis Software (Nikon, Japan) and all the data analyzed statistically by SPSS for Windows 16.0. For statistical analysis One Way ANOVA with Tukey HSD test was used. In the evaluation of all slides it was found that p53, Bax, NFkB and E2F expressions were significantly increased when compared Control and IR groups .On the other hand, in the evaluation between Control and I/R+Rotenone groups, it was determined that there were no significant differences in E2F and NFkB expressions At last, although p53 and Bax expressions were decreased, there were also significant differences in these groups
Conclusion: The present results suggest that rotenone is a potentially beneficial agent in protecting testicular I/R in rats.

The expression of splicing factors in digestive system tumours and cell lines

E. Jakubauskiene[1], S. Butkyte[2], A. Scerbakovaite[1], G. Vilkaitis[2], A. Kanopka[1]
[1]Department of Immunology and Cell Biology, [2]Department of Biological DNA Modification, Vilnius University, Institute of Biotechnology, Vilnius, Lithuania

The removal of introns and joining together of exons through pre-mRNA splicing is an essential part of eukaryotic gene expression. The most of human genes pre-mRNAs undergo alternative splicing, which is a very precise process and plays a major role in the regulation of gene expression and the generation of proteomic and functional diversity. Recently was showed that splicing also is essential for one of alternative microRNA biogenesis when short intronic miRNA, mirtrons, are produced. While hundreds of splicing-derived mirtrons have been recognized by bioinformatics analysis, only three mirtrons (hsa-mir-877, hsa-mir-1224, hsa-mir-1226) are experimentally proved.

In the cell, splicing takes place in nucleus within a large macromolecular complex, the spliceosome, which consists of five small nuclear ribonucleoproteins (snRNPs) and numerous proteins, the expressions of which are different. Changes in the expressions of splicing factors affect tumour formation. MicroRNA also have been implicated in the suppression and induction of oncogenesis. Almost all cancers displayed differentially expressed miRNA compare with normal cell, but until today practically nothing known about mirtrons expression profiles in tumours or cancer cell lines.

In this study, we aim to compare the expression of various splicing factors in the digestive system tumours and cell lines, and define how these factors can influence mirtron hsa-mir-1226 expression.
We report that: (1) The expression of splicing factors between the digestive system healthy and cancer tissues are different. Obtained results revealed that expression of splicing factors in pancreas, stomach and colon tumours are decreased compare to healthy tissue; the expression of mirtron hsa-mir-1226 is decreased in colon, increase in stomach and no changes were detected in pancreas tumours compare to healthy tissues.

(2) In pancreas, stomach, kidney, colon cancer cell lines compare to 293A cell line, the expression of splicing factors and the expression of mirtron hsa-mir-1226 are decreased.

(3) The expression of splicing factors and mirtron hsa-mir-1226 in colon tissue and the colon cancer cell line correlates, therefore the cell line can be used as colorectal carcinoma model system.

Influences of altered expression of splicing factors for cancer associated gene splicing are under further investigation.
Keywords: splicing factors, mirtron, cancer.

WED-224
The first complete transcriptome study of the two mitochondrial genomes of a species with Doubly Uniparental Inheritance (DUI) of mtDNA: unique features unveiled

E. Kyriakou[1], E. Chatzoglou[1], E. Zouros[2], G. C. Rodakis[1]
[1]Faculty of Biology, Department of Biochemistry and Molecular Biology, National and Kapodistrian University of Athens, Athens, [2]Department of Biology, University of Crete, Heraklion, Crete, Greece

The majority of mitochondrial transcriptome studies conducted to date come from maternally transmitted mtDNAs. However, certain mitochondrial genomes are exclusively paternally transmitted. Such genomes occur in a group of bivalvian mollusks, which are known to have Doubly Uniparental Inheritance (DUI) of mtDNA. These organisms have an egg-transmitted (F) and a sperm-transmitted (M) mitochondrial genome in stable co-existence for over 200 million years.

We studied the start/end points of mRNA, rRNA and tRNA transcripts of F and M genomes of *Mytilus galloprovincialis*, the most extensively studied species with DUI. All coding genes are transcribed from the same DNA strand. The primary transcript is cleaved into ten mRNA transcripts, eight of which are monocistronic, one is tricistronic and one is most likely, but not certainly, bicistronic (see Figure 1). Cleavage is mediated either by the excision of a tRNA or in some cases, by the presence of a stem-loop structure. The identification of a tricistronic transcript is a novel finding for metazoan mtDNA. The three co-transcribed genes participate in the same respiratory chain complex. The cleavage signals of each gene probably existed in the past, but were lost due to the replicative advantage of smaller mtDNA molecules.

© 2014 The Authors. FEBS Journal © 2014 FEBS

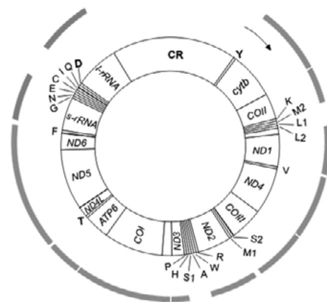

Fig. 1. Gene map of *Mytitus galloprovincialis* mtDNA. All genes are transcribed clockwise. The one-letter amino acid code is used for tRNA designation. Designation: L1, L2, M1, M2, S1, S2**.** tRNAs recognizing codons CUN, UUR, AUA, AUG, AGN and UCN, respectively; *ATP6,* ATP synthase subunit 6; *COI-III,* cytochrome c oxidase subunits I, II, and III; *Cytb,* cytochrome b apoenzyme; *ND1-6* and *ND4L* nicotinamide adenine dinucleotide dehydrogenase subunits 1–6 and 4L; *s-rRNA* and *l-rRNA,* small and large ribosomal RNA genes; CR, main control region. In blue are the mRNA transcripts, while in orange – the rRNA transcripts.

We also found polyadenylated and non-adenylated transcripts for both rRNAs and tRNAs, with heterogenous 3′ ends. The l-rRNA 3′end was found 48 nucleotides upstream from the one assigned by previous annotation, which makes the adjacent main control region (CR) correspondingly longer. We observed poly-adenylated tRNA transcripts carrying the CCA trinucleotide, mRNA, s-rRNA and l-rRNA transcripts with truncated 3′ ends and polyadenylated RNA remnants carrying the sequences of the control region, all of which strongly suggest RNA degradation activity and thus the presence of degradosomes in *Mytilus* mitochondria.

Keywords: degradosome, mitochondrial DNA, tricistronic mitochondrial transcript.

The identification and characterization of heavy metal stress responsive genes in *Brassica juncea*

E. Dalyan[1], B. Yüksel[2], E. Yüzbaşıoğlu[1], M. Ünal[1]

[1]Department of Biology, Faculty of Science, Istanbul University, [2]Plant Molecular Biology Laboratory, Advanced Genomics and Bioinformatics Research Group, TUBITAK, The Scientific and Technological Research Council of Turkey, Marmara Research Center, Genetic Engineering and Biotechnology Institute, İstanbul, Turkey

Heavy metals are important environmental pollutants, and many of them are toxic even at very low concentrations. *Brassica juncea* is a dry-land plant with developed root system known to hyperaccumulate certain heavy metals such as copper, zinc. In this study, lead (50 μM $Pb(NO_3)_2$) and cadmium (25 μM $CdSO_4$) were applied to *B. juncea* var. P78 for 24 hours. *B. juncea* var. P78 was identified as a good accumulator of Pb and hyperaccumulator of Cd. Even though the elucidation of the genes which show expressional differentiation upon exposure to heavy metals is important for understanding the phytoremediation capacity, there has been limited number of reports on this subject. We conducted microarray analysis on the roots of *B. juncea* grown in a media containing 50 μM $Pb(NO_3)_2$. Since there is no *Brassica*-specific microarray, interspecific hybridization was done with *Arabidopsis thaliana* Affymetrix gene chips for the expression profiling. A total of 183 genes were identified to be differentially expressed. However, only 20 of the up-regulated and 18 of the down-regulated genes among them statistically significant ($p < 0.05$) expressional difference. The majority of 38 differentially- expressed genes were significantly conserved at cross-species level. These results suggested that cross-species hybridization approaches are not convenient for the expressional profiling. To further gauge the utility of interspecific expressional profiling approaches, we also conducted comparative in silico studies between *Arabidopsis* Affymetrix probes and *Brassica* EST databases. Furthermore, the validity of the microarray data was confirmed by expressional profiling of 6 genes obtained by microarray analyses with quantitative reverse transcription PCR. Thus, the identified and expressionally characterized genes in this study contributed significantly to better comprehension of metal metabolism in plants paving the way for the improvement of plant remediation capacity for the studies in the removal of heavy metals from different environments.

Keywords: cross-species hybridization, microarray, quantitative reverse transcription PCR.

WED-226

The impact of stress factors on the induction of violaxanthin cycle in diatom *Phaeodactylum tricornutum*

P. Kuczyńska[1], M. Jemioa-Rzemińska[1,2], W. Strzaka[2,3], K. Strzaka[1,2]

[1]Plant Physiology and Biochemistry, Jagiellonian University, [2] Maopolska Centre of Biotechnology, [3]Plant Biotechnology, Jagiellonian University, Kraków, Poland

Diatoms are a major group of microalgae found in both marine and freshwater environments and are responsible for about 40% of the global primary photosynthetic production. Due to their ecological success, as well as fast-evolving and novel biological processes absent in other model organisms, diatoms are considered among the most important living organisms, however, still poorly understood. An unusual physiological feature of diatom cells is the presence of two types of xanthophyll cycles. Apart from diadinoxanthin cycle, which is a major mechanism protecting their photosynthetic apparatus from photodamage, accumulation of zeaxanthin is also observed under high light conditions.

We chose *Phaeodactylum tricornutum* to our studies as it is an ideal model diatom of known genome and great ecological importance. Changes in amount of xanthophylls were analyzed during the exponential phase of growth under optimal (15°C) and higher (20°C) temperature, osmotic stress (100, 150 mM NaCl) and light stress (700 μE for 6 h a day and 1250 μE continuously). Concurrently, we studied differences in relative steady state mRNA transcript levels.

It was found that at both temperatures proportions of xanthophylls are comparable with only slightly higher pigment level observed at 15°C. While violaxanthin cycle was induced neither in samples from elevated temperature conditions nor in those treated by osmotic stress, light intensity of 700 μE for 6 h a day caused significant increase in Ddx cycle pigments and induction of Vx cycle (strong increase in xanthophylls amount during the first day of stress). Continuous light (1250 μE) had an adverse impact on the diatoms survival. Not only Vx cycle was strongly induced but it increased until the death of diatoms. Ddx cycle that was enhanced at first, showed decreased rate after few days of strong light treatment. At optimal temperature, relative steady state mRNA transcript levels (six genes of xanthophylls cycle) were higher than at 20°C. Light stress caused an increase in VDL2 and ZEP3 transcript levels, which are normally almost

© 2014 The Authors. FEBS Journal © 2014 FEBS

undetectable. Alterations in mRNA are not directly proportional to changes in amount of xanthophylls.

This work was supported by project No. 2013/09/N/NZ1/01031.
Keywords: diatom, xanthophyll cycle.

WED-227
The influence of NFAT transcription factor on CacyBP/SIP gene expression

B. Kadziolka[1], W. Lesniak[1], A. Filipek[1]
[1]*Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warsaw, Poland*

The CacyBP/SIP protein binds several ligands and seems to be involved in different cellular processes such as ubiquitination, proliferation, differentiation, tumorigenesis or cytoskeletal rearrangement (Schneider and Filipek, 2011). The most important function discovered quite recently is its phosphatase activity towards ERK1/2 kinase and tau protein (Kilanczyk et al. 2011; Wasik et al., 2013). Studies concerning distribution of CacyBP/SIP show that it is present in various mammalian tissues with a particularly high level in brain and spleen. The level of CacyBP/SIP is also up-regulated in cells exhibiting a differentiating potential such as neuroblastoma NB2a, SH-SY5Y or pheochromocytoma PC12 cells (Filipek et al., 2002) as well as in cells highly proliferating, such as colon cancer HCT116 (Kilanczyk et al, 2012).

Due to the tissue and cell specific distribution of CacyBP/SIP as well as its involvement in different cellular functions it seems very important to determine the regulation of CacyBP/SIP gene expression. Thus, in this work we focused on identification of factors, external stimuli, signaling molecules or transcription factors, which might affect CacyBP/SIP expression. For that we examined the sequence of CacyBP/SIP gene promoter (1,6 kb upstream from the Transcription Start Site, TSS) using both the MatInspector and TESS programs to search for binding sites of potential transcription factor(s). We found the binding sites, among others, for factors such as NFAT (Nuclear Factor of Activated T cells), CREB (cAMP response element-binding), E2F transcription factors and DREAM (downstream regulatory element antagonist modulator). We found that among those transcription factors, NFAT seems to modulate the activity of CacyBP/SIP gene promoter and to evoke changes in CacyBP/SIP mRNA and protein level in the colon cancer HCT116 cells. Our results show that the effect of NFAT on the CacyBP/SIP protein level might depend on intracellular calcium concentration.

This work was supported by grant from the National Science Center (NZ1/00595) and by statutory funds from the Nencki Institute of Experimental Biology.
Keywords: CacyBP/SIP, NFAT, transcription factors.

WED-228
The localization and mRNA expression of poorly characterized members of SDR superfamily in human tissues

B. Malcekova[1], J. Hofman[1], L. Skarydova[1], P. Matouskova[1], H. Stambergova[1], T. Lundova[1], M. Safr[2], V. Wsol[1]
[1]*Department of Biochemical Sciences, Faculty of Pharmacy in Hradec Kralove,* [2]*Department of Biochemical Sciences, Medical Faculty of Charles University and University Hospital in Hradec Králové, Hradec Králové, Czech Republic*

The SDR (the short-chain dehydrogenase/reductase) superfamily represent one of the largest and oldest groups of carbonyl reducing enzymes, whose members occur in all life forms including mammals. In humans, these enzymes are involved in the metabolism of a large variety of compounds containing carbonyl groups, including endogenous (aldehydes, steroids, prostaglandins, retinoids and lipids) and xenobiotic (NNK, alfatoxin B1, quinones, doxorubicin and daunorubicin) compounds (Skarydova L. and Wsol V. 2012). The SDR enzymes also play an important role in some serious pathological diseases as some types of cancer, obesity, metabolic syndrome and endometriosis (Jansson A. 2009, Morton N.M. 2010). Over 75 SDR genes have been identified within the genome of human beings (Persson B. and Kallberg Y. 2013).

The most of the known information refers about the role of cytosolic forms of carbonyl reducing enzymes in the metabolism of xenobiotics (e.g. CBR1, AKR1C1-4). The knowledge about microsomal forms is limited and only one well-known microsomal form involved in biotransformation of xenobiotics - 11β-hydroxysteroid dehydrogenase 1 (11β-HSD1) - has been reported so far (Maser E. et al. 2006). But it is probable that other microsomal members of SDR superfamily participate in biotransformation. This study has investigated expression and tissue localization of mRNA of four human poorly characterized microsomal enzymes included to SDR superfamily - DHRSX, DHRS1, DHRS8 and DHRS12.

The total of 16 tissues were collected from humans. The RNA was extracted using Trizol reagent from all tissues and subsequently RNA was reversely transcribed to cDNA. The expression and tissue localization of mRNA was determined using real-time SYBR Green absolute qPCR with specific primers.

Tissue localization together with knowledge of enzyme activity of these four carbonyl reducing enzymes will open the way for studies of its potential role in the metabolism of important endogenous and xenobiotic compounds in human.

Publication is co-financed by the European Social Fund and the state budget of the Czech Republic. Project no. CZ.1.07/2.3.00/30.0022 and Grant. No. 677012/C/2012.

Pancreatic cancer is characterized by an aggressive biology being a rapidly disseminating disease with a dismal prognostic and survival rate. There is an urgent need to identify early molecular diagnostic markers that could contribute in improving patients' survival. S100A4 is a member of calcium-binding protein family

© 2014 The Authors. FEBS Journal © 2014 FEBS

and has a functional EF-hand domain mediating its activity. The gene S100A4 encodes a calcium-binding protein involved in invasion and metastasis by binding to several intracellular target proteins and modulating their function. The aim of this study was to evaluate the clinical significance of S100A4 mRNA and protein expression in pancreatic ductal adenocarcinoma and their role as early biomarker in PDAC.

Materials and methods: Pairs of non-tumoral and tumoral tissues from a total of 73 patients with PDAC were included in our study. Gene expression of S100A4 was assessed by two-step qPCR using TaqMan hydrolysis probes. Protein expression of S100A4 was evaluated by immunohistochemistry and nanoLC – MS.

Results: Gene expression values of S100A4 increased with advances stages of PDAC, with degrees of tumors differentiation and with lymph node status. Kaplan Meier curves showed a statistically significant difference in survival outcome of patients according to their S100A4 protein expression by immunohistochemistry as either lower or higher than 10% (P-value=0.043). The same statistical test showed statistically semnificative correlations with cliniopathological parameters: presence of metastasis (P-value=0.08), lymph node ratio (cut-off=0.16, P-value=0.06), type of resection (P-value=0.003) and CA19-9 level (cut-off=1000 ng/ml, P-value=0.054). Multiple regression Log Rank (Mantel-Cox) test confirmed that resection type (P = 0,07) and S100A4 protein expression (P = 0,057) has statistically significant value correlated to PDAC. NanoLC-MS identified S100A4 as being repetitively higher expressed in tumoral compared to non-tumoral tissues.

Conclusions: Our results showed that S100A4 plays an important role in PDAC and might be a valuable marker by addressing the problem of early diagnostic. Identification of S100A4 in early stages of the disease could represent a real benefit for public health care.

Study financially supported by the research grant PNII-PT-PCCA 90/2012.

Keywords: molecular biomarker, pancreatic cancer.

WED-230
The SRI domain family: a common scaffold for RNA polymerase II CTD binding

J. Rebehmed[1], P. Revy[2], G. Faure[1], J.-P.de Villartay[2], I. Callebaut[1]

[1]*Institut de Minéralogie, de Physique des Matériaux, et de Cosmochimie (IMPMC), Sorbonne Universités - UPMC Univ Paris 06, UMR CNRS 7590, Muséum National d'Histoire Naturelle, IRD UMR 206, F-75005 Paris,* [2]*Genome Dynamics in the Immune System, INSERM UMR1163, Institut Imagine, Université Paris Descartes, F-75015 Paris, France*

The carboxyl-terminal repeat domain (CTD) of the largest subunit of the RNA polymerase II (RNAPII) serves as docking platform for a wide range of nuclear factors at different stages of the transcription cycle *(Egloff and Murphy, 2008)*. A wide variety of folds are involved in CTD recognition *(Meinhart et al. 2005)* including a small domain discovered in the histone methylytansferase Set2, called SRI after Set2 Rpb1 Interacting, which alters RNAPII elongation *(Kizer et al. 2005)*. It was recently showed that SRI domain is also present in the C-terminal domain of the RECQ5 helicase, which is critical for maintaining genome integrity *(Li et al. 2011)*. The purpose of this work is to search and study the conservation of the SRI domain during evolution in different protein families and highlight the structural and/or functional features of key residues.

We combined here original tools we previously developed for detecting hidden relationships between remote sequences: (1) SEG-HCA *(Faure et Callebaut, 2013b)* delineates foldable domains (*i.e* domains which may form stable 3D structures) from the only knowledge of a single amino acid sequence; (2) TREMOLO-HCA *(Faure et Callebaut, 2013a)* adds to the results of sequences similarities searches information on domain architecture of the aligned sequences extracted from the Conserved Domain Database *(Marchler-Bauer et al. 2013)* as well as on the conservation of hydrophobic core residues. I-TASSER threading program *(Roy et al. 2010)* was used to predict the 3D structure models.

We show that SRI domains are found outside the Set2 and RECQ5 proteins, in which they are also involved in RNAPII CTD or RNAPII CTD-like recognition. Interestingly, SRI domains are always located in the C-terminal extremity of all the proteins of the SRI domain family. The whole family showed a large sequence divergence, especially within the loop between the first 2 helices that is much longer in SET2 proteins than in other members of the SRI family. Despite this divergence that made this domain undetectable by the present SRI CDD profile, it is worth noting that important amino acids for RNAPII CTD binding are highly conserved in the whole family as well as the core hydrophobic residues responsible of maintaining the left-handed three helix bundle fold.

These results allow getting insights into the diversity of this family of domains and into its critical structural and functional features.

This work is supported by a grant from INCa (DIREP).

The zinc finger protein lastin-mediated inhibition of cell proliferation in a cell density-dependent manner

R. Yuki[1], K. Aoyama[1], S. Kubota[1], N. Yamaguchi[1], S. Kubota[1], H. Hasegawa[1], M. Morii[1], M. N. Fukuda[2], N. Yamaguchi[1]

[1]*Department of Molecular Cell Biology, Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan,* [2]*Sanford-Burnham Medical Research Institute, La Jolla, USA*

Zinc finger proteins are involved in transcriptional regulation through their zinc finger domain, and regulate various cellular functions, including cell proliferation and differentiation. Approximately one third of the zinc-finger proteins contain the Krüppel-associated box (KRAB) domain, which is involved in transcription repression. Lastin is a member of KRAB-containing zinc finger proteins. However, the functions of the most of the KRAB-containing zinc finger proteins, including lastin, are largely unknown. In this study, we examined functions of lastin.

First, we examined the subcellular localization of lastin. We found that lastin was mainly localized to the nucleus. Furthermore, to examine a region in lastin responsible for its nuclear localization, we constructed two lastin mutants lacking the KRAB domain (lastin-ΔKRAB) and the zinc finger domain (lastin-Δzinc). Lastin-Δzinc was localized to the cytoplasm, whereas lastin-ΔKRAB was localized to the nucleus. These results suggest that lastin is localized to the nucleus in its zinc finger domain-dependent manner. Next, to examine the involvement of lastin in cell proliferation, we generated cell lines inducibly expressing lastin, lastin-ΔKRAB, or lastin-Δzinc. Intriguingly, lastin expression drastically inhibited cell proliferation at low cell density but slightly inhibited cell proliferation at high cell density. Lastin-Δzinc expression did not inhibit cell proliferation, whereas lastin-ΔKRAB expression did inhibit cell proliferation. The nuclear localization and the expression levels of lastin were not altered both at low cell density and high cell density. These results suggest that lastin is involved in inhibition of cell proliferation at low cell density in its zinc finger domain-dependent manner.

In conclusion, we show that lastin plays a critical role in inhibition of cell proliferation in a cell density-dependent manner. The

© 2014 The Authors. FEBS Journal © 2014 FEBS

zinc finger domain of lastin is involved in its nuclear localization and inhibition of cell proliferation. Now, we are trying to identify the lastin-target genes and to clarify the mechanism of inhibition of cell proliferation in a cell density-dependent manner.
Keywords: cell density, proliferation, zinc finger.

Transcription factors from Sox family regulate zebrafish Gla-rich protein 2 gene

C. Fazenda[1,2], N. Conceição[1,3], L. Cancela[1,3]
[1]Centre of Marine Sciences (CCMAR/CIMAR-LA), [2]PhD Program in Biomedical Sciences, Department of Biomedical Sciences and Medicine, [3]Department of Biomedical Sciences and Medicine, University of Algarve, Faro, Portugal

Gla-rich protein (GRP) is a vitamin K-dependent protein previously identified in our group with orthologs described in all taxonomic groups of vertebrates and a paralog (GRP2) in bony fish. It was initially appointed as specific for cartilage but later also detected in blood, soft tissues and bone. Because of the extensive number of Gla residues and the absence of other identifiable functional domains we hypothesized that GRP might be a physiological modulator of soft tissue calcification. However, conflicting information is available from mouse and fish deletion experiments. While in mouse the knockout did not show any phenotype, in zebrafish the morpholino-mediated knockdown showed a mild phenotype affecting cartilage development recovering after few days. Although *GRP* expression was repressed in retinoic acid treated dedifferentiated chondrocyte and in chondrocytes exposed to either BMP-2 or TGF-β1, no data is available indicating a direct transcriptional regulation of the GRP gene by any of those potential regulators.

We chose to use zebrafish as our model organism and we cloned and analyzed *grp2* promoter transcription using p*grp2*-Luc and a serial of 5′ promoter deletion constructs in transfection experiments. The entire *grp2* promoter showed high levels of luciferase activity when compared with 5′ deletion constructs. This result was confirmed *in vivo* by microinjection of zebrafish embryos. To identify putative transcription factor binding sites (TFBS), an *in silico* analysis was performed and several putative binding sites for SOX, ETS1 and MEF2 were found. These TFs are known to affect transcription of several skeleton and cartilaginous genes. Co-transfection assays were performed indicating an up-regulation by Sox9b and Sox10. The transactivation of *grp2* promoter by the Sox10 was confirmed in co-transfection assays using a Sox10 mutated construct. The results were confirmed *in vivo* following microinjection of xenopus eggs with p*grp2*-Luc construct and Sox9b and Sox10 mRNA.

Data obtained provide the first relevant information demonstrating that *grp* is a target of these TFs thus providing new insights towards understanding the function of this gene.

CF and NC are supported, respectively, by a doctoral and a post-doctoral grant from FCT (SFRH/BD/66745/2009 and SFRH/BPD/48206/2008).

This research was partially supported by the ERDF through the COMPETE and national funds through FCT, under the project “PEst-C/MAR/LA0015/2011”.

Transcriptional regulation of the starch branching enzyme isoforms in the leaf and the stem under long and short photoperiod in lentil

K. Boztas[1], I. Baris[2], H. Kavakli[2], H. Morgil[1], G. Cevahir Oz[1]
[1]Istanbul University, Biology, [2]Koc University, Chemical and Biological Engineering, Istanbul, Turkey

Starch is the predominant carbohydrate reserve in many plants and is observed in both photosynthetic and non-photosynthetic tissues. In addition, starch constitutes most of the dry matter accumulating in the harvested organs of crop plants and therefore is not only the primary source of calories in the human diet, but can also be regarded as renewable resource that may be utilized in many industrial applications.

Starch branching enzyme catalyze branch point formation by the cleavage and reattachment of a-1,4-linked Glc chains to -1,6 branch points in the growing starch molecule. Branching enzymes are proposed to interact with starch synthases in formation of amylopectin. In all plant species examined so far, although more than two starch-branching enzyme (SBE) isoforms often occur, all isoforms can be separated into two classes based on their predicted primary protein sequences deduced from primary amino acid sequences. A recent stdy suggested that transcriptional control of the starch biosynthetic enzymes is under the control of circadian clock. Therefore, in this study, we explored the transcriptional regulation of SBEI and SBEII in stem and leaf under different photoperiods length in lentil. To this end, we first isolated and characterized BEI and BEII of lentil, then we performed quantitative real time PCR (qPCR) to see the effect of photoperiod length on the transcription of SBEI and SBEII in lentil. Our preliminary results indicated that transcriptions of the BEs are under the control of the circadian clock.
Keywords: Lentil, Real time-PCR, Starch Branching Enzyme.

WED-234
Transcriptional regulation of the starch synthases isoforms in the leaf and the stem under long and short photoperiod in lentil

Y. C. Gercek[1], I. Baris[2], H. Kavakli[2], **G. Cevahir Oz**[1]
[1]Istanbul University, Biology, [2]Chemical and Biological Engineering, Koc University, Istanbul, Turkey

Starch is the predominant carbohydrate reserve in many plants and is observed in both photosynthetic and non-photosynthetic tissues. Starch is a staple in the diet of much of the world’s population and is also widely used in different industries as a raw material. Starch biosynthesis requires three enzymes: ADP-glucose pyrophosphorylase, starch synthase and branching enzyme.

Among those enzyme starch synthases (SS) catalyze the transfer of the glucosyl moiety from ADP-glucose to the nonreducing end of an α-1,4-glucan. Collectively, the starch synthases are able to extend α-1,4-glucans in both components of starch, amylose, and amylopectin *in vitro*. Based on sequence comparisons, they can be divided into at least four different classes. These are designated GBSS, for granule-bound starch synthase, SSI, SSII, and SSIII.

Recent studies showed that transcription of the starch biosynthetic enzymes under the control of circadian clock. Therefore, in this study, we explored the transcriptional regulation of SSI and SSIII in stem and leaf under different photoperiod’s length in lentil. To this end, we first isolated and characterized SSI and SSIII of lentil, then we performed quantitative real time PCR (qPCR) to see the effect of photoperiod length (duration of the

© 2014 The Authors. FEBS Journal © 2014 FEBS

dark and light photoregiems) on the transcription of SSI and in lentil. We have seen that the differential regulation of the lentil SS at transcriptional level. Our results will be highlighted the importance of photoperiod length, in turn circadian clock, on the transcriptional regulation of SBE isoforms in stem and leaves.

Transcriptomic signature of mature endocrine pancreatic cells

E. Tarifeño-Saldivia[1], A. Lavergne[1], K. Padamata[1], I. Manfroid[1], M. Voz[1], B. Peers[1]
[1]GIGA-Research, University of Liege, Liège, Belgium

Pancreas is a mixed gland composed of endocrine and exocrine tissues and plays a crucial role in the metabolism of all vertebrates. The endocrine cells are mainly grouped into the islets of Langerhans and secrete distinct hormones, such as glucagon (α-cell), insulin (β-cell), somatostastin (δ-cell) and ghrelin (ε- cell). Diabetes occurs when insulin production by the β-cells is unable to counteract increase of glycemia. Better knowledge on pancreatic cell differentiation, regeneration and physiology is needed to design novel therapies for diabetes. While several transcription factors have been identified as pivotal for the differentiation of the various pancreatic cell types, there is still no comprehensive list of genes presenting cell type-specific expression. In a first step, we have determined the transcriptional landscape of the zebrafish mature alpha, beta and delta endocrine cells as well as exocrine cells. This was achieved by dissecting pancreas from the transgenic insulin:GFP, glucagon:GFP, somatostatin:GFP and ptf1a:GFP lines, dissociation and sorting GFP cells by FACS, RNA extraction, synthesis of cDNA and sequencing on Illumina platform. Experiments were performed in duplicates for each cell type and about 40 millions of sequenced reads were obtained per sample. Sequences were aligned to the zebrafish genome and expression level per-gene was measured using HTSeq software. Heatmap plot and principal component analysis show that samples belonging to the same cell type cluster together, indicating that transcriptome profiles are characteristics to different cell types. Cell type specific transcripts were identified using the DEseq and EBSeq software. Among these genes are transcription factors known to control pancreatic cell differentiation (i.e. pdx1, nkx6.2, ptf1a). Some new cell type specific transcripts were selected based on their GO annotation and studied by ISH. In order to define a common vertebrate signature, comparative transcriptomics for endocrine and exocrine tissue were performed using previous published data. This cross-species comparison should highlight genes having an evolutionary conserved action distinguishing them as important for the pancreas physiology.

Transforming growth factor-β1 represses testicular steroidogenesis through ALK5/Smad3 signaling

K. Lee[1], E. Park
[1]School of Biological Sciences and Technology, Chonnam National University, Gwangju, Republic of Korea

Transforming growth factor-β1 (TGF-β1) has been reported to be an autocrine/paracrine factor that inhibits LH mediated-steroidogenesis in testicular Leydig cells. However, the mechanism by which TGF-β1 controls the steroidogenesis in Leydig cells is not well understood. In this study, we investigated the molecular mechanism for TGF-β1-mediated repression of testicular steroidogenesis. In primary Leydig cells and rat R2C cell line, TGF-β1 treatment inhibited mRNA expression of cAMP-induced steroidogenic genes, decreasing the production of testosterone. The repressed mRNA expression by TGF-β1 treatment was rescued by the treatment of ALK5 inhibitor, SB431. Moreover, overexpression of ALK5 TD, a constitutively active TGF-β type I receptor, repressed the cAMP-induced promoter activity of steroidogenic genes. Interestingly, the transactivation of steroidogenesis-related transcription factors such as Nur77 was significantly repressed by the overexpression of both ALK5(TD) and Samd3. Taken together, these results suggest that TGF-β1/ALK5/Smad3 signaling represses the expression of steroidogenic genes in mouse Leydig cells probably via the suppression of the transcriptional activity of steroidogenesis-related transcription factors.
Keywords: gene regulation, steroidogenesis, TGF-β1.

Cross-talk between the two helicase cassettes of the spliceosomal RNP remodeling enzyme, Brr2

K. Dos Santos[1], M. Theuser[1], S. Mozaffari-Jovin[2], D. Burakovskiy[3], P. Milon[3], M. V. Rodnina[3], R. Lührmann[2], M. Wahl[1]
[1]Department of Structural Biochemistry, Free University Berlin, Berlin, [2]Department of Cellular Biochemistry, [1]Department of Physical Biochemistry, Max-Planck-Institute of Biophysical Chemistry, Göttingen, Germany

Splicing entails the removal of non-coding intervening sequences from eukaryotic pre-mRNA and the ligation of the neighboring coding regions and is carried out by the spliceosome. An active spliceosome evolves on the substrate by a stepwise assembly that is driven by members of superfamily 2 ATPases/RNA helicases. Major conformational and compositional RNP remodeling is required to convert an initially inactive complex into an active spliceosome. The Brr2 protein is the key player in this catalytic activation process. Brr2 belongs to a unique group of nucleic acid helicases, whose members are exceptionally large and contain two expanded helicase units fused in tandem. Unlike other spliceosomal helicases, Brr2 is preassembled with its substrate, the U4/U6 di-snRNP, before incorporation into the spliceosome. After catalytic activation, Brr2 remains associated with the spliceosome throughout the splicing cycle until spliceosome disassembly. The enzyme has been suggested to be required again during splicing catalysis and spliceosome disassembly, but presumably does not act as an ATPase/RNA helicase during these stages. Thus, both before recruitment to the spliceosome and after spliceosome catalytic activation, Brr2 may have to be shut off. Recently, we have determined the crystal structure of an active, 200 kDa portion of Brr2, showing that its two helicase units intimately interact and functionally cooperate. The C-terminal unit, while inactive in ATP hydrolysis and RNA duplex unwinding, strongly stimulates the N-terminal helicase *via* an extensive interaction interface between the two cassettes. However, it is not clear how the communication channels between the two helicase cassettes of Brr2 modulate the N-terminal cassette activity. Using pre-steady state kinetics, we probed the nucleotide binding preferences and worked out possible nucleotide binding mechanisms of each cassette. We also observed that the affinity of the active N-terminal cassette towards ATP and RNA is affected when the inactive C-terminal cassette carries interface or ATP binding pocket mutations or is pre-bound to different nucleotides. Interestingly, mutations in the ATP binding pocket of the C-terminal cassette not only reduce Brr2 helicase activity in vitro but also induce growth defects in yeast. We suggest a

© 2014 The Authors. FEBS Journal © 2014 FEBS

possible mechanism by which Brr2 interactors and ligands may exploit the C-terminal cassette as a "remote control" to regulate the N-terminal helicase of the enzyme.

Yap1-mediated repression of the yeast low affinity iron transporter gene, FET4, confers cadmium tolerance

S. M. Caetano[1], R. Menezes[1], C. Amaral[1], C. Rodrigues-Pousada[1], C. Pimentel[1]
[1]*Genomics and Stress Laboratory, ITQB – ANTÓNIO XAVIER/UNL, Oeiras, Portugal*

Cadmium is a well-known mutagenic metal, which can enter cells via non specific metal transporters, causing several cellular damages and eventually leading to death. In the yeast *S. cerevisiae*, the transcription factor Yap1 plays a determinant role in the regulation of several genes involved in metal stress response. Recently we have shown that Yap1 negatively regulates *FET4* gene, encoding a low affinity iron transporter[1]. In the present work we study the relevance of this repression in cell tolerance to cadmium. Our results indicate that *yap1* mutant exhibits increased *FET4* protein and mRNA levels compared to the wild-type strain. This data correlates well with the increased intracellular levels of cadmium observed in the mutant, as measured by ICP-AES. These results suggest that Yap1 repression of *FET4* prevents cadmium uptake. Nevertheless, Yap1 is not a direct repressor of this gene, as no Yap1 consensus site was found in its promoter. Our previous microarray data suggested that Yap1 regulates *ROX1* expression[1], a well known repressor of *FET4*. Using Chromatin-Immuno Precipitation and Real-Time PCR approaches, we show that Yap1 directly regulates *ROX1*, which in turn represses *FET4*. After cadmium induction we observed an abrupt decrease of *FET4* mRNA levels in the wild-type and *yap1* mutant strains. We also show that *FET4* transcript stability after stress relies on the 5′-3′ exoribonuclease Xrn1. Together, our results highlight the role of Yap1 in mediating cadmium tolerance revealing a new route for cell protection.

Yeast YIL096C binds and methylates 25S rRNA

J. Kutner[1], A. Dziembowski[2,3], M. Rowicka[4,5,6], K. Ginalski[1]
[1]*Centre of New Technologies, Laboratory of Bioinformatics and Systems Biology,* [2]*Institute of Genetics and Biotechnology, Faculty of Biology, University of Warsaw,* [3]*Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland,* [4]*Department of Biochemistry and Molecular Biology,* [5]*Institute for Translational Sciences,* [6]*Sealy Center for Molecular Medicine, University of Texas Medical Branch, Texas, USA*

The ribosomal RNA contains 109 specific modifications that affect translation and ribosome biogenesis. Only few of them correspond to base methylations catalyzed by methyltransferases (MTases). In eukaryotes, most of the rRNA modifications are maintained by enzymes that require guide snoRNA. In this work we identify a specific substrate for *Saccharomyces cerevisiae* YIL096C (BMT5) [1, 2], a snoRNA-independent MTase, using *in vitro* isotope dependent assays. We show that YIL096C binds and methylates yeast 25S rRNA and possesses substrate specificity to oligoRNA containing already known methylation site m^3U2634. This is highly consistent with the recent study by independent group showing that BMT5 is a new m^3U2634 MTase [3]. Our results contribute to better understanding of rRNA base methylation process, ribosome biogenesis and function. Presented approach should be helpful in further studies on substrate specificity of rRNA base MTases.

CSIV-07 – Education, training and career planning in molecular life sciences

WED-241
Education and public engagement spotlight on "Genomics and Bioinformatics"

R. Kalra[1], J. Williams[2], A. Nisselle[2], M. Claude-Blatter[3], V. Schneider[1]
[1]361° Division, The Genome Analysis Centre (TGAC), Norwich, UK, [2]DNA Learning Centre, Cold Spring Harbor Laboratory, New York, USA, [3]Training and Outreach, Swiss Institute of Bioinformatics, Geneva, Switzerland

The 361° Division at The Genome Analysis Centre (TGAC) specialises in Scientific Training, Education and Learning. Here we share our initiatives and impact from our first year as well as future efforts. We illustrate four key projects from our Education and Public Engagement Team:

1. TGAC4Kids, an online series of interactive activities aiming to introduce key areas of molecular biology and bioinformatics, reflecting current research and its impact on our daily lives. It is a free resource geared towards children aged 4–11. Our objective is to empower teachers to first acquaint themselves with current trends as well as to facilitate their teaching of such concepts in the classroom.

2. TGAC4Kids on the road, where schools apply for a TGAC4Kids visit, and we also conduct formative evaluation, collecting views and ideas about TGAC4Kids effectiveness in its current state to inform future developments. The schools are invited to help build TGAC4Kids with us.

3. SIB Swiss Institute of Bioinformatics: Creating new activities around the exhibition ChromosomeWalk.ch based on plants and animals

4. DNA Learning Centre (DNALC), Cold Spring Harbor Laboratory: The Genomics and Bioinformatics of Stem Cells. The DNALC is the world's first science center devoted entirely to genetics education and is an operating unit of Cold Spring Harbor Laboratory, an important center for molecular genetics research. DNALC pioneered the concept of providing genetics labs and bioinformatics experiences to large numbers of students and teachers. The DNALC will work with us to develop a complete teaching module aimed at middle school (US Grades 6–8) students using tissue culture techniques developed at Kew Botanical Gardens and Science and Plants for Schools (http://www.saps.org.uk/). The goal is to deploy a hands-on lab in which cauliflower cuttings (which contain stem cells) can be propagated into clonally reproduced plants. The collaboration will be an opportunity to gain knowledge from the DNALC's expertise in developing Internet multimedia that compliment classroom learning. Possible extensions of the laboratory could include an online lab notebook with detailed protocols, and reagent recipes. Expanding on the topic of stem cells and genomics in general, computer exercises relevant to the topic could also leverage DNALC's expertise in developing classroom-friendly bioinformatics workflows.

ELIXIR: The UK node

V. Schneider[1], on behalf of ELIXIR-UK, G. Rustici[2], on behalf of ELIXIR-UK
[1]361° Division, The Genome Analysis Centre, Norwich, [2]Training, University of Cambridge, Cambridge, UK

ELIXIR's UK Node contributes the country's substantial expertise in bioinformatics training for life science researchers and computer scientists. With the advent of next-generation sequencing and other high-throughput techniques, the major bottleneck in the life sciences has shifted from data production to data analysis and interpretation. ELIXIR-UK considers sustained professional training to be central to building data analysis capacity in Europe.

Plugging the skills gap: In a rapidly changing technological environment, researchers working in the clinic, on model organisms or crunching large datasets each use bioinformatics in different ways and have distinct training needs. Accordingly, supporting widely differing disciplines is one of ELIXIR-UK's core values. ELIXIR-UK will serve all of Europe through a flexible mix of learning opportunities. Face-to-face training at different centres of excellence in the UK remains the highest-impact training, complemented by a wide-reaching online learning programme. In all its activities, ELIXIR-UK will exploit the most effective tools available to help an international and diverse audience get to grips with all manner of biological data.

A critical mass of training excellence: ELIXIR-UK adopts a multi-agency approach, leveraging internationally recognised UK expertise in the biomedical, bioscience and environmental sectors.

Training in data, tools and resources for molecular life scientists

S. L. Morgan, L. Emery, R. Grandison, T. Hancocks, M. Adams, K. Costa, C. Brooksbank
EMBL-European Bioinformatics Institute, Hinxton, Cambridge, United Kingdom

With the wealth of data being generated by laboratories worldwide, and the depositing of such data into publically accessible databases, there is an increased need for bench biologists to gain the skills required to mine, analyse and interpret this data. EMBL-European Bioinformatics Institute develops and maintains a variety of data tools and resources for application across the life sciences, but also provides a number of mechanisms for scientists to learn how to become better users of biological data through a range of training opportunities.

EMBL-European Bioinformatics Institute develops and maintains a variety of data tools and resources for application across the life sciences, but also provides a number of mechanisms for scientists to learn how to become better users of biological data through a range of training opportunities.

Our trainees are diverse, many are from a bench background and at PhD / Postdoctoral level, but whilst they have expertise in their area of scientific interest they are often lacking in computational skill and knowledge of the tools available to them. Our aim is not to produce a new generation of bioinformaticians, but rather to develop a group of scientists who are more confident users of data tools and resources.

© 2014 The Authors. FEBS Journal © 2014 FEBS

We have created a programme that delivers training in three modes – on-site, off-site and on-line. This enables us to provide training to a wide audience, and to provide different focus for courses, from subject specific analysis through to advanced use of a specific resource.

Providing such a programme is challenging due to the diverse nature of our potential trainees, but we present here the approach we take to meeting these challenges and to providing training that enables life scientists to become more confident data users.

Posters at academic/scientific conferences: meeting the needs of viewers, presenters and society

N. Rowe

Faculty of Education, University of Lapland, Pello, Finland

Generally, posters are used to give a visual aspect to opinions or findings, with the aim of engaging and swaying a wider audience. Posters are the second most prolific form of knowledge dissemination in the sciences and academia, after journal article publication, and offer an established format for large numbers of researchers to present and discuss their research at conferences. Since their mainstream inception in 1969, poster practice itself has changed very little. This is incongruent with the developing needs of poster users, be they presenters, viewers, conference organisers or members of the global society. As such, a paradox has arisen where although we continue to present posters in ever-increasing numbers, we also take issue with the lack of appreciation given to the medium, the lack of exposure and longevity posters receive, and the ill-applied conception of a 'second-rate publication'.

Posters are an under-researched medium of scientific / academic communication, especially when we consider their predominance in professional practice. This poster looks to raise the awareness of this paradox, and to ask the question: How can we better develop a popular medium to meet the needs of users in the 21st century ? Answers may lie in the way we conduct future poster sessions, the way institutions appreciate and value the medium as a marker of professional practice and engagement, or perhaps how we enable others to engage with our work ... long after the last conference delegate has gone home.

Of course, of perhaps primary note is the wealth of subject information presented in the poster medium, and further development may help to ensure that considerable amounts of hard work and enquiry do not get consigned to 'undiscovered public knowledge' – a dustbin from which great discoveries have been gleaned.

Nicholas Rowe is currently conducting research into the development of posters at scientific/academic conferences – please feel free to contact him at: nrowe@ulapland.fi .

The characteristic of microfertilizer for increasing of the productivity of cereals plants and their tolerance to stress factors

A. Erezhepov[1], A. A. Yesmambetov[1]

[1]*Kazakh national University, Scinitific research Institute of the problems of ecology, Almaty, Kazakhstan*

The preparation of microfertilizer (PMF) was purified from green seeds of *Ulmus parvifolia* by hydrophobic chromatography on octyl-sepharose column and reverse phase chromatography on column type RP 18 column. It was developed the new specific test for PMF. It is property to activate of NADPH specific – glutamate dehydrogenase (NADPH-GDh) in aleuronic layer of the wheat seeds. Among all phytohormones only fusicoccin has the same ability. The experiments which were carried out on the fields of the North Kazakhstan were established that MPF increases the productivity of the winter rye on 35%. PMF also increases the tolerance of the wheat and barley to cold stress and to salinity. The most convenient for ecology of the property of PMF is ability to stimulate the germination of seeds which have lost the ability to germinate. As well as PMF is well convenient for vegetative reproduction of the fruit and forest trees plants. PMF stimulates the formation of the main and adventitious roots whereas auxin stimulates only the formation of adventitious roots. The main difference of PMF in comparison with auxin is next PMF stimulates the formation of the new leaves and stems whereas auxin inhibits formation of the above-ground part of plants.

Keywords: The preparation of microfertilizer, NADPH specific – glutamate dehydrogenase, auxin.

CSV-01 – Autophagy

WED-247
Autophagy is positively regulated by 17β-estradiol and progesterone during functional development of alveolar structures formed by bovine mammary epithelial cells in 3D culture

K. N. Zielniok[1], M. Gajewska[1]
[1]Department of Physiological Sciences, Faculty of Veterinary Medicine, Warsaw University of Life Sciences, Warsaw, Poland

Sex steroids: 17β-estradiol and progesterone, play a crucial role in the process of mammary gland development. Their regulatory actions, mediated mainly by specific steroid receptors are necessary to fulfill proper lobulo-alveolar structure formation. The growing importance of their role during mammogenesis lies in the ability to regulate crucial cellular processes such as apoptosis and autophagy, which were proven to determine the proper development of mammary alveoli. Immunofluorescence staining of p62 in BME-UV1 bovine mammary epithelial cells cultured on reconstituted basement membrane (rBM) demonstrated induction of autophagy in the centrally localized cells of developing spheroids, and this process was enhanced by sex steroids. The same 3D culture model was used to elucidate the mechanism of autophagy regulation by estradiol and progesterone. Real Time PCR analysis of autophagy related genes (ATGs) showed that both steroids increased the expression of *ATG3*, *ATG5* and *BECN1* when acted singly, and this effect was accelerated in the presence of estradiol and progesterone together. The functional interaction of sex steroids was also reflected by increased levels of autophagy proteins Atg5, Atg3 and LC3-II determined by Western Blot analysis. To explore the nongenomic actions of sex steroids, we examined the activity of Akt, ERK, AMPK and mTOR kinases, which are known to be involved in autophagy regulation. We observed a slightly increased level of phosphorylated AMPK in parallel with diminished phosphorylation of Akt and mTOR. Our observations clearly indicate, that synergistic action of 17β-estradiol and progesterone enhance autophagy in bovine mammary epithelial cells forming acini by upregulation of ATGs and their protein products, and partially by regulation of AMPK and MAPK signalling pathways. All collected data indicate, that physiological role of 17β-estradiol and progesterone in the process of mammary alveoli formation is based on complex interplay of their individual actions.

Autophagy regulates cell differentiation and proliferation within germline tumors in *C. elegans*

L. C. Gomes[1], I. Dikic[1], C. Pohl[1]
[1]Buchmann Institute for Molecular Life Sciences, Goethe University Frankfurt, Frankfurt am Main, Germany

Teratomas are germ cell derived tumors that result from precocious differentiation of somatic cells in the gonads or in the embryo. A teratoma model can be induced in *C. elegans* germline by depletion of GLD-1, a major suppressor of translation similar to mammalian Quaking [1]. Recently, it has been shown that reducing nutrient/energy supply triggers a proliferation arrest in teratomas [2], although the mechanism has not yet been clarified. Here we show that autophagy-related proteins are expressed in a subset of teratoma cells, in particular differentiated neuronal cells. Interestingly, knocking-down autophagy impairs neuronal differentiation and increases germ cell number in the teratoma. Accordingly, autophagy depletion leads to a faster invasion of the head and vulva regions and an increase in the percentage of animals displaying a tumor prolapse. On the other hand, autophagy induction by fasting or LET-363 depletion leads to a reduction in the germ cell number in the tumor and a decrease in the percentage of animals presenting a tumor prolapse. Furthermore, fasting significantly delays death caused by teratomas in an autophagy-dependent manner. In conclusion, we propose that autophagy plays a role in regulating the balance between cellular differentiation and proliferation within the teratoma.

Structure of the human Rod-Zw10-Zwilch (RZZ) complex

S. Mosalaganti
Physical biochemistry, Max Planck Institute for Molecular Physiologie, Dortmund, Germany

Faithful chromosome segregation lies at the heart of mitotic cell division. The fidelity of this process is of unquestionable importance, failing which cells are left with irreparable consequences. Kinetochores are dynamic multi-protein assemblies, built on the chromosomes, which are at the helm of above process. On one hand, they help chromosomes bind to microtubules and modulate their stability, and, on the other they oversee that these attachments are not faulty by a complex mechanism called spindle assembly checkpoint. The 3-subunit Rod-Zw10-Zwilch (RZZ) complex is a crucial component of the spindle assembly checkpoint (SAC) in higher eukaryotes. It is required for kinetochore localization of the Mad1-Mad2 checkpoint complex and of the microtubule motor dynein, thus contributing not only to kinetochore-microtubule attachment but also to the dynein dependent stripping of SAC components upon checkpoint satisfaction.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Although much is known about spatial and temporal organization of the RZZ complex, it remains poorly understood from a purely structural perspective. We used single particle Cryo-Electron Microscopy (cryo-EM) to determine the first 3D structure of RZZ. We also elucidated the architecture of the complex by interweaving cross-linking mass spectrometry and antibody labeling studies. We aim, ultimately, to unravel the molecular basis of SAC.
Keywords: Kinetochores, Single particle cryo-EM.

Ceramide-activated protein phosphatase Sit4p deregulates macroautophagy, mitophagy and mitochondrial dynamics in isc1Δ cells

V. Teixeira[1,2], T. Medeiros[1], R. Vilaça[1,2], P. Moradas-Ferreira[2,3], V. Costa[1,2]
[1]Redox Cell Signalling, Institute for Molecular and Cell Biology, University of Porto, [2]Departamento de Biologia Molecular, Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, [3]Cellular and Applied Microbiology, Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal

Sphingolipids regulate crucial biological processes, such as stress response and apoptosis. The budding yeast *Saccharomyces cerevisiae* has been pivotal to uncover the impact of sphingolipid dynamics on eukaryotic cell physiology and metabolism. The bioactive sphingolipid ceramide can be generated by the *de novo* biosynthetic pathway or through the hydrolysis of complex sphingolipids, the last catalysed by the inositol phosphosphingolipid phospholipase C protein, Isc1p (the yeast orthologue of the mammalian neutral sphingomyelinase 2). Cells lacking Isc1p display shortened chronological lifespan (CLS), oxidative stress sensitivity and severe mitochondrial dysfunctions. We demonstrated that Isc1p acts upstream of Sit4p, the catalytic subunit of mammalian type 2A protein phosphatase (PP2A). The deletion of *SIT4* restores mitochondrial function in *isc1Δ* cells, increasing oxidative stress resistance and extending CLS.

The regulatory role of macroautophagy in mitochondrial function has been demonstrated in *S. cerevisiae*. Since *isc1Δ* cells exhibit mitochondrial dysfunctions, we intended to assess any defect on macroautophagy impacting on mitochondrial function. The results show that the process is impaired in *isc1Δ* cells, ultimately leading to mitochondrial dysfunction. Importantly, *SIT4* disruption re-established the autophagic flux in the mutant strain, which correlates with the restoration of mitochondrial function in *isc1Δ sit4Δ* cells.

Mitophagy and mitochondrial dynamics are key quality control mechanisms by maintaining a healthy mitochondrial network sustaining overall cellular energetics. We demonstrate that mitophagy was impaired during ageing and this was correlated with mitochondrial fragmentation and decreased cell viability in *isc1Δ* cells. Sit4p had also a regulatory role on mitophagy and contributed to mitochondrial fragmentation in the mutant strain.

Overall, our work demonstrates that Isc1p-driven ceramide signaling is crucial for proper regulation of macroautophagy, mitophagy and mitochondrial dynamics by Sit4p-dependent mechanisms.
Funding: This work was financially supported by FEDER (Fundo Europeu de Desenvolvimento Regional) through the program "Programa Operacional Fatores de Competitividade-COMPETE", by FCT (Fundação para a Ciência e Tecnologia) and by "Programa Operacional Regional do Norte (*ON.2 – O Novo Norte*)", through the projects NORTE-07-0124-FEDER-000001 and FCOMP-01-0124-FEDER-028210.V.T. WED-251
Cross-talk between autophagy and apoptosis of tumor cells by knockdown of antisense non-coding mitochondrial RNAs (ASncmtRNAs)

S. Vidaurre[1,2], V. A. Burzio[2,3], L. Burzio[2,3]
[1]Ciencias Quimico Biologica, Universidad Bernardo O'Higgins, [2]Andes Biotechnologies, Fundacion Ciencia & Vida, [3]Facultad Ciencias Biológicas, Universidad Andres Bello, Santiago, Chile

The novel family of non-coding mitochondrial RNAs (ncmtRNAs) displays a differential expression pattern according to proliferative status. Normal proliferating cells express the sense (SncmtRNA) and antisense ncmtRNAs (ASncmtRNAs), whereas tumor cells express the sense transcript and down-regulate de ASncmtRNAs. By using chemically modified oligonucleotides directed against the antisense ncmtRNAs, we have achieved a massive degree of death of tumor cells, while normal cells are unaffected by the same treatment, suggesting a potential application of this treatment for the development of selective cancer therapy. Tumor cell death elicited in this manner exhibits molecular and morphological features typical of cell death type I (apoptosis), such as phosphatidylserine translocation, loss of mitochondrial membrane potential (MOMP), caspase activation, nuclear condensation and DNA fragmentation. At earlier post-transfection times, we have observed accumulation of autophagic vacuoles, together with LC3-I to LC3-II conversion only in cells treated against the antisense ncmtRNA. Electron microscopy revealed double-membraned structures and mitochondrial collapse only in tumor cells. Inhibition of the autophagic pathway does not necessarily block the onset of apoptosis. Our results indicate that knockdown of ASncmtRNAs in tumor cells elicits autophagy as a cytoprotective mechanism cross-talked to a point of no return towards cell death by apoptosis.

Expression of the autophagy genes in cancer cells overexpressed constitutively active PKC epsilon

E. Toton[1], N. Lisiak[1], J. Hofmann[2], M. Rybczynska[1]
[1]Department of Clinical Chemistry and Molecular Diagnostics, Poznan University of Medical Sciences, Poznan, Poland, [2]Division of Medical Biochemistry, Innsbruck Medical University, Innsbruck, Austria

Introduction: Protein kinase C epsilon (PKCε), a novel PKC isotype is characterized as a calcium-independent and phorbol ester/diacyloglycerol sensitive serine-threonine kinase. PKCε is involved in many signaling pathways including adhesion, migration, proliferation, secretion, differentiation, gene expression and apoptosis. PKCε, among all PKC isozymes, shows the greatest oncogenic potential. This protein participates not only in tumor development but also in tumor invasion and metastasis. Overexpression of PKCε was found in cancers of the colon, breast, prostate, thyroid and lung.

Autophagy is an evolutionarily conserved, a multi-step, lysosomal degradation pathway that eliminates long-life proteins and converts damaged or old organelles into basic biomolecules which are returned from lysosomes to the cytoplasm. Autophagy plays an important role in the regulation of survival and death

© 2014 The Authors. FEBS Journal © 2014 FEBS

signalling pathways in a variety of human diseases, including cancer.

Aim: The aim of this study was to investigate the expression of the autophagy genes in cancer cells overexpressed constitutively active PKCε.

Material and methods: A human epitheloid cervix carcinoma cells HeLaPKCεA/E (transfected with pBl-PKCεA/E) were tested. In the present study the technique of qPCR was used to shown the expression of genes contributing to autophagy pathways using Real Time Primers ready Human Autophagy Primer Library 96 (HATPL-1) (Biomol, Germany) that enables profiling of 88 target genes and 4 reference genes. The amplification products of crucial autophagy regulators were resolved by 1.5% agarose gel electrophoresis and visualized by ethidium bromide staining. Moreover the technique of electrophoresis, WB, immunoidentification with appropriate antibodies were used to shown the crucial autophagy proteins level.

Results: In HeLaPKCεA/E cells treated with doxycycline (inductor of *PKCεA/E* gene) from 3 up to 72 hours the highest level of PKCεA/E mRNA was observed by 3 hours of induction. The highest level of PKCεA/E protein detected by Western blot analysis was indicated in 24 hours induction of *PKCεA/E* gene expression.

The anti-autophagic effect was observed in tested cells and manifested by significantly lower levels of *BECN1, ATG-5, PI3K, LC3* transcript and higher level of *mTOR* in cells overexpressed PKCεA/E compared to cells without doxycycline-induced PKCεA/E expression.

Interestingly, in cells overexpressed PKCεA/E inhibition of mTOR by rapamycin caused autophagy induction. We have shown increased levels of Beclin-1, Atg-5, PI3K and LC3 protein and decreased level of mTOR.

Conclusions: Our results suggest *PKCε* as a possible target in anticancer therapy.

Functional study of the IRE1 interactome: fine tunning of UPR signaling

D. Rojas-Rivera[1,2], D. Rodriguez[1,2], D. Sepulveda[1,2], J. Sierralta[1,3], C. Hetz[1,2]

[1]Biomedical Neuroscience Institute (BNI), [2]Center for Molecular Studies of the Cell, [3]Physiology and Biophysics, University of Chile, Santiago, Chile

Adaptation to Endoplasmic Reticulum (ER) stress depends on the activation of the unfolded protein response (UPR) stress sensor inositol-requiring enzyme 1 (IRE1), which functions as an endoribonuclease that splices the mRNA of the transcriptional factor X-box-binding protein 1 (XBP1). XBP1 mediates the upregulation of crucial UPR-related genes involved in folding, secretion, protein quality control, and many other functions. Besides, active IRE1 degrades mRNAs encoding certain proteins through a process known as regulated Ire1-dependent decay of messenger RNAs (RIDD). Under prolonged ER stress IRE1 is turned off, which may sensitize irreversible damaged cells to undergo apoptosis. The mechanisms underlying IRE1 activation/inactivation are not well defined, but we have recently described a cluster of new function for major apoptosis-related proteins in the control of the kinetic and amplitude IRE1 signaling through a regulatory protein platform termed the *UPRosome*. Using several proteomic approaches here we have characterized the *UPRosome* and identified novel regulators of IRE1 that modulate both activation and inactivation phase. Some of these interactores connect IRE1 with unexpected biological function related to cytoskeleton, mitochondria and ER-resident chaperones, which have the capability to activate or repress the amplitude and kinetics of IRE1. Thus, we used *Drosophila melanogaster* in order to validate the effect of these new IRE1 regulators in both xbp-1 splicing and RIDD processes. All this evidence suggests that IRE1 is finely regulated and together with its regulators constitute a functional platform, the *UPRosome*, which is functional *in vitro* and *in vivo*.

Mechanism of autophagy induction in breast cancer cells treated with synthetic triterpenoids

N. Lisiak, E. Toton, B. Rubis, M. Rybczynska

Clinical Chemistry and Molecular Diagnostics, Poznan University of Medical Sciences, Poznan, Poland

Introduction: Autophagy, a process of self-degradation and turnover of cellular components, is engaged not only in tumor growth and progression but also functions as a cell death and tumor suppression mechanisms. Thus, the ability of autophagy modulation became a promising potential anticancer strategy. Especially natural-derived compounds and their derivatives seem to constitute an abundant source of autophagy modulators. Here we reveal the mechanism of autophagy induction in breast cancer cells after treatment with two synthetic derivatives of oleanolic acid (OA), HIMOXOL and Br-HIMOLID, showing a higher cytotoxicity in breast cancer cells than the maternal compound, OA.

Materials and methods: MCF7 (ER+), MDA-MB-231 (ER-) and MDA-MB-468 (ER-) breast cancer cells and non-tumorigenic MCF-12A (ER+) breast cells were treated by methyl 3-hydroxyimino-11-oxoolean-12-en-28-oate (HIMOXOL) and 12α-bromo-3-hydroxyimonoolean-28→13-olide (Br-HIMOLID) in different concentrations, corresponding to 0.5–1.5 IC_{50} values. On the basis of preliminary autophagy screening tests with monodansylcadaverine (MDC) staining and LC3 assessment (a specific-autophagy marker) we obtained information about selective, pro-autophagic effect of OA's derivatives in breast cancer cells. To evaluate the mechanism of action of studied compounds, expression of the crucial autophagy regulators: *LC3, Beclin 1 (BECN1), Atg5, PI3K* and *mTOR* was assessed in breast cancer cells by qPCR.

Results and discussion: We demonstrated that pro-autophagic effect, observed only in studied breast cancer cells, depended on a type and concentration of applied oleanolic acid derivatives. In MCF7 cells treated with HIMOXOL autophagy induction was mediated by overexpression of *BECN1*, *PI3K*, *Atg 5* and downregulation of *mTOR*. However, after treatment of these cells with Br-HIMOLID, we observed *LC3* and *PI3K* upregulation accompanied by a decrease in *mTOR* expression. In MDA-MB-231 cells, the autophagy process provoked by treatment with HIMOXOL was associated with *BECN1* and *PI3K* upregulation. However, treatment of this cells with Br-HIMOLID caused *BECN1* and *Atg5* overexpression accompanied by *mTOR* downregulation. Moreover, autophagy induced by HIMOXOL and Br-HIMOLID in MDA-MB-468 cells was mediated by *BECN1* and *mTOR* genes.

Conclusions: Autophagy in breast cancer cells provoked by synthetic triterpenoids is mediated by *LC3*, *BECN1*, *PI3K*, *Atg5* and *mTOR*. The effect of OA derivatives depends on a type of chemical modification, concentration and characteristics of target, breast cancer cells.

Mechanisms involved in the induction of cell death by desacetylnemorone in colorectal cancer cells

A. J. Araújo[1], J. D. B. Marinho-Filho[1], K. B. Lima[2], E. R. Silveira[2], M. O. de Moraes[1], L. V. Costa-Lotufo[1]
[1]Fisiologia e Farmacologia, [2]Química Orgânica e Inorgânica, Universidade Federal Do Ceará, Fortaleza, Brazil

Introduction: The desacetylnemorone (HCRH), previously isolated from *Salvia* species, is an abietane diterpene with para-quinone ring in its structure, and then classified as a tanshinone that are often described by their broad spectrum of biological activities. The aim of this study was to evaluate the mechanisms underlying the anticancer activity of HCRH isolated from *Hyptis carvalhoi* roots.
Methods: The cytotoxicity of HCRH was tested against several human cancer and normal cell lines by MTT assay, after 72 h of incubation. The antiproliferative effect was also determined by reduction of BrdU incorporation in HCT-116 cells. To further investigate the mechanisms involved in the cytotoxic activity, the effects of HCRH were determined by flow cytometry, confocal microscopy and western blot test at different times in HCT-116 cell line.
Results and Discussion: After 72 h of incubation, HCRH showed IC_{50} values ranging from 3.9 to 32 μM in HCT-116 and HL-60 cancer cells, respectively. While for normal cells IC_{50} values ranged from 35.7 μM in V-79 to higher than 72 μM in 3T3-L1 and PBMC cells. In HCT-116 cells HCRH showed antiproliferative potential of time-dependent manner, leading to increased number of cells in the G_0/G_1 phase of the cell cycle and a substantial decrease in DNA synthesis. These effects were accompanied by changes in the levels of cyclins and CDKs, in addition to the increase in the levels of proteins $p21^{waf1/cip1}$ and $p27^{kip1}$, independent of p53 activation. The study of cell death pathway revealed that treatment with HCRH induces apoptosis in a small population of cells in time-dependent manner, suggesting that apoptosis is not the main death pathway. Autophagy was detected by the formation of acid compartments within the cell visualized by staining with AO and MDC. Autophagy was confirmed by analysis of the expression of related proteins such as LC-3, beclin-1 and Bcl-2. Among the initial events induced by HCRH are the generation of ROS that can lead to DNA damage detected by increased phosphorylation of histone γH2AX, since the first 6 h of treatment. These effects may induce cell death primarily by autophagy then the secondary activation of apoptotic pathways.
Conclusion: The results suggest that HCRH has potent antiproliferative activity associated with ROS generation leading to DNA damage, which prevents cell cycle progression and drive cells to the process of death by autophagy and apoptosis.

WED-256
Mutation in VPS35 associated with Parkinson's disease impairs WASH complex association and inhibits autophagy

E. Zavodszky[1], M. N. J. Seaman[2], K. Moreau[1], M. Jimenez-Sanchez[1], S. Y. Breusegem[2], M. E. Harbour[2], D. C. Rubinsztein[1]
[1]Medical Genetics, [2]Clinical Biochemistry, University of Cambridge, Cambridge, UK

The retromer complex is important in endosomal protein sorting, including the endosome-to-Golgi retrieval of membrane proteins such as the cation-independent mannose 6-phosphate receptor. In addition, retromer recruits the actin nucleation-promoting WASH complex to endosomes. Together, these complexes are responsible for the sorting and localization of many physiologically important proteins and are linked to several neurodegenerative diseases. In fact, the D620N mutation in VPS35 results in a rare form of autosomal dominant Parkinson's disease (PD). This mutant is impaired in binding the WASH complex and in recruiting it to endosomes. Furthermore, PD mutant VPS35 as well as WASH1 depletion lead to autophagy defects by impairing the trafficking of the autophagy protein ATG9A. Thus, the Parkinson's disease-causing D620N mutation in VPS35 reduces WASH complex recruitment to endosomes, and reveals a novel role for the WASH complex in autophagosome formation.
Keywords: autophagy, neurodegeneration, retromer.

WED-257
New autophagy inducer from phenotypic screening induces autophagy in vitro and in vivo

Y. S. Cho[1], J. Liu[2], Y.-A. Chen[1], G.-H. Kim[1], E. Cheong[1], **H. J. Kwon**[1,3]
[1]Department of Biotechnology, Yonsei University, Seoul, Republic of Korea, [2]Department of Pharmacology and Molecular Sciences, Johns Hopkins University, Baltimore, USA, [3]Department of Internal Medicine, Yonsei University, Seoul, Republic of Korea

Autophagy is the process of mass degradation of unnecessary elements within the cell. It is related to many diseases such as cancer, atherosclerosis, and neurodegenerative diseases, but the detailed mechanism mostly remains to be uncovered. Therefore, autophagy inducers are useful chemical probes for exploring autophagy biogenesis and potential candidates as new drug entity. In the present study, a novel autophagy inducer, inda, was discovered from the cell based screening with John's Hopkins Drug Library (JHDL). Inda is an antidepressant as a no-specific monoamine reuptake inhibitor, but its effect on autophagy was not examined before. Inda-induced autophagy was validated by Lysotracker and MDC staining. EGFP-LC3 stable cell line and TEM images were examined for autophagosome formation. Molecular validation resulted in LC3 conversion in inda-treated cells. Inda suppressed mTOR/S6K activity by inducing AMPK. Furthermore, inda exhibited antidepressant effects in mouse behavior test and molecular validations revealed LC3 conversion and mTOR suppression in the mouse cortex. In conclusion, inda induces autophagy *in vitro* and *in vivo*, and its effects on autophagy results from AMPK induction and mTOR suppression. These results provide the possible relationship between antidepressant and autophagy signaling, and the mechanism behind inda-induced effects *in vivo*.

Rapamycin-loaded solid lipid nanoparticles for brain targeting

A. Polchi[1], S. Giovagnoli[2], A. Magini[1,3], J. Mazuryk[4,5], B. Tancini[1], A. Patkowski[4,5], C. Emiliani[1]
[1]Department of Chemistry, Biology and Biotechnology, [2]Department of Pharmaceutical Sciences, University of Perugia, Perugia, [3]Department of Medical and Biological Sciences, University of Udine, Udine, Italy, [4]Molecular Biophysics Division, Faculty of Physics, Adam Mickiewicz University, [5]The NanoBioMedical Centre, Poznań, Poland

Neurodegenerative diseases are very debilitating conditions with an increasing impact on the world population and as yet without an effective remedy. Therefore, the development of new strategies for early diagnosis and treatment of these diseases is becoming a priority. The selectivity of the blood-brain barrier (BBB) strictly limits the number of therapeutic substances able to reach the brain and therefore, in recent years, many studies have been directed to the development of systems that facilitate the passage of drugs to the central nervous system (CNS). One of the most crucial protein complexes, that regulates vital processes within signal transduction, proliferation and autophagy pathways, is the mammalian target of rapamycin (Rp) complex (mTOR). Specific inhibition of mTOR by Rp in-feed administration has been recently demonstrated to ameliorate the cognitive behavior in an Alzheimer's mice model [1]. Rp is an immunosuppressive drug that can pass the BBB, but its systemic administration produces a number of side effects that may impair its therapeutic efficacy [2].

Nanoparticles represent one of the most innovative and non-invasive approaches for drug targeting. In particular, due to an average size below 100 nm and lipophilic properties, the use of P80-coated solid lipid nanoparticles (SLNs) can overcome the BBB and allow accumulation of drugs directly into the brain tissue, through the apolipoprotein blood-to-brain pathway. Here, we report the development of a novel formulation of Rp loaded SLNs and the investigation of the effect upon treatment of SH-SY5Y neuroblastoma cells. Our results show that Rp loaded SLNs are able to inhibit mTOR activity over a longer period of time compared to free Rp. This prolonged action is rather evident even at concentrations as low as 2 nM and it is consistent with a longer retention of Rp due to a slower release from the SLNs. On the basis of the data obtained, we will perform experiments to assay *in vivo* the ability of Rp-SLNs to deliver Rp therapeutic doses to the CNS, limiting systemic exposure to the drug side effects.

Seeing is believing – visualizing the autophagic membrane-scaffold

A. Kaufmann[1], V. Beier[1], H. Franquelim[2], T. Wollert[1]
[1]Molecular Membrane and Organelle Biology, [2]Cellular and Molecular Biophysics, Max Planck Institute of Biochemistry, Martinsried (Munich), Germany

Autophagy is a catabolic pathway that delivers cytoplasmic components to the lysosome for degradation. During macroautophagy, a *de novo* generated membrane sack progressively encloses cytoplasm, giving rise to a double-membrane autophagosome after sealing. Numerous proteins orchestrate the formation, closure, and fusion of autophagosomes with lysosomes. Two Ubiquitin-like conjugation systems are involved in these processes: one involves the conjugation of ubiquitin-like Atg12 to Atg5, which forms a constitutive complex with the coiled-coil protein Atg16. The second conjugation system covalently attaches Atg8 to the lipid phosphatidylethanolamine (Atg8-PE) in autophagic membranes. We reconstituted the *S. cerevisiae* Atg8 conjugation reaction on giant unilammelar vesicles to investigate the interactions of the proteins involved during autophagosome formation. These experiments indicated that upon association of Atg12–Atg5-Atg16 with Atg8-PE, immobile multimeric complexes are formed, which might represent a new kind of membrane scaffold. In order to visualize the scaffold, we reconstituted the conjugation-reaction on supported lipid bilayers and analyzed them by Atomic Force Microscopy (AFM). Our investigations demonstrated that membrane-anchored Atg8-PE is cross-linked by the Atg12–Atg5-Atg16 complex to form a two dimensional membrane scaffold with meshwork-like architecture. A quantitative analysis of our AFM-data revealed important insights into the molecular structure of the scaffold. Yeast cells, expressing Atg16-mutants which do not support scaffold formation *in vitro*, exhibit strongly decreased autophagic activity, suggesting scaffold formation to be required for autophagosome generation *in vivo*.

The role of polyamines in the stress response

L. Miller-Fleming[1], M. O. Sandoval[1], A. Kruger[1], M. Ralser[1,2]
[1]Biochemistry, University of Cambridge, Cambridge, [2]MRC national Institute for Medical Research, London, UK

P { margin-bottom: 0.21 cm; }Polyamines – putrescine, spermidine and spermine – are essential organic cations for cell growth that are present in all living organisms. Dysregulation of the polyamine metabolism is associated with ageing and several pathological conditions such as cancer and neurodegenerative diseases. These conditions are intimately associated with an imbalanced stress response. Recently, we found that the yeast Tpo1, a polyamine transporter not only regulates the levels of these metabolites but also controls the expression of proteins associated with stress, such as Hsp90 an Hsp70. We are currently studying the role of Tpo1 and other players of polyamine metabolism to further dissect their role in the stress response.

Keywords: ageing, Oxidative stress, polyamines.

WED-261
WAC is a positive regulator of autophagy that interacts with GM130 on the cis Golgi

J. Joachim[1], N. McKnight[2], H. Jefferies[1], S. Tooze[1]
[1]London Research Institute – Cancer Research UK, London, [2]Mount Sinai School of Medicine, New York, UK

Background: Autophagy is a conserved cell-survival membrane trafficking pathway implicated in pathologies such as cancer. Much is still unknown about how autophagy is regulated.

WAC was discovered in our genome-wide screen to be an effector of autophagy (McKnight et al., 2012). WAC is in the nucleus and on the Golgi, where it affects transcription and Golgi biogenesis respectively (Totsukawa et al., 2011; Zhang and Yu, 2011).

© 2014 The Authors. FEBS Journal © 2014 FEBS

Aims & Methods: We aim to understand the mechanism behind WAC's regulation of autophagy and how WAC itself is regulated. We hypothesise WAC is affecting autophagy through its nuclear and cytoplasmic functions. WAC's effect on genome-wide transcription has been analysed. In conjunction, cytoplasmic binding partners of WAC have been investigated by mass spectrometry. Furthermore, we are employing a high-throughput imaging approach with a chemical library to investigate how WAC's subcellular localisation is controlled.

Results: We have investigated: Atg9 localisation, ULK1 signalling, LC3 lipidation, p62 degradation, LC3B and WIPI2 puncta formation. This has confirmed that WAC is a positive regulator of autophagy that acts early on in the pathway. Moreover, reintroduction of WAC into WAC-depleted cells rescues WIPI2 and LC3B puncta formation, two markers for autophagosomal structures. BeadArray analysis and qPCR validation shows that depletion of WAC reduces the mRNA expression of genes involved in autophagy. Additionally, through its coiled-coil domain WAC interacts with GM130 on the cis Golgi, whereas WAC is excluded from the trans Golgi. Knockdown and rescue experiments suggest that GM130 is the receptor for WAC on the Golgi. Autophagy assays reveal that GM130 is a negative regulator of autophagy. Finally, the WAC:GM130 interaction is enhanced upon starvation.

Conclusion: WAC is a novel positive regulator of autophagy that acts early on in the pathway. In the nucleus, WAC regulates the mRNA expression of genes involved in autophagy, whereas on the Golgi WAC interacts with the negative autophagic regulator GM130. We propose a model whereby upon amino acid starvation the WAC:GM130 interaction is enhanced, in order to supress the negative impact of GM130 on autophagy.

Xanthohumol from *Humulus lupulus* L. induces glioma cell autophagy via inhibiting Akt/mTOR/S6K pathway

K.-H. Lin[1], W.-J. Lu[2]
[1]*Central Laboratory, Shin-Kong Wu Ho-Su Memorial Hospital,*
[2]*School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan*

Xanthohumol is the principal prenylated flavonoid in the hop plant (*Humulus lupulus* L.). Xanthohumol has potent cancer chemopreventive properties that occur through the regulation of various mechanisms. Although, xanthohumol-induced apoptosis of glioma cells has been demonstrated, the details of the effects of xanthohumol-induced autophagy on glioma cells remain unclear. The aim of our study was to determine the effects of xanthohumol on the C6 and U87 glioma cell lines. Using a tetrazolium-based colorimetric assay, we showed that xanthohumol (5~50 microM) possesses anti-proliferative activities. Xanthohumol also induced autophagy in C6 and U87 glioma cells, as evidenced by acridine orange staining. Moreover, we found that xanthohumol inhibited phosphorylation of Akt, the mammalian target of rapamycin (mTOR), and p70S6 kinase (S6K), a downstream effector of mTOR. The formation of LC3-II, an autophagic maker, and p62 degradation also occurred in xanthohumol-treated glioma cells. In addition, xanthohumol treatment resulted in the activation of mitogen-activated protein kinases (MAPKs), including p38, Erk, and JNK. The xanthohumol-mediated formation of LC3-II was partially reversed by the Erk inhibitor PD98059 and the JNK inhibitor SP600125, but not by the p38 inhibitor SB203580, indicating that Erk and JNK may be involved in xanthohumol-induced glioma cell autophagy. This study demonstrates for the first time that xanthohumol induces glioma cell autophagy at least in part through inhibition of the Akt/mTOR/S6K pathway, the activation of MAPK cascade, and subsequent LC3-II formation and p62 degradation, which lead to inhibition of glioma cell growth and migration. Therefore, the multiple biologic activities of xanthohumol may represent a high therapeutic potential for treatment or prevention of glioblastoma multiforme.

Keywords: Autophagy, Glioblastoma multiforme, Xanthohumol.

"Rods and Rings" inclusions formed by Inosine-5′-monophosphate dehydrogenase 2

P. Juda[1], J. Smigova[1], I. Raska[1]
[1]*Institute of Cellular Biology and Pathology, Charles University in Prague, First Faculty of Medi, Prague 2, Czech Republic*

Inosine-5′-monophosphate dehydrogenase catalyzes the critical step in the de novo synthesis of guanosine nucleotides, the oxidation of inosine monophosphate to xanthosine monophosphate. This reaction can be inhibited by specific inhibitors like ribavirin or mycophenolic acid that are widely used in clinical treatment when required to inhibit the proliferation of viruses or cells. However, it was recently found that such an inhibition affects the cells, leading to redistribution of IMPDH2 and appearance of IMPDH2 inclusions in cytoplasm. According to their shape, these inclusions have been termed "Rods and Rings" (R&R). In this work we focused on subcellular localization of IMPDH2 protein and ultrastructure of R&R inclusions. Using microscopy and Western blot analysis, we showed the presence of nuclear IMPDH2 in human cells. We found that the nuclear pool has an ability to form Rod structures after inhibition by ribavirin. Concerning the ultrastructure, we observed that R&R inclusions in cellulo correspond to accumulation of fibrous material that is not surrounded by a biological membrane. The individual fibers were made up of regularly repeated subunits with length about 11 nm. Together, we showed the localization of IMPDH2 also inside the nucleus of human cells and described the ultrastructure of R&R inclusions.

Keywords: Inclusions, Inosine-5′-monophosphate Dehydrogenase, Rods and Rings.

An essential role for an RNA polymerase III subunit in determining sites of retrotransposon integration

A. Bridier-Nahmias[1], A. Tchalikian-Cosson[2], J. Baller[3], A. Flores[4], A. Saïb[1], M. Werner[4], D. Voytas[3], P. Lesage[2]
[1]*UMR7212 CNRS/P7, U944 Inserm, CNAM,* [2]*UMR7212 CNRS/P7, U944 Inserm, Institut Universitaire d'Hématologie, Hôpital St Louis, Paris, France,* [3]*Department of Genetics, Cell Biology & Development and Center for Genome Engineering, University of Minnesota, Minneapolis, USA,* [4]*FRE3377, Institut de Biologie et de Technologies de Saclay, CNRS, Université Paris-Sud, Saclay, France*

Mobile genetic elements are ubiquitous and dynamic components of genomes, and their integration site choice influences genome stability and gene expression. The Ty1 retrotransposon of the yeast *Saccharomyces cerevisiae* is closely related to retroviruses and replicates by reverse transcribing its genomic RNA into cDNA, which is then integrated into the host cell genome. Ty1 integrates upstream of RNA polymerase III (Pol III)-transcribed genes, yet, the primary determinant of target specificity has remained elusive. Here, we describe a functional interaction between Ty1 integrase and a subunit of Pol III. Whereas the absence of interaction does not significantly affect Ty1 integration frequency, it dramatically alters target site choice, leading to a redistribution of Ty1 insertions in the genome. Therefore, this Pol III subunit through its interaction with Ty1 integrase is the major determinant of Ty1 integration targeting upstream of genes transcribed by Pol III.

Keywords: Integration site determination, Retrotransposon, RNA polymerase III.

Comparison of oxaliplatin and carboplatin binding affinity to chromatin

H. Soori[1], A. Rabbani-Chadegani[1]
[1]*Biochemistry, Institute of Biochemistry and Biophysics, University of Tehran, Tehran, Islamic Republic of Iran*

Platinum anticancer drugs are potent chemotherapeutic agents currently used to treat a number of cancers. Carboplatin and oxaliplatin are second and third generation platinum drugs. They exert their cytotoxic effects mostly through DNA damage and form intra and interstrand crosslinks in cellular DNA and induce apoptosis. In the cell nucleus, DNA is compacted with histone proteins into a nucleoprotein complex known as nucleosome that is repeating unit of chromatin.

Thus chromatin not DNA, is the major target for platinum anticancer drugs *invivo*. How chromatin structure is affected by the binding of this drug is poorly understood.

In the present study, we have investigated the binding affinity of oxaliplatin and carboplatin to chromatin by equilibrium dialysis and fluorescence spectroscopy techniques.

Fluorescence quenching data were analyzed in term of Stern–Volmer constant, Ksv. The association constant (K_a) and number of binding sites (n) were determined using modified Stern-Volmer equation and Scatrchard plot obtained from equilibrium dialysis.

The results of fluorescence spectroscopy indicated that upon addition of oxaliplatin, emission intensity of chromatin was significantly decreased, but in the case of carboplatin this reduction was negligible. Stern-Volmer curves showed positive and linear relationship and the higher temperature exhibited the higher Stern–Volmer constant for both drugs.

The calculated binding constants for oxaliplatin and carboplatin from modified Stern-Volmer plots indicated that the value of K_a for oxaliplatin in both 25 and 37 °C was higher than for carboplatin. In both cases, Scatchard plot exhibited a cooperative binding pattern and K_a of oxaliplatin (58.1×10^3 M^{-1}) was higher than carboplatin (0.332×10^3). Hill coefficient for both drugs was higher than 1 that confirmed positive cooperative binding pattern of the drugs.

Based on the results, it is calculated that oxaliplatin exhibits higher quenching effect compared to carboplatin and in both cases mechanism of chromatin fluorescence quenching is dynamic which indicates that binding forces are mainly hydrophobic. The results suggest higher binding affinity of oxaliplatin to chromatin compared to carboplatin, which may help in combination therapy and drug design.

Keywords: carboplatin, equilibrium dialysis, oxaliplatin.

WED-268
ERH structurally differentiates between the highly homologous SAFB1 and SAFB2 proteins

E. Georgatsou[1], S. Drakouli[1], M. Papathanassiou[1], D. Tsianou[1], A. Lyberopoulou[1]
[1]Laboratory of Biochemistry, Faculty of Medicine, University of Thessaly, Larissa, Greece

SAFB1(Scaffold Attachment Factor) is a nuclear matrix protein that is implicated in a multitude of cellular processes including chromatin organization, transcriptional regulation, RNA processing, as well as stress response. SAFB2, a protein highly homologous to SAFB1 (70% in its whole length) shares with it numerous highly conserved functional domains. Their genes are localized head to head on the same chromosome and they share a common promoter. The function the best established of SAFB1 is as transcriptional co-repressor of nuclear receptors and particularly of the Estrogen Receptor a (ERa), a property SAFB2 harbors too. Although indirect evidence suggests that SAFB1 and SAFB2 might have unique properties, their biologic and functional differences are still obscure.

We have examined the interaction of SAFB2 with already known SAFB1 molecular partners in a directed two hybrid system. Among the clones tested, one clearly distinguishes between the two SAFB proteins and was chosen for further examination of its structural and functional relation to SAFB1 and SAFB2. ERH (Enhancer of Rudimentary Homolog), a small protein (104 aa) of strikingly high inter-species conservation (100% amino acid sequence identity between human and *xenopus*, 80% similarity between human and *dyctyostelium*), was bacterially expressed and shown by pull down assays to bind *in vitro* to SAFB1 but not to SAFB2. Studies on the effect of ERH on the ERa corepressor activity of SAFB1/2 are currently under way.

The significance of the SAFB1/ERH interaction and SAFB1-SAFB2 discrimination by ERH will improve our knowledge on both ERH and SAFB protein function.

Genotoxicity on essential oils of *Origanum onites* L., *Laurus nobilis* L. and *Salvia fraticosa* in cultured human lymphocytes

B. Tuylu[1]
[1]Biology, Anadolu University, Eskisehir, Turkey

Essential oils extracted from several plants have a wide spectrum of use ranging from aromatherapy, cosmetics and food production to pharmaceutical industry and production of pesticides and household products such as detergent and soap due to their different biological activities. These biological activities include mainly antibacterial, antifungal and antioxidant effects. The potential toxic and genotoxic effects of these compounds with uncontrolled and unconscious consumption are important for humans. In the present study, genotoxic effects of essential oils extracted from *Origanum onites L.*, *Laurus nobilis L.* and *Salvia fraticosa* were investigated after 24 and 48 hours treatment with cultured human lymphocytes at doses of 0.05, 0.025, 0.01, 0.006, 0.003, 0.001 μl/ml by using Cytokinesis Blocked Micronucleus (CBMN) and Hypoxanthine Guanine Phosphoribosyltransferase (HGPRT) methods. The findings of the experiment supported that *Origanum onites L.* essential oil has clastogenic effect on cultured human lymphocytes through significant increase in micronucleus formation at doses of 0.05, 0.025, 0.01 and 0.006 μl/ml when compared to control experiment. In addition, *Laurus nobilis L.* essential oil displayed significant activity only at dose of 0.025 μl/ml, while *Salvia fraticosa* essential oil did not display significant activity at any doses after 48 hours treatment. No mutagenic effect was detected when cells pretreated with a positive mutagen were treated with *Laurus nobilis L.* and *Salvia fraticosa* essential oils which were found to be non-mutagenic in terms of MN formation. On the other hand, by HGPRT gene mutation test that investigate genotoxic effects able to cause gene mutations, it was seen that *Origanum onites L.* essential oil was effective on HGPRT gene mutation by causing considerable increase in variance frequency at all doses applied. However, *Laurus nobilis L.* and *Salvia fraticosa* essential oils caused HGPRT gene mutation in a dose-dependent manner by increasing variance frequency compared to control solvent at doses of 0.05, 0.025, 0.01 μl/ml. Together with these findings, it was concluded that *Origanum onites L.* essential oil have significant genotoxic activity on human cells at chromosomal and gene levels, while *Laurus nobilis L.* and *Salvia fraticosa* essential oils have more limited and weak mutagenic activity in terms of gene mutation.

Keywords: essential oil, genotoxicity, human lymphocytes.

HP1 dynamics reports a rolling continuum of chromatin states in pluripotent and terminally differentiated cells

A. Christogianni[1], K. Soupsana[2], E. Chatzantonaki[1], I. Giannios[3], A. Politou[2,3], **S. Georgatos**[1,3]
[1]Biology, [2]Biological Chemistry, Medical School, University of Ioannina, [3]Biomedical Research, Institute of Molecular Biology and Biotechnology, FORTH-ITE, Ioannina, Greece

Differentiation of embryonic stem cells (ESCs) is associated with progressive immobilization of chromatin proteins, decrease of bulk transcription and selective induction of lineage-specific genes. Employing mouse ESCs and primary fibroblasts (MEFs) isolated from either normal or developmentally compromised (ichthyosic) embryos, we show here that the average mobility of heterochromatin protein-1 (HP1) correlates closely with the transcriptional status and the expression profile of a cell population, but does not predict exit from the pluripotent state or change of cellular phenotype. In fact, large differences in HP1 mobility can be detected even among the cells of a clonally derived, synchronous population, in parallel to packing and fractal geometry differences that occur naturally across the same chromatin landscape. These observations are consistent with the concept of a rolling chromatin state "continuum" that shifts subtly and in a stochastic fashion when embryonic cells attempt to differentiate or functionally compensate in the course of disease.

Keywords: chromatin, heterochromatin protein 1, protein dynamics.

Top preferred session: Chromatin organisation and the nucleus

The complex formed by lamin A/C and emerin is an essential component of the inner nuclear envelope, located at the interface between the nuclear membrane and chromatin. It is at the center of the nuclear force response pathway and it is mutated in patients with Emery-Dreifuss Muscular Dystrophy (EDMD), which suggests that its biological function is particularly important in skeletal and cardiac muscle cells. Emerin role in nuclear mechanics was recently enlightened. It was shown that emerin depletion increases nuclear rigidity and prevents nuclear adaptation to force (Guilluy et al., *Nat Cell Biol* 2014). At the molecular level, mechanical force strongly induces tyrosine phosphorylation of emerin by the kinase Src. Emerin also regulates signaling and related transcription events. It controls transcription factor localization by influencing polymerization of nuclear actin (Ho et al., *Nature* 2013). Moreover lamin and emerin binds chromatin. Here we present a structural characterization of the emerin nucleoplasmic region. We had already determined the 3D structure of the emerin N-terminal LEM domain (Wolff et al., *FEBS Letter* 2001). We now show that a larger emerin fragment can be produced that dimerizes *in vitro*. We identify the impact of EDMD-causing mutations on this emerin fragment structure and oligomerisation properties. We analyze the impact of emerin structural characteristics and phosphorylation states on its capacity to bind lamin A/C tail, actin and chromatin, and we discuss the impact of EDMD-causing mutations in emerin and lamin A/C on these interactions.

Muscle-specific laminopathies – developing regulatory elements for high-level lamin A expression in muscle tissue

K. Piekarowicz[1], M. Machowska[1], R. Rzepecki[1]
[1]*Faculty of Biotechnology, University of Wroclaw, Wroclaw, Poland*

Muscle-specific laminopathies are rare, currently not curable diseases, caused by mutations in gene *LMNA* coding for nuclear proteins – A type lamins. Lamins are responsible for mechanical functions, organization of chromatin, DNA replication, regulation of transcription factors, epigenetics, DNA repair, transcription, cell cycle regulation, cell development and differentiation, nuclear positioning and apoptosis. We showed that *in vitro* overexpression of lamin A mutants causes nuclear lamina disruptions, translocation of lamin C to the cytoplasm, changes in proliferation rate and broad spectrum of nuclear phenotypes, depending on mutation.

Probably the only possible method for muscle-specific laminopathies treatment is a gene therapy, but two major problems need to be solved first: development of muscle-directed virus vector providing long term expression of the genetic drug and muscle specific, highly efficient expression cassette. We designed a muscle-specific, highly active expression cassette containing hybrid promoter for therapeutic virus.

The hybrid promoter is composed of various, mammalian, muscle specific regulatory elements, that provides a high level of a gene expression in myoblasts, myotubes and cardiomyocytes. It consists of elements such as enhancers, core promoter and intron with small intronic enhancer. They originate from murine, muscle specific genes chosen and modified basing on their expression profiles, previous research data and *in silico* analysis.

The studies on the activity of the hybrid promoter's variants were performed by analyses of expression of a reporter genes – secretory luciferase and EGFP. Our data shows, that developed promoter provides several folds higher level of the expression in C2C12 cell line that promoter of desmin, currently used in gene therapy of muscular dystrophies, but providing too low level of expression. The activity and specificity of the promoter was also examined using different cell lines and primary cells. The influence of the particular components of the hybrid promoter on the expression level in muscular and non-muscular cell lines was also investigated.

We also analyzed efficiency and effects of prelamin A expression under control of hybrid promoter, delivered by pseudotyped lentiviral vector in myoblasts and cardiomyocytes cell lines *in vitro*.

Keywords: gene therapy, laminopathies, muscle-specific promoter.

Posttranslational modifications of the nucleosome can affect stability of chromatin both on local and large-scale levels as well as accessibility of DNA to chromatin remodeling factors. Mounting evidence supports the hypothesis that the nucleosome is in dynamic equilibrium with its different intermediate states; these states are characterized by varying degrees of wrapping of the DNA around the histone core and the composition or stoichiometry of the core. Existence of several intermediate structures, lacking one or more histone heterodimers, is assumed. However, these structures are still not well characterized, either experimentally or theoretically; in particular, no atomistic models of them exist.

We have constructed all-atom models of the nucleosome intermediate states including two variants of the hexasome and the tetrasome. The complete nucleosome was represented as the octasome structure, with all the histones present. Dynamic characteristics of these structures were obtained from a series of 75 ns long molecular dynamics simulations in implicit solvent. During the simulations the octasome, hexasome and tetrasome retain the over-all o, σ and υ-shape respectively, while the "tails" of unbound DNA fluctuate with varying amplitudes. Dynamic

© 2014 The Authors. FEBS Journal © 2014 FEBS

characteristics of structures were described in terms of following parameters: RMSD of individual histone subunits, distances between centers of mass of histone dimeres, distances from each pair of nucleotide to the closest amino acid of histones, angle of entry of two DNA arms to histone core, and distances between two nucleotides marked with FRET labels, as described in literature[1]. Based on the latter distances, ensembles of possible conformations were divided into low-, middle- and high-FRET intensity subpopulations and frequencies of their occurrence were calculated and compared with experimentally observed values[1].

The existence of the modeled structures was further corroborated by an AFM-based analysis of reconstituted nucleosomes in different concentrations and NaCl salt conditions. Three main parameters, namely – volume of core particle, number of turns of DNA wrapped around the core and angle of entry of DNA arms to the core, allowed us to divide the observed nucleosome images into three partially intersecting arrays that were interpreted as the octasome, hexasome and tetrasome moieties respectively.

Post-translational modifications of nuclear proteins of placenta in complicated pregnancy

T. Pogorelova[1], V. Gunko[1], V. Linde[1], I. Alliluev[1]
[1]Rostov Scientific-Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russian Federation

Background: Metabolic sufficiency of placenta is largely determined by the state of its protein component. An important contribution to the maintenance of protein properties and functions is made by post-translational modification reactions, the disturbance of which is accompanied with the imbalance of cellular regulation processes in placenta. Particularly negative consequences for the functional metabolic state of placenta might be brought by post-translational damages of nuclear proteins involved in the formation of chromatin structure and regulation of gene expression.

The aim of this research is the study of intensity of cyclic nucleotide-dependent phosphorylation, carbonylation and amidation of nuclear proteins in placenta in placental insufficiency (PI).

Methods: Full-term placentas were obtained after delivery (39–40 weeks of gestation) from women with physiological pregnancy (n = 21) and with PI (n = 26). Histones and non-histone proteins of chromatin were separated from placental tissue after differential ultracentrifugation, isoosmotic lysis and multistage extraction. The intensity of post-translational modifications of those proteins was determined using kits.

Results: The activity of cAMP- and cGMP-dependent phosphorylation of histones in PI is lower as compared with physiological pregnancy by 24% and 18%, correspondingly. The phosphorylation degree of non-histone proteins of chromatin, especially of those which are labile associated with DNA, is more expressed and equals to 32% and 24%. The intensity of carbonylation of non-histone proteins and histones in PI increases by 30% and 23%, which indicates an increase of their oxidative modification under the conditions of intrauterine hypoxia and may be accompanied with the disturbance of different levels of protein structure. A reversed situation is characteristic of dynamics of amidation of placental nuclear proteins: the content of amide groups in histones is reduced by 27%, in non-histone proteins – by 34% that results in an increase of the negative charge of protein molecules. The detected changes of post-translational modifications of placental nuclear proteins will affect their regulatory activity.

Conclusion: Changes in the intensity of post-translational reactions may be important causes of PI development and may serve as markers of this obstetrical pathology.

P { margin-bottom: 0.21 cm; direction: ltr; color: rgb(0, 0, 0); } P.western { font-family: "Times New Roman",serif; font-size: 12pt; }P.cjk { font-family: "DejaVu Sans","MS Mincho"; font-size: 12pt; }P.ctl { font-family: "Lohit Hindi","Times New Roman",serif; font-size: 12pt; }A:link { }

Solution NMR studies of four B-DNA dodecamers were used to investigate the intrinsically preferred shape of free DNA, sequence-dependent, *via* the phosphate linkage behavior (BI ↔ BII equilibrium).

The study provided extensive evidence of the DNA intrinsic mechanics through a consistent series of correlations between NMR observables. The differences between two successive Residual Dipolar Couplings (ΔRDCs) on one hand and internucleotide distances on the other hand are both correlated to ^{31}P chemical shifts (δP), which reflect the populations of the BI and BII backbone states. Using high resolution X-ray structures as templates showed that ΔRDCs depend mostly on roll while internucleotide distances are sensitive to both roll and twist. In addition, NMR data showed that the backbone behavior is intimately coupled to the minor groove dimension. Therefore δP measurements probe not only the BI ↔ BII backbone equilibrium but, crucially, also inform on helicoidal parameters of B-DNA.

Importantly, the δP collected here confirmed that specific δP values and, hence, specific BI/BII ratios characterize the 10 complementary dinucleotides composing DNA. Combining this sequence effect and the structural couplings allowed the generalization of an NMR-based quantitative TRX scale previously proposed, which now predicts the sequence dependent intrinsic structural properties of each of the 10 complementary dinucleotides in any B-DNA in solution.

Finally, our NMR data highlight the significant progress achieved with the recent force field CHARMM36 towards a realistic description of phosphate group motions modulated by the sequence, resulting in a credible representation of B-DNA by molecular dynamics.

In sum, the prediction of the intrinsic structural DNA behavior by TRX, supplemented by molecular dynamics, offers a powerful framework to illuminate the molecular basis of the reading of DNA by proteins.

WED-276
Resveratrol activates SIRT1 in a Lamin A-dependent manner

Z. Zhou[1]
[1]*Department of Biochemistry, University of Hong Kong, Hong Kong, Hong Kong*

Human sirtuin1 (SIRT1), the closest homolog of the yeast sir2 protein, functions as an NAD+-dependent histone and non-histone protein deacetylase in several cellular processes, like energy metabolism, stress responses, aging, etc. We found that lamin A (a major nuclear matrix protein) directly binds with and activates SIRT1. Resveratrol, a natural phenol, has long been known as an activator of SIRT1. However, resveratrol's direct activation of SIRT1 has been refuted several times. We identified a novel mechanism underlying the activation of SIRT1 deacetylase by resveratrol. Resveratrol activates SIRT1 by increasing its binding with lamin A, thus aiding in the nuclear matrix (NM) localization of SIRT1. We found that rescue of adult stem cell (ASC) decline in laminopathy-based premature aging mice by resveratrol is SIRT1-dependent. Further, resveratrol's ameliorating effects on progeria and its capacity to extend lifespan in progeria mice has been established. Our data suggested that Lamin A is an endougenous activator of SIRT1 deacetylase and resveratrol can enhance the binding between SIRT1 and lamin A, therefore promote its activity. Treatment of progeroid mice with resveratrol significantly ameliorates premature aging and extends lifespan in progeria mice. Our finding suggests a new therapeutic strategy for Hutchinson-Gilford Progeria Syndrome and aging associated disorders.

Sequence-dependent conformations and microsecond-scale dynamics of B-DNA and bound cations

M. Pasi[1], J. H. Maddocks[1], R. Lavery[2], The Ascona B-DNA Consortium**
[1]*Section de Mathématiques, Swiss Federal Institute of Technology (EPFL), Lausanne, Switzerland,* [2]*Bases Moléculaires et Structurales des Systèmes Infectieux, CNRS UMR 5086/ University Lyon I, IBCP, Lyon, France*

It is well recognised that DNA is more than just a passive vector of genetic information. Instead, its mechanical properties play a significant role in protein-DNA interactions, which are important in all cellular processes that involve DNA, including genome organization and transcription regulation. As these properties depend strongly on the local base sequence, their variations along the genome effectively represent a second genetic code. Understanding how these two layers of genetic information interact, and how their interplay contributes to the regulatory network of the cell, requires extensive structural and dynamical knowledge of B-DNA, which is currently unavailable from experiment.

The Ascona B-DNA Consortium (ABC) was formed in order to obtain such information using molecular simulations. The collaboration and joint computational effort of thirteen laboratories around the world allowed the collection of more than 50 microseconds of state-of-the-art molecular dynamics (MD) simulations of a wide array of DNA sequences in water at physiological salt concentration. The ABC dataset is, to date, the most complete collection of simulation trajectories for the systematic study of the molecular-detail mechanical properties of B-DNA.

By performing detailed statistical analysis of this large database, we were able to identify the mechanical couplings at the basis of the correlated motions that characterise the nanosecond time-scale interconversion between few well-defined local B-DNA conformational sub-states. The unique features of the ABC dataset allowed us, on one hand, to define the relationship between these collective movements and specific interactions within the double helix, and on the other hand to exhaustively establish sequence-dependent variations in the relative population of the conformational sub-states. Furthermore, the analysis of the distribution of positive ions around DNA using helicoidal coordinates revealed sequence-dependent variability of the cation densities that is coupled to the conformational fluctuations of the double helix.

These results represent an important step towards a detailed mechanical understanding of the sequence dependence of B-DNA fluctuations and recognition by proteins, and are of great relevance in guiding future endeavours aimed at modeling the physics of B-DNA.

** The Ascona B-DNA Consortium is composed of the Authors and David Beveridge, Thomas C. Bishop, David A. Case, Thomas Cheatham III, Surjit Dixit, B. Jayaram, Filip Lankas, Charles Laughton, Roman Osman, Modesto Orozco, Jiri Sponer and Krystyna Zakrzewska.

Structural basis of a Polycomb body

J. Smigova, P. Juda, I. Raska
Institute of Cellular Biology and Pathology, Charles University in Prague, First Faculty of Medi, Prague 2, Czech Republic

A Polycomb (PcG) body is a microscopically visible nuclear subcompartment initially characterized by accumulations of Polycomb repressive complex 1 (PRC1) proteins. Even though the PcG bodies were described 15 years ago, the structural basis of the PcG body is still under debate. To directly visualize the fine structure of the PcG body in human U-2 OS cells stably expressing recombinant polycomb BMI1-GFP protein, we used correlative light electron microscopy combining live cell imaging and high-pressure freezing. The immunolabeled BMI1 polycomb protein was detected to be specifically enriched within condensed chromatin fascicles, large scale heterochromatin fibers, throughout the nucleus. The accumulation of label in PcG foci was shown to be generated by the local accumulation of condensed chromatin fascicles in space. However, seemingly contradictory reports have appeared that describe the PcG bodies either as protein-based bodies in the interchromatin compartment or chromatin domains. In order to settle this contradiction, crowding experiments, that represent a convenient model distinguishing between interchromatin and chromatin compartments, were carried out. By crowding approach, we observed that the behaviour of the fluorescent PcG foci in cells grown under changed molecular crowding conditions vastly differs from the behaviour of nucleoplasmic bodies. We detected that, in cells grown in hypertonic medium, PcG foci disappeared, whereas typical nuclear bodies were maintained. Importantly, "PcG bodies" as nuclear domains characterized by accumulations of DNA persisted. Our findings clearly indicate that the PcG body in U-2 OS cells is a chromosomal domain, rather than a nucleoplasmic body.

Structural features and molecular interactions of Lamin B Receptor: an interplay between order and disorder

P. Georgoulia[1], S. Liokatis[1], K. Soupsana[1], A. Louka[1], I. Giannios[2], S. Georgatos[2,3], **A. Politou**[1,2]
[1]*Biological Chemistry, Medical School, University of Ioannina,* [2]*Biomedical Research, Institute of Molecular Biology and Biotechnology, Forth-ITE,* [3]*Biology, Medical School, University of Ioannina, Ioannina, Greece*

Lamin B Receptor (LBR) is a ubiquitous protein of the nuclear envelope thought to connect the inner nuclear membrane with the underlying nuclear lamina and peripheral heterochromatin. The nucleoplasm-facing amino-terminal part of the protein has been shown to mediate most of LBR interactions and harbors a 40-residue region rich in Arg-Ser repeats (RS region) that has the typical features of an IDP protein and is flanked between two globular domains (a well-folded Tudor domain and a 110-amino acid segment with no apparent homologues). LBR-Tudor exhibits tight and stoichiometric binding to the “histone fold” region of free histone H3, suggesting an interesting role in histone assembly. In addition, robust binding to native nucleosomes, both unassembled and assembled H3/H4 histones and several other LBR partners, such as nuclear lamins and heterochromatin proteins, is observed, when LBR-TD is extended towards its carboxy-terminus to include the RS region. The RS region is also responsible for LBR homopolymerization. However, its conformational and functional properties are most likely modulated by the type and the extent of post-translational modifications, mainly phosphorylation and methylation. Here, we present the results of a biochemical, biophysical and computational study of LBR regions addressing the effect of physiologically relevant PTMs and interdomain interactions on LBR structure and function.

WED-280
The pattern of reorganization of nucleosome structure chromatin in coding region under gene activation

E. Kotriakhova[1], T. Priyatkina[1]
[1]*Department of Biochemistry, Saint Petersburg State University, St. Petersburg, Russian Federation*

The analysis of nuclease DNA fragmentation within cell nuclei that reveals the changes in DNA-histone interactions is a helpful approach to elucidate pattern of nucleosome remodeling under gene activation. We studied fragmentation with micrococcal nuclease (MNase) and DNase I of coding region chromatin of trp-dioxygenase gene (*tdo*) in rat liver nuclei where its copies are presented in two states, i.e., transcriptionally competent and transcriptionally active. DNase I introduces nicks (single-stranded breaks) in free DNA. Coincidence of nick positions on complementary chains produce double-stranded breaks. MNase generates symmetric double-stranded breaks. It was found that under short-term action of MNase at saturating concentration (at limit of MNase digestion of total chromatin DNA), two kinds of *tdo* gene fragments are mainly are produced: about full-size *tdo*-transcription units (19000 bp) and their large (from 1500 bp) segments heterogeneous in length. This means that these fragments originate from two distinct varieties of *tdo*-transcription units coexisted in liver nuclei. Some of them do not contain MNase accessible sites across their length, whereas in others resistant regions alternate with rare irregular located MNase-sensitive regions. Under similar conditions the whole of *tdo*-DNA converts into acid-soluble products in rat liver nuclei treated with DNase I. We presume that the inaccessibility of DNA to MNase over entire length of coding region is inherent transcriptionally competent *tdo*-copies. Transcription generates MNase sensitive areas that it is possible flank elongating RNA polymerases.

After the gentle ultrasound treatment of liver nuclei, three subfractions of chromatin (DNP) fragments were isolated by selective extraction. By dot blot analysis, we showed that *tdo*-DNA is 20 – 30-fold enriched in these fractions. Minor fraction (nearly 1% of total DNA) in 0,005 M MgCl2 solution releasing (DNP-AI), consisted of long fragments (6000–20000 bp on DNA scale); the fraction extracted by 0,2 M NaCl solution (DNP-AII) is represented by single peak of short DNP fragments (200–1000 bp). The dissoluble in the 0,05M Na-pyrophosphate with 0,005 M MgCl2 solution fraction (DNP-AIII) included both DNA-peaks. Fragments of 5′-flanking *tdo* gene region predominated in low-molecular DNAs of DNP-AII and DNP-AIII. Transcription units of *tdo* were represented in DNP-AI and DNP-AIII by DNA fragments more than 10000 bp long. Non-equimolar ratio of four core histones is a distinctive feature of the fractions under study: content of H2A and H2B is lower in all the fractions; only alone H4 is revealed in DNP-AII.

Possibility of coupled linearization of DNA and histone octamers in coding regions of chromatin at gene activation is discussed.

Keywords: chromatin of active genes.

Transcription shutdown induced by heat shock in Drosophila induces reorganization of chromatin and increases the binding of lamin Dm and topoisomerase II to chromatin and DNA

R. Rzepecki[1], M. Czekaj[1], P. Gagat[1], P. A. Fisher[2], D. Rzepecka[1]
[1]*Laboratory of Nuclear Proteins, Faculty of Biotechnology, Department of Biotechnology University of Wroclaw, Przybyszewskiego Str. 63/77, 51–148 Wroclaw, Poland,* [2]*Department of Pharmacological Sciences, State University of New York, Stony Brook, NY, USA*

Drosophila lamins and topo II are major karyoskeletal proteins important in chromatin organization, remodeling and regulation of gene expression. Both lamin Dm and topo II proteins interact with and bind DNA and chromatin components in vivo. Some of these in vivo interactions occur through AT rich DNA sequences (SAR/MAR DNA). In flies, the induction of heat shock induces genome wide epigenetic changes in chromatin which results in total transcription shutdown except the induction of six heat shock loci. This offers the unique opportunity to induce the genome wide epigenetic changes in chromatin and research the role of lamin Dm and topo II and other proteins in transcription regulation and chromatin organization on genome wide scale as well as ability to visualize this processes on particular loci using salivary glands polytenic chromosmes. With transcription activation (or shutdown) within several minutes time of heat shock induction this method allows for detection of precise correlation between transcriptional activity of locus and its chromatin modification.

© 2014 The Authors. FEBS Journal © 2014 FEBS

We analyzed the in vivo DNA and chromatin binding ability of lamin Dm, lamin C and topo II binding and showed that lamin Dm binds about 3–4 fold weaker with chromatin than topo II in vivo in normal conditions. The change in chromatin organization induced by heat shock increased overall lamin Dm binding with chromatin by 4 - folds while topo II binding was increased about 15 – fold. Specificity of binding to target chromatin elements (DNA, RNA, histones) was also detected for both proteins. Soluble (low salt extractable) fraction of lamin Dm and topo II was the most efficient in chromatin binding. Upon heat shock induction/transcription shutdown several fold increase in chromatin binding was detected in insoluble (nuclear matrix) fraction of lamin Dm and topo II. This correlated with redistribution of karyoskeletal proteins and changed solubility of lamins, topo II and F/G repeat nucleoporins. Changes in distribution of modified histones as well different staining pattern for lamin Dm and topo II have been detected as well. Our data indicate that lamin Dm (similarly to topo II) may be involved in chromatin opening and closing in vivo.

Two new insulator proteins, Pita and ZFPIC, target CP190 to chromatin

N. Zolotarev[1], O. Maksimenko[2], M. Bartkuhn[3], V. Stakhov[2], M. Herold[3], A. Bonchuk[4], A. Fedotova[4], O. Kyrchanova[4], R. Renkawitz[3], P. Georgiev[1]

[1]Department of the Control of Genetic Processes, [2]Laboratory of Gene Expression Regulation in Development, Institute of Gene Biology RAS, Moscow, Russian Federation, [3]Institute for Genetics, Justus-Liebig-University Giessen, Giessen, Germany, [4]Group of Transcriptional Regulation, Institute of Gene Biology RAS, Moscow, Russian Federation

Insulators are multi-protein–DNA complexes that regulate the nuclear architecture. The Drosophila CP190 protein is a cofactor for the DNA-binding insulator proteins Su(Hw), dCTCF, and BEAF-32. The fact that CP190 has been found at genomic sites devoid of either of the known insulator factors has until now been unexplained. We have identified two DNA-binding zinc-finger proteins, Pita and a new factor named ZFPIC, that interact with CP190 in vivo and in vitro at specific interaction domains. Genomic binding sites for these proteins are clustered with CP190 as well as with dCTCF and BEAF-32. Model binding sites for Pita or ZFPIC demonstrate a partial enhancer-blocking activity and protect gene expression from PRE-mediated silencing. The function of the dCTCF-bound Mcp insulator sequence requires binding of Pita. These results identify two new insulator proteins and emphasize the unifying function of CP190, which can be recruited by many DNA-binding insulator proteins.

Keywords: chromatin organization, insulator.

Unique mechanical properties of isolated nuclei regulated by chromatin compaction

C. J. Chan[1,2], W. Li[1], J. Scholze[1], M. Schürmann[1], J. Guck[1,2]

[1]Biotechnology Center, TU Dresden, Dresden, Germany, [2]Physics, University of Cambridge, Cambridge, UK

Nuclear mechanics and structure could affect gene regulation and gene expression. Chromatin, a major component of cell nuclei, could play an important role in maintaining nuclear integrity and their mechanical properties. Previous studies on isolated nuclear mechanical properties have focused largely on the role of the nuclear lamina, using techniques such as AFM and micropipette aspiration. In this work, we explicitly address the contributions of chromatin to nuclear rheology using a microfluidic optical stretcher, which probes the mechanical response of isolated nuclei to an optically induced stress applied in their *suspended* state. Intriguingly, we find that isolated nuclei expand in volume when stretched in one direction, and exhibit significant softening with increased nuclear size. In addition, changes to the state of chromatin condensation using enzymatic perturbations or ionic conditions dramatically alter the nuclear morphology and compliance. Specifically, isolated nuclei stiffen significantly in the presence of high salt concentration, and exhibit contraction in the presence of multivalent ions due to hyper-condensation of chromatin. The presented work suggests that the unique nuclear mechanical properties may be linked to the compaction state of chromatin, which can be modulated by a change in nuclear volume or electrochemical environment.

WED-285
Association of DNA damage response genes polymorphism with individual radiosensitivity in Kazakhstan population

B. Bekmanov[1], B. Zhunussbekova[1], K. Djantaeva[1], F. Muratova[1], N. Nurzhibek[1]
[1]*institute of General Genetics and Cytology, Almaty, Kazakhstan*

It is suggested that inherited variations in radiosensitivity genes may contribute to formation of response to cancerogenic agents of anthropogenic etiology. Considering the fact that induction of DNA damage as number one marker of radiation influence, variations in genes involved into DNA repair and cell cycle regulation maybe implied as strong markers of individual radiosensitivity.

The ATM gene plays crucial role in responding to DNA damage, in particular to double strand breaks. In order to maintain the genome integrity it is believed that ATM tightly cooperates with TP53. Therefore alteration in genes encoding these proteins may result in accumulation of genomic mutations including deletions and translocations.

The aim of the study was to investigate the association between variants of DNA damage response genes and radiosensitivity in population from Kazakhstan. DNA and blood samples were obtained from the unique biobank, representing people living in close proximity to former Semipalatinsk nuclear testing site as exposed cohort and residents of "radiation free" districts of Almaty region as control group. PCR and PCR-RFLP methods were used to study *ATM* G5557A and *TP53* Arg72Pro polymorphisms.

According to cytogenetic study results, total frequency of chromatid and chromosome aberrations in exposed cohort is more that 2.5 times higher in contrast to control group. The high frequency of chromosomal aberrations (more than 3%) was considered as a criterion of radiation exposure for the analysis of the association with individual radiosensitivity.

Obtained results demonstrate association between high frequency of chromocomal aberrations and studied genotypes: *TP53* Arg72Pro (OR = 1.36, p = 0.009) and *ATM* Asn1853Asn (OR = 1.41, p = 0.98).

We believe our results can be useful in early identification individuals under greater genetic risk in order to improve health issues.

BRCA1/BARD1 retention at sites of DNA damage through HP1gamma interaction with BRCT domain of BARD1

W. Wu[1], H. Nishikawa[2], A. S. Sedukhina[1], T. Fukuda[1], T. Ohta[1]
[1]*Department of Translational Oncology,* [2]*Institute of Advanced Medical Science, St. Marianna University Graduate School of Medicine, Kawasaki-City, Japan*

Stable retention of the BRCA1/BARD1 complex at sites of DNA damage, which is mediated by the BRCT domains of BRCA1, is required for the proper response to DNA double-strand breaks (DSBs). Here, we demonstrate that the BRCT domain of BARD1 is also required for the retention of the complex at damaged sites through its interaction with HP1gamma. In response to DNA damage, BARD1 interacts with Lys9-dimethylated histone H3 (H3K9me2) in an ATM-dependent but RNF168-independent manner. This interaction is mediated by HP1gamma. A conserved HP1-binding motif in the BARD1 BRCT domain directly interacts with the chromoshadow domain of all three isoforms of HP1 *in vitro*; mutations in this motif disrupt the retention of BRCA1/BARD1 at DSB sites and allow ectopic accumulation of RIF1, an effector of non-homologous end joining, at the damaged loci in S-phase. The histone lysine methyltransferase (HKMT) inhibitors chaetocin and UNC0638 abolish the retention and exhibit synergistic inhibition of clonogenic cell growth with the poly (ADP-ribose) polymerase (PARP) inhibitor olaparib. We reveal that the BRCT domain of BARD1 promotes retention of a non-BRCA1-Abraxas BRCA1/BARD1 complex at damaged DNA sites and demonstrate the therapeutic potency of HKMT inhibitors that disrupt the response of BRCA1/BARD1 to DNA damage.

Keywords: BRCA1/BARD1, HP1gamma, DNA damage.

WED-287
Cdc7, Rad53 and Asf1 stabilize Rad52 binding to replicative DNA damage

M. J. Cabello-Lobato[1], R. González-Prieto[1], F. M. Prado[1]
[1]*Molecular Biology, Cabimer-CSIC, Seville, Spain*

The response to DNA lesions that impair the advance of replication forks relies on DNA damage tolerance (DDT) mechanisms, which facilitate fork bypass across the lesions and repair of the ssDNA fragments generated during this process. One of these mechanisms is Homologous Recombination (HR), which uses the information of an intact template to repair DNA breaks. We have recently shown that the recombination proteins Rad52 and Rad51 contribute to tolerate replicative DNA damage through replicative and repair activities, which are regulated during the cell cycle. In S phase, Rad52 and Rad51 travel with the fork and facilitate replication bypass across the lesion by unknown mechanisms. Repriming of the DNA synthesis downstream of the lesion leaves Rad52 and Rad51 loaded at the ssDNA lesions left behind the fork, which are repaired at HR centers formed in G2/M (González-Prieto et al. 2013, EMBO J 32:1307). Here, we report a role for the kinase Cdc7 in promoting the loading/stabilization of Rad52 to the ssDNA lesions generated upon treatment with the alkylating agent methyl-methane sulfonate (MMS). This effect is partially mediated by phosphorylation of Mcm2. In addition, we show that Rad53, which requires the kinase activity of Cdc7 for full activation, is also required for Rad52 binding to DNA damage. Notably, Mec1 does not share this function. In addition, we have observed that the histone chaperone Asf1, which forms a complex with Rad53, is also required for Rad52 binding to replicative DNA damage. This role is independent of histone H3K56 acetylation and chromatin assembly, but also of the interactions between Asf1 with Rad53 and histones. We are currently exploring the mechanisms by which Cdc7, Rad53 and Asf1 stabilize Rad52 at replicative lesions during S phase.

Keywords: DNA damage, DNA repair.

Combined Wee1 and Rad51 inhibitor treatment decrease repair of double-strand breaks, survival and alters cells cycle of irradiated T-leukemia cells

R. Havelek[1], J. Cmielova[2], K. Kralovec[1], L. Bruckova[1], J. Vavrova[3], M. Rezacova[2], Z. Bilkova[1]
[1]Department of Biological and Biochemical Sciences, University of Pardubice, Faculty of Chemical Technology, Pardubice, [2]Department of Medical Biochemistry, Charles University in Prague, Faculty of Medicine in Hradec Kralove, [3]Department of Radiobiology, University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic

Aim: To evaluate cytotoxic and apoptosis-inducing effects of ionizing radiation, specific inhibitor of Wee1 kinase 681641, novel inhibitor of Rad51 recombinase RI-1 and its combination on Jurkat (p53 deficient) and MOLT-4 (p53 wild-type) leukemic cell lines. We also aim to clarify basic cellular and molecular mechanisms involved in ionizing radiation induced double-strand breaks (DSBs) repair in presence or absence of examined inhibitors.

Methods: In this work, we measured the mitochondrial dehydrogenase activity to quantify survival of Jurkat and MOLT-4 cells. Flow cytometry based methods were used to assess the effect of the two inhibitors on cell cycle and apoptosis quantified by means of Annexin V-FITC and propidium iodide dual staining. Immunofluorescence stained gammaH2AX positive cells were detected 24 h after irradiation to semiquantitatively analyse delayed DSBs repair by epi-fluorescence microscopy under low magnification. Visual aspects of persistent gammaH2AX foci with 53BP1 colocalization were captured by high-resolution imaging using confocal microscope. Expressions of selected proteins involved in DNA repair and cell cycle arrest were detected by Western blot.

Results: Combining Wee1 681641 and Rad51 RI-1 with ionizing radiation significantly reduced the cell survival for both Jurkat and MOLT-4 cells. Pre-treatment with Wee1 681641 or Rad51 RI-1 inhibitor alone increased the sensitivity of Jurkat cells to the irradiation, however combining both inhibitors together resulted in further enhancement of apoptosis. Jurkat cells pretreated with inhibitors were positive for gammaH2AX foci 24 h upon irradiation. MOLT-4 cells were less affected by inhibitors application followed by ionizing radiation exposure. Pre-treatment with Rad51 RI-1 had minimal effect on increased apoptosis induction; however Wee1 681641 increased ionizing radiation-induced cell death in MOLT-4. When dosed together, the combination had additive effect on MOLT-4 cell death.

Conclusion: This work suggests that further investigation of Rad51 inhibitors in combination with Wee1 inhibitors as potential anticancer therapy sensitizers preferentially for p53-deficinet cancer cells is warranted.

Comparison of metabolome and proteome profiles of *E. coli* lacking HU protein

D. A. Korzhenevskiy[1], A. Vanyushkina[2], D. Kamashev[2], T. Rakitina[1,3], A. Lipkin[1], V. Govorun[2,3]
[1]National Researc Center Kurchatov Institute, [2]Research Institute of Physico Chemical Medicine, [3]Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

HU is a nucleoid associated protein (NAP) that is present in every bacterial species. HU binds non-specifically to duplex DNA with a particular preference for targeting nicked or bent DNA. HU deletion is lethal for the majority of bacteria. Although *E.coli* lacking HU is viable, it is sensitive to a variety of stresses.

The effects of the HU protein on gene expression are known from microarray analysis. Absence of this DNA architectural protein causes a disorder in *E.coli* gene regulation. On the other hand, *E.coli* growth at standard conditions is almost unaltered in the absence of HU. To understand how bacteria withstand the chromosomal disorder we performed a proteomic analysis to compare *E.coli* lacking HU with wild-type *E.coli*. Comparison of the proteomic profiles was performed using SWATH acquisition on QqQ-TOF 5600 AB-Sciex mass-spectrometer. Among the proteins up-regulated in *E.coli* lacking HU are the proteins responsible for amino acid biosynthesis aminoacid-tRNA ligases as well as proteins, whose expression is altered by aerobic/anaerobic conditions. Proteins responsible for the stresses are usually down-regulated in the absence of HU.

In this study we also compared metabolomes of wild-type *E. coli* and *E. coli* lacking HU protein using QTOF mass spectrometry. Here we present reliable measurement of a hundred of metabolites. Detected changes in the E. *coli* metabolome profile caused by the lack of HU correlate well with the changes in protein content observed in proteomic studies.

Combined results of comparative metabolome and proteome studies show that oxygen consumption, protein and amino acid biosynthesis, and stress adaptation are the most altered functions in *E. coli* lacking HU protein.

The work was supported by the RFBR (grant 13-04-12084).

Conformational changes and unzipping of DNA by surface modified gold nanoparticle

K. Sanyal[1], S. C. Bera[1], P. P. Mishra[1]
[1]Chemical Science division, Saha Institute of Nuclear Physics, Kolkata, India

Damage to DNA in biological environment has been associated with alterations in DNA sequence. In the repairing process of this kind of damage, DNA unzipping or DNA unwinding is an important step. In biological system this type of unzipping is carried out by specific enzymes or heliceses. Besides that, some of non-biological complexes also show this kind of unzipping properties.

Adsorption of DNA on the surface of gold nanoparticle is a common phenomenon. This was a remarkable observation as in this case DNA and goldnanoparticle both were negatively charged. So by virtue of the electrostatic charge both the particle should repel each other that can be overcome by the use of salts. Here we have shown the interaction between dsDNA with gold nanoparticle, surface modified with L-cysteine, in biological condition. DNA-modified AuNP interaction causes a conformational change as well as unzipping of the DNA double strands. This unique observation was studied by the help of circular dichroism (CD) spectrophotometer, UV-Vis and Fluorescence techniques. It

© 2014 The Authors. FEBS Journal © 2014 FEBS

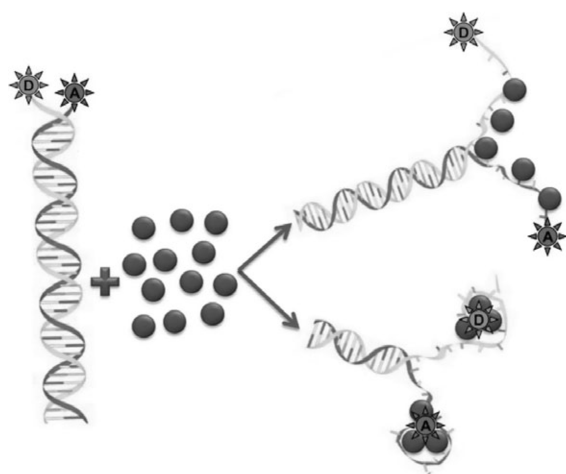

Fig. 6: Possible Mechanism of interaction of AuNPs to dsDNA.

was also supported by time resolved fluorescence and single-molecule fluorescence microscopic techniques.

The above results showed that in presence of AuNPs, surface modified with L-cysteine, DNA unzipping happening in case of both long as well as short DNAs. These AuNPs, having surface with positively charged, interacts with the phosphate group of the dsDNA and breaks the H-bonding responsible for DNA double strand formation. The actual mode of interaction still under investigation, but the possible way of interaction was proposed in the Figure.

Keywords: Dna unzipping, Goldnanoparticle.

Contribution of multifunctional protein YB-1 in the BER pathway during oxidative DNA lesions repair

E. Fomina[1], P. Pestryakov[1], O. Lavrik[1,2]
[1]Institute of Chemical Biology and Fundamental Medicine SB RAS, [2]Novosibirsk State University, Novosibirsk, Russian Federation

Aim: Single oxidative DNA lesions (such as abasic sites, single-stranded DNA breaks, oxidized bases) and their combinations that are referred to as oxidative clustered DNA lesions – OCDLs are generally corrected by base excision repair pathway (BER). During BER, the damaged DNA strand is cleaved by AP endonuclease APE1 or bifunctional DNA glycosylases like NEIL1 that results in nicked intermediate. Due to this fact, repair of abasic sites located within bistranded OCDLs or single-stranded DNA regions is closely connected with the risk of high cytotoxic DNA double strand breaks formation. Pleiotropic protein YB-1 is extensively studied in the context of cellular response to genotoxic stress, but its unmediated role in DNA repair is still open to question. The aim of present research was to investigate multifunctional protein YB-1 influence on repair of abasic sites located within oxidative clustered DNA lesions (OCDLs) or single-stranded DNA fragments.

Methods: In present work bistranded OCDLs in DNA were imitated by combination of abasic site and 5-formyluracil (potential product of thymine oxidation) in opposite DNA strand. YB-1 interaction with oxidative DNA lesions was determined by $NaBH_4$-mediated crosslinking. YB-1 influence on major components of BER machinery was performed by functional studies and gel retardation assays. Posttranslational modification of YB-1 was analyzed by Western-blot analysis and Coomassie staining. Results

The data obtained demonstrated that YB-1 directly interacts with abasic site and 5-formyluracil in DNA via intermediate Schiff base formation. YB-1 was shown to promote APE1- and NEIL1-depending cleavage of either single abasic sites or AP sites within OCDLs. YB-1 influence on APE1 occurs during substrate-binding step. Presence of high YB-1 concentrations resulted in blocking APE1-depending pathway via inhibition of APE1 activity as well as polβ dRP lyase activity. With AP sites being in the single-stranded DNA regions, YB-1 inhibited both APE1 and NEIL1 activities. In vitro studies revealed a possibility of a novel posttranslational modification of YB-1 that could influence on its interaction with DNA.

Conclusions: Pleiotropic protein YB-1 directly interacts with AP sites and 5-formyluracil within DNA and possesses the capability of modulating of APE1- and NEIL1-depending AP site cleavage. YB-1 is able to go through posttranslational modification that can affect the role of YB-1 in DNA repair.

Crosstalk of repair mechanisms and replication in pluripotent stem cells

A. Baumeisterova[1], M. Krutá[2,3], I. Raska[2], P. Dvořák[2,3], V. Rotrekl[2,3]
[1]Department of Biology, Faculty of Medicine, Masaryk University, Kamenice 5, Brno, Czech Republic, [2]Department of Biology, Faculty of Medicine, Masaryk University, Kamenice 5, Brno, Czech Republic, [3]International Clinical Research Center, St. Anne's University Hospital Brno, Kamenice 5, Brno, Czech Republic

Human embryonic stem cells (hESC) may present a breakthrough in regenerative medicine. In order to obtain enough cells for possible cell replacement therapy or research it is necessary to maintain hESC in *in vitro* cultivation. Long term propagation of hESC is associated with genome mutagenesis. To defend their genome hESC possess elevated mechanisms that repair DNA damage and errors. Some of the repair mechanisms such as base excision repair (BER), however elevated in early passage, are decreasing with prolonged cultivation. The BER seems to be involved in double strand break (DSB) release when dealing with clustered damage. DSBs can further be repaired either by homologous recombination (HR) or non homologous end joining (NHEJ). HR, being considered error-proof, is usually active when sister chromatid is present in the cell while NHEJ, the believed error-prone mechanism, ligates DSBs′ ends throughout the whole cell cycle. Thus the pathway choice seems to be one of the crucial moments in genome stability maintenance. Our results suggest that BER plays an important role in DSBs′ repair pathway choice due to DSBs released upon BER repair of clustered oxidative damage. Subsequently the BER-mediated DSB-damage released after ionizing radiation is repaired by the cells' repair machinery within 45 minutes. That suggests that NHEJ is involved in amelioration of the damage. Moreover, inhibition of BER results in replication stress-coupled HR shown by elevated Rad51 foci and sister chromatid exchange (SCE). Interestingly, the mutation frequency (MF) is significantly elevated in the absence of the BER-mediated DSB release, when cells activate their replication stress coupled HR. Contrary to generally accepted model, we propose that hESC employ NHEJ or its subpathways to ameliorate the BER mediated DSB damage in order to minimize the mutagenesis of their genome.

Dissecting NUP98 function in human leukaemogenesis

N. Nilles, B. Fahrenkrog
Biologie moléculaire, Université Libre de Bruxelles, Gosselies, Belgium

Acute myeloid leukaemia (AML) is a heterogeneous disease characterized by uncontrolled proliferation of neoplastic haematopoietic precursor cells, which leads to the disruption of normal haematopoiesis and bone marrow failure. Impaired haematopoiesis is often associated with balanced chromosomal translocations that involve the nucleoporin Nup98 fused to more than 30 different partner genes, such as the homeobox genes, HoxA9 and PMX1. Nup98-associated AML is characterized by the poor prognosis and poor treatment outcome for the patients. Our aim is to better understand the underlying molecular mechanism that leads to chemotherapy-resistance and we found that the expression of Nup98-fusion proteins cause versatile alterations in nuclear organization, including changes in chromatin organization. As changes in DNA topology might affect DNA damage response and as chemotherapeutic drugs are typically DNA double-strand break (DSB) causing agents, we investigated whether the Nup98-fusions alter DSB break repair pathways. To do so, we studied the impact of the Nup98-fusions on exogenously induced DNA DSB repair by treating cells with the topoisomerase II inhibitor etoposide (ETO) or the γ-radiation mimicking agent neocarzinostatin (NCS). We found that cells expressing Nup98-fusion proteins show less DSB foci as compared to control cells. This suggests that the Nup98-fusions render the cells less sensitive towards ETO- and NCS-induced DSB, or that early events of the DSB repair pathways that allow foci formation are inhibited in presence of Nup98-fusion proteins. Experiments to further distinguish these two possibilities are under way, as well as the analysis, which part or specific domain of the fusion proteins is contributing to the altered DSB repair mechanism.

DNA mismatch repair in *Neisseria gonorrhoeae*: beyond the *E.coli* paradigm

R. N. Desirazu[1], S. Nirwal[2], D. Kulkarni[1], S. Namadurai[2], D. Nair[2]
[1]Biochemistry, Indian Institute of Science, [2]National Centre for Biological Sciences, Bangalore, India

Neisseria gonorrhoeae causes gonorrhoeae, a debilitating disease and the continuous appearance of new drug-resistant strains is fast rendering standard treatments ineffective. The development of an effective prophylactic vaccine has been hindered by the fact that this organism exhibits phase variation. Successful phase variation is dependent on regulating mismatch repair (MMR) pathway in appropriate manner. In *E. coli*, the specific components of MMR are MutS, MutL and MutH. Of these proteins, MutH is a site specific endonuclease and plays a vital role in strand discrimination and creation of a nick in the daughter strand. *Neisseria gonorrhoeae* lacks a homolog of MutH and therefore, it is expected that it will show significant differences in MMR pathway especially in the strategies utilized for strand discrimination and nick-creation. The key question is how recognition of a mismatch on duplex DNA by NgoS is coupled to nicking activity by homodimeric NgoL directed towards the newly synthesized strand. Our overall strategy towards this end includes detailed biochemical charaterization of the various proteins involved in MMR (MutS, MutL, β-clamp, RecJ, UvrD helicase) and determining structures of the components of MMR in their apo- and functional states.

All the components of MMR have been purified to high homogeneity and a rigorous structural and biochemical characterization of these proteins is currently ongoing. Single crystals of MutS in its apo-state shows that MutS exists in the form of a dimer but there are significant differences(as compared to the functional complexes of MutS from *E.coli* and *T.aquaticus*) in the manner in which the two monomers associate to form a dimer. Overall, the structure of NgoS in the apo-state reveals how a functional MutS-DNA complex is assembled. In addition, we see that MutL interacts with β -clamp through its C-terminal domain (CTD). The nicking endonuclease activity is resident in this CTD of MutL and is dependent on the integrity of a conserved metal binding motif. We had earlier shown that the CTD *Neisseria gonorrhoeae* MutL acts as a nicking endonuclease and exists in the form of an elongated inverted homodimer placing the two composite active sites in each subunit on opposite lateral sides of the homodimer. Due to this arrangement, only of the active sites is presented to DNA, thereby preventing the creation of a double stranded break. Overall, our efforts have shed more light on how the functional mismatch repairosome is assembled and the repair reaction initiated.
Keywords: mismatch repair.

Formamidopyrimidine-DNA glycosylase from *E.coli*: new mechanistic details of the enzyme activity

A. Endutkin, D. Zharkov
Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

Formamidopyrimidine DNA glycosylase (Fpg) from Escherichia coli is one of the main tools protecting the bacterial genome from lesions caused by environmental and internal insults. Fpg initiates base excision repair in DNA by removing oxidized nucleobases. A major DNA oxidation product is 8-oxoguanine (8-oxoG), a base with a high mutagenic potential. We have used kinetic and thermodynamic approaches to analyze 8-oxoG recognition and excision by Fpg. First, we have found that the energy of stacking interactions of 8-oxoG was in strict dependence on nucleotide environment, which may affect lesion recognition and the efficiency of eversion of 8-oxoG from the double helix by DNA glycosylases. In addition, we observed that the presence of the lesion affects the kinetics of association of oligonucleotides into a duplex. Using site-directed mutagenesis, we have addressed the functions of many previously unstudied amino acid residues that were predicted to be important for Fpg activity and structure maintenance. Of note, many substitutions abolished the excision of 8-oxoG but did not affect the cleavage efficiency of abasic substrates. Finally, we investigated the contribution of separated structural domains of Fpg to specific enzyme-substrate interactions. Surprisingly, despite the absence of the catalytic domain, C-terminal domain of Fpg possessed a low residual ability to recognize and cleave abasic substrates. This is can shed light on unknown functions of truncated Fpg homologs from Mycobacte-

© 2014 The Authors. FEBS Journal © 2014 FEBS

rium tuberculosis. Our study uncovers new mechanistic details of Fpg activity, allowing us to consider Fpg as a promising scaffold for applied nanotechnology and molecular medicine.

Functions of WT Apn1 from *Saccharomyces cerevisiae* and its H83A mutant involved in BER and NIR pathways

E. S. Dyakonova[1], V. V. Koval[1,2], O. S. Fedorova[1,2]
[1]Institute of Chemical Biology & Fundamental Medicine, [2]Novosibirsk State University, Novosibirsk, Russian Federation

Apurinic/apyrimidinic endonuclease from *Saccharomyces cerevisiae* Apn1 is one of the key enzymes involved in base excision (BER) and nucleotide incision (NIR) DNA repair pathways. In BER Apn1 is mainly involved at the stage of cleavage of abasic sites, which are abundant and very genotoxic DNA damages. In NIR Apn1 is known to incise phosphodiester backbone 5′ to the damaged nucleotide (Ishchenko A. A., et al. 2003). In view of unresolved spatial structure of Apn1 from *S. cerevisiae*, based on the high aminoacid homology of yeast Apn1 to *E. coli* Endo IV, His-83 is believed to coordinate one of three Zn atoms in the active site of Apn1 like His-69 in Endo IV (Hosfield D. J., et al. 1999; Garcin E. D., et al. 2008). Substitution of His-83 for Ala is proposed to decrease AP endonuclease activity of the enzyme owing to weak coordination of Zn ion involved in catalysis. The kinetic analysis of the interactions of Apn1 and its mutant form with DNA should shed light on the key points of recognition and catalysis, namely, the role of conformational dynamics of the reactants, the participation of His-83 in metal ions coordination, etc.

In this study, kinetics of the interaction of WT and H83A Apn1 with DNA substrates was investigated. A stopped-flow method with the detection of fluorescence intensity of 2-aminopurine located adjacent to the damage allows conformational dynamics of DNA to be monitored. Substitution of His-83 for Ala was found to influence substrate binding and catalysis of the mutant Apn1. The location of 2-aPu relative to the damage was shown to have no influence on substrate cleavage by WT Apn1; but in the case of Apn1 H83A location of 2-aPu is essential. The experimental data analysis reveals that not only the catalysis is influenced by the location of fluorophor in DNA but also by the nature of damages. The initial conformation of double-stranded nucleic acid is of great importance for the formation of the proper enzyme-substrate complex in the case of H83A mutant because of weak coordination of active site Zn ion.

Silicium dioxide nanoparticles (SiO_2NPs) are widely used in daily life. Toxic effects of these nanoparticules to living systems are gaining attention. In this study, we investigated the genotoxic effect of different sizes of SiO_2NPs in Wistar rat lymphocyte cells.

Thirty-five healthy male Wistar albino rats weighing 150–250 g (5-6 weeks of age) were used in this study. The experimental design of the study was conducted according to the international validation of the in vivo rodent alkaline comet assay for detection of genotoxic carcinogens for evaluating potential genotoxic effect of different size of SiO_2NPs (6, 20, 50 nm, 150 μg/mL) in case of chronic treatment (28 days). Rats were equally divided into five groups (n = 7 rats) which were treated with SiO_2NPs in physiological serum intraperitoneally in a volume of 1 mL. Group 1 was the vehicle (physiological serum) treated group. Group 2 was administered low particule size SiO_2NP (6 nm, 150 μg/mL/day). Group 3 was treated with medium particule size SiO_2NP (20 nm, 150 μg/mL/day). Group 4 received high particule size SiO_2NP (50 nm, 150 μg/mL/day) once a day throughout 28 days of the study for chronic treatment. Group 5 was positive control group (n = 7 rats), ethylmethane sulfonate was dissolved in physiological serum and administred intraperitonally 200 mg/kg BW, 24 h before sacrifice. Blood were sampled from the all groups for genotoxicity assessment. The alkaline comet assay was performed. After the staining process, a hundred cells were analysed using double slides. For quantification of DNA damage, comet tail length, tail intensity and tail moment were measured and calculated by the Comet Assay III image analysis system.

Tail length significantly decreased in 20 nm and 50 nm size groups and tail moment significantly decreased only 20 nm size group in comprasion to positive control group ($p < 0.05$). There was significant decrease between the 6 nm nanoparticule size group and 20 nm and 50 nm nanoparticule size groups ($p < 0.05$) for tail intensity and tail moment.

The results of DNA damage obtained in the comet assay indicated genotoxic potential of SiO_2NP in lymphocyte cells. This genotoxic potential is dependent on particle size.

Keywords: comet assay, genotoxicity, Silicium dioxide.

Human DNA polymerases catalyze lesion bypass across benzo[a]pyrene-derived DNA adduct in cluster of DNA lesions

L. V. Starostenko[1], N. A. Lebedeva[1], N. I. Rechkunova[1], A. Kolbanovskiy[2], N. Geacintov[2], O. I. Lavrik[1]
[1]Institute of Chemical Biology and Fundamental Medicine Siberian Branch of Russian Academy of Science, Novosibirsk, Russian Federation, [2]Department of Chemistry, New York University, New York, USA

The genome is continuously affected by a variety of endogenous and exogenous factors that damage genomic DNA. The combined action of oxidative stress and genotoxic polycyclic aromatic hydrocarbons derivatives can lead to cluster-type DNA damage that includes both a modified nucleotide and a bulky lesion. As an example, we investigated the possibility of repair of an AP site located opposite a minor groove–positioned (+)-*trans*-BPDE-dG or a base-displaced intercalated (+)-*cis*-BPDE-dG adduct (BP lesion) by a BER system. Oligonucleotides with single uracil residue in certain position were annealed with complementary oligonucleotides bearing either a cis- or trans-BP adduct. Digestion with uracil DNA glycosylase was utilized to generate AP site which was then hydrolyzed by APE1, and the resulting gap was processed by X-family DNA polymerases β (Polβ) and λ (Polλ) or Y-family polymerase ι (Polι). By varying reaction conditions, namely, Mg^{2+}/Mn^{2+} replacement/combination and ionic strength decrease, we found that in the certain conditions both Polβ and Polι can perform lesion bypass across both *cis*- and *trans*-BP adducts in the presence of physiological dNTP concentrations. Polβ and Polι catalyzed gap filling trans-lesion synthesis in the error prone manner. In the contrast, Polλ introduced selectively correct dCTP opposite the modified dG in the case of *cis*-BP-dG adduct only and did not bypass the stereoisomeric *trans*-adduct in any conditions used in the study. The data obtained can suggest Polλ as a specialized polymerase in the process of repair of this kind of lesions.

Influence of cytokines with anticancer activity on MGMT gene expression in human cell lines

K. Kotsarenko[1], V. Lylo[1], T. Ruban[1], L. Macewicz[1], O. Stoliar[2], L. Lukash[1]
[1]Institute of Molecular Biology and Genetics of NASU, [2]Taras Shevchenko National University, Kyiv, Ukraine

Repair enzyme O^6-methylguanine-DNA methyltransferase (MGMT) eliminates O^6-methylguanin adducts in DNA and protects normal cells from damaging effects of alkylating agents. At the same time MGMT makes tumor cells resistant to alkylating drugs. Therefore in medicine MGMT is considered as a target which needs to be regulated. Interferon alfa 2b (IFN-α2b) and endothelial monocyte-activating polypeptide (EMAP) II were chosen by us for investigating their possible influence on *MGMT* gene expression.

The aim was to study the effect of IFN-α2b and EMAP II and their medical forms on *MGMT* gene expression in human cell lines.

Materials and Methods: Such cell lines were used: Hep-2 (laryngeal cancer); A102 (skin fibroblasts), provided by J.McCormick, USA; 4BL (fibroblast-like cells), obtained in our laboratory has MGMT-deficient phenotype. Such agents were used: recombinant protein IFN-α2b, IFN-α2b-containing preparations Laferon (Interpharmbiotech) and Laferobion (Biofarma), EMAP II and nanocomposite protein EMAP II (NCP EMAP II) provided by A.I.Kornelyuk, Ukraine. *MGMT* gene expression was analyzed at a protein level by Western blotting.

Results: *MGMT* gene expression was increased by EMAP II treatment at concentrations 0.2 and 0.02 μg/ml in Hep-2 cells. In MGMT-deficient 4BL cells EMAP II at a concentration 2 μg/ml induced *MGMT* expression. Increase of EMAP II dose to 2 μg/ml and 10 μg/ml for Hep-2 and A102 cells respectively resulted in complete inhibition of this expression. NCP EMAP II, unlike recombinant protein EMAP II, in a wide concentration range (0.002–2 μg/ml) did not induce *MGMT* gene expression in 4BL cells. We suppose that the cytokine activity may be affected by salt compounds of NCP EMAP II.

Recombinant protein IFN-α2b and Laferon with activity of 200 and 2000 IU/ml were shown to cause slight increase of *MGMT* gene expression in tumor Hep-2 cells. But Laferobion with the same activity on the contrary decreased the level of *MGMT* gene expression in 3 and 8 times respectively in Hep-2 cells. A102 cells were treated only with Laferon preparation with activity of 20 IU/ml and expression of *MGMT* gene was completely inhibited in such conditions. In 4BL cells we didn't observe any changes of *MGMT* gene expression after the treatment with IFN-α2b and IFN-α2b-containing preparations.

Conclusions: EMAP II influence on *MGMT* gene expression depending on the concentration while NCP EMAP II did not show any effects. The effect IFN-α2b and IFN-α2b-containing preparations depended on their compositions and type of cell lines.

Keywords: MGMT, IFN-α2b, EMAP II.

WED-301
Interaction of Ddc1 and RPA with single-stranded/double-stranded DNA junctions in *Saccharomyces cerevisiae* whole cell extracts

O. I. Lavrik[1,2], M. Sukhanova[1], C. D'Herin[3], O. Dontsova[4], S. Boiteux[3]
[1]Institute of Chemical Biology and Fundamental Medicine, [2]Novosibirsk State University, Novosibirsk, Russian Federation, [3]Centre de Biophysique Moleculare, Orleans, France, [4]A.N. Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University, Moscow, Russian Federation

DNA lesions and structural alterations induce binding of repair and checkpoint proteins to site of DNA damage to initiate DNA damage response. Checkpoint sensor proteins act at the early steps of the checkpoint response that involves primary detection of DNA damage. The proteins recognize DNA repair/replication intermediates containing single-stranded DNA (ssDNA), double-stranded/single-stranded (ds/ss) DNA junctions, gaps or specific DNA-protein complexes such as ssDNA coated by replication protein A (RPA). To characterize proteins that interact with single-stranded/double-stranded (ss/ds) DNA junctions in whole cell free extracts of Saccharomyces cerevisiae, we used [^{32}P]-labeled photoreactive partial DNA duplexes containing a 3′-ss/ds-junction (3′-junction) or a 5′-ss/ds-junction (5′-junction). Identification of labeled proteins was achieved by MALDI-TOF mass spectrometry peptide mass fingerprinting and genetic analysis. In wild-type extract, the checkpoint sensor protein, Ddc1, was found to be photocrosslinked at a 3′-junction independently of the two other components of the (Ddc1-Mec3-Rad17) checkpoint clamp. On the other hand, the large subunit of the replication protein A (RPAp70) was the predominant crosslinking product at a 5′-juction. Interestingly, ddc1Δ extracts did not display photocrosslinking of RPAp70 at 5′-junction. The results show

© 2014 The Authors. FEBS Journal © 2014 FEBS

that the RPAp70-DNA covalent product at a 5′-junction is subject to limited proteolysis in ddc1Δ extracts, whereas it is stable in WT, rad17Δ and mec3Δ extracts. The degradation of the RPAp70-DNA adduct in ddc1Δ extract is reduced in the presence of the proteasome inhibitor MG 132. We also addressed the question of the stability of RPA not covalently attached to DNA using anti-RPA antibodies. The data show that RPAp70 is also subject to proteolysis without photocrosslinking to DNA upon incubation in ddc1 extract. The data point to a novel property of Ddc1, modulating the degradation of DNA binding proteins such as RPA by the proteasome, which in turn could be used to regulate biological processes in yeast.

Investigation of the cytotoxic mechanicms induced by airborne particulate matter on human lung cells (MRC-5)

A. A. Pantazaki[1], E. E. Velali[1], E. Papachristou[1], T. Choli-Papadopoulou[1], C. Samara[1]

[1]Laboratory of Biochemistry and [2]Environmental Pollution Control Laboratory, Department of Chemistry, Aristotle University of Thessaloniki, 54124 Thessaloniki, Greece.

The capacity of the airborne particulate matter to induce cytotoxic responses in human lung cells (MRC-5) cultures was investigated by testing aqueous and organic solvent extracts of different particle size fractions (d < 0.49, 0.49-0.95, 0.95-3, 3-7.2, and >7.2 μm) [1] for their biological impact in terms of DNA damage of cells and of levels of poly (ADP)ribosylation to elucidate the cytotoxic mechanism. Poly(ADP-ribose) polymerase 1 (PARP-1) is a zinc-finger DNA-binding enzyme that is activated by binding to DNA breaks. The enzyme is a global monitor of chromatin structure and DNA damage repair. Poly(ADP-ribosyl) ation of nuclear proteins by PARP-1 converts DNA damage into intracellular signals that activate either DNA repair by the base-excision pathway or cell death. In this study chromosomal DNA fragmentation was monitored in MRC-5 cells exposed to these particles by agarose gel electrophoresis of the isolated DNA and by single cell gel electrophoresis (Comet assay). The levels of PARP-1 were studied on MRC-5 cells extracts after 72 h of exposure to these particles to study a possible induced apoptosis mechanism using the universal colorimetric PARP assay kit. Most samples showed an increase of the PARP activity. Both Dot and Western blot analysis were performed to confirm PARP activity using anti-PARP monoclonal antibody (clone C2-10; Trevigen). During apoptosis, PARP activity (115 kDa) is increased triggering apoptotic mechanicms but later falls due to auto-modification and cleavage by caspases. Specific proteolytic cleavage of PARP constitutes a reliable marker for apoptosis in a wide variety of cell types, generating 85 kDa (including the catalytic and NAD-binding domain) and 26 kDa fragments, which corroborate with study.

Ku80 interaction with apurinic/apyrimidinic sites depends on the structure of DNA ends

A. A. Kosova, S. N. Khodyreva, O. I. Lavrik

Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

Apurinic/apyrimidinic (AP) sites are among the most frequent DNA damages. Of particular interest is the repair of AP sites in clustered DNA damages presented by combinations of AP sites, oxidized bases and single strand breaks within 1–2 turns of DNA helix. Such lesions arise in DNA under the action of ionizing radiation or radiomimetic drugs.

The aim of this study was to identify a human cell extract protein which specifically interacts with the AP site in the partial DNA duplex containing both 5′- and 3′-dangling ends of 8 nt and mimicking clustered DNA damage (DDE-AP DNA). The methods included the Schiff base-dependent cross-linking of proteins to AP DNA (borohydride trapping) in combination with gel electrophoresis and MALDI-TOF-MS.

The human cell extract protein which forms a major covalent adduct with an apparent molecular mass of 100 kDa with DDE-AP DNA was identified as Ku80 subunit of Ku antigen by peptide mass mapping based on MALDI-TOF-MS data. Ku antigen consisting of two subunits with molecular masses about 70 kDa (Ku70) and 83 kDa (Ku80) is a eukaryotic DNA-binding component of DNA-dependent protein kinase. The main function of Ku antigen is participation in the double-strand break repair by nonhomologous end joining. We have previously identified Ku antigen as a protein forming the predominant product of cross-linking with an apparent molecular mass of 90 kDa with the blunt-ended AP DNA duplex (Ilina et al. 2008).

The appearance of the Ku80 adduct with a lowered electrophoretic mobility characteristic for DDE-AP DNA can reflect the existence of two different modes of Ku80 binding with DNA or the highly efficient cross-linking of DNA with another Ku80 isoform. The Ku antigen purified from the HeLa cell extract was shown to form the covalent adducts with the same mobility as observed in cell extracts. Thus, Ku80 subunit of Ku antigen can specifically interact with AP DNA forming the Schiff base-mediated adducts, their electrophoretic mobility depending on the structure of DNA ends. The difference in electrophoretic mobility can be caused by the cross-linking of AP DNA to distinct target amino acids that appears to reflect unequal positioning of AP DNAs in the complex with Ku antigen.

Loss of SOD1 is connected to yeast selenite resistance

H. Heluani[1], E. Fernández[1], R. Wllinger[1]
[1]*Molecular Biology, CABIMER, Seville, Spain*

Oxidative stress can lead to reactive oxygen species (ROS) leading to DNA damage and genomic instability. Selenium (Se) is a trace element that is essential for human health, but unbound Se can generate ROS. In addition, inorganic selenium (*sodium selenite*; Na_2SeO_3) may serve as an anticancer agent because of its toxic properties. Based on selenite toxicity, yeast has been used as a tool to study cellular mechanism(s) involved in selenite detoxification. E.g. yeast mutants devoid of DNA repair activities or antioxidant molecules like glutathione (GSH) have been shown to be hypersensitive to selenite. *CYS3* codes for a cystathionine gamma-lyase, which is essential for the synthesis of the GSH precursor cysteine. Surprisingly, yeast mutants lacking Cys3 are hypersensitive to selenite even if excess levels of cysteine are provided in the medium. In this work, we identified *sod1Δ* being a suppressor of *cys3Δ* selenity hypersensitivity. Interestingly, *SOD1* encodes for a superoxide dismutase needed for the tolerance to ROS by the conversion of ROS ion superoxide (O_2^-) into oxygen (O_2) and hydrogen peroxide (H_2O_2), and we therefore questioned, how *sod1Δ* mutants acquired selenite resistance. We will present a model how selenite suppression can be archived in *sod1Δ* mutants pointing to a complex interplay between mechanisms involved in oxidative stress response.

Keywords: ROS, Sod1, Sodium Selenite.

WED-305
Lys/Asp functionality in DNA glycosylases of HhH-GPD structural superfamily

A. Kuznetsova[1,2], O. Kladova[1,2], M. Barsukova[1,2], T. Tyugashev[1,2], A. Ishchenko[3], M. Saparbaev[3], **N. Kuznetsov**[1,2], O. Fedorova[1,2]
[1]*Novosibirsk State University,* [2]*Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation,* [3]*Institute Gustave Roussy, Paris, France*

The common feature of DNA glycosylases of HhH-GPD structural superfamily is a helix-hairpin-helix (HhH) motif followed by a Gly/Pro-rich loop and terminating in an Asp residue, which is entirely conserved in these enzymes. The monofunctional glycosylases of this superfamily AlkA and MutY use the Asp residue as the catalytic nucleophile. In the cases of hOGG1 and EndoIII, which are bifunctional DNA glycosylases, a lysine is present in the active site. Presumably, the catalytic mechanism of bifunctional DNA glycosylases involves an attack on C1′ of the damage-containing nucleotide by the ε-amino group of lysine that leads to the cleavage of the N-glycosidic bond, producing an abasic site (apurinic/apyrimidinic site, AP-site). The incision of the DNA at the 3′-side of AP-sites proceeds via Schiff base formation and subsequent β-elimination reaction leaving a 3′-α,β-unsaturated aldehyde and a 5′-phosphate. The functional role of the invariant Asp residue in the bifunctional glycosylases is not fully understood. Recently it was shown (Dalhus B et al 2011) that Asp can be involved in base excision catalysis in the double mutant K249C C253K of hOGG1. Our previous data (Kuznetsova et al 2014) suggest that in hOGG1 the Lys-249 residue directly participates in the process of DNA distortion and the flipping out of the oxoG base.

Here we examined the role of Lys and Asp residues in mono- and bifunctional DNA glycosylases and described their involvement in the enzymatic pathway of N-glycosidic bond cleavage and incision of the DNA backbone. The conformational dynamics of mutant forms of hOGG1, EndoIII, AlkA and MutY, bearing mutations of Asp and Lys, as well as conformational dynamics of DNA-substrates, were investigated by the fluorescence stopped-flow method. The obtained data illustrate that the mechanisms of action of mono- and bifunctional DNA glycosylases are quite similar, so that a single amino acid change is enough to convert a monofunctional glycosylase to a bifunctional glycosylase/AP lyase and *vice versa*.

WED-306
Mechanisms of UVA-induced DNA single-strand breaks and alkali-labile sites formation

N. Smetanina[1], M. Pustovalova[1], A. Osipov[1]
[1]*Burnasyan Federal Medical Biophysical Center, Moscow, Russian Federation*

The aim of this work was to examine mechanisms of single-strand breaks (SSB) and alkali-labile sites (ALS) DNA of human blood lymphocytes under exposure to 365-nm UV radiation in vitro. We used the blood of five healthy donors aged 21-26 years. For irradiation was used Bio-Link system BXL-365 giving the dose rate of 2.92 kJ/m^2 at 1 min at 4°C. The modified comet assay under alkali conditions was performed for analysis of SSD and ALS. Exposure of 365-nm UV-radiation at doses of 10-50 kJ/m^2 (nucleoids) or 5-20 kJ/m^2 (lymphocytes) induces a dose-dependent increase SSB and ALS DNA detected by comet-assay. Adding 10% dimethyl sulfoxide (DMSO, scavenger of HO·radicals) reduces the SSB and ALS yields ~ in 3 times. It is shown that the SSB and ALS yields in human blood lymphocytes under exposure to 365-nm UV radiation at dose of 10 kJ/m^2 correspond effect of X-ray at dose of ~ 1 Gy. Effect of incubation in NaCl hypertonic solutions (0.2, 0.35 and 0.5 M for 1 h at 4°C) on the SSB and ALS DNA yields induced by long-wave UV-radiation (365 ± 10 nm) in human blood peripheral lymphocytes in vitro was investigated. It was shown, that compared to the cell incubated in NaCl isotonic solution (0.14 M) statistically significant increases in the yields of both spontaneous (~ 2 times) and UV-A radiation induced (~ 1.7 times) DNA damages were observed only at a NaCl concentration of 0.5 M. It is assumed that at this concentration of NaCl dissociation of linker histone H1 occurs, is disrupted the structure of chromatin and dramatically increases the free radical-induced DNA damage output. Results have revealed significance of free-radical processes in formation of biological effects under UV-radiation influence.

Molecular dynamics and QM/MM free energy profiles of the reaction mechanisms in DNA N6 and C5 methyl transferases

J. Aranda Moratalla, I. Tuñón García de Vicuña, M. T. Roca Moliner[1], K. Zinovjev
Department of Physical Chemistry, University of Valencia, Valencia, Spain

In this work we present a theoretical analysis of the mechanism for the reactions catalysed by M.TaqI and M.Hhai; enzymes that belong to the restriction-modification system of *Thermus Aquaticus* and *Haemophilus haemolyticus* respectively, which play and important role in the epigenetic regulation of gene function in vertebrates and carcinogenesis. We have studied the reaction consisting on the methyl transfer from S-adenosil-L-metionine (SAM) to N6 position of an adenine base generating N6-methyl-adenine, or to C5 position of a cytosine base of DNA leading to C5-mehtyl-cytosine.

The x-ray structure of the enzyme complexed with SAM and a DNA sequence was the starting point of our simulations. We performed all calculations considering the whole enzymatic and DNA environment, including the enzyme in an orthorhombic box of TIP3P water molecules with sodium counterions. Using the NAMD program we equilibrated the system by means of 10 ns of classical molecular dynamics (MD) with the AMBER force field, employing periodic boundary conditions, Ewald summations and a time step of 1 fs. The target temperatures were 333K for N6-MTase and 300K K for C5-Mtase, We then performed 100 ns of MD simulation in order to analyze the most important interactions formed between the enzyme and DNA, the interactions within the active site, how the unpaired base is stabilized and how the DNA helix accommodates the perturbation provoked by a flipped out base.

To analyse the chemical reaction we performed calculations using quantum mechanics/molecular mechanics (QM/MM) hybrid methodology using the fDynamo program. The quantum subsystem was treated using the AM1 semiempirical hamiltonian adding corrections at the M06-2x/6-311 + G** level. By means of the on-the-fly string method the minimum free energy path (MFEP) for each step of the reaction was obtained. Then, the path collective variable was defined along these paths, to obtain the potential of mean force (PMF) using umbrella sampling.

Our simulations show that for the N6-MTase the reaction takes place with methylation preceding N6-deprotonation through a water molecule and that the rate-limiting step is the methyl transfer. For the DNA-C5 MTase we unravelled the whole reaction mechanism which consists of five steps where the rate limiting step is the methylation. We have also performed free energy perturbation calculations to unravel which nucleophile is participating into the β-elimination step.

Our results agree with experimental data available and the experimental rate constants. The knowledge of these insights can lead to the design of new antibiotics and inhibitors for this family of enzymes.

Nuclear basket nucleoporins ensure a correct accumulation of DNA damage response proteins at the site of DNA double strand breaks

V. Duheron, B. Fahrenkrog
[1]Biology of the Nucleus Laboratory, Institute of Molecular Biology and Medicine, Université Libre de Bruxelles, Gosselies, Belgium

Nuclear pore complexes (NPCs) are large structure embedded in the nuclear enveloppe, which mediates the molecular exchanges between the cytoplasm and the nucleus of eukaryotic cells. Nucleoporins (Nups), proteins that are key components of the NPC, are reported to take part in a constantly growing number of functions that go beyond their role in nucleocytoplasmic transport. Along this line, Nup153, a component of the NPC's nuclear basket, has been shown to be involved in DNA double strand breaks (DSBs) repair. Here we show that not only Nup153, but also the two other components of the nuclear basket, Tpr and Nup50, have roles in DSB repair. We observed that human osteosarcoma U2OS cells lacking Nup153 and Tpr respectively, have a higher sensitivity to DSB-inducing agents, such as neocarzinostation (NCS), which coincided with alteration of both DSB repair pathways: non-homologous end joining (NHEJ) and homologous recombination (HR). Nup50 depletion, in contrast, leads to an inhibition of NHEJ, but not of HR. We furthermore found that the recruitment of 53BP1 (NHEJ specific) and BRCA1 (HR specific) to DSBs per se is not affected upon Nup153 and Tpr depletion, but that the kinetics of both repair pathways are altered. In particular, we observed an inefficient growth of the repair foci, indicating an inefficient accumulation of the repair factors at damage sites in the absence of Nup153 and Tpr, respectively. We provide evidence that this is due to SUMO-modification of 53BP1 and BRCA1.

Keywords: Double strand break foci, Nucleoporins, SUMOylation.

WED-309
Nuclear organization and chromatin status impact on homologous recombination efficiency and outcome

A. Batté[1], C. Brocas[1], A. Hocher[2], M. Ruault[2], A. Taddei[2], **K. Dubrana**[1,2]
[1]IRCM, CEA/INSERM, Fontenay aux roses, [2]UMR 3664, CNRS/Institut Curie, Paris, France

The folding of eukaryotic genome in chromatin into the nucleus of cells can influence many genome functions, including genome stability. Genome integrity is insured by conserved DNA repair mechanisms among which Homologous Recombination (HR) that uses an intact homologous sequence to repair a broken chromosome. HR can be separated in two sub-pathways: Gene Conversion (GC) transfers genetic information from one molecule to its homologous and Break Induced Replication (BIR) establishes a replication fork than can proceed until the chromosome end. Using the budding yeast as a model, we characterized the contribution of chromatin status and 3D genome organization on DSB repair by homologous recombination.

Saccharomyces cerevisiae chromosomes are arranged in a Rabl-like configuration with their centromeres anchored to the spindle pole body and their telomeres grouped into 3 to 5 foci at the nuclear periphery. Telomeric foci form subnuclear compartments repressive for transcription in which the yeast heterochromatin factors (SIRs silent information regulators) concentrate. This organization can be modified through the overexpression of

© 2014 The Authors. FEBS Journal © 2014 FEBS

the Sir3 or sir3A2Q mutant proteins that both lead to the grouping of the majority of telomeres into a "hypercluster" localized into the interior of the nucleus. Whereas this clustering occurs in the absence of heterochromatin following sir3A2Q overexpression, Sir3 overexpression results in heterochromatin spreading along the subtelomeric regions. We used Sir3 and sir3A2Q overexpression to modify the physical distances between telomeres and/or the spreading of heterochromatin in subtelomeric regions and measured ISceI induced recombination rates between recombination cassettes positioned at various locations in the genome.

We observed that increasing spatial proximity between subtelomeres through sir3A2Q overexpression increased recombination rates supporting the former proposal that homology search is a limiting step for recombination. Whereas the sole viable repair event occurring at intrachromosomal DSB is GC, we observe that both GC and BIR account for the repair events stemming from subtelomeric DSB. The GC/BIR balance is modified following heterochromatin spreading either at the DSB site or on the recombination donor sequence. Heterochromatinization of the recipient locus favours GC by limiting resection whereas heterochromatin spreading at the donor site disfavours BIR.

These results highlight the contribution of spatial proximity to recombination efficiency and the importance of chromatin status onto repair events.

WED-310
PARP1 as a mediator of the enzyme activities processing apurinic/apyrimidinic sites

O. I. Lavrik
Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

The apurinic/apyrimidinic (AP) sites are considered to be mutagenic and cytotoxic DNA lesions. The specific capacity of poly (ADP-ribose) polymerase 1 (PARP1) to interact with the AP sites has been demonstrated by us [1]. The identity of PARP1 cross-linked to AP sites in DNA in cell extracts was determined by mass spectrometry. PARP1 was weakly activated to conduct poly(ADP-ribose) synthesis upon binding to the AP site containing DNA. PARP1 interacting with AP sites catalyzes DNA strand incision by its AP lyase activity and shows 5′dRP lyase activity. The interaction of PARP1 with AP sites modulates activity of apurinic/apyrimidinic endonuclease 1 (APE1) in the case of DNA substrate containing single or clustered AP sites. The capacity of the other enzyme, tyrosyl-DNA phosphodiesterase (Tdp1), to the AP site cleavage was determined. Tdp1 catalyzes the cleavage of AP site and its synthetic analog, 3-hydroxy-2(hydroxymethyl)-tetrahydrofuran (THF), in DNA by hydrolysis of the phosphodiester bond between the substituent and 5′-adjacent phosphate. The product of the Tdp1 cleavage in the case of AP site is unstable and is hydrolyzed with the formation of 3′- and 5′-margin phosphates. The following repair demands the ordered action of polynucleotide kinase phosphatase, with XRCC1, DNA polymerase β and DNA ligase. In the case of THF, Tdp1 generates break with the 5′-THF and the 3′-phosphate termini [2]. PARP1 stimulates activity of Tdp1 in the AP site cleavage. The protein–protein interactions of PARP1 with APE1 and Tdp1 detected by various techniques were suggested as a key of the modulation of APE1 and Tdp1 activities by PARP1 in the AP site processing.

Perturbation of iron homeostasis promotes the evolution of antibiotic resistance

B. Bogos, O. Méhi, B. Csörgő, F. Pál, Á. Nyerges, B. Papp, C. Pál
Biological Research Centre of the Hungarian Academy of Sciences, Institute of Biochemistry, Szeged, Hungary

Evolution of antibiotic resistance in microbes is frequently achieved by acquisition of spontaneous mutations during antimicrobial therapy. These spontaneous mutations usually emerge from direct, antibiotic specific mutational processes (DNA damage) or might originate from the antibiotic inhibition dependent, oxidative mutagenesis. By employing genome wide screen for evolutionary modulators and long term selection experiments against a DNA gyrase inhibitor (ciprofloxacin) we demonstrated that in addition to the common mutator-phenotypes, inactivation of a central transcriptional regulator of iron homeostasis (Fur) facilitates laboratory evolution of ciprofloxacin resistance in *Escherichia coli* BW25113. To describe the underlying molecular mechanisms, we performed a global transcriptome analysis and demonstrated that the transcriptional pattern regulated by Fur change substantially in response to antibiotic treatment. In accordance with previous literature, we hypothesized that the impact of *fur*-mutation on evolvability under antibiotic pressure is due to the elevated intracellular concentration of free, ferrous iron and the consequent enhancement of oxidative damage-induced mutagenesis. As expected, inhibition of iron transport (1), overexpression of iron storage proteins (2), or anaerobic conditions (4) drastically suppressed the evolution of resistance, while inhibition of the SOS response-mediated mutagenesis had no substantial effect in Fur deficient populations. Importantly, we provide evidence that by binding unincorporated, intracellular iron using a cell permeable iron chelator (phenantroline) (3), the development of resistance was slowed down. Our work clearly revealed the importance of iron metabolism in the *de novo* evolution of antibiotic resistance, a pattern that could influence the development of novel antimicrobial compounds or inhibition of resistance formation.

Pre-steady-state kinetics of APE1 in the presence of various divalent metal ions

A. Kuznetsova[1], A. Miroshnikova[2], N. Kuznetsov[1], O. Fedorova[1]
[1]Laboratory of Biopolymer Modification, Institute of Chemical Biology and Fundamental Medicine, [2]Novosibirsk State University, Novosibirsk, Russian Federation

Exposure of cellular DNA to reactive oxygen species (ROS), generated either by normal cell metabolism or by chemical and physical exogenous agents, leads to several types of lesions. A DNA lesion may be mutagenic and block replication and transcription. Failure to repair DNA can lead to mutations, genomic instability, premature ageing, mental retardation, or other developmental disorders and cancer. Over several decades, DNA damage and repair mechanisms have been the focus of numerous investigations, including structural, biochemical, and genetic studies on organisms ranging from bacteria to humans.

One of the major pathways to remove DNA lesions is the base excision repair (BER). BER pathway is a multi-step process, and can be reconstituted with a limited number of proteins. It involves a cascade of enzymes, which typically begins with a damage-specific DNA glycosylases that interact with DNA to specifically find target damaged bases and cleave the N-glycosidic bond of the lesion. This generates an abasic (apurinic/apyrimidinic (AP)) site. The toxic AP-intermediates must be recognized and processed by AP endonuclease immediately after the action of a DNA glycosylase. Bifunctional DNA glycosylases can also catalyze a β- or β-δ-elimination reaction (AP-lyase activity) to affect the strand scission after base removal. Short patch BER requires two additional enzymes to replace the damaged nucleotide: DNA polymerase β and DNA ligase III/XRCC1 heterodimer or DNA ligase I.

The endonuclease activity of APE1 has been well characterized for its preference for abasic site-containing DNA and by steady-state kinetic analysis in the presence of divalent cation. In order to understand the kinetic basis for enzyme specificity and efficiency, each step in the reaction pathway needs to be characterized. Here we examined the role of divalent metal ions in APE1 enzymatic pathway. The conformational dynamics of APE1 was investigated by the fluorescence stopped-flow method. The AP endonuclease activity of APE1 was abolished by treatment with EDTA, but was restored on subsequent addition of a molar excess of Mg^{2+} and, to lesser extent, Mn^{2+}, Ni^{2+}, Zn^{2+}, Ca^{2+}, Cu^{2+}. The role of metal ions in the DNA-substrate binding and catalysis was specified.

Radio-sensitization of normal and tumor cells by DNA repair inhibitors

K. Durisova[1], A. Tichy[1], Z. Sinkorova[1], L. Zarybnicka[1], J. Pejchal[2], J. Vavrova[1]
[1]Department of Radiobiology, [2]Centre of Advanced Studies, Faculty of Military Health Sciences, University of Defence, Hradec Kralove, Czech Republic

Background: The use of specific inhibitors, which prevent double strand breaks (DSB) repair in tumor but not normal cells after ionizing radiation (IR) is a promising therapeutic strategy for cancer treatment. Here we describe the effects of inhibitors of DNA repair on molecular mechanisms triggered by IR. Since these are often p53-dependent, we employed normal human lung fibroblasts (NHLF, p53-wildtype) and compared their DNA damage response to lung carcinoma cell line (H1299, p53-negative). Prior irradiation, the cells were treated by NU7441 (1 μM), a specific inhibitor of DNA-PK; KU55933 (10 μM), a specific inhibitor of ATM, and VE-821 (10 μM), a specific inhibitor of ATR.

Methods: The experimental design consisted of five groups: control+dimethyl sulfoxide (DMSO), IR-treated+DMSO, and combination of IR with each of the inhibitors. We used epifluorescence microscopy for detection of γH2AX, flow-cytometry for cell cycle analysis and Western blotting for assessment DNA repair proteins.

Results: IR in combination with NU7441 caused more DSB than with VE-821 in the later time periods after irradiation in normal cells. Additionally, NU7441 increased G2-arrest in fibroblasts meanwhile KU55933 caused G1-arrest. On the other hand, in H1299 cells the highest amount of γH2AX corresponding to DNA damage was detected in the later time periods after treatment with combination of IR and VE-821, which also led to abrogation of G2-arrest.

Conclusion: Inhibitor VE-821 together with ionizing radiation increases level of DNA damage, shortens G2-arrest, and thus diminishes DNA repair of lung carcinoma cells but not normal lung fibroblasts. These results indicate that targeting ATR in p53-deficient tumors is a promising therapeutic strategy since it does not influence the normal cells.

Keywords: DNA repair, inhibitor, Ionizing radiation.

Recombination and the roles of the RAD51-like proteins in *Arabidopsis*

C. I. White[1], O. da Ines[1], H. Serra[2], F. Degroote[2], M. Olivier[2], C. Goubely[1], S. Amiard[1], M. E. Gallego[2]
[1]UMR CNRS 6293 - Clermont Université - INSERM U1103, CNRS, [2]UMR CNRS 6293 - Clermont Université - INSERM U1103, Université Blaise Pascal, Clermont-Ferrand, France

Repair of DNA double-strand breaks by recombination is key to the maintenance of genome integrity in all living organisms. It can however generate mutations and chromosomal rearrangements, making the regulation and the choice of specific recombination mechanisms of great importance. In addition to end-joining through non-homologous recombination, DNA breaks are repaired by multiple homology-dependent pathways that can be distinguished through their dependence or not on strand invasion catalysed by the RAD51/DMC1 recombinases.

With some exceptions (*Drosophila*, *C. elegans*), it is RAD51/DMC1 -dependent homologous recombination which establishes the chiasmata that physically link pairs of homologous chromosomes in meiosis, ensuring their balanced segregation at the first meiotic division. This is essential for fertility and generate the genetic variation which fuels evolution. The visible manifestation of genetic crossing-overs, chiasmata are the result of an intricate and tightly regulated process involving induction of DNA double-strand breaks and their repair through invasion of a homologous template DNA duplex, catalysed by the strand transfer proteins RAD51 and DMC1 in eukaryotes.

The viability of KO mutants and the strong conservation of recombination proteins/pathways makes the flowering plant *Arabidopsis thaliana* particularly well adapted to studies of the roles of these essential genes in the developing organism. A synthesis of recent results on the roles of RAD51/DMC1 and the RAD51

Stopped-flow FRET analysis of DNA structural dynamics during interaction with mutant forms of human 8-oxoguanine-DNA glycosylase

M. V. Lukina[1,2], V. V. Koval[1,2], D. O. Zharkov[1,2], O. S. Fedorova[1,2]
[1]Institute of Chemical Biology and Fundamental Medicine, [2]Novosibirsk State University, Novosibirsk, Russian Federation

DNA bases are constantly modified by numerous environmental and endogenous agents, such as reactive oxygen species (ROS). 8-Oxoguanine is one of the most often generated and highly mutagenic oxidative damage in DNA. This may cause misincorporations of adenine during replication, resulting in C:G to A:T transversion mutations. 8-Oxoguanine-DNA-glycosylase hOGG1, the key DNA-repair enzyme in human cells, recognizes and removes 8-oxoguanine from DNA. This enzyme is bifunctional N-glycosylase/AP-lyase.

Although the structure of hOGG1 bound to DNA is known, the dynamic aspects of 8-oxoguanine recognition and removal are not well comprehended. According to X-ray data the amino acids Cys-253 and Gln-315 of hOgg1 participate in coordination of damaged base extruded from DNA helix to the base-binding pocket. In order to clarify the role of such base coordination and to reveal the elementary steps in overall enzymatic process we have investigated the enzymatic processes catalysed with hOGG1 mutant forms containing substitution of Cys-253 or Gln-315 with bulky amino acids (Cys-253 was changed for either Ile or Leu, Gln-315 for Trp).

The changes in the DNA structure were followed by registration of the FRET (Fluorescence Resonance Energy Transfer) signal using Cy3/Cy5 labels in DNA substrates. Comparison and analysis of shapes and kinetic parameters of the fluorescent curves obtained for non-damaged DNA substrates, or substrates containing 8-oxoguanine, natural AP-site or its synthetic analogue provide information about the dynamics of damage recognition and binding.

Stopped-flow kinetic study for mutant forms C253I, C253L and Q315W revealed that such amino acid substitutions reduce hOGG1 activity but play substantial roles on different stages of enzymatic process. It was shown that although base-binding pocket occlusion distorts the active site of hOgg1 C253I and C253L and greatly decreases the catalytic proficiency of the enzyme, it does not influence significantly the binding step and does not fully prevent 8-oxoguanine and AP-site recognition, sampling and excision. Otherwise, hOGG1 Q315W was not able to place properly the damaged base in the active site and to remove 8-oxoguanine in the course of N-glycosylase reaction. This enzyme form retains the ability to cleave AP-site, although such activity is reduced in comparison with the wild-type.

Structural and dynamic basis for distinguishing 8-oxoguanine from guanine by three different structural folds in DNA repair glycosylases

D. Zharkov
SB RAS Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

8-oxoguanine (oxoGua) is a potent pre-mutagenic oxidative DNA lesion often encountered in a genome due to leaking aerobic respiration chain and environmental genotoxic stress. Normally, oxoGua is removed from DNA by enzymes belonging to the class of DNA glycosylases, Fpg in bacteria and OGG1 in eukaryotes. While recognizing the common substrate, these proteins share no homology and fall into different structural families: Fpg defines its own family while the structure of OGG1 is similar to endonuclease III. In addition, another enzyme of endonuclease III family, DNA glycosylase MutY (MUTYH in eukaryotes), removes adenine misincorporated by DNA polymerases opposite oxoGua but recognizes the damaged base in a completely different mode through an extra domain similar to NUDIX hydrolases. In order to clarify the source of specificity for the lesion vs non-damaged guanine, we performed molecular dynamic simulations of normal and damaged DNA bound by Fpg from *Lactococcus lactis* and *Geobacillus stearothermophilus*, human OGG1, and MutY from *Geobacillus stearothermophilus*, and supplemented the computation with steady-state and stopped-flow kinetic studies of the corresponding wild-type proteins or mutants in which we modified critical residues at the protein–DNA interface. In both Fpg and OGG1, the ability of the enzyme to evert the damaged nucleotide into a catalytically competent conformation, rather than the events within the active site, seem to be the deciding factor in their substrate specificity; mutant forms of these glycosylases that are unable to evert oxoGua retain their activity on abasic substrates that are intrinsically partially extrahelical. Destabilization of the everted pre-catalytic complex of Fpg or OGG1 by amino acid substitutions or introducing adenine opposite oxoGua may be tolerated due to DNA backbone adjustment. In MutY, we have identified a set of interactions both within the p13 domain responsible for oxoGua specificity and between p13 and other domains that distinguish oxoGua from guanine in the complex. Overall, early events in the path to the catalytically competent complex seem to play a predominant role in oxoGua recognition by DNA glycosylases.

Structural basis for the phosphorylation-dependent recruitment of Tel2 to Hsp90 by Pih1

R. M. Morgan, M. Pal, S. Phelps, J. Downs, L. Pearl, C. Prodromou
Genome Damage and Stability Centre, University of Sussex, Brighton, UK

The recruitment of client proteins to Hsp90 requires specific co-chaperones that simultaneously bind the client and Hsp90 to mediate their interaction. As part of the RT2P complex, Pih1 is involved in the assembly and regulation of snoRNPs, RNA polymerase II and PI3-kinase-like kinases (PIKKs). Previous reports show that Pih1 is tethered to Hsp90 via its interaction with the TPR-containing protein Tah1, and also that Pih1 interacts in a phosphorylation-dependent manner with Tel2. Here we present the crystal structures of both the Hsp90-Tah1-Pih1 and the Pih1- Tel2 complexes. Structural and biochemical characterization of these interactions show how the C-terminal CS domain of Pih1 interacts with an unstructured region of Tah1, and how a novel N-terminal fold of Pih1 interacts with a phosphorylated Tel2 motif. Furthermore we discuss the implications these observations have on the recruitment of Pih1 to Hsp90 in both yeast and metazoa.

Keywords: Hsp90, Pih1D1, Tel2.

WED-319
The 5′–3′ exonuclease is essential for high constitutive SOS expression in *recA730* mutants of *Escherichia coli*

A. Simatovic[1], I. Vlasic[1], K. Brcic-Kostic[1]
[1]*Ruder Boskovic Institute, Zagreb, Croatia*

The RecA protein is a central component of the recombination machinery which is required for double-strand break (DSB) repair, repair of single stranded gaps (SSG), production of genetic variation during conjugation and induction of the SOS response. In wild-type (wt) *Escherichia coli* strains, DSBs are processed into RecA filaments by the RecBCD pathway, whereas SSGs utilize the RecF recombination pathway [1]. In a *recB1080* mutant, the components of the two recombination machineries act together to produce a RecA filament [2]. There are three enzymatic activities essential for the RecA filament formation: helicase, 5'-3' exonuclease, and RecA loading onto single-stranded DNA [1].

We studied a specific *recA* mutant named *recA73*0 (RecAE38K) which encodes a form of RecA protein that is able to suppresses recombination and DNA repair deficiency in cells where both mechanisms for RecA filament formation are inactivated by mutations in genes for mediator proteins involved in RecA loading [3]. This gain of function mutant also exhibits high constitutive SOS expression (cSOS). The SOS response involves the elevated expression of more than 50 genes with various functions that are induced in response to damage of chromosomal DNA.

By studying the genetic requirements for high cSOS expression in *recA730* mutants, we found that three different genetic backgrounds (wt, *recB1080* and *recB* null), have different genetic requirements. In wt background, the high cSOS expression of a *recA730* mutant is partially dependent on RecBCD function, implying that RecBCD can moderately enhance the already excellent intrinsic abilities of the RecA730 enzyme. In *recB1080* background, the high cSOS expression of the mutant is partially dependent on the helicase activity of the RecB1080CD enzyme and is strongly dependent on the RecJ nuclease. The cSOS expression of a *recA730* mutant in a *recB* null background is dependent on the RecJ nuclease. These results emphasize the importance of the 5′–3′exonuclease for high cSOS expression in *recA730* mutants.

The influence of base-diet on 1,2-dimethylhydrazine induced carcinogenic damage in rat liver

H. Oszkiel, M. Jank
Department of physiological sciences, Warsaw University of Life Sciences WULS – SGGW, Warsaw, Poland

According to the Hippocrates' theorem …Let food be your medicine and medicine be your food", dietary interventions may induce changes in the metabolic and inflammatory state by improving the antioxidative status and modulating the expression of important genes involved in the chronic disorders. The aim of the present study was to evaluate the preventive properties of long term (14-months) use of biologically active substances-enriched diet (BASE–diet) against tumor alternations induced by injection of 1,2-dimethylhydrazine (DMH) in rats liver. The experiment was conducted on 32 Sprague-Dawley rats divided into two experimental groups (fed with control or BASE-diet, both n = 16). Control diet was a semi-synthetic diet formulated according to the nutritional requirements for laboratory animals. The BASE-diet was enriched with a mixture of polyphenolic compounds, β-carotene, probiotics, and n-3 and n-6 polyunsaturated fatty acids.

BASE diet decreased lipid peroxidation and C-reactive protein activity induced by injection of DMH compared to control group. Also the changes in activity of carcinogen-metabolizing enzymes (CYP1A1 and GST) caused by DMH-treatment in control rats were offset by BASE diet. The microarray technique allowed to identified 308 differentially expressed genes after DMH injection in control rats and 471 differentially expressed genes in rats fed with BASE diet. Analysis carried out using Pathway Studio allowed to identified 46% more differentially expressed genes associated with antioxidant activity in rats fed with BASE diet than in control group. BASE-diet treatment caused also changes in expression of 50 genes involved in direct DNA repair pathway after DMH-treatment.

BASE diet have shown the preventive properties against tumor alternations induced by injection of DMH, evidenced by the clinical results. Transcriptomic results indicate also that long term use of BASE diet caused the activation of defense mechanisms against DMH-treatment.

The p400 ATPase regulates homology-directed repair of DNA double-strand breaks independently of H2A.Z histone variant incorporation

G.-C. Taty-Taty[1], C. Courilleau[1], C. Chailleux[1], M. Quaranta[1], D. Trouche[1], **Y. Canitrot**[2]
[1]*CNRS université de Toulouse, Toulouse, France,* [2]*CNRS UMR5088, CNRS université de Toulouse, Toulouse, France*

DNA damage signalling and repair take place in a chromatin context. Consequently, chromatin modifying enzymes, including ATP-dependent chromatin remodelling enzymes play an important role in the management of DNA damage and particularly for DNA double strand breaks (DSB). Here, we show that the p400 ATPase (member of the Tip60 complex) play a role in DNA repair by homologous recombination (HR). Indeed, while p400 is not required for DNA damage signalling, DNA double strand breaks repair is defective in the absence of p400. We demonstrate that p400 is important for HR-dependent processes, such as recruitment of Rad51 to DSB, homology-directed repair and survival following DNA damage. In addition, we observed that p400 and Rad51 interact and both favour chromatin remodelling around DSBs. The p400 ATPase activity drives to the incorporation of the histone variant H2A.Z into nucleosome. However, we did not observe any link between H2A.Z incorporation and the phenotypes observed after p400 depletion. Altogether, our data provide a direct molecular link between Rad51 and a chromatin remodelling enzyme involved in chromatin remodelling around DNA double strand breaks. We identified the p400 ATPase as an actor of the regulation of DSB repair by HR independently of its ability to incorporate the histone variant H2A.Z. Thus, p400 could be a brake to the generation of genetic instability.

UHRF1: a link between epigenetics and DNA damage response?

A. Fournier, L. Ferry, P.-A. Defossez
UMR7216 - Epigenetics and Cell Fate, CNRS/Universite Paris Diderot, Paris, France

UHRF1 is a methyl-CpG-binding protein (MBP) that recognizes both methylated DNA and H3K9me2/3, thus linking DNA methylation and histone modifications. UHRF1 is the only MBP that is essential in mammals. It is a crucial epigenetic regulator that ensures the maintenance of DNA methylation through cell divisions by recruiting and activating the DNA methyltransferase DNMT1 on newly replicated DNA. Besides its interest for basic research, understanding UHRF1 role could have some very significant interest for human health, as UHRF1 is deregulated in many cancers, and thought to be causally involved in the abnormal proliferation of cancer cells.

Given the biological importance of UHRF1, and in order to elucidate its functions, we sought to identify its partners and targets. Proteomics approach revealed important and interesting hits that we validated by microscopy and biochemical experiments. Our results indicate a link between UHRF1 and the DNA damage response – a crucial process for maintaining genomic integrity, which is systematically altered in cancer.

Keywords: Cancer, DNA repair, Epigenetics.

The first active layer of plant innate immunity relies on the perception of pathogen-associated molecular patterns (PAMPs) by surface-localised pattern-recognition receptors (PRRs). Many known plant PRRs are receptor kinases, which are annotated as serine/threonine kinases. However, the exact phosphorylation events that lead to receptor activation and initiation of PAMP-triggered immune signaling remain unknown. Here, we report that the Arabidopsis receptor kinase EFR, which perceives bacterial EF-Tu (or the derived peptide elf18), is phosphorylated on tyrosine residues and that this modification is critical for EFR activation upon ligand binding. We identify a single tyrosine residue required for EFR activation, downstream responses and immunity to the phytopathogenic bacterium *Pseudomonas syringae*. Pathogenic bacteria employ type-III secreted effectors to suppress PAMP-triggered immunity and cause disease. The effector HopAO1 is important for the virulence of *Pseudomonas syringae* and possesses tyrosine phosphatase catalytic activity, but its plant targets were still unknown. We found that HopAO1 directly interacts with EFR and FLS2, and blocks elf18-induced EFR activation and immune responses, revealing that HopOA1 targets tyrosine phosphorylation of plant PRR to block their activation. Our results shed light on a novel regulatory mechanism controlling plant immune signaling and highlight a host-pathogen battle to take control of PRR tyrosine phosphorylation that is critical for anti-bacterial immunity.

Listeria monocytogenes is an opportunistic, food-borne bacterial pathogen of human and cattle. Listeriosis can constitute a life-threatening disease in the elderly and in immunocompromised patients; it also has serious outcomes in pregnant women, causing still-birth or frequently lethal neonatal infections. *L. monocytogenes* can cross the intestinal, foeto-placental and blood brain barriers, allowing its dissemination throughout the organism. This facultative intracellular bacterium can enter and multiply in the cytosol of most cell types and spread to neighbouring cells, using an arsenal of virulence factors that target diverse cellular components and subsequently hijack various host cell functions.

We have recently discovered and characterized LntA, a virulence factor from *Listeria monocytogenes* belonging to the emerging family of nucleomodulins. After secretion in the host cell cytosol, LntA enters the infected cell nucleus, interacts directly with a chromatin component, BAHD1, and inhibits its activity [1,2]. BAHD1 participates in the nucleation and spreading of a repressive chromatin complex, which induces gene silencing when recruited at promoters [3]. *Listeria* infection of epithelial cells induced the production of type I and III interferons; however,

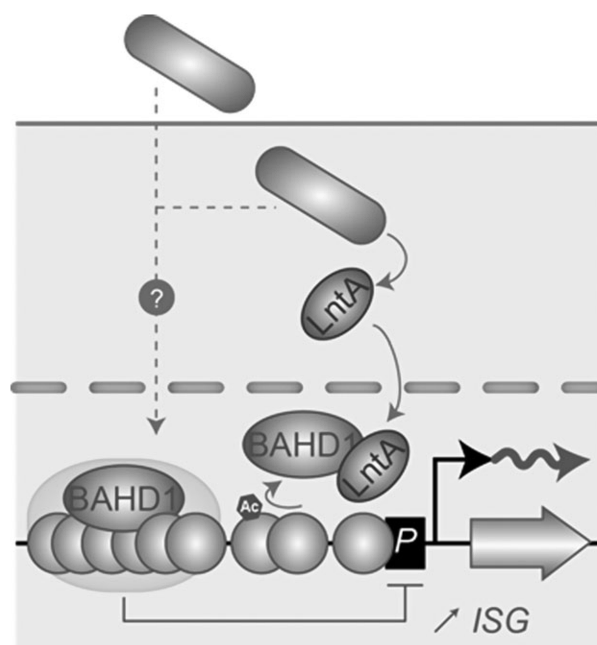

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

the BAHD1-associated chromatin complex represses the expression of interferon-stimulated genes (ISG), by a so-far unknown mechanism. Upon interaction with LntA, BAHD1 dissociates from the promoters of ISGs, resulting in a reactivation of these genes, and affecting the outcome of *in vivo* infections in mice. Strikingly, the expression of *lntA* is tightly regulated, thereby avoiding uncontrolled activation of host innate immune responses. Altogether, the LntA-BAHD1 interplay fine-tunes the expression of ISGs during the progression of infection.

A dormancy protein Rv0574c is required for cell wall integrity and virulence of *Mycobacterium tuberculosis* H37Rv

R. Garg[1], D. Tripathi[2], S. Kant[3], H. Chandra[4], R. Bhatnagar[2], N. Banerjee[2]
[1]School of Biotechnology, [2]School of Biotechnology, Jawahar Lal Nehru University, New Delhi, India, [3]Department of Pathology, Ohio State University College of Medicine, The Ohio State University, Columbus, OH, USA, [4]Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH, USA

Virulence of *Mycobacterium tuberculosis* is intimately related to its distinctive cell wall. The proteins involved in synthesis of the polymer, poly-α-L-glutamine (PLG) in the cell wall of virulent mycobacteria have not been explored adequately. The genetic locus Rv0574c codes for a conserved protein, which is a member of 48 genes dormancy regulon of *M. tuberculosis*. The focus of this study is to investigate whether this locus, coding for polyglutamate synthase like protein has any role in synthesis of PLG, in the context of mycobacterial virulence. Rv0574c is expressed maximally in the late log phase of bacterial growth, which coincides with maximum synthesis of this polymer. Evaluation of Rv0574c gene expression in *M. tuberculosis* demonstrated its activation under conditions, e.g. hypoxia, nitric oxide, acid and CO_2, prevalent in the tubercular granuloma. PLG synthesis in the cell wall of the wild type bacterium was also increased marginally under these conditions. To investigate the matter further, we produced a knockout mutant of the gene by allelic exchange. Phenotypic characterization of the strain showed that PLG content was substantially reduced in the cell wall compared to the wild type bacteria. The mutant grew normally in the enriched culture medium, but was attenuated in THP-1 macrophages and in the organs of BALB/c mice. This was in agreement with histopathological evaluation of the lungs, showing slow growth and less severe pathology than the wild type and the complemented counterpart. Additionally, the mutant was more sensitive to detergents like SDS, enzymes like lysozyme, mechanical disruption and drugs, concomitant with drastic reduction in ability to form biofilm. The lipid and protein content in the cell wall of wild type, the mutant and the complemented strain was estimated and found to be unperturbed, supporting the hypothesis that changes in the cell wall integrity of the mutant are due to effect on PLG only and not on any other constituent of the cell wall. In summary, this study demonstrates that the protein encoded by Rv0574c locus, by virtue of depleting PLG in the cell wall, weakens bacterial resistance and compromises pathogenicity of *M. tuberculosis*.

Keywords: *Mycobacterium tuberculosis*, poly-α-L-glutamine, Rv0574c locus.

A human proteome microarray identifies that the heterogeneous nuclear ribonucleoprotein K (hnRNP K) recognizes the 5′ terminal sequence of the hepatitis C virus RNA

C.-S. Chen
Graduate Institutes of Systems Biology and Bioinformatics, National Central University, Jhongli, Taiwan

Stem-loop I (SL1) located in the 5′ untranslated region of the hepatitis C virus (HCV) genome initiates binding to miR-122, a microRNA required for hepatitis HCV replication. However, proteins that bind SL1 remain elusive. In this study, we employed a human proteome microarray, comprised of $\sim$17,000 individually purified human proteins in full-length, and identified 313 proteins that recognize HCV SL1. Eighty-three of the identified proteins were annotated as liver-expressing proteins, and twelve of which were known to be associated with hepatitis virus. siRNA-induced silencing of eight out of 12 candidate genes led to at least 25% decrease in HCV replication efficiency. In particular, knockdown of heterogeneous nuclear ribonucleoprotein K (hnRNP K) reduced HCV replication in a concentration-dependent manner. Ultra-violet-crosslinking assay also showed that hnRNP K, which functions in pre-mRNA processing and transport, showed the strongest binding to the HCV SL1. We observed that hnRNP K, a nuclear protein, is relocated in the cytoplasm in HCV-expressing cells. Immunoprecipitation of the hnRNP K from Huh7.5 cells stably expressing HCV replicon resulted in the co-immunoprecipitation of SL1. This work identifies a cellular protein that could have an important role in the regulation of HCV RNA gene expression and metabolism.

A protein extract from *Jatropha curcas* seed cake has in vitro anti-Toxoplasma activity

A. A. M. Soares[1], L. P. Carvalho[2], **H. Costa**[3], E. J. T. Melo[2], I. M. Vasconcelos[3], J. T. A. Oliveira[3]
[1]Centre for Agrarian and Environmental Sciences, Federal University of Maranhão, Chapadinha, [2]Centre for Bioscience and Biotechnology, North Fluminense State University of Darcy Ribeiro, Rio de Janeiro, [3]Biochemistry and Molecular Biology, Federal University of Ceará (UFC), Fortaleza, Brazil

Toxoplasma gondii is a parasite of great medical and veterinary importance, which has worldwide distribution and causes toxoplasmosis. There are few treatments available for toxoplasmosis and the search for plant extracts with anti-Toxoplasma activity is of utmost importance for the discovery of new active compounds. The objective of this study was to investigate the action of the protein extract from *J. curcas* seed cake on developing tachyzoites of *T. gondii*-infected Vero cells. The protein extract (*Jc*CE) was obtained after solubilization of the *J. curcas* cake with sodium borate buffer (100 mM, pH 10), centrifugation and dialysis (*cutoff: 12 kDa*) of the supernatant with the extracting

© 2014 The Authors. FEBS Journal © 2014 FEBS

buffer. Typically, *Jc*CE had around 0.75 mg protein (mgP)/mL and inhibitory activity against papain [28.2 inhibitory units (IU)/mg P] and trypsin (50.7 IU/mgP). *Jc*CE was used for the *in vitro* assays at 0.01; 0.1; 0.5; 1.5; 3.0 and 5.0 mg/mL concentrations for 24 h. At 3.0 mg/mL, *Jc*CE reduced the percentage of infection and parasites to 26.2% and 18%, respectively, but had no effect on the morphology of Vero cells. During treatment with *Jc*CE parasitophorous vacuole-containing tachyzoites had progressive disorganization. These results suggest that *Jc*CE interferes with the intracellular growth of *T. gondii*. Supported by: CNPq and FAPEMA.

Keywords: anti-*T. gondii*, *Jatropha curcas*, protease inhibitor.

A putative arginine-ornithine antiporter ArcD in *Streptococcus gordonii* controls *de novo* arginine biosynthesis, low pH tolerance and biofilm formation

A. Sakanaka[1], M. Kuboniwa[1,2], H. Takeuchi[1], E. Hashino[1], A. Amano[1]
[1]*Department of Preventive Dentistry, Osaka University Graduate School of Dentistry, Suita, Osaka,* [2]*CREST, JST, Saitama, Japan*

Background: Arginine deiminase system (ADS) is a major ammonia-generating pathway and plays important roles in oral biofilm ecology. ADS catabolizes arginine to ornithine, ammonia, and CO_2 with the concomitant production of ATP. *Streptococcus gordonii,* which is one of the most abundant ADS-positive species in oral cavity, has *de novo* arginine biosynthesis pathway to control total arginine metabolism in conjunction with ADS. *S. gordonii* expresses a putative arginine-ornithine antiporter (ArcD) formimg a component of ADS, whereas the function of ArcD is yet to be investigated. The aim of this study is to elucidate the role of ArcD in *S. gordonii*.

Materials and methods: We generated an ArcD deletion mutant (ΔArcD) by replacing *arcD* ORF in *S. gordonii* DL1 (Challis) with *ermAM* ORF, and examined its growth and biofilm formation under various pH conditions in a chemically-defined medium (CDM). Biofilm microstructure and bacterial surface morphology were microscopically observed. Following the incubation in CDM for various periods, the bacterial internal metabolites were comprehensively analyzed with CE-TOFMS.

Results: Growth of ΔArcD reached more slowly to an identical plateau with WT at mild acidic condition (pH 6.0), whereas it was significantly suppressed below pH 5.5. Exogenous arginine enhanced WT growth at pH of 7.0, while ΔArcD showed suppressed growth regardless of arginine existence. Microscopic observation demonstrated that ΔArcD formed sparse and loose biofilms with less biovolume than WT and faild to express pilus-like surface appendages. Metabolome analysis revealed that decrease of ornithine, citrulline and arginine enhanced the early phase of *de novo* arginine biosynthetic pathway from glutamate to *N*-Acetyl-Ornithine via *N*-Acetyl-Glutamate, catalyzed by ArgDBJC in WT. In contrast, lack of ArcD suppressed the arginine biosynthesis with retention of ornithine, citrulline and arginine.

Conclusion: These results indicate that ArcD is involved in the control of *de novo* arginine biosynthesis to maintain homeostasis in *S. gordonii* and may be also necessary for proper expression of a pilus-like cell surface component and biofilm formation.

A role for peroxisomes on the cellular antiviral response to Cytomegalovirus infection

A. C. Magalhaes[1], S. Gomes[1], A. R. Ferreira[1], F. Camões[1], R. Nascimento[2], M. Schrader[1,3], D. Ribeiro[1]

Viruses are able to develop specific mechanisms of evasion of the host cell antiviral defense. The Cytomegalovirus (CMV) encodes vMia, a protein responsible for circumventing two important cellular responses to viral infection: apoptosis and RIG-I/MAVS signaling. Although still poorly understood, its anti-apoptotic activity involves the recruitment of Bax to mitochondria and blocking of the mitochondrial outer membrane permeabilization. The RIG-I/MAVS signaling pathway is initiated by the recognition of the viral genome by the cytoplasmic protein RIG-I. Upon viral stimulation, this protein interacts with the mitochondrial antiviral signaling adaptor (MAVS), leading to a signaling pathway that culminates in antiviral defense. Although always assumed to localize exclusively to mitochondria, it has been recently demonstrated that MAVS is also present at peroxisomes and that these two organelles perform different but complementing functions within the antiviral response. vMia has been shown to dampen signaling downstream from mitochondrial MAVS and was also shown to trigger mitochondria fragmentation, a phenomenon proven to be essential for the signaling inhibition. However, no studies were yet performed taking into account a possible effect of vMia on the peroxisomal MAVS-dependent antiviral signaling cascade.

Our studies have uncovered a novel peroxisomal localization for CMV's vMia. Interestingly, we have also demonstrated that vMia interacts with Pex19, the cytoplasmic chaperone responsible for the transport of peroxisomal membrane proteins to this organelle. These results suggest that peroxisomes, similarly to mitochondria, may act as an important platform for vMia-dependent evasion of the cellular antiviral defense against CMV.

Keywords: Cytomegalovirus, Peroxisomes, vMia.

Adhesive and antimicrobial properties of *Lactobacillus acidophilus* strain Er 317/402 "Narine" for its use in some types of blood cancer

K. V. Harutyunyan[1], L. Hakobyan[2], A. Trchounian[1]
[1]*Department of Microbiology, Plants and Microbes Biotechnology, Yerevan State University,* [2]*Scientific and Production Center "Armbiotechnology" of the National Academy of Sciences of Armenia, Yerevan, Armenia*

In the pathogenesis of leukemia the role of microorganisms is not excluded, the leading role being played by pathogenic bacteria, *Staphylococci, Escherichia coli* etc [1].

We used the probiotic strain *L. acidophilus* Er 317/402 "Narine". Antimicrobial properties of bacteria were determined by diffusion method in agar and by serial dillutions method. As test microorganisms were taken *E. coli, Staphilacoccus aureus, Salmonella typhimurium, Shigella flexneri, Vibrio cholera El-Tor, Yersinia pestis, Brucella abortus* etc. To identify the adhesion properties and adhesins in bacterial cells hemagglutination reaction with red blood cells of animals and humans was used. CFA I and CFA II type of fimbrial antigens of adhesion were determined in the reaction of D-mannose-resistant hemmaglutination

© 2014 The Authors. FEBS Journal © 2014 FEBS

with II A group of human, chickens, sheep and bovine erythrocytes. 3% suspension of erythrocytes was used in the experiment. Identification of isolates strain in children with acute leukemia was carried out.

Probiotic strain of *L. acidophilus* Er 317/402 "Narine" was shown to possess high adhesion and antimicrobial properties. The latter were established for a wide range of test-microorganisms including pathogenic ones. It was revealed that *L. acidophilus* Ep 317/402 "Narine" had a CFA I kind of adhesins. From the children with acute leucosis were isolated and identified *St. aureus, St. epidermidis, E. coli*, which differed from the phage types. It was determined that the pathogenic microorganisms were isolated at a stage of acute leucosis, while saprophyte microorganisms – at a stage of remission. The quantity of *Escherichia* was decreasing in blood when *L. acidophilus* strain Er 317/402 "Narine" was enterally applied, while on the 10–12th days after acidophilotherapy, hemolytic escherichia were not detected.

The results obtained indicate that probiotic strain of *L. acidophilus* Er 317/402 "Narine" exhibits high adhesion and antimicrobial activity and it is recommended in treatment of childhood acute leucosis.

Amidate prodrugs of 9-[2-(Phosphonomethoxy)ethyl]adenine (PMEA) as inhibitors of adenylate cyclase toxin from *Bordetella pertussis*

M. Šmídková[1], A. Dvořáková[1], E. Tloušt'ová[1], M. Česnek[1], Z. Janeba[1], H. Mertlíková-Kaiserová[1]
[1]IOCB ASCR, Prague, Czech Republic

Adenylate cyclase toxin (ACT) is the key virulence factor of *Bordetella pertussis* that facilitates its invasion into the mammalian body. 9-[2-(Phosphonomethoxy)ethyl]adenine diphosphate (PMEApp), the active metabolite of the antiviral drug bis(POM) PMEA (adefovir dipivoxil), has been shown to inhibit ACT. The objective of this study was to evaluate six novel amidate prodrugs of PMEA, both phenyloxy phosphonamidates and phosphonodiamidates, for their ability to inhibit ACT activity in J774A.1 macrophage cell line. The two phenyloxy phosphonamidate prodrugs exhibited higher inhibitory activity (IC50 = 22 and 46 nM) than the phosphonodiamidates (IC50 = 84–3960 nM). The inhibitory activity of the prodrugs correlated with their lipophilicity and the degree of their hydrolysis into free PMEA in J774A.1 cells. Although they did not inhibit ACT as effectively as bis(POM)PMEA (IC50 = 6 nM), they were significantly less cytotoxic. Moreover, they all reduced apoptotic effects of ACT and prevented an ACT-induced elevation of intracellular [Ca2+]i. The total amount of bis(POM)PMEA (including the hydrolytic products mono(POM)PMEA and PMEA) transported across Caco-2 monolayers was higher than that of the studied amidate prodrugs. On the other hand, the amidate prodrugs were less susceptible to degradation in Caco-2 cells than bis(POM)PMEA. As a consequence, high amount of intact amidate prodrug is expected to be available to target macrophages *in vivo*. This feature makes nontoxic amidate prodrugs attractive candidates for further investigation as novel antimicrobial agents.

AMPK/Sirtuin1 activators inhibit herpes simplex virus type 1 replication and protect neurons from neurodegenerative events triggered during infection

C. Otth[1], L. Leyton[1], C. Martin[1], M. I. Concha[2]
[1]Instituto de Microbiologia Clinica, [2]Instituto de Bioquimica y Microbiologia, Universidad Austral de Chile, Valdivia, Chile

Herpes simplex virus type 1 (HSV-1) is ubiquitous, neurotropic, and the most common pathogenic cause of sporadic acute encephalitis in humans. Data suggest that it is able to establish latency in the CNS, and that this condition would not be harmless. In addition, it has been estimated that in approximately 70% of the population over 50 years old, the virus enters the brain and infects neurons, suggesting the existence of recurrent reactivations. Currently, it is unclear whether a neuron, that undergoes viral reactivation, survives and resumes latency or is killed. Taking in consideration that the stress sensor AMP-dependent kinase (AMPK) and Sirtuin 1 (Sirt1) are involved in neuroprotection, we recently demonstrated that HSV-1 modulates the AMPK/Sirt1 axis differentially during the course of infection interfering with pro-apoptotic signaling and regulating mitochondrial biogenesis. Therefore we evaluated the effects of AMPK/Sirt1 modulators such as resveratrol and AICAR on viral replication efficiency, neuronal viability and neurodegenerative events triggered during neuronal HSV-1 infection. In agreement with our previous results, we found that 1 mM AICAR (a specific AMPK activator) and different concentrations of resveratrol increased viability in infected neurons, and inhibited to some extent the viral replication and the expression of HSV-1 immediate-early genes (ICP27), early (ICP8) and the latency associated transcript (LAT). Moreover, pretreatment of neurons with resveratrol significantly reduced the increase in tau hyperphosphorylation triggered by HSV-1 infection. These results highlight the potential relevance of pharmacological activators of the AMPK/SIRT1 axis in diminishing HSV-1 productive infection and cellular damage associated with reactivation episodes at neuronal level.

Antimicrobial studies on porous hydroxyapatite used in the environment and biological applications

C. S. Ciobanu, S. L. Iconaru, **D. Predoi**
Laboratory of Multifunctional Materials and Structures, National Institute of Materials Physics, Magurele, Romania

Due to non-biodegradable behaviour and their incapacity of metabolization and decomposition, PTTE like Pb, Cu, Cd, Zn and Hg are the main contaminants of soils and ground or surface waters. Their progressive accumulation in the human body can cause significant health problems, inducing chronic illness which untreated, can lead to a painful death.

© 2014 The Authors. FEBS Journal © 2014 FEBS

The aim of this study was to synthetize new porous nanoparticles based on methyltrimethoxysilane coated hydroxyapatite (MTHAp) for environment and biological applications. The functional groups present in the prepared powder were identified by FTIR spectroscopy. All the diffraction peaks of MTHAp powders could be assigned to the standard characteristic peaks of hexagonal hydroxyapatite and no secondary phases were detected, indicating that the phase of the samples was of pure HAp.

Removal performance of Pb^{2+} ions by the MTHAp composite powders was investigated by batch experiments, monitoring the change of Pb^{2+} ion concentration in the aqueous solution. For this experiments, 5 g of MTHAp composite sample was added to 500 ml aqueous solution with various initial Pb^{2+} ion concentrations and pH values. The initial Pb^{2+} ion concentrations of the aqueous solutions were controlled and the values were set in the range 0.1–0.9 $g \cdot L^{-1}$ by dissolving lead nitrate [$Pb(NO_3)_2$] in deionized water.

The powders after the removal of Pb^{2+} were a mixture of $Ca_{2.5}Pb_{7.5}(PO_4)_6(OH)_2$, $Pb_2Ca_4(PO_4)_2(SiO_4)$ and $Ca_{10}(PO_4)_6(OH)_2$.

This study showed that MTHAp with $x_{Ag} = 0.5$ presented an antimicrobial activity against *Staphylococcus aureus* (ATCC 6538) and *Escherichia coli* (ATCC 25922). The *in vitro* bacterial adhesion study indicated a significantly decreased number of *E. coli* and *S. aureus* on MTHAp with $x_{Ag} = 0.5$. Furthermore, for $x_{Ag} = 0$ the MTHAp stimulated the growth and multiplication of the tested *Staphylococcus aureus* (ATCC 6538) and *Escherichia coli* (ATCC 25922) bacterial strains.

The antimicrobial effects of the MTHAp powders after the removal of Pb^{2+} were investigated against Pseudomonas sp a gram-negative bacteria that live in soil and decomposing organic matter. A significantly number of Pseudomonas sp bacteria were observed in the Pb-contaminated MTHAp for all Pb concentrations. Our studies have shown that the strain- Pseudomonas sp. presented a resistance at Pb.

Keywords: bacterial strains, Pb-contaminated MTHAp, silica matrix.

Application of proteomics for identification of virulence factors associated with poultry host preference of *Staphylococcus aureus* strains

E. Bonar[1], I. Wójcik[1], S. Kędracka-Krok[2,3], G. Dubin[3,4], A. Dubin[1,3], B. Wadyka[1,3]
[1]Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, [2]Department of Physical Biochemistry, Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, [3]Malopolska Centre of Biotechnology, [4]Department of Microbiology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Staphylococcus aureus in an opportunistic pathogen of humans and animals. It secretes a range of proteins into extracellular milieu, many of which act as virulence factors giving the bacterium the ability to effective host colonization and disease development. *S. aureus* exhibits a huge phenotypic and genetic diversity, however genomic studies show a clear distinction between the strains from human and animal origin. Unfortunately, biochemical basis of host preference and proteome components responsible for this phenomenon are largely unidentified.

Our previous studies revealed the correlation between the genotype of poultry isolated *S. aureus* strains and their virulence in chicken embryo but not nematode model [1], what may suggest the existence of host specific virulence factors. This study have been conducted to verify whether the differences in virulence of the strains are reflected at the proteome level. For this purpose extracellular proteomes of well characterized poultry-originated virulent (VS) and non-virulent (NVS) *S. aureus* strains were compared. Extracellular proteins were precipitated, labeled with fluorescent dyes and subjected to two-dimensional difference gel electrophoresis in pairs VS *vs.* NVS.

The proteome images among the strains were highly diverse. In total, 465 differentiating protein spots were cut out from the gels, trypsin digested and subjected to mass spectrometry (MS) analysis. The MS analysis revealed that 80 and 135 proteins exhibited higher abundance in VS and NVS, respectively. However, only a few proteins were identified in all VS and all NVS proteomes. Interestingly, 42 proteins were classified as differentiating in both types of proteomes. Closer inspection of protein localization on the gels and sequence coverage during MS identification indicated different posttranslational processing and/or degradation which may affect their biological activity. The high number of identifications of alpha-hemolysin and lipases as differentiating in VS and NVS proteomes suggest the importance of these known virulence factors in *S. aureus* host preference as well as turns the attention to proteases as possible agents switching between virulent and commensal phenotype.

Assesment of oral cavity microbiota – potential risk factors of local/general opportunistic infections in Polish patients with congenital malformations

K. Perkowski[1], L. Chomicz[2], P. Zawadzki[3], M. Marczyńska-Stolarek[1], M. Padzik[2], P. Piekarczyk[3], B. Starościak[4]
[1]Department of Orthodontics, [2]Department of Medical Biology, [3]Clinic of Cranio-Maxillo-Facial and Oral Surgery and Implantology, [4]Department of Pharmaceutical Microbiology, Medical University of Warsaw, Warsaw, Poland

Introduction: The oral cavity is an open system with complex and dynamic relations between human host and microbiota. Cleft lip and palate is one of the most common congenital malformations. In Poland, it appears every year in 800 newborns, as a single disorder or syndrome. Environmental and genetic factors, both have influence on development of this pathology. As treatment of patients with cleft malformations is comprehensive and long-lasting, an information on microorganisms colonizing oral cavity is essential to decrease a risk of medical complications. We examined composition and genetic characteristics of species of the oral cavity microbiota in cleft patients, in term of host-microorganism relationships and a risk of local and general invasion.

Material and methods: Sixty patients, 14 to 23-years old, with and without congenital malformations, treated orthodontically were examined; data from clinical, microbiological and genetic examinations were analyzed.

Results: There were differences in the conditions of the patients' oral cavities, expressed by the values of bleeding index, dental plaque index, highest in orthodontic patients with malformations. Different strains of bacteria, yeast-like fungi and protozoan were found. Among others, strains of *E. coli*, *Enterobacter cloacae*, *E. agglomerans*, *Candida* sp., *C. albicans* were often identified. Seven non-Enterobacteriaceae strains, including *P. aeruginosa*,

© 2014 The Authors. FEBS Journal © 2014 FEBS

were also detected. Relatively often *Enterococcus faecalis* and *E. faecium* occurred; five strains of *Staphylococcus,* also MRS were found.

Conclusion: Although many microorganisms may be found in the oral cavity, there are no standards for its microbiological examination regarding their potential role in local/general infections. Analysis of the data implicates that there are co-infections with different opportunistic/pathogenic strains and, potentially, a serious risk of local and general complications in orthodontic patients with congenital malformations. It should be emphasized that the human oral cavity may act as a major, not fully known, source of strains that can induce clinically important infections. The examination of the oral cavity, in term of presence of opportunistic bacteria and fungi, particularly in persons with congenital malformations, is highly recommended before/during treatment.

Keywords: oral cavity microbiota, opportunistic species, congenital malformations.

Atomic structure of a bacterial filament: the type III secretion system needle

A. Loquet[1,2], K. Giller[3], J. P. Demers[3], B. Habenstein[3], S. Veniamin[3], R. Gupta[4], M. Kolbe[4], S. Becker[3], A. Lange[1]
[1]NMR-Based Structural Biology, MPIbpc, Göttingen, Germany, [2]CBMN (UMR5248) - IECB, Pessac, France, [3]MPIbpc, Göttingen, [4]MPIib, Berlin, Germany

Bacterial filaments such as pili or secretion needles are complex macromolecular assemblies that play an essential role in host pathogen interaction. Cryo-electron microscopy combined with crystal subunit structures has recently provided a powerful hybrid approach to study such nanomachines, resulting in low- and medium-resolution models. However, such approaches can not deliver atomic details, especially the crucial subunit-subunit interfaces, due to the limited cryo-EM resolution. For many bacterial filaments, the mechanisms for molecular assembly are still unknown.

Here, I will show that state-of-the-art Solid-State NMR methodology (1–4) is able to reveal the supramolecular interfaces and ultimately the complete atomic structure of a bacterial filament. Our approach is demonstrated on the *Salmonella typhimurium* Type III Secretion System Needle, a filamentous assembly that mediates the injection of pathogen effector proteins to the cytosol of host cells during bacterial infection. Using an integrated approach combining Solid-State NMR, STEM, and computational modeling, we present an atomic resolution model of the needle (5) in its native filamentous state. Additional data based on Solid-State NMR and immuno-labeling techniques on a homologous needle from *Shigella flexneri* have allowed us to propose a common architecture for the type III secretion system needles (6).

Bacterial effector CagA induces factors involved in EMT phenotype of gastric epithelial cells in experimental *in vitro* infection with *Helicobacter pylori*

I. Sougleri, K. Papadakos, A. Mentis, D. Sgouras
Medical Microbiology, Institut Pasteur Hellénique, Athens, Greece

Following adhesion of *H. pylori* to gastric epithelial cells, the bacterial oncoprotein CagA is translocated intracellularly, through a Type IV secretion system (T4SS) and deregulates cellular polarity, inducing the appearance of a scattering phenotype that resembles to the EMT. Hierarchic phosphorylation of CagA by Src and Abl kinases, on repetitive EPIYA motifs, located at the carboxyl-terminus of the protein plays a pivotal role in this transition. In clinical isolates the type of EPIYA motifs has been shown to vary depending on the surrounding sequence namely, EPIYA-*A*:EPIYAKVNK, EPIYA-*B*:EPIYAQVAKK and EPIYA-*C*:EPIYATIDDLG. In this study, we investigated the potential involvement of CagA protein, after *H. pylori*-infected gastric epithelial cells, in the activation of MMP-3, which has been suggested to be required for the change in cell shape, inducing EMT. We utilized isogenic *H. pylori* mutants, based on the reference P12 strain, expressing CagA protein with variable numbers (n = 0–3) of functional terminal EPIYA-C and phosphorylation-deficient EPIFA-C motifs, as well as the corresponding P12 *cagA*-knock out and *cagE*-knock out (T4SS-defective) strains. These strains were used to infect gastric epithelial cells (AGS and MKN45) *in vitro* and MMP-specific transcriptional activation was measured by RT-quantitative Real Time PCR, at several time points. MMP expression in total cell lysates and cell culture supernatants was also determined by western blot analysis at 24 h post-infection. Increased transcriptional activation of MMP-3 gene was observed in AGS cells infected by *H. pylori* strains, appeared to be linked to expression and translocation of CagA and was proportional to the number of functional (EPIYA-C) phosphorylation motifs. Although, MMP-3 expression in total cell lysates of *H. pylori*-infected AGS and MKN45 cells was associated to CagA expression and translocation, it was found to be unrelated to the number of EPIYA motifs and their state of phosphorylation. In contrast, the levels of secreted MMP-3 in cell culture supernatants appeared to be CagA phosphorylation-dependent, suggesting that metalloproteinase release in the extracellular matrix may be related to CagA phosphorylation-dependent intracellular signaling downstream events. We also checked MMP-10 expression, due to its 82% amino acid homology to MMP-3 and observed that its expression in total cell lysates of *H. pylori*-infected AGS cells was infection-independent. An analysis of the molecular pathways of MMP-3, involved in epithelial to mesenchymal transition of gastric epithelial cells, leading the cells to a metastatic phenotype, during chronic *H. pylori* infection, is under way.

Candida albicans enolase interacts with neutrophil proteins involved in the formation of neutrophil extracellular traps in response to candidial infections.

K. Seweryn, M. Zawrotniak, O. Bochenska, A. Kozik, M. R. Kozik
Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Introduction: Neutrophils constitute the first line of host defense at the site of microbial infection, where the formation of extracellular traps (NETs) is one of mechanisms exploited by the host to combat pathogens. NETs are formed by decondensed chromatin, decorated with granular proteins such as myeloperoxidase, elastase, histones, lactoferrin and azurocidin.

Candida albicans yeasts belong to the physiologic microflora of healthy individuals but can convert into a dangerous pathogen in immunocompromised patients. It is equipped with numerous virulence factors, of which the major roles are played by the cell wall adhesive proteins and the secreted hydrolytic enzymes.

Objective: Analysis of possible involvement of a major *C. albicans* cell wall protein, enolase in the entrapment of fungal cells in NETs via their proteinaceous components.

C. albicans enolase is a vital glycolytic enzyme and also a highly conserved immunodominant antigen presented on the fungal surface where it belongs to a large group of moonlighting proteins, loosely bound with the cell wall.

Results: The analysis of chromatographically separated *C. albicans* cell wall proteins allowed to classify enolase as one of the major proteins capable of interacting with granular components of NETs. After purification to homogeneity, enolase was found to bind myeloperoxidase, lactoferrin and azurocidin but not histones. The complexes formed were characterized in terms of thermodynamic parameters with the use of surface plasmon resonance (SPR) measurements. For the catalytic process this enzyme requires bivalent metal ions which were also found to stabilize the enolase interactions with proteinaceous components of NETs. For the strongest binding of enolase to myeloperoxidase, an influence of this interaction on the enzyme activities of both proteins was analyzed. The enolase activity was inhibited, in contrast to the preserved activity of myeloperoxidase, known as critically important for antimicrobial defense of the host.

Conclusions: The production of NETs at the place of infection is one of possible mechanisms for the neutralization of microbial pathogens by the host. This process can involve the direct immobilization of pathogen by the decondensed chromatin, but also some pathogen surface proteins such as enolase can be tightly bound by proteinacous component of NETs, thereby increasing the efficiency of local antimicrobial defense.

Keywords: *Candida albicans*, enolase, Neutrophil extracellular traps.

Chaperon activity of heat shock protein 90 (HSP90) is required for the production of paramyxovirus polymerases

L.-M. Bloyet, J. Welsch, C. Mathieu, J. Rabilloud, B. Horvat, B. Grigorov, D. Gerlier
CIRI, INSERM U1111, CNRS UMR5308, Université Lyon 1, ENS Lyon, Lyon, France

HSP90 is an essential chaperon protein which is known to facilitate the folding, the stabilization and/or the activation of client proteins. HSP90 is a highly conserved and abundant cellular protein which can be induced upon stress. When studying the thermosensitivity phenotype of Measles virus (MeV) vaccine strain in chicken cells, a correlation between the level of expression of HSP90 and the viral growth was found. Further experiments showed that HSP90 appeared to be strictly required for an efficient viral growth of vaccine and wild-type MeV strains both *in vitro* and in an *ex vivo* model of a mouse brain infection. In infected cells, polymerases and nucleocapsids containing the viral genomes are concentrated in structures named “viral factories”. Immunostaining of infected cells showed a colocalization of HSP90 in these viral structures. In the absence of HSP90 activity, the viral transcription was inhibited. Using different approaches, we show that the production of viral polymerase, composed of the large protein L and its cofactor the phosphoprotein P, in a soluble and functional form transiently requires HSP90 activity. In the absence of HSP90 activity, the L protein is mostly degraded by the proteasome or insoluble. Moreover, both HSP90 and P protein were found to be required to produce L protein in a stable and soluble form. Interestingly, mature polymerases do not required HSP90 activity for their function, indicating that HSP90 acts as an authentic compulsory chaperon for MeV polymerase. The HSP90-dependence has also been seen for Nipah virus which belongs to another viral genus (*Henipavirus*) in the *Paramyxoviridae* family indicating that this mechanism may be conserved in the whole family.

Characterization of a novel phase variable Type IIS restriction endonuclease from *H. pylori* strain 26695

S. Kumar, R. Kumar, R. N. Desirazu
Biochemistry, Indian Institute of Science, Bangalore, India

Helicobacter pylori is a Gram-negative bacteria that infects about 50% of the human population, and is responsible for 5.5% of all gastric cancer, per year. *H. pylori* shows extraordinary genetic diversity and this property is key to its success as a human pathogen. Genome sequences of various clinical strains of *H. pylori* reveal an abundance of DNA restriction endonucleases and methyltransferases (R-M systems). Recent studies have shown that components of R-M systems are involved in transcriptional regulation of several genes including virulence, besides their role in regulation of DNA uptake in bacteria. Interestingly, many genes encoding R-M enzymes are strain specific and phase variable in *H. pylori*. The *hp1366-hp1367-hp1368* ORFs in the *H. pylori* strain 26695 codes for an active Type IIS R-M system. The *res* gene is encoded by *hp1366* ORF (HpyAII) which is a novel Type IIS phase variable restriction endonuclease that recognizes the sequence 5′GAAGA3′/5′CTTCT 3′ and cleaves 8 bp downstream on the top strand, and 7 bp downstream on the bottom strand. In *H. pylori* J99 strain the homolog of *hp1366* is inactive due to phase variation. The *hp1366* gene is highly strain specific among Indian strains and other sequenced strains, and hence it would interesting to study its role in the adaptation and possible host-pathogen interaction of *H. pylori*.

The *hp1366* gene of a putative Type IIS R-M system from 26695 strain of *H. pylori* was cloned and purified to near homogeneity. HpyAII prefers for a two-site substrate over one-site substrate for maximal activity. HpyAII is less stringent in metal ion requirement and shows higher cleavage activity with Ni^{2+} over Mg^{2+}. This sheds light on the importance of Ni^{2+} ions, as various studies have shown that *H. pylori* maintains a pool of Ni^{2+} for successful colonization of the host. Why HpyAII prefers Ni^{2+} over Mg^{2+} for maximal activity and what *in vivo* significance it

© 2014 The Authors. FEBS Journal © 2014 FEBS

can confer on the activity of HpyAII is an interesting question. Mutational analysis of the putative residues of HNH motif of HpyAII confirms that the protein has an active HNH site for the cleavage of DNA. However, mutation of first His residue of the HNH motif to Ala does not abolish the enzymatic activity, instead causes loss of fidelity compared to wild type HpyAII. The novelty of this observation lies in the fact that mutation of first His residue of the HNH motif in all other known HNH motif containing enzymes completely abolishes enzymatic activity. Mutation at a single amino acid residue leading to the loss of fidelity provides probable insight into the evolution of restriction enzymes. This study further exemplifies our understanding about the role of R-M systems in *H. pylori* biology.

Keywords: endonuclease, *Helicobacter pylori*, phase variation.

WED-343
Characterization of bacteriophage Pet-CM3-4 infecting *Cronobacter* spp.

L. Oslanecová[1], M. Kajsík[2], T. Szemes[2], H. Drahovská[2], J. Turna[2]

[1]Department of Molecular Biology, [2]Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia

Cronobacter spp. (formerly known as *Enterobacter sakazakii)* is an opportunistic pathogen associated with severe infections in neonates and infants which can lead to necrotizing enterocolitis, bacteremia and neonatal meningitis, with high fatality rates. An infection in neonates is often associated with the consumption of contaminated dried infant formula. To improve food quality, is important to find an efficient method for pathogen elimination. For such a purpose, bacteriophages could be the appropriate tool in the protection of infant formula from this pathogen.

The aim of this work was to characterize *Cronobacter* specific bacteriophage Pet-CM3-4 as a suitable candidate for application in food control. The bacteriophage was isolated from sewage water on *C. malonaticus* 161007/29 indicator strain. Phage was purified from single plaque by ultracentrifugation in CsCl gradient. Based on whole genome sequencing this phage belonged to the T4-like group of *Myoviridae* family. The whole DNA was 172 kbp long containing 39.8% GC pairs. The sequence had the highest similarity to the CC31 enterophage. The phage had the broad host specificity, it was able to infect 36 from 50 tested *Cronobacter* strains belonging to species *C. sakazakii*, *C. malonaticus*, *C. dublinensis*, *C. turicensis*, *C. muytjensii* and *C. condimenti*. The efficiency of plating reached 0.04–105% comparing with titer on the indicator strain. Inhibition of bacterial growth by Pet-CM3-4 was also observed in liquid medium, the highest effect was detected using high phage concentrations and in the presence of low amounts of bacteria. In these conditions bacterial growth was not observed for the first eight hours, but overgrowth of the phage resistant bacteria occurred in some strains during overnight cultivation. Therefore application of the Pet-CM3-4 phage in the mixture with some other phages will be more practicable in food control applications.

Keywords: bacteriophages, *Cronobacter*.

WED-344
Cloning and expression analyses of an endo-β-(1-6)-D-galactanase gene in two races of *Colletotrichum lindemuthianum* with different life style

M. G. Villa-Rivera[1], M. G. Zavala-Páramo[1], U. Conejo-Saucedo[1], E. López-Romero[2], A. Lara-Márquez[3], H. Cano-Camacho[1]

[1]Centro Multidisciplinario de Estudios en Biotecnología, Universidad Michoacana de San Nicolás de Hidalgo, Morelia, [2]Departamento de Biología, División de Ciencias Naturales y Exactas, Universidad de Guanajuato, Guanajuato, [3]Escuela Nacional de Estudios Superiores, Universidad Autónoma de México, Morelia, Mexico

Microorganisms produce cell-wall-degrading enzymes as part of their strategies for plant invasion/nutrition. The endo-β-(1-6)-D-galactanase catalize the hydrolysis of β-(1-6)-galctosyl side chains of arabynogalactans (AGPs). Since the AGPs of the plant cell wall are classified between signal molecules, we think that their degradation is related to defense in plants. We performed the cloning and the expression analysis of the endo-β-(1-6)-D-galactanase gene *Clebg* in two races from *C. lindemuthianum* with different life style, pathogenic and saprophytic. Additionally, we performed a phylogenetic analysis of galactanases from Colletotrichum species.

Clebg gene of both races, pathogenic and saprophytic, contained an open reading frame consisting of 1398 bp (347 amino acids). The deduced amino acid sequence of both proteins showed similarity with other known endo-β-(1→6)-galactanases. The genetic expression of *Clebg* from *C. lindemuthianum* was analyzed by qPCR in mycelium grown in culture medium with glucose for 8 h, and Mathur′s medium containing arabinogalactan, xylan or cell wall from *Phaseolus vulgaris* as carbon source at 0, 2, 4, 6, 12, 24, 48 h and 3, 4, 5, 7 and 9 days. Expression of *Clebg* do not showed catabolic repression in presence of glucose. When mycelium of both races grew with plant cell wall, an increase of relative expression of *Clebg* (~8 fold) was detected in the pathogenic race (1472) but not in saprophytic race (0). This suggest that endo-β-(1-6)-D-galactanase might be a virulence factor. In culture medium with xylan or arabinogalactan, the pathogenic race (1472) showed major relative expression of *Clebg* (~6-12 fold respectively) compared with the saprophytic race (~4–4.5 fold respectively). These results suggest that other components of the cell wall besides AGPs and xylan are inducers of expression of *Clebg* in the pathogenic race but not in the saprophytic race.

Phylogenetic analysis of endo-β-(1→6)-galactanases of *Colletotrichum* species reveled clustering into clades related to host preference: monocots or dicots, where the *C. lindemuthianum* was grouped with the galactanase of *C. orbiculare*, which are both pathogens of dicots. It has been observed that the pathogenic fungi of monocot plants are better adapted to degrade the cell walls of monocot plants, and pathogens of dicot plants are better able to degrade the cell walls of dicot plants, a phenomenon that reflects host preference. This suggest that the galactanases from *C. lindemuthianum* species envolved according to their invasion/nutritional strategy and host preference.

Keywords: arabynogalactans, *Colletotrichum lindemuthianum*, endo-β-(1-6)-D-galactanase.

Combating norovirus-dependent gastroenteritis through RdRp inhibitors

M. Bolognesi[1], R. Croci[1], M. Pezzullo[1], D. Tarantino[1], M. Milani[1], E. Mastrangelo[1], S.-C. Tsay[2], J. R. Hwu[2], R. Sureshbabu[3], Y.-J. Tsay[3], J. Rohayem[4]
[1]Department Biosciences, University of Milano, Milano, Italy, [2]Department of Chemistry, National Central University, Jhongli, [3]Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan, [4]Riboxx GmbH, Pharmapark Radebeul, Radebeul, Germany

Noroviruses are members of the *Caliciviridae* family of positive sense RNA viruses, which cause rapid onset diarrhea and vomiting. Currently Norovirus infection is responsible for 21 million gastroenteritis yearly cases in the USA. Nevertheless no effective vaccines/antivirals are yet available to treat Norovirus infection. Since the activity of RNA-dependent RNA polymerase (RdRp) plays a key role in genome replication, the enzyme is considered a promising target for antiviral drug development.

In this context, we identified Suramin and NF023 as Norovirus RdRp inhibitors[1] that, however, are hampered by pharmacokinetics/toxicity problems. To overcome such problem, we analyzed the potential inhibitory role of naphthalene di-sulfonate (NAF2), a fragment derived from these two molecules[2] and of the related molecule pyridoxalphosphate-6-(20 -naphthylazo-60 -nitro-40,80 -disulfonate) tetrasodium salt (PPNDS)[2,3]. The crystal structures of human Norovirus RdRp/NAF2 and RdRp/PPNDS complexes revealed a new binding site that differs from that characterized for NF023/suramin. To further map the new potential inhibitory site, we focused on structurally related molecules that were synthesized following structure-driven information[4]. The synthesis process of Suramin-derivative compounds, led to the isolation of lower molecular weight intermediates hosting one sulphonate head. The crystal structures of both hNV/mNV-RdRps in complex with one of these compounds were analyzed, providing new knowledge on the interactions that a small fragment can establish with NV-RdRps, and establishing a platform for structure-guided optimization of potency, selectivity and drugability.

This work is supported by the European Commission SILVER project, withinthe 7th Framework Program Cooperation Project Grant Agreement No. 2606444.

Comparative analysis of virulence of a novel, avian-origin H3N2 canine influenza virus in various host species

K.-S. Lyoo[1], J.-K. Kim[2], B. Kang[3], R. G. Webster[4], D. Song[5]
[1]Chonbuk National University, Ik-San, [2]Korea University, Sejong, [3]Green Cross Veterinary Products, Yongin, Korea, [4]St. Jude Children's Research Hospital, Memphis, TN, USA, [5]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea

Background: A novel avian-origin H3N2 canine influenza A virus (CIV) that showed high sequence similarities in hemagglutinin and neuraminidase genes with those of non-pathogenic avian influenza viruses was isolated in our routine surveillance program in South Korea. We previously reported that the pathogenicity of this strain could be reproduced in dogs and cats. Here, we aimed to determine the comparable infectivity and pathogenicity of the avian-origin H3N2 CIV in different animal species, including chickens, pigs, mice, guinea pigs, and ferrets.

Materials and Methods: Chickens, pigs, mice, guinea pigs, and ferrets were inoculated with A/Canine/Korea/01/2007 (H3N2), and then the samples collected form the animals were examined for antibody response, virus quantification by viral shedding, and pathologic lesions.

Results: The CIV infection resulted in no overt symptoms of disease in these host species. However, sero-conversion, virus shedding, and gross and histopathologic lung lesions were observed in guinea pig and ferrets but not in chickens, pigs, or mice.

Discussion and Conclusion: Based on the genetic similarity of our H3N2 CIV with currently circulating avian influenza viruses and the presence of α–2,3–linked rather than α–2,6–linked sialic acid receptors in the respiratory tract of dogs, we believed that this strain of CIV would have avian virus-like receptor specificity, but that seems to be contrary to our findings in the present study. Further studies are needed to determine the co-receptors of hemagglutinin or post-attachment factors related to virus internalization or pathogenesis in other animals.

Keywords: canine influenza virus, H3N2, interspecies transmission, sialic acid, model animals.

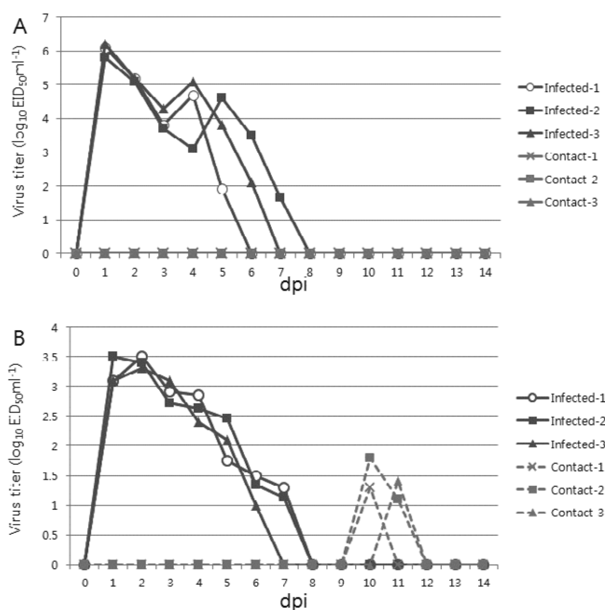

Fig. 1. Nasal shedding of H3N2 CIV from intranasally infected guinea pigs (A) and ferrets (B) and from directly contacted naïve animals. Guinea pigs and ferrets were intranasally inoculated with $10^{7.1}$ EID_{50} of virus, and naïve animals were paired with each infected animal species 6 hours post-inoculation. Nasal swabs were collected daily until 14 dpi, and relative viral titers were determined by a commercial one-step real-time reverse transcriptase-PCR (RT-PCR) kit.

WED-347
Comparison of the thermotolerance genomic island present in *Cronobacter* spp.

M. Orieskova, J. Turna, H. Drahovska
Molecular Biology, Comenius University, Bratislava, Slovakia

Cronobacter (formerly *Enterobacter sakazakii*) is a wide-spread opportunistic foodborne pathogen associated with serious infections in preterm neonates and immunocompromised adults. Rehydrated infant milk formula is the most common source of infection. *Cronobacter* is particularly tolerant to osmotic stress and desiccation and some strains of this genus are also tolerant to elevated temperatures. Thermotolerant strains are able to survive heating during infant formula reconstitution, therefore represent increased risk of infection. Up to 10% of *Cronobacter* strains contain a 18 kbp genomic island, which is responsible for increased thermotolerance. However, despite of the presence of the genomic island, differences in thermo-surviving ability between some strains were observed.

The aim of our study was to compare gene content of the thermotolerance islands from five *Cronobacter* and one *E. coli* strains and to establish its influence on thermal resistance. We observed that the island contained a cluster of conserved genes (*orf*B-Q), most of them had significant homologies with bacterial proteins involved in some type of stress response, including heat, oxidation and acid stress. By sequence comparison, two types of the genomic island were present in strains. Four strains contained full length sequenceand two other strains possessed shortened version of the island (genes *orf*B-D, *orf*O-P). The thermotolerance of all island-positive strains was higher than that of the mutant lacking the island. Measurements were also in agreement with the type of the island, strains containing complete region displayed higher thermotolerance than strains containing only partial island. Similar results were obtained in study of *E. coli* cells transformed with plasmids containing complete and shortened versions of island from *Cronobacter*. One exception were *C. sakazakii* NTU 696 and NTU 701 strains, despite of the similar organization of the islands, *C. sakazakii* NTU 696 possessed decreased thermal tolerance. However, this difference was caused by determinants outside from the thermotolerance region as transformation of *E. coli* with plasmids containing whole island from *C. sakazakii* NTU 696 or NTU 701 both increased thermotolerance. In conclusion, we propose that genes located at the beginning of this genomic island (*orf*C-D) contribute noticeably to the ability of the cells to withstand elevated temperatures, the other genes (*orf*H-Q) increase the thermotolerance of strains in lesser extent.

Keywords: *Cronobacter*, thermotolerance island.

Compartive genomics of *Entrococcus faecium*

A. Shami[1], M. J. Horsburgh[2], A. Darby[1]
[1]Functional and Comparative Genomics, Institute of Integrative Biology, Liverppol, [2]Functional and Comparative Genomics, Institute of Integrative Biology, Liverpool, UK

Enterococci are Gram-positive bacteria that inhabit the gastrointestinal tract of humans and animals as commensal flora. In recent years two species, *E. faecalis* and *E. faecium* have become an increasing medical concern by virtue of their ability to gain and spread antibiotic resistance. We report the sequencing of vancomycin-resistant isolates of *E. faecium* from pig, chicken and cow. The assembled genomes were studied to determine if these strains differed from human isolates and to identify whether they had acquired genes for colonising each animal host. Phylogenomics of *E. faecium* were also performed to investigate the relationship between animal and human strains. The genomes of the chicken, pig and cow isolates differed in size (2.5–3.3 Mb) with the size difference due to acquisition of horizontally acquired elements (mostly phage, transposons and insertion sequences), for example the chicken isolate genome contained 10 prophages. A megaplasmid present in all three isolates was integrated into the genome of the chicken isolate. Comparison of the genomes also identified putative niche adaptation genes with a variety of proposed functions, including carbohydrate utilisation.

Keywords: None.

Contribution of secreted aspartic proteases of pathogenic yeast *Candida albicans* to the neutralization of antimicrobial function of human high molecular weight kininogen

O. Bochenska[1], M. Rapala-Kozik[1], N. Wolak[1], W. Kamysz[2,3], D. Grzywacz[3], W. Aoki[4], M. Ueda[5], A. Kozik[1]
[1]Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, [2]Faculty of Pharmacy, Medical University of Gdansk, Gdansk, [3]LipoPharm.pl, Zblewo, Poland, [4]Division of Applied Life Sciences, Graduate School of Agriculture, Kyoto University, Kyoto, [5]Department of Pathology, Osaka City University Graduate School of Medicine, Osaka, Japan

Candida albicans is nowadays the most common fungal pathogen to humans. Its virulence depends on the production of multiple virulence factors, among which the secreted aspartic proteases (SAPs) have been proven to play major roles at various stages of candidial infections. This family comprises ten closely related proteolytic enzymes which display broad substrate specificity at different pH and have been shown to cleave numerous peptides and proteins of the host, with deregulating effect on the biochemical homeostasis of the host organism.

Human high molecular weight kininogen is a multifunctional glycoprotein composed of six domains, with the best recognized functions of a cysteine protease inhibitor (the D2 and D3 domains) and a precursor of vasoactive proinflammatory peptides, the kinins (the D4 domains). Only recently, it has been discovered to possess two distinct internal sequences in the domains D3 (NAT26) and D5 (HKH20) which can be excised by various proteases, such as neutrophil elastase, to release strong antimicrobial peptides (AMPs).

Taking into consideration constantly growing interests in the contribution of AMPs in the host defense against fungal infections, the current study was undertaken to verify a hypothesis that the diverse group of ten SAPs can neutralize the antifungal activity of kininogen-derived AMPs against *C. albicans*. It was shown that synthetic NAT26 and HKH20 significantly differed in susceptibility to SAP action. The helical, positively charged peptide, NAT26, was effectively cleaved by all SAPs but SAP10, whereby loosing its fungicidal properties, while the histidine- and lysine-rich peptide, HKH20, was cleaved and inactivated only by SAP9. The early products of SAP9-dependent cleavage of NAT26 and HKH20 included the NATFYFKIDNVKK plus ARVQVVAGKKYFI and the HKHGHGHGKHKNK plus GKKNGKH mixtures, respectively, and on their expense the NATFYFKID and HKHGHGHGK peptides appeared at the later phase. Similar peptides, devoid of antifungal activity, were also found among the products, obtained after fragmentation of the intact kininogen molecule by SAPs.

Taken together, the current results strongly suggest that SAP9 plays the exceptional, among all SAPs, role in the neutralization of recently discovered fungicidal activity of human kininogen.

Cytotoxicity and expression pattern of thermostable direct hemolysin (TDH), a main virulence factor of *Vibrio parahaemolyticus*

H.-J. Noh, S.-J. Park
Department of Environmental Medical Biology and Institute of Tropical Medicine, Brain Korea 21 PLUS Project for Medical Science, Yonsei University, Seoul, Korea

Vibrio parahaemolyticus, a gram-negative marine bacterium, is a worldwide cause of food-borne gastroenteritis. Thermostable direct hemoysin (TDH) is a factor responsible for Kanagawa phenomenon caused by pathogenic *Vibrio parahaemolyticus*. Two tdh genes, *tdhA* and *tdhS*, were identified in the genome sequence of wildtype *V. parahaemolyticus*, RIMD2210633 and TDH-deficient mutant strains were constructed. They showed a complete abolishment of hemolytic activity, an attenuated cytotoxicity against human cell lines, and a significant reduction in mouse lethality. Cytotoxicity of *V. parahaemolyticus* against cell lines occurred independently from caspase, as shown in an experiment using pan-caspase inhibitor. TDH-induced cell death demonstrated characteristics of necrosis, and was diminished by necrostatin-1, an inhibitor of necroptosis. Reporter fusions between the tdh protmotors and the luciferase gene indicated that the *tdhA* gene is expressed higher than *tdhS*, and expression of both tdh genes was induced by presence of crude biles or an iron chelator in the medium. Two global regulators, ToxR (cholera toxin transcriptional activator) and IscR (Fe-S cluster regulator), were found to control expression of the *tdhA* gene. These studies on TDH identified physiological signals and/or transcription factors responsible for modulation of pathogenesis of *V. parahaemolyticus*.

Keywords: thermostable direct hemolysin, *Vibrio parahaemolyticus*.

WED-351
Degradation of proteinaceous components of neutrophil extracellular traps by aspartic proteases secreted by pathogenic yeasts, *Candida albicans*

M. Gogol[1], O. Bochenska[1], N. Wolak[1], W. Aoki[2], M. Ueda[3], A. Kozik[1], M. Rapala-Kozik[1]
[1]*Department of Analytical Biochemistry, Jagiellonian University, Krakow, Poland,* [2]*Division of Applied Life Sciences, Kyoto University, Kyoto,* [3]*Department of Pathology, Osaka City University Graduate School of Medicine, Osaka, Japan*

Introduction: A dimorphic yeast-like fungus, *Candida albicans* is an opportunistic pathogen in humans. It can be detected in up to 70% of healthy individuals as a normal component of endogenous microflora but in patients with weakened immune system or imbalanced microbial environment causes disorders with variable severity. The manifestation of the pathogenic nature of *C. albicans* depends on its numerous virulence factors, with one of the most important role played by secreted aspartic proteases (SAPs).

Neutrophils serve as the first line of defense and the critical part of the innate immunity. Apart from the phagocytosis and extracellular degranulation, they are able to kill microbes through the release of neutrophil extracellular traps (NETs) that consist of DNA and antimicrobial proteins such as histones, myeloperoxidase, lactoferrin and azurocidin.

Aims: Classification of the major proteinaceous components of NETs in terms of their susceptibility to proteolytic action of SAPs – identification of potential SAP targets as well as proteins that are resistant to this degradation, thereby being potential weapons in the fight against *C. albicans*.

Results: The identification of proteinaceous components of NETs that can be the substrates for SAPs was conducted with the use of supernatants from the cultures of two morphological forms of *C. albicans*. Five potential targets for SAPs were selected. Four of them were histones (H2A, H2B, H3 and H4), known to constitute the main NET components, while the fifth one was an antifungal protein, calprotectin. To verify the obtained results, a number of degradation assays with purified enzymes were carried out. It was demonstrated that SAPs displayed variable ability to degrade components of NETs, with histones being the most susceptible to the proteolysis, mainly by the action of SAP1, SAP2, SAP3 and SAP9. The citrullination of histones, a posttranslational modification likely to occur during the NET formation, significantly slowed down the SAP-dependent degradation of these proteins. The proteolysis of calprotectin occurred at a limited rate, while myeloperoxidase, lactoferrin and azurocidin were resistant to the degradation by any SAP.

Conclusions: The results of the current study suggest that *C. albicans* may use SAPs for the neutralization of the fungicidal forces of NETs. On the other hand, the resistance of myeloperoxidase, lactoferrin and azurocidin to SAPs suggests a role of these proteins in the fight against *C. albicans*, this major fungal pathogen to humans.

Differential intestinal colonization of *Escherichia coli* Nissle 1917

J. Santander[1,2], T. Schoffer[1], M. Ayala[1], I. Vasquez[1], M. Diaz[2], G. Saavedra[3], N. Favi[3], R. Rojas[2,3]
[1]*Microbial Pathogenesis and Vaccinology Laboratory, Nucleus for Microbiology and Immunity,* [2]*Animal Facility,* [3]*Mucosal Immunity Laboratory, Nulceus for Microbiology and Immunity, University Mayor, Huechuraba, Chile*

Escherichia coli Nissle 1917 (here after EcN) is a probiotic isolated during World War I and since then utilized to treated intestinal disorders, like chronic constipation and colitis. Since its discovery, EcN has been widely used to shorten the duration of diarrhea in children and to alleviate intestinal inflammation in patients with inflammatory bowel disease and ulcerative colitis. EcN is such a great probiotic because is highly protective against intestinal pathogens and trigger both pro- and anti-inflammatory local cytokines. Also, EcN has also been shown to mitigate experimental colitis in mice while also reducing expression of the pro-inflammatory cytokines. EcN oral administrated can also induce systemic humoral immunity in infants as well as induce specific antibodies in the mucosa. The unknown aspects of EcN are its intestinal colonization preferences, levels of mucosal penetration and the influence of the microbiota on EcN colonization. Here we evaluated EcN intestinal lumen and mucus colonization preferences using the colitis mice model versus mice with normal intestinal microbiota. We determined that EcN colonized the ciego and colon, mainly in the proximal and middle in streptomycin treated mice. EcN did almost not colonize the small intestine in streptomycin treated mice in contrast to normal mice. EcN colonize the entire intestine in not

© 2014 The Authors. FEBS Journal © 2014 FEBS

treated mice, however its colonization was transient in contrast to microbiota-depleted mice. In all cases, EcN penetrate the mucus layers system. The mucus layer system organization is probably instrumental for a balanced and symbiotic relation between host and bacteria. The Muc2 mucin is the major protein component of the mucus layer and this mucus system occurs in two distinct layers: an inner layer that is devoid of bacteria and an outer layer that is the habitat of the microbiota. Using purified mouse Muc2 mucin from different regions along the intestinal tract we determined that that EcN has a chemotactic responses to Muc2 mucin from the duodenum, proximal and middle colon. These results suggest that EcN has a preference for colon, and Muc2 and microbiota influence this differential colonization.

DNA binding activities of DicA, H-NS and Cnu on the promoter region of the *dicA* gene in *Escherichia coli*

Y. Lee, W. Xun, H. M. Lim

Department of Biological Sciences, College of Bioscience and Biotechnology, Chungnam National University, Daejeon, Korea (S)

Cnu, a small protein (71 amino acids), complex with H-NS and the complex binds DNA. Over production of a variant of Cnu, CnuK9E and H-NS complex has been reported to cause filamentous growth of WT *E. coli* cells at 37 °C but not at 25 °C (PLoS ONE 7(9): e45236, 2012). The charge reversal from positive to negative at 9th residue of Cnu might have caused unstable binding activity of DicA to its own promoter only at 37 °C, resulting in filamentous growth of the host cells. In this study, we have investigated the DNA binding activities of the three proteins, Cnu, H-NS and DicA to the promoter of *dicA*, *PdicAC*. We employed 'Crude EMSA': A crude protein preparation was subjected to EMSA (Electrophoretic Mobility Shift Assay). The specific DNA binding activity of DicA to *PdicAC* was detected from the crude protein preparation of the WT *E. coli* cells. To examine the role of Cnu and H-NS in DNA binding activity of DicA to *PdicAC*, we analyzed the mobility shift of the DicA bound 89 nucleotides-long *PdicAC* DNA fragment in crude protein preparations from mutant strains where the gene for Cnu or H-NS was deleted. We also performed Crude EMSA by adding the missing protein (purified) to the mutant crude protein. The binding reactions were performed at 2 different temperatures, 25 °C and 37 °C. The followings are the results we obtained from these experiments.

1. DicA binding to *PdicAC* occurs at a specific site (20 nucleotides) called *Oc*, and this binding can occur without H-NS or Cnu both *in vivo* and *in vitro*.
2. In order for a stable DNA-Protein complex to be formed on *PdicAC*, the DicA protein should be bound to *PdicAC* for H-NS and Cnu to bind.
3. The nucleoprotein complex of the DicA-HNS-Cnu bound on *PdicAC* is stable at 25 °C but becomes unstable at 37 °C.

Keywords: DicA, H-NS, Cnu, filamentous growth, temperature-dependent DNA binding.

Dogs' susceptibility to human influenza viruses (A/H1N1, A/H3N2, and B): a mixing vessel to threaten human health?

D. Song[1], S. Kim[1], J.-K. Kim[2], B. Kang[3], H. Moon[3], M. Hong[1], W. Na[1]

[1]*Viral Infecious Disease Research Center, KRIBB, Daejeon,* [2]*College of Pharmacy, Korea University, Sejong,* [3]*Research unit, GCVP, Yongin, Korea*

Consecutive outbreaks of epidemics of canine influenza virus from avian (H3N2) and equine origin (H3N8) among dogs in various countries have raised concern regarding the role of canines in the zoonotic transmission and novel recombination of influenza viruses. We investigated the pathogenicity and transmissibility of the human seasonal H3N2, pandemic (pdm) H1N1 (2009) and B influenza viruses in dogs so as to elucidate the probability of reverse zoonosis of human influenza viruses in canines. Further, seropositive samples from dogs, collected between 2007 and 2011, were screened for these viruses. Dogs inoculated or exposed to humn H3N2 virus developed symptoms of viral infection and we confirmed transmission of the virus from inoculated to naïve dogs. In contrast, the transmissibility of pdm H1N1 from dogs inoculated with this virus was limited. Further, evidence of pdm H1N1 infection as well as dual infection with pdm H1N1 and canine H3N2 virus were found in sera collected from field dogs during 2010 and 2011. We found no evidence of pathogenicity and viral reproduction after inoculation with influenza B virus. Our results indicate that dogs could potentially be potential hosts for human origin flu viruses (pdm H1N1 and seasonal H3N2), which would imply the possibility of dual infections with those human influenza viruses and canine-specific influenza virus.

Keywords: dogs, influenza virus, Mixing vessel.

Dynamic modularity of host protein interaction networks outcome for *Salmonella Typhi* infection

P. K. Dhal

Biomedical Informatics Centre, National Institute of Cholera and Enteric Diseases (NICED), Kolkata, India

The availability of large scale protein-protein interaction networks represents the backbone of molecular activity within cells, thus providing an opportunity to comprehensively understand the mechanism of diseases. Integration of expression data with protein-protein interaction network may provide clues to the dynamic features of these networks. *Salmonella Typhi* infection that leads to typhoid fever is a leading concern for human health in the developing world. Although previous studies had identified putative therapeutic targets of typhoid fever, the underlying molecular mechanism of pathogenesis remains unclear.

We developed a network-based comparative analysis approach that integrates protein-protein interactions with gene expression profiles to reveal conditional specific subnetworks. Applying this method to a group of typhoid fever-infected Nigerian children, we identified Salmonella infection specific subnetwork. We found that a number of hub proteins of this subnetworks tend to be differentially expressed between different biological conditions. The difference in dynamics of that network in typhoid fever in compared to other disease conditions further suggest a potential molecular model of typhoid fever.

Here, we propose a method to analyse the interaction networks in different biological states specifically in infection dis-

© 2014 The Authors. FEBS Journal © 2014 FEBS

eases. It successfully reveals condition specific subnetwork of human protein-protein network; more importantly, these network dynamics provide new insights into the pathogenesis of typhoid fever. The revealed components (both hub and their selected interactors) of subnetwork might be used as potential drug targets and provide new directions for typhoid fever prevention.

Dynamic regulation of Pathogenicity Islands and multiple antibiotic resistance loci in *Salmonella typhimurium*

S. Saini, K. Jain
Chemical Engineering, Indian Institute of Technology Bombay, Mumbai, India

Salmonella enterica serovar typhimurium (*S. typhimurium*) is a common food borne pathogen capable of causing diseases ranging from the self-limiting gastroenteritis to the life-threatening systemic infections. For successful infection, the bacterium employs flagella, fimbriae, and Type 3 secretion systems encoded on loci, called Salmonella *Pathogenicity* Island (SPI)-1 and SPI-2. SPI1 is critical for the bacterium to gain entry into the host cell, while SPI2 is essential for survival once inside the host. In response to the immune response from the host, *Salmonella* activates the genes expressed in the *mar/sox/rob* regulon which are responsible for enabling the bacterium to survive in the harsh and toxic intra-cellular environment.

In this work, we present evidence that the expression of SPI1 and SPI2 are controlled by the *mar/sox/rob* regulon in *Salmonella*. We demonstrate that this enables the cell to control the timing of activation and deactivation of the SPIs, both at the population and single-cell level. We also demonstrate that feedback from the *mar* regulon is an active part of this control strategy, and is responsible for switching off SPI1 and switching on SPI2, once the bacterium gains entry into the host.

Keywords: gene regulation, *Salmonella typhimurium*, SPIs.

Dynamics of linker residues modulate the nucleic acid binding properties of the HIV-1 nucleocapsid protein zinc fingers

L. Zargarian[1], C. Tisné[2], P. Barraud[2], X. Xu[3], N. Morellet[4], B. René[1], Y. Mély[5], P. Fossé[1], **O. Mauffret**[1]
[1]LBPA, ENS de Cachan/CNRS, Cachan, [2]LCRB, Université Paris Descartes/CNRS, Paris, France, [3]Life Sciences, ECNU, Shanghai, China, [4]ICSN, ICSN/CNRS, Gif sur Yvette, [5]UMR 7213 CNRS, Université de Strasbourg, Strasbourg, France

The HIV-1 nucleocapsid protein (NC) is a small basic protein containing two zinc fingers (ZF) separated by a short linker. It is involved in several steps of the replication cycle and acts as a nucleic acid chaperone protein in facilitating nucleic acid strand transfers occurring during reverse transcription. Recent analysis of three-dimensional structures of NC-nucleic acids complexes established a new property: the unpaired guanines targeted by NC are more often inserted in the C-terminal zinc finger (ZF2) than in the N-terminal zinc finger (ZF1). Although previous NMR dynamic studies were performed with NC, the dynamic behavior of the linker residues connecting the two ZF domains remains unclear. This prompted us to investigate the dynamic behavior of the linker residues. Here, we collected ^{15}N NMR relaxation data and used for the first time data at several fields to probe the protein dynamics. The analysis at two fields allows to detect a slow motion occurring between the two domains around a hinge located in the linker at the G35 position. However, the amplitude of motion appears limited in our conditions. In addition, we showed that the neighboring linker residues R29, A30, P31, R32, K33 displayed restricted motion and numerous contacts with residues of ZF1. Our results are fully consistent with a model in which the ZF1-linker contacts prevent the ZF1 domain to interact with unpaired guanines, whereas the ZF2 domain is more accessible and competent to interact with unpaired guanines. In contrast, ZF1 with its large hydrophobic plateau is able to destabilize the double-stranded regions adjacent to the guanines bound by ZF2. The linker residues and the internal dynamics of NC regulate therefore the different functions of the two zinc fingers that are required for an optimal chaperone activity.

Efficacy of *Parthenium hysterophorus* for subduing the cause of *Fusarium* wilt in potato

S. Shafique, S. Shafique
Punjab University, Lahore, Pakistan

Fusarium wilt, caused by *Fusarium solani,* is an economically important disease of potato in Pakistan. Presently, pathogenic potential of *F. solani* was studied by inoculating potato plants with three *F. solani,* strains to screen the most virulent isolate among *F. solani* FCBP-016, *F. solani* FCBP-434 and *F. solani* FCBP-470. Pathogenicity test depicted that *F. solani* FCBP-434 was the most pathogenic isolate with variation in genetic level that was determined by RAPD-PCR. *F. solani* FCBP-434 was 55.66% different with both isolates. This disparity in genetic constitution might be cause of high pathogenicity. Afterwards, antifungal bioassays were conducted to confirm mycotoxic potential of root, shoot and leaf of *Parthenium hysterophorus* against *F. solani* FCBP-434 using 1–4% concentrations of aqueous, methanol and n-hexane extracts. Bioassays revealed that growth of *F. solani* FCBP-434 was greatly inhibited at 1 and 2% concentrations of aqueous and methanol leaf and stem extracts while 3 and 4% concentrations of n-hexane extract proved more effective in suppressing the growth. Among root extracts, higher concentrations of aqueous and n-hexane exhibited more promising results by causing reduction of 85 and 74%, of the growth, respectively, whereas in methanol extract again lower concentrations were more inhibitory.

Elucidating the genetic and molecular basis of gut immunocompetence variation in a *Drosophila melanogaster* population

D. Osman[1], M. Bou Sleiman[1], A. Massouras[2], A. A. Hoffmann[3], B. Lemaitre[1], B. Deplancke[2]
[1]GHI, [2]Institute of Bioengineering, EPFL, Lausanne, Switzerland, [3]Department of Genetics, Bio21 Institute, The University of Melbourne, Melbourne, Australia

Drosophila melanogaster is emerging as a valuable model system to study the intestinal response to infection. Many aspects of this response have been uncovered using classical genetic approaches including pathogen recognition, the induction of antimicrobial peptides, the production of reactive oxygen species, and the restoration of gut homeostasis. However, little is known about the rel-

© 2014 The Authors. FEBS Journal © 2014 FEBS

ative contribution and relevance of each mechanism in a natural population. We have performed enteric infection with the entomopathogenic bacterium *Pseudomonas entomophila* of 140 lines from the Drosophila Genetic Reference Panel (DGRP), and observed extensive variation in survival following infection. To investigate the genetic basis of this variation, we performed a genome-wide association analysis, which allowed the identification of multiple loci with small effects. In parallel, we explored global differences in intestinal gene expression before and after infection in resistant and susceptible lines and found distinct transcriptome signatures between the two phenotypic groups. The main findings of this study will be presented and discussed in details.

Elucidation of immune recognition of zwitterionic polysaccharides by synthetic oligosaccharides

B. Schumann[1], C. Anish[2], C. Pereira[2], P. Seeberger[1]
[1]Max Planck Institute of Colloids and Interfaces, Freie Universität, [2]Max Planck Institute of Colloids and Interfaces, Berlin, Germany

Capsular polysaccharides (CPSs) are crucial for the survival of bacteria in a mammalian host. CPSs are constantly exposed to the environment, interact with and actively modulate the host's immune system. Zwitterionic polysaccharides (ZPSs) are found on the surface of commensal and pathogenic bacteria and contain both positive and negative charges in each repeating unit. ZPSs are key players in the immunomodulatory function of commensal bacteria and induce an immune response in a T-cell dependent manner [1]. However, the precise mechanisms of immunomodulation by ZPSs are still ill-defined.

To unravel the biological implications of ZPSs, structurally defined oligosaccharide probes are needed that can be chemoselectively conjugated to suitable reporter molecules. However, the presence of a free amino group in the unusual monosaccharide 2-acetamido-4-amino-2,4,6-trideoxy-D-galactose (D-AAT) is incompatible with most common conjugation methods[2].

We describe here the synthesis and immunological evaluation of zwitterionic oligosaccharides that can be chemoselectively coupled to reporter moieties, such as microarray surfaces. By applying these conjugation-ready glycans in immunological settings, we elaborate on the role of the rare sugar D-AAT on the recognition of ZPSs by the immune system.

Evaluation of detergent efficiency in controlling *Enterococcus faecalis* propagation

J. Keyhani[1], E. Keyhani[2]
[1]Laboratory for Life Sciences, [2]Laboratory for Life Sciences, Tehran, Iran, Republic of Islamic

Enterococcus faecalis, a gram-positive bacterium ubiquitous in the environment and normal inhabitant of the gastrointestinal tracts of humans and other mammals, has now emerged as a major health problem. The threat is exacerbated by *E. faecalis* ability at surviving adverse conditions, including prolonged stay on environmental surfaces. Its proneness to acquire resistance to various antibiotics by horizontal gene transfer mechanisms and the potential retention of antibiotics resistance in *E. faecalis* biofilms after treatment, have furthered the difficulty in controlling this pathogen's propagation. Here we report *E. faecalis* tolerance to sodium N-lauroylsarcosinate (sarkosyl) and sodium dodecyl sulfate (SDS), two anionic detergents that are routine household chemicals.

A clinical isolate of *E. faecalis* and *Escherichia coli* strains HB101, HB101(pBR322), HB101(pBR325) were grown in Luria-Bertani (LB) broth or on LB-agar with various concentrations of either detergents and various antibiotics concentrations. Results showed that the *E. faecalis* strain exhibited plasmid-mediated resistance to kanamycin (kan) (minimum inhibitory concentration (MIC) 2 mg/ml) and tetracycline (tet) (MIC 50 μg/ml). Rapid plasmid isolation was facilitated by the use of sarkosyl and produced two small plasmids (~ 7 and 5.7 kb) as identified by gel electrophoresis in 1% agarose. The plasmid DNA thus prepared would transform *E. coli* and render it resistant to kan (MIC 2 mg/ml) and tet (MIC 50 μg/ml). Compared to *E. coli*, *E. faecalis* was very sensitive to sarkosyl and SDS, with a sarkosyl MIC of 0.1% (10% for *E. coli*) and a SDS MIC of 0.05% (6% for *E. coli*). Attempts to cure *E. faecalis* with SDS or acridine orange remained unsuccessful, but 3% curing was observed after growth in the presence of sarkosyl, reducing kan MIC to 50 μg/ml and tet MIC to 25 μg/ml. In contrast, 35% curing of plasmid-bearing *E. coli* was observed after growth in the presence of either SDS or acridine orange, but none was observed after growth in the presence of sarkosyl. A mutant *E. faecalis* strain with accrued sarkosyl resistance (MIC = 0.6%) was isolated after growth of the bacterium in the presence of 0.06% sarkosyl. The mutant did not exhibit cross-resistance to SDS, but it grew faster than the original strain and still carried kan and tet resistance plasmids. While the findings reported here showed the usefulness of sarkosyl in handling *E. faecalis*, they also emphasized the remarkable capacity of *E. faecalis* to resist harsh treatment and the potential emergence of strains with increasing tolerance to detergents commonly used for cleaning purposes in households. This, in turn, further increases the challenge of finding ways to control the spread of *E. faecalis* -propagated infections.

Keywords: *Enterococcus faecalis*, plasmid, sarkosyl.

Exclusive potential of tagetes erectus for the management of alternaria diseases of tomato

S. Shafique, S. Shafique
Punjab University, Lahore, Pakistan

Tomato (*Lycopersicum esculentum* Mill.) is one of the most economically important vegetable crops in the world. It is estimated that diseases reduce tomato production to a greater extent worldwide. Natural plants derived compounds contribute a lot in fight against pathogens. In the current study the tomato plants were inoculated with *A. alternata* FCBP-573, *A. alternata* FCBP-479

© 2014 The Authors. FEBS Journal © 2014 FEBS

and *A. alternata* FCBP-349 for the scrutiny of the most pathogenic isolate among these. *A. alternata* FCBP-573 was screened out as the most pathogenic isolate. RAPD analysis confirmed that *A. alternata* FCBP-573 had variability in its genetic constitution with other two isolates; thus this disparity in genetic constitution might be a cause to stir up more pathogenicity in this isolate. Therefore, *A. alternata* FCBP-573 was selected as the most pathogenic isolate and subjected to biological control through *Tagetes erectus* L. In antifungal bioassays different plant parts of *T. erectus* with 1–4% concentrations of aqueous, methanol and n-hexane extracts of each part were evaluated against *A. alternata* FCBP-573. Results revealed that the growth of *A. alternata* FCBP-573 was greatly inhibited at 4% concentration of methanol extract followed by aqueous and n-hexane extract. Among different plant parts tested, root extract exhibited more promising results by causing 81–92% reduction in biomass. The study concludes that aqueous and organic extracts of ornamentals have potential to obstruct dreadful effect of pathogenic fungi by suppressing their growth. *T. erectus* conferred vital and surprisingly stable compounds having inhibitory potential against *A. alternata* FCBP-573.

Keywords: *Alternaria alternata*, *Tagetes erectus*, tomato.

WED-364
Exploiting the *Burkholderia pseudomallei* acute phase antigen BPSL2765 for structure-based epitope discovery/design in structural vaccinology

M. Bolognesi, L. J. Gourlay, P. Lassaux
Department Biosciences, University of Milano, Milano, Italy

Structure-based antigen engineering is frequently used in the vaccine development process to specifically modify protein antigens of a pathogen, to enhance their immunogenic properties, with the aim of improving their protective efficacy. Such approaches may entail engineering epitope-containing regions of the protein, or simply the epitope sequences themselves in the form of synthetic peptides.

In this context, we are involved in a multi-disciplinary ‘Genome-to-Antigen’ (GtA) project that aims to identify *Burkholderia pseudomallei* antigen candidates to enter into the vaccine discovery pipeline. 3D antigen structures form the basis for the application of *in silico*-based B-cell epitope predictions, combined with experimental validation and immunological testing. Overall, we aim to connect the understanding of structural properties at atomic resolution, to the reactivity properties of the protein (or specific epitopes) in an immunological context.

Among other antigens, we solved the crystal structure of *B. pseudomallei* acute phase antigen BPSL2765 in the context of a structural vaccinology study, in the area of melioidosis vaccine development. Based on the 3D-structure, we applied a recently developed method for epitope design that combines computational epitope predictions with *in vitro* mapping experiments. We successfully identified a consensus sequence within the antigen that, when engineered as a synthetic peptide, was selectively immune-recognized to the same extent as the recombinant protein in sera from melioidosis-affected subjects. Antibodies raised against the consensus peptide were successfully tested in opsonization bacterial killing experiments and antibody-dependent agglutination tests of *B. pseudomallei*. Our strategy represents a step in the development of immunodiagnostics in the production of specific antibodies and in the optimization of antigens for vaccine development, starting from 3D structural principles.

Keywords: *Burkholderia pseudomallei* antigen, structural biology, structure-based antigen engineering.

Expression of mycobacterial glycosyltransferase GlfT1 in fusion with MBP

P. Kysel[1,2], N. Kostlánová[2], S. Huszár[3], K. Mikušová[3], M. Wimmerová[1,2,4]
[1]*NCBR,* [2]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic,* [3]*Department of Biochemistry, Comenius University in Bratislava, Bratislava, Slovakia,* [4]*Department of Biochemistry, Masaryk University, Brno, Czech Republic*

Mycobacterium tuberculosis is a gram positive bacterium causing chronic illnesses. Tuberculosis is characterized by a disease persistence and difficulties with treatment. Fight against multi-drug resistant strains requires new antituberculosis drugs.

The mycobacterial cell wall is a complex of arabinogalactan, mycolic acids and peptidoglycan. Arabinogalactan consists of 30 5- and 6-linked β-d-galactofuranose (Gal*f*) units. It anchores in peptidoglycan by a α-l-rhamnopyranosyl-(1→3)-*N*-acetyl-α-d-glucosaminyl-phosphate linker. Two to three arabinan chains with 31 d-arabinofuranose (Ara*f*) units each, composed of 5-linked α-d-Ara*f* with branching by 3,5-α-d-Ara*f*, are bound to the galactan. (1) Mycobacterial GlfT1 is a membrane associated galactofuranosyl transferase cosynthesizing arabinogalactan (1). This enyme transfers the first and the second Gal*f* units from donor UDP-Gal*f* to the C50-P-P-GlcNAc-Rha acceptor, creating b-(1–>4) and b-(1–>5) linkages. GlfT1 is a member of the inverting GT-2 family and belongs to the GT-A superfamily (2). Glycosyltransferases are in difficult to express and purify.

A new MBP-GlfT1 construct has been created. Fusion to maltose binding protein (MBP) is useful for difficult targets. Various purification strategies have been combined delivering the protein in a quality for structural studies. The protocol prevents proteolysis, aggregation and chaperone inpurities. Glycosyltransferase assay confirmed activity after purification.

The research leading to the results obtained financial contribution from the EU under the 7th Framework Programme by CEITEC (CZ.1.05/1.1.00/02.0068) project from European Regional Development Fund

Fecundity as one of possible factors contributing to the dominance of the wMel genotype of Wolbachia in natural populations of *Drosophila melanogaster*

S. Serga[1], O. Maistrenko[1], A. Rozhok[2], I. Kozeretska[1]
[1]Depertment of General and Molecular Genetics, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]University of Colorado Denver, Denver, CO, USA

Alphaproteobacteria of the genus *Wolbachia* are common intracellular endosymbionts of a variety of insects (O'Neill et al. 1997). *Drosophila melanogaster* is infected with a single *Wolbachia* strain (*w*Mel), the proportion of infected individuals may range from as high as 40–60% to as low as 8% in populations from different regions (Solignac et al. 1994; Verspoor and Haddrill 2011). Among the known diversity of *Wolbachia* infecting *D. melanogaster*, a single genotype, *w*Mel, within the *w*Mel strain has been found to dominate over other genotypes world-wide (Riegler et al. 2005). The reasons for *w*Mel domination over the other genotypes remain unrevealed.

We have analyzed the infection frequency and genotypes of *Wolbachia* in 13 natural populations of *D. melanogaster* Ukraine (Chornobyl, Poliske, Chernobyl Nuclear Power Plant (CNPP), Kyiv, Motovylivka, Varva, Pyriatyn, Uman', Odesa, Yalta, Kharkiv, Inkerman, Drogobych). Sampling was carried out in late summer (August-September) of 2011-2013. Infection by *Wolbachia* was justified by PCR-analysis of the DNA from F1 individuals derived from wild-caught flies as described at O'Neil et al 1992 and Zhou et al 1998 and by genotype analysis as according to Riegler et al. (2005).

The results showed that the prevalence of infection ranges from 0.27 to 0.79. In some populations it remains stable over three sampling years (Kyiv), in others it significantly varies in different years (Uman', Odesa). For populations of Odessa and Kyiv we analyzed prevalence of infection during the period of imago fly-out (May-November), which showed a stable frequency in a given period in 2012 and considerable fluctuations in 2013. The analysis of genotypes showed the dominance of *Wolbachia* genotype *w*Mel in all populations in Ukraine. However, there is a stable population in Uman' showing rare genotype *w*MelCS, and in some populations (Varva, Odesa, Kyiv, Uman'2) a few individuals with the genotype *w*MelCS were found as well. This result indicates the genotype *w*MelCS is being maintained in population, but at a very low frequency which can indicate its much greater prevalence in nature.

Flies infected with *w*Mel demonstrated a significantly higher number of produced eggs (17.59 ± 1.96) per female compared with those infected with the genotype *w*MelCS (8.65 ± 1.24; $t = 8.94$, $p < 0.05$), which suggests that *w*Mel can confer some fitness advantage to its infected host by elevating the host's fecundity.

Our results suggest that different *Wolbachia* genotypes may confer differential fecundity in the infected host females, which we hypothesize, could be one of factors contributing to differential dispersal of the bacteria in *D. melanogaster* populations worldwide.

Keywords: *Drosophila melanogaster*, genotyping, Wolbachia.

Fibronectin, a multifunctional human glycoprotein, tightly binds to proteins exposed on the cell wall of pathogenic yeasts, *Candida parapsilosis* and *Candida tropicalis*

J. Karkowska-Kuleta[1], D. Zajac[1], O. Bochenska[1], S. Kedracka-Krok[2], A. Kozik[1]
[1]Department of Analytical Biochemistry, [2]Department of Physical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Candida parapsilosis and *Candida tropicalis* are currently considered as some of the most important fungal pathogens in humans amongst non-albicans *Candida* species. Both cause severe, often life threatening infections in immunocompromised individuals, but *C. parapsilosis* is more common infectious agent within neonates and patients with prosthetic devices, stents, or undergoing the parenteral nutrition while *C. tropicalis* is responsible for severe candidiasis in intensive care units patients, individuals with cancer and those treated with broad-spectrum antibiotic therapy.

One of the initial steps essential for the development of candidial infections is the adherence of fungal cells to the extracellular matrix (ECM) proteins, particularly to multifunctional, high-molecular weight glycoprotein, fibronectin, which is also involved in clotting, wound repair and host cell adhesion. Fibronectin adsorbed by yeasts provides a bridge to deeper tissues, facilitating the colonization of human organism by pathogens. The aim of the current work was to characterize fibronectin binding at the surface of *C. parapsilosis* and *C. tropicalis*, and to indicate the major fungal cell wall components involved in these interactions.

Our study showed the strong adsorption of fibronectin by *C. tropicalis*, as compared to significantly weaker binding of this ECM protein to *C. parapsilosis* cell surface. In both species, the fibronectin binding to filamentous, pseudohyphal forms was much stronger than that to unicellular yeast forms. Analysis of fibronectin binding by pseudohyphae with enzymatically decomposed major constituents of the fungal cell wall, i.e., glucan, mannan and cell wall proteins (CWPs), strongly suggested a predominant role of CWPs in this adsorption phenomenon. This hypothesis was also confirmed by a direct binding assay, using microplate-immobilized fibronectin and biotinynaled CWPs extracted with beta-1,3-glucanase. Moreover, with the use of affinity chromatography and chemical cross-linking coupled with mass spectrometric analysis, the major individual fibronectin-binding CWPs were identified, including amidase, hexokinase and elongation factor 2 in *C. parapsilosis* and fructose-1,6-bisphosphatase and transaldolase in *C. tropicalis*.

The detailed mapping of the interactions between ECM components and fungal surface can contribute to deeper understanding the pathogenesis of infections caused by these two emerging fungal pathogens.

Fragilysin as a sheddase: identification of released proteins

D. Kharlampieva[1], V. Manuvera[1], O. Podgorny[1,2], E. Grafskaia[1,3], S. Kovalchuk[1,4], O. Pobeguts[1], I. Altukhov[3], D. Alexeev[1,3], V. Lazarev[1,3]
[1]Scientific Research Institute of Physical-Chemical Medicine, Federal Medical and Biological Agency, 119435 Malaya Pirogovskaya str. 1a, [2]Koltzov Institute of Developmental Biology of the Russian Academy of Sciences, 119334 Vavilov str. 26, Moscow, [3]Moscow Institute of Physics and Technology (State University), 141700 Institutskiy per. 9, Dolgoprudny, [4]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, 117997 Miklukho-Maklaya str., 16/10, Moscow, Russian Federation

Fragilysin (BFT) is a metalloprotease that is secreted by enterotoxigenic *Bacteroides fragilis*. There are three closely related fragilysin isoforms of identical length (BFT-1, -2, -3). In our study we have obtained recombinant BFT-1, -2, -3 in heterological system of *E. coli*. All the recombinant protein samples had biological activity when tested on HT-29 cells. We observed cell rounding and revealed E-cadherin cleavage after HT-29 cells treatment with fragilysin isoforms. We hypothesized that E-cadherin is a substrate for fragilysin. Nevertheless, all the recombinant fragilysins did not cleave recombinant E-cadherin obtained in *E. coli* and in Expi293 cells.

For identification of potential fragilysin substrate on cell surface we used LC-MS analysis of cultural medium after HT-29 cells treatment with BFT-2. We have identified 791 proteins by ProteinPilot software v 4.5 (833 proteins by Mascot search engine v2.2.07) in the cultural medium of HT-29 cells after BFT-2 treatment, compared to 552 proteins (636 by Mascot) in the control medium. Analysis of proteins released after BFT-2 teatment showed presence of several membrane proteins. Among them there are cell adhesion proteins (members of cadherin superfamily), membrane receptors, including ones involved in regulation of cell contact and adhesion, growth control, tumor invasion and metastasis. Beyond that, there were proteins with functions that are still unknown.

Keywords: *Bacteroides fragilis*, fragilysin, metalloproteinase.

From monomer to tetramer: crystal structures of related restriction endonucleases AgeI and BsaWI

G. Tamulaitiene, V. Jovaisaite, M. Rutkauskas, G. Tamulaitis, V. Siksnys
BNSTS, Vilnius University Institute of Biotechnology, Vilnius, Lithuania

Type II restriction endonucleases recognize short 4–8 bp nucleotide sequences and cleave phosphodiester bonds within or close to their target site. Due to their high specificity restriction endonucleases became invaluable molecular tools in genetic engineering and attractive models for studying protein-DNA interactions. Structural and bioinformatics studies revealed that group of restriction endonucleases, which share CCGG motif within their target sites, is evolutionary related. Seven crystal structures of restriction endonucleases, recognizing five variants of the CCGG containing were solved and structure comparison revealed that all these enzymes have a similar fold and CCGG recognition determinants. On the other hand, the DNA cleavage mechanisms of this small family represent the variety of the restriction endonucleases: they are active as dimers or tetramers, require the binding of one, two or three DNA targets for their optimal activity.

Here, we present crystal structures of two new members of this family AgeI (recognition sequence ACCGGT) and BsaWI (WCCGGW, W stands for A or T). These enzymes are composed of two domains: the N-terminal helical domain and the C-terminal catalytic domain. Despite the low sequence similarity (~15% identical aa), the domain structures of AgeI and BsawI are very similar. However, the relative position of the domains within the AgeI and BsaWI differs and results in differences of DNA binding and cleavage mechanisms. The N-terminal domain of AgeI is folded over the C-terminal domain and AgeI is a monomer, which dimerises only upon binding to the symmetric DNA target. Differently, the N-terminal domain of BsaWI is folded onto the C-terminal domain of the other BsaWI subunit, thus making a tight dimer. Moreover, the BsaWI dimers form tetramers through the contacts by the C-terminal domains. The BsaWI tetramer binds and cleaves two DNA targets. Interestingly, at high protein concentrations the BsaWI dimers can form inactive networks of proteins by the C-terminal domains' contacts with the different dimers.

Functional characterization of a thrombospondin structural repeat containing rhoptry protein from *Plasmodium falciparum* merozoites

F. A. Siddiqui[1], C. Chitnis[2]
[1]ICGEB, New Delhi, International Centre for Genetic Engineering and Biotechnology, Delhi, India, [2]Department of Parasitology and Mycology, Institut Pasteur, Paris, France

Plasmodium falciparum invades a variety of host cells as it completes its complex life cycle in humans and mosquitoes. Host cell invasion requires multiple molecular interactions between host receptors and parasite ligands. A family of parasite proteins that contains the conserved thrombospondin structural repeat motif (TSR) has been implicated in receptor binding during the invasion of both hepatocytes and erythrocytes. In this study we have characterized the functional role of a TSR containing blood stage protein referred to as *P. falciparum* thrombospondin related apical merozoite protein (PfTRAMP). Both native and recombinant PfTRAMP bind normal human erythrocytes as well as erythrocytes treated with neuraminidase, trypsin or chymotrypsin suggesting that it binds a novel host receptor to mediate erythrocyte invasion. PfTRAMP is localized in the rhoptry bulb and is secreted during invasion. Adhesion of released microneme protein EBA-175 with glycophorin A (gly A), its receptor on erythrocytes, provides the signal that triggers release of PfTRAMP from the rhoptries. Purified rabbit antibodies against PfTRAMP blocked erythrocyte invasion by *P. falciparum* in growth inhibition assays suggesting that PfTRAMP plays an important functional role during erythrocyte invasion. Combination of antibodies against PfTRAMP with antibodies against microneme protein EBA175 provides an additive inhibitory effect against invasion. These observations suggest that targeting multiple conserved parasite ligands involved in different steps of the invasion process may provide an effective strategy for the development of vaccines against blood stage malaria parasites.

Functions of regulatory proteins encoded by the German cockroach densovirus: studying by transgenic *Drosophila melanogaster* model system and yeast two-hybrid technique

E. Martynova[1], T. Kapelinskaya[2], D. Mukha[3], Laboratory of the Genetic Bases of Biodiversity

[1]Laboratory of Genetic Bases of Biodiversity, [2]Laboratoty of the Genetic Bases of Biodiversity, Vavilov Institute of General Genetics, [3]Laboratory of Genetic Bases of Biodiversity, Vavilov Institute of General genetics RAS, Moscow, Russian Federation

Densovirus of German cockroach, BgDV1, belongs to a group of densoviruses that are insect infecting parvoviruses (Parvoviridae family, Densovirinae subfamily).

BgDV1 possess three regulatory proteins: NS1, NS2, and NS3, which are expressed during the virus productive infection. There exists significant basis to speculate that densovirus regulatory proteins play pivotal role in many processes of viral pathogenesis. Functional role of NS1 may be predicted based on the comparison with proteins of vertebrate parvoviruses and includes replication initiation, genome transcription and encapsidation regulation; the functional role of the NS2 and NS3 remains completely unknown and we predict it only by the comparison with protein databases.

In order to shed light onto the functions of BgDV1 NS proteins and to study their potential cytopathological effects, we aimed at developing a new model system simulating the virus host organism and based on a set of transgenic *Drosophila melanogaster* strains. Three of them contain in their genome NS1, NS2, and NS3 genes and are thus expressing one of the NS proteins under the control of GAL4-UAS system. Two other strains contain regions of two BgDV1 promoters allowing for the investigation of the NS impact on their activity. The model system can be further supplemented by additional strains expressing other virus proteins or containing the whole BgDV1 genome for the purposes of testing virus NS functions.

Utilizing the *Drosophila* model system developed we demonstrated that the expression of NS3 alone can cause the pathological effects. Namely, the flies expressing NS3 in all tissues of an adult organism showed slower development, extremely low eclosion rate, and decreased fertility if compared with the corresponding F1 progeny expressing NS1 or NS2 proteins. The highest mortality was observed during the pupae stage. We speculate that NS3 protein ability to induce the pathological effects can be mediated by its ability to transactivate the host cell promoters.

To further test this hypothesis we utilized the GAL4-based yeast two-hybrid system and when testing only one plasmid encoding GAL4 DNA-binding domain fused with one of the NS1, NS2, or NS3 proteins to restore potential transcription activator domain, we showed that NS3 protein only was able to induce the transcription of reporter gene.

Using the two-hybrid system we also studied the ability of BgDV1 proteins to interact with each other. We showed that NS2 protein is able to interact with itself forming homodimers. This ability may be rendered by the coiled-coil domain we bioinformatically predicted in the protein.

Keywords: densovirus pathology, protein interactions, transcription regulation.

G4-DNA inhibitors of HIV entry

A. M. Varizhuk[1,2], M. M. Prokofjeva[2], V. Tsvetkov[1], V. S. Prassolov[2], S. N. Mikhailov[2], G. E. Pozmogova[1]

[1]Institute for Physical-Chemical Medicine, [2]Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

We report here new anti-HIV DNA aptamers that inhibit an attachment step of the viral entry pathway. Their supposed mechanism of action involves interaction with the HIV envelop glycoproteins gp120 on the surface of virions, which prevents gp120 from binding CD4 receptors on the cellular membrane. The new DNA aptamers are monomolecular G-quadruplexes (GQs). Multiple studies of the last decade confirm anti-HIV activity of various GQs targeted against gp120, HIV-integrase or both. However, all known active structures are intermolecular GQs, and their potential folding variability (ambiguity) is an obvious disadvantage. Monomolecular structures are easier to handle and refold correctly after denaturation. The advantages of monomolecular GQs are generally acknowledged, therefore, certain attempts have been made, for instance, to link covalently the strands of tetramolecular aptamers to gp120. We report and compare for the first time several active monomolecular GQs, both natural and chemically-modified (thiophosphoryl), and discuss the impact of a particular folding type (antiparallel and parallel) on GQ inhibitory activity. Four-tetrad parallel native and various thio-modified GQs appear to be efficient HIV entry inhibitors (IC_{50} in the nanomolar range).

Our results suggest that a number of monomolecular GQs could be used in the development of new anti-HIV therapeutics or microbicides.

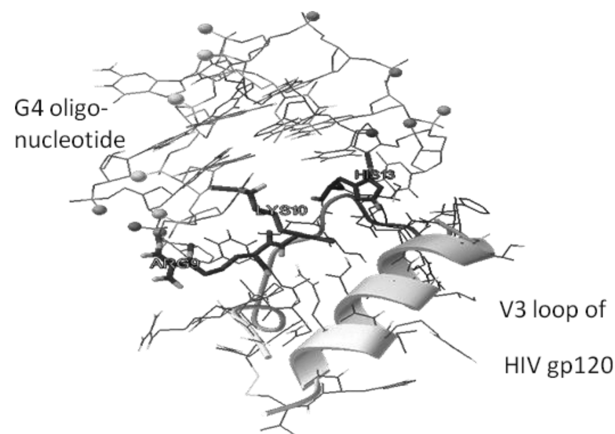

Fig. 1. Model, representing possible interaction of the gp120 V3 loop and the thiophosphoryl-DNA GQ (thio-GGTTGGTGTGGTTGG, IC_{50} about 70 nM).

Genome-wide analysis identifies gain and loss/change of function within the small multigenic insecticidal Albumin 1 family of *Medicago truncatula*

P. Da Silva[1], L. Karaki[1], Y. Rahbe[2], C. Royer[3]
[1]INSA Lyon, [2]INRA, Villeurbanne, France, [3]SPE, INRA, Villeurbanne, France

Background: Albumin 1b peptides are small disulfide-knotted insecticidal peptides. To date, their diversity among the Fabaceae has been essentially investigated through biochemical and PCR-based approaches. The availability of high-quality genomic resources for the model species *Medicago truncatula* (*Mtr*) allowed for a genomic analysis of this protein family aimed at (i) deciphering the evolutionary history of this legume-specific protein family and (ii) exploring the genomic biodiversity within this species for novel bioactive molecules.
Results: Investigating the *Mtr* genome revealed a remarkable and hitherto unique expansion, mainly through tandem duplications, of A1 genes retaining nearly all of the canonical structure at both gene and protein levels. Phylogenetic analysis resolved six clades among the 53 homologous unigenes detected, and revealed that the ancestral molecule was most probably the insecticidal one giving rise to, among others, a clade of short disulfide-bonded peptides, non-insecticidal and involved in root nodule signaling (A1b-nodulins). Expression meta-analysis revealed many silent genes and a wide tissue distribution of the A1 transcripts/peptides within plant organs. *Mtr* did not use the original peptide as a form of seed insecticidal defense, but it has given rise to two other clades expressing derived insecticidal function in roots/nodules. Evolutionary rate analyses highlighted branches and sites with positive selection signatures, including two sites shown to be critical for insecticidal activity (Da Silva *et al. JBC* 2010). Seven peptides were chemically synthesized and folded *in vitro*, then assayed for their biological activity. Among these, AG41 (*aka MtrA1013* isoform, encoded by the orphan TA24778 contig.), showed an unexpectedly high insecticidal activity.
Conclusion: Our study highlights the unique burst of diversity of this peptide family within the Trifoliae clade compared to the other taxa for which full-genomes are available: no A1 member in *Lotus* and only a few in soybean and in *Cajanus*. Such expansion is reminiscent of the situation described for other disulfide-rich peptide families (NCR) discovered within the same species.

WED-374
Getting an insight into the antibacterial activity of the plant derived alkaloid (-)-roemerine against *E. coli* cells

N. Budeyri-Gokgoz[1], K. Wozny[2], D. Kazan[1], B. Sariyar Akbulut[1]
[1]Department of Bioengineering, Marmara University, Istanbul, Turkey, [2]Biochemiezentrum Heidelberg, University of Heidelberg, Heidelberg, Germany

Seeking new antibacterials that weaken bacterial resistance mechanism(s) is one of the remedies to counteract increasing antibiotic resistance. Plant-derived alkaloids are in the limelight for screening potential drug candidates due to their substantial biological activities that includes antibacterial, antifungal, antimalarial and anti-HIV activities. Unfortunately, to a large extent different multidrug resistance pumps reduce their effects. Hence it is important to identify their targets in designing new molecules. (-)-Roemerine is an alkaloid synthesized by several plant families possessing antimicrobial activity. Yet its mechanism of action of this alkaloid remains unclear. To this end, the effect of this alkaloid has been investigated using a proteomics approach. Upon treatment with 100 microgram/ml (−)−roemerine, we have identified 15 differentially expressed proteins in *E. coli* TB1 cells. 9 of these proteins were down-regulated whereas 6 were up-regulated. Among the up-regulated proteins were proteins involved in cell adhesion, outer membrane component, phosphoenolpyruvate-dependent sugar phosphotransferase system, bacteriosin transport, amino acid transport and cell redox homeostatis. The down-regulated proteins were involved in carbohydrate transport, asparagine metabolic process, protein biosynthesis and amino acid biosynthesis. These results give clues on how the bacterial defense mechanism becomes ineffective. This work has been supported by TUBITAK-MAG Project with the number 113M052.
Keywords: (-)-roemerine, *E. coli*, proteomics.

WED-375
Gingipains, cystein proteases produced by *Porphyromonas gingivalis*, disregulate the system controlling activity of kallikreins

K. Paza[1], K. Falkowski[1], A. Sitarska[1], I. B. Thogersen[2], J. J. Enghild[2], J. Potempa[1,3], T. Kantyka[1]
[1]Department of Microbiology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland, [2]Department of Molecular Biology, Center for Insoluble Protein Structures (inSPIN) and Interdisciplinary Nanoscience Center (iNANO), Aarhus University, Aarhus, Denmark, [3]Department of Periodontics, Endodontics and Dental Hygiene, University of Louisville Dental School, Louisville, KY, USA

Porphyromonas gingivalis is the main etiological agent of periodontitis, also implicated in the development of rheumatoid artritis and aspiration pneumonia. The latter life-threatening condition could be caused by inhalation of bacteria into respiratory system by accidental aspiration of saliva or during medical procedures. Although the importance of *P. gingivalis* in development of disease is well documented, the exact mechanism still remains elusive. Animal studies showed massive destruction of lung tissue, what may suggests upregulated activity of proteases responsible for degradation of extracellular matrix proteins. One of the largest group of such enzymes is kallikrein-related protease family (KLKs). Due to the fact that their action is tightly controlled by production as inactive zymogens and expression of specific protein inhibitors from SPINK (serine protease inhibitor Kazal-type) family, dysregulation of this control systems may lead to excessive proteolytic activity within tissue. The aim of presented study was to verify if gingipains, main extracellular proteases produced by the pathogen, could activate proforms of KLKs on one hand, and degrade their inhibitors on the other. For that purpose we created and developed a novel system based on soluble proteolytically-resistant carrier protein with exposed amino acid sequence representing cleavage site responsible for activation of KLKs. Moreover, we found out that gingipains are able to degrade SPINK6 and domens of SPINK5 leading to their inactivation.

We conclude that ability of gingipains to activate proKLKs together with hydrolysis of SPINK inhibitors may in part explain massive degradation of tissue leading to severe impairment of host homeostasis and defense systems enabling spreading and progression of disease.
Keywords: aspiration pneumonia, gingipains, kallikreins.

Hepcidin is a war tool between uropathogenic *E. coli* and renal host cell during urinary tract infection

D. Houamel[1], N. Ducrot[1], T. Lefebvre[1], B. Moulouel[1], M.-A. Sari[2], O. Bouvet[3], E. Denamur[3], H. Puy[4], L. Gouya[1], C. Beaumont[1], Z. Karim[1]
[1]Team L. Gouya/H. Puy: Heme, Iron and Inflammatory Diseases, INSERM U1149 - Center for Research on Inflammation "CRI", [2]UMR 8601CNRS, Université Paris Descartes, [3]Infection, Antimicrobiens, Modélisation, Evolution (IAME), [4]Team L. Gouya/H. Puy: Heme, Iron and Inflammatory Diseases, UMR 1137 INSERM, Universités Paris Diderot, Paris, France

Introduction: Urinary tract infection (UTI) is mainly due to uropathogenic *Escherichia coli* (UPEC), which have the ability to adapt to iron limitation, acidic pH of urine and strong host defenses of the urinary tract. Hepcidin is a 25 amino acid peptide that regulates iron homeostasis but it has also been shown to exhibit an antimicrobial activity. The liver is the major source of bloodstream hepcidin although this peptide was recently found to be expressed in several epithelial barriers that are frequently confronted to pathogen infection, including renal tubules. We have recently shown that hepcidin controls iron excretion by regulating its reabsorption in distal nephron (B. Moulouel et al., kidney Int, 2013). However, whether hepcidin plays a role in the protection against UTI, has never been investigated.

Methods: Two different bacterial strains (CFT073 and K12) were tested and the impact of their infection was analyzed in WT and hepcidin Knockout (Hepc−/−) mice. We measured renal cytokines levels by multiplex ELISA and Bacterial growth with a Tecan Infinite reader. Structural architecture of CFT073 was analyzed by electronic microscopy. The expression of hepcidin in liver and kidney were estimated by RT-qPCR. BMP/SMAD and IL6/STAT3 signaling pathways that control hepcidin expression were investigated in mice, and in renal mIMCD-3-and hepatic HepG2-infected cells.

Results: (i) Using microdissected renal tubules, we showed that hepcidin is preferentially expressed in distal nephron tubules. (ii) Significant UPEC infection was observed in the Hepc−/− kidneys compared to control. However, pre-treatment of WT mice or of CFT073 with hepcidin synthetic peptide, significantly blocked the UTI. (iii) Incubation of CFT073 with Hepcidin synthetic peptide inhibited considerably their growth and disturbed their cell envelope with obvious cell lysis. (iv) In Hepc−/− kidneys, iron was accumulated in the medulla, both renal atp4a and atp12a pumps were repressed and urine alkalinized. (v) In infected Hepc−/−, excess iron was widely consumed by CFT073, and the inflammatory response was significantly attenuated. (vi) CFT073 significantly repressed renal hepcidin despite large increase of TLR4- and IL6-signaling. Infection of mIMCD-3 and HepG2 cells with fixed CFT073, also inhibit hepcidin expression. This effect was mediated via reduction of SMAD-signaling both in mice and cell lines.

Conclusions: These data strongly suggest that renal hepcidin may be one of the targets that UPEC trigger to become highly pathogenic and evade renal host defenses during UTI.

Higher parasite burden in asymptomatic individuals in endemic areas of Visceral Leishmaniasis

A. K. Singh, A. Chourasia, M. Rai, S. Sundar
Department of Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Background: In an area endemic for Visceral Leishmaniasis (VL), subclinical or asymptomatic infections play a crucial role in progression of disease. We determined the parasite load by quantitative PCR (qPCR) in healthy infected population living in an area endemic for Visceral Leishmaniasis. We enrolled 13366 persons from 11 villages of highly endemic region of Bihar, India.

Materials and Methods: We conducted two sero-surveys by rK-39 ELISA and DAT with 1 year time interval for identification of incident infected healthy (Asymptomatic) individuals. Parasite load by using TaqMan based qPCR were done on peripheral blood using kDNA specific primers and probe on these sero-converted individuals and its matched control populations. Individuals having parasite load greater than 1 genome/ml of blood was considered as positive by qPCR. Follow-up visit to the homes of each individual were made to monitor the disease conversion in this cohort.

Results: Between seroconversion and qPCR were accessed by kappa value. Total 235 persons were converted their serology within 12 month intervals. Of these 235 sero-converters 105 (44.6%) individuals were also positive by qPCR. However, similar number of controls groups (87/ 237, 37%) also showed positivity by qPCR. The agreement between sero-converter and qPCR was poor (k = 0.12). And among all individuals only one was progress to disease.

Conclusion: So there is no major difference in qPCR result between sero-negatives and sero-converters and among all individuals only one were converted into disease that has parasite load 146 parasite genome/ml of blood. These findings suggest the usefulness of parasite load in healthy individuals living in an endemic area of Bihar and contribute as a good tool for VL elimination programme.

Host-pathogen interrelations in human corneal infections difficult to diagnose and treat

M. Padzik[1], L. Chomicz[1], J. P. Szaflik[2], A. Lass[3], J. Szaflik[2]
[1]Department of Medical Biology, [2]Department of Ophthalmology, Medical University of Warsaw, Warsaw, [3]Department of Tropical Parasitology, Medical University of Gdansk, Gdynia, Poland

Several species of the genus *Acanthamoeba* that complete their life cycles in natural environments of various parts of the world including Poland can infect man and exist as pathogens. Humans are exposed to both, the non-pathogenic and pathogenic strains of *Acanthamoeba*. Some strains of the amphizoic organisms present a serious risk to human health as causative agents of a vision-threatening corneal infection, *Acanthamoeba* keratitis that develops particularly in contact lens wearers. In the pathogenesis, extracellular proteases, among others, are host tissue degradation determinants in *Acanthamoeba* infections. The amoebae may act as carriers for more than 20 bacterial species pathogenic for humans from genera *Legionella, Pseudomonas, Mycobacterium, Escherichia, Listeria* that are able not only to survive but even proliferate within the amoebae, thus play an important role in

© 2014 The Authors. FEBS Journal © 2014 FEBS

the dispersion of potentially pathogenic microorganisms. Recently, it is considered that vision-threatening *Acanthamoeba* keratitis emerging disease in more than 85% is linked with isolates of the T4 genotype. The disease is difficult to treat due to misdiagnosis as a viral infection with *Herpes simplex*, fungal with *Fusarium spp*. or keratitis caused by *Pseudomonas aeruginosa*. Here, we present complicated, difficult to diagnose and treat incidences of keratitis suspected of fungal, bacterial and/or amoebic aetiology in three Polish patients.

We analyzed selected data in terms of usefulness of *in vivo* and *in vitro* investigations for the diagnosis and therapeutic management. The severe pain, epithelial defects and reduced visual acuity appeared in affected eyes of all patients. Active epithelial inflammations and hyper reflective tissue in corneal ulcer were revealed by slit-lamp. A diagnosis of corneal infection in terms of mixed bacterial, fungal and A*canthamoeba* or amoebic only aetiology has been made by microbiological investigations. Use of corneal scrabs cultured *in vitro* and PCR techniques allowed to detect mixed infections of eye with *Pseudomonas aeruginosa* and *Acanthamoeba sp*. in one patient and identify mixed corneal infection with yest-like *Candida sp*. and *Acanthamoeba* sp. in the other one. Hyper reflective objects visualized by *in vivo* confocal microscope in the affected eye of third patient have determined by *in vitro* cultures as severe amoebic infection. Complex aetiology, late detection of corneal infections, factors influencing diagnostic and therapeutic difficulties in the cases analyzed are discussed.

Keywords: bacterial, fungal, amoebic keratitis, in vitro cultures, genotype determination.

Host stress hormone noradrenaline interferes with *Pseudomonas aeruginosa* social behaviors in an iron dependent manner

A. M. Holban[1,2], S. Heeb[1], M. C. Chifiriuc[3], P. Williams[1], V. Lazar[2]
[1]*Centre for Biomolecular Sciences, University of Nottingham, Nottingham, UK,* [2]*Department of Microbiology and Immunology,* [3]*Microbiology and Immunology, University of Bucharest, Bucharest, Romania*

Bacteria are able to recognize and respond to host-related signaling compounds, as hormones, by mechanisms that are widely unknown. Even if there is a great interest on deciphering pathogens-host communication during infection, very few data regarding the role of catecholamine stress hormones on the opportunistic pathogen *Pseudomonas aeruginosa* can be found. In this study we investigated the impact of the neurohormone Noradrenaline (NA) on the physiology and social behavior of this pathogen, using both phenotypic and molecular approaches. In order to best mimic the host internal medium, all experiments were performed in RPMI 1640 cell culture medium, supplemented or not with 10% serum. The viable cell count results proved that NA is able to significantly promote growth only in serum-containing minimal medium, displaying a toxic effect in serum-free minimal medium because of its iron binding affinities in different circumstances, as revealed by ICP-MS (Inductively Coupled Plasma Mass Spectrometry) analysis. The iron-uptake mechanism was also incriminated for the NA effects on Quorum Sensing (QS) controlled social phenotypes as swarming motility, pyoverdine and pyocyanine production and also biofilm formation. NA has proved to stimulate *P. aeruginosa* growth by an endogenous siderophore-independent mechanism, supporting and promoting the growth of a siderophore deletion mutant (*P. aeruginosa PAOI ΔpvdD/pchEF*), by acting itself as an exogenous pseudosiderophore. Nevertheless, our molecular data demonstrate that NA interferes with bacterial ferrienterobactin iron uptake Two Component Systems Pir and Pfe, modulating *pirA* and *pfeA* gene expression in *P. aeruginosa*. None of the observed phenotypes could be totally reversed by using alpha- and beta-adrenergic antagonists: phentolamine and propranolol. Our results demonstrate that iron uptake modulation represents a key element in NA signaling in *P. aeruginosa*, and supports the idea that a special adrenergic receptor is not absolutely required for NA induced response in bacteria.

Keywords: bacterial behavior, host-pathogens communication, stress hormones.

Superficial cutaneous fungal infections are caused by yeasts (e.g. *Candida* species and *Malassezia* species), dermatophytes, and non–dermatophyte species of filamentous fungi /dermatomycoses. They are among the most common infections in the world and dermatophytes are the major causative agents. However, despite enormous advances in the treatment of these infections in recent years, nail infections (onychomycosis) are difficult to eradicate, with recurrence reported in up to 10 to 53% of cases. Similarly, in some cases, chronic mucocutaneous candidiasis, which is consists of persistent and recurrent infections of the mucous membranes, skin, and nails, along with a variety of other manifestations. A current challenge for health care providers is to prevent the recurrence of these infections after a successful treatment. Therefore, the search for new, more effective therapies continues to be pursued. Topical therapy has been recently proposed to treat dermatophytosis and onychomycosis as well as other nail disturbances without subsequent occurrence of relapses and re–infections. Interestingly, the ointments of the *Piper betle* L., leaves extract have been used for the treatment of various skin diseases. Our *in vitro* and *in vivo* as well as toxicological data indicates that hydroxychavicol would be a promising antifungal agent of topical use for the treatment of cutaneous candidiasis and dermatophytosis (tinea corporis) because it is highly effective in achieving mycological eradication without subsequent occurrence of relapses along with its significant cutaneous retention capacity (prophylactic efficacy) and low toxicity. The mechanisms of action of hydroxychavicol appear to originate from the inhibition of ergosterol biosynthesis and the disruption of membrane integrity.

Keywords: fungicidal, Candida biofilm, prophylaxis, dermatophytosis, relapse, cutaneous candidiasis.

Identification of an exported Heat Shock Protein 70 in *Plasmodium falciparum*

M. Grover, S. Chaubey, U. Tatu
Biochemistry, Indian Institute of Science, Bangalore, India

With the emerging evidence that physiological state of the parasite is different in culture than in patient, we initiated clinical proteomics studies in malaria few years back with an idea to identify proteins which are significantly/specifically expressed in the real disease scenario. Being a chaperone biology group we were excited to identify an Hsp70 family protein, PfHsp70-x, to be uniquely present in the clinical stages. Adding to our surprise

© 2014 The Authors. FEBS Journal © 2014 FEBS

and its clinical relevance, we found that this gene was a pseudogene in 3D7 strain of *Plasmodium falciparum* while a functional counterpart was present in all other strains. Therefore, we believed PfHsp70-x to be involved in some biochemical pathway which is operational exclusively in the actual disease condition.

Ongoing initiatives involving genome sequencing brought a twist in the field when PlasmoDB released its updated version with re-annotated sequence of many genes. Original annotation of PfHsp70-x described it as a gene with one intron which upon getting spliced resulted in the formation of a pre-mature stop codon. The SNP present in PfHsp70-x, which was responsible for it to be a pseudogene, was now found to be a genome sequencing error. Thus, 3D7 also had A in place of T like other strains of *P. falciparum*. This generated an ATG codon and resulted in the formation of an alternate start site. The re-annotated coding sequence of PfHsp70-x now began within the predicted intron sequence and encoded the entire ORF. The new PfHsp70-x sequence lacked intron and encoded for a full length Hsp70 having sequence conservation with other PfHsp70s. Interestingly, the additional sequence added from the intron at the N-terminus represented an ER signal peptide and thus it could enter the secretory pathway.

Sub-cellular fractionation of infected erythrocytes revealed that PfHsp70-x is present in the parasitophorous vacuole (PV) as well as the erythrocyte cytosol. IFA further supported this finding as PfHsp70-x showed punctate distribution in the erythrocyte cytosol and around the PV apart from signal within the parasite. However, only a small fraction of PfHsp70-x was exported beyond the parasitophorous vacuolar membrane (PVM) into the erythrocyte cytosol, suggesting its potential involvement in processes on either side of PVM. A major population of the exported PfHsp70-x showed overlap with MAHRP1, a Maurer's cleft marker, in the erythrocyte periphery. This suggested that PfHsp70-x associates with Maurer's clefts and might be involved in protein sorting and trafficking activities.

Hsp70s generally work in association with Hsp40s. However, until recently only PfHsp40s were known to get exported. Our study provides answer to the long standing question of lack of an exported Hsp70 and thereby fills an important gap in malaria chaperone biology.

WED-382
Identification of potential periodontal pathogens based on genetic specificity

Y.-J. Song, J.-H. Jang, H. S. Son
Graduate School of Public Health, Seoul National University, Seoul, Korea

Background: Periodontal disease is a destructive, inflammatory disease of the supportive structures of the teeth and oral bacteria and their products are the causes of tissue destruction. So far about 600 species of oral microorganisms have been identified. Among them, only about 10 species were identified as causative agents of periodontal diseases and these are mainly anaerobic, gram-negative bacteria. Periodontal pathogen should possess virulence factors relevant to the inflammation on periodontal tissue. In this study, it compares the degree of genetic similarity with all of the species of oral microorganisms using the destructive virulence factors as genetic marker.

Observations: The genetic sequences of 11 of destructive virulence factors and 653 species of oral microorganisms were retrieved from GenBank (http://www.ncbi.nlm.nih.gov/genbank/) and data for constructing database were parsed with the JAVA programming language. Using 'Pair-wise Alignment', between the each of 5 of major periodontal pathogens the degree of genetic similarity was compared and the minimum value of the results was 69.48% as a thresholds. The degree of genetic similarity between the each of destructive virulence factors and each oral microbial was also compared and analyzed. With the result data, we created a phylogenetic tree using the ML method. Among the results it should be noted that 14 species of oral microorganisms have been found as potential pathogens of periodontal disease. These are consisted of estimated periodontal pathogen in other studies and normal oral microflora of health population. Their own pathogenecity is very low but they are opportunistic pathogens. When the balance of the normal flora is broken in the mouth and abnormal host immune system occurs, their pathogenecity will become very strong.

Conclusion: The results of this study revealed some potential periodontal pathogens among species, whose relevance with periodontal disease was previously remained uncertain. And this will provide basic information for accurate diagnosis and identification of causal relationships about periodontal disease. It is hoped that this research will be further developed for the practical use.

Keywords: periodontal pathogens.

In vitro characteristics of tobravirus nonstructural 16K protein

S. Makarova[1], M. Nartova[1], J. Shaw[2], A. Love[2], M. Taliansky[2], N. Kalinina[1]
[1]*Faculty of Biology, Lomonosov Moscow State University, Moscow, Russian Federation,* [2]*The James Hutton Institute, Dundee, UK*

Using computer prediction and circular dichroism, we demonstrated that the nonstructural 16K protein of tobacco rattle virus (TRV, tobravirus), a suppressor of post-transcriptional gene silencing, consists of two structural parts: an ordered N-terminal region containing two putative α-structure "zinc fingers", and a fully disordered C-terminal region with two independent bipartite nuclear localization signals (NLSs) (Ghazala et al., 2008). The protein possesses RNA-binding and oligomerization activities. We have shown that the protein has at least three RNA-binding sites, interacts with small RNAs and binds to single-stranded sRNAs more efficiently than to double-stranded (ds) sRNAs. We identified plant coilin as a major cellular partner of the viral 16K protein. Coilin acts as the structural scaffolding protein of Cajal bodies (CBs), which are dynamic subnuclear compartments. According to our results (Shaw et al., 2014) coilin/CB deficient *Nicotiana benthamiana* RNAi knockdown plants have intensified TRV infection, resulting in persistent severe systemic symptoms. We have demonstrated that the TRV 16K protein and plant coilin directly interact *in vitro* and have mapped the sites of the interaction using Far-Western assays and a set of deletion and point mutant proteins. The 16K protein is a multifunctional protein that participates in several biological activities *in vivo*. The *in vitro* properties could reflect many roles of the 16K protein in the infection cycle. This work was supported by RFBR, the grant 13-04-01467a.

WED-385
In vivo toxicity studies of superparamagnetic iron oxide nanoparticles in a silica matrix

S. L. Iconaru[1,2], A. M. Prodan[3], C. S. Ciobanu[1], M. Motelica-Heino[2], D. Predoi[1]
[1]Laboratory of Multifunctional Materials and Structures, National Institute of Materials Physics, Magurele, Romania, [2]ISTO, University Orleans, Orleans, France, [3]Emergency Hospital Floreasca, Bucharest, Romania

The goal of this study was to evaluate the *in vivo* toxicity of superparamagnetic iron oxide nanoparticles in silica matrix (IOSi-NPs) after intratracheal instillation in rats.

Superparamagnetic iron oxide nanoparticles in silica matrix were obtained by dropping into silica xerogel composite the mixture of ferrous chloride tetrahydrate and ferric chloride hexahydrate. The EDAX analysis indicated that the embedded particles were iron oxide. The particle size of iron oxide nanoparticles in silica matrix calculated from X-ray diffraction (XRD) analysis was estimated at around 10 nm. The average size deduced from transmission electron microscopy (TEM) was 12.2 ± 0.7 nm in good agreement with XRD analysis.

Histological evaluation of the nanoparticles effects on rat tissues after a single intratracheal instillation of IOSi-NPs in male Brown Norway rats at various concentrations were realized to clarify the controversial toxicity of nanoparticles.

The lung examination at 24 h after the intratracheal instillation with 0.5 mg/kg of IOSi-NPs the lung parenchyma of the rats showed a preserved alveolar architecture with rare macrophages in the alveolar septa. The pathological micrographs of lung in rats after the intratracheal instillation with 0.5 mg/kg dose of IOSi-NPs show that the lung has preserved the architecture of the control specimen. After the intratracheal instillation of the rats with a 2.5 mg/kg dose of IOSi-NPs, the lung parenchyma of the rats showed preserved alveolar architecture with rare macrophages in the alveolar septa, discreet anisokaryosis and anisochromia of type II pneumocytes with rare nucleoli. Lung parenchyma of the specimen after intratracheal instillation of IOSi-NPs in rats at concentration of 5 mg/kg showed preserved alveolar architecture with macrophages in the alveolar septa, discreet anisokaryosis and anisochromia of type II pneumocytes, with chromocenters and nucleoli. In the lung parenchyma it is also observed focal ectatic capillaries in the alveolar septa.

Our data suggest that IOSi-NPs are not capable of translocating from the lung to the liver via the circulation at all the tested concentrations. The histopathological appearance of the liver after intratracheal instillation of IOSi-NPs in rats show that the different pathological alterations such as enlargement of hepatocytes, hydropic degeneration of hepatocytes, nuclear enlargement and dilatation of the sinusoids were not presented at concentrations of 0.5, 2.5 and 5 mg/kg.

Keywords: *in vivo* assays, intratracheal instillation, iron oxides-silica matrix.

Increase in white blood cells correlated with plasma water soluble antioxidants in exposed but seronegative HIV individuals found in a segment of Nigerian population

B. O. Ibeh[1], O. Obidoa[2], J. Habu[3]
[1]Medical Biotechnology, National Biotechnology Development Agency, Abuja, [2]Biochemistry, University of Nigeria, Nsukka, [3]Bioresources, National Biotechnology Development Agency, Abuja, Nigeria

Previous work has shown that micronutrient deficiency can cause immune function suppression with a resultant effect on both innate T-cell-mediated immune and adaptive antibody responses, thus altering the balanced host response. Antioxidants could enhance the cytolytic activity of Natural killer cells and increase the amount of Interferon-gamma produced by T cells. Our study thus seeks to investigate the correlation between immune cell responses and the activity of water soluble antioxidants in HIV serodiscordant partners of black origin. Thirty-four (34) serodiscordant heterosexual partners (serodiscordant- seronegative {SSN group} and serodiscordant-seropositive {SSP group}) and 15 seronegative healthy individuals {(SNH group} were recruited for the study. HIV statuses were confirmed using enzyme immuno assay method (immune comb 11) while the total and differential WBC count was assessed by Coulter sysmex haematology analyzer. FACScan flow cytometer was used to measure CD4, CD3 and CD8 cells. Isolation of HIV mRNA was by Nuclisens Magnetic extraction method, and quantification by Nucleic acid sequence- based amplification assay (NASBA). Reduced glutathione and ascorbic acid assays were determined spectrophotometrically. The results showed a significant increase ($P < 0.05$) of total WBC count by 39% in SSN when compared with SSP, similarly, ascorbic acid and glutathione concentration were significantly increased($P < 0.05$) in the SSN by 58.2% and 43.8% respectively. In group B eosinophils and basophil were absent, conversely monocytes were significantly increased ($P < 0.05$) in SSN. FACScan flow cytometric measurement of CD4, CD3 and CD8 cells were also increased in SSN group. The concentration of water soluble antioxidants and total WBC count showed a positive correlation ($P < 0.01$; $r = 0.89$) while mRNA was not detected in SSN. Our study showed for the first time the relationship between water soluble vitamins and immune cells in resistant but HIV exposed individuals of black origin. Since water soluble antioxidants may play a significant role in actively strengthening immune cells to fight against infections especially in HIV disease, it therefore indicates that serodiscordant HIV infection could be used as a model in understanding immunological differences and strengths for effective therapeutic targets.

Keywords: HIV/AIDS, CD4, serodiscordant.

Induction of systemic resistance in tomatoes against soil borne pathogen using indigenous *Bacillus* strains

T. Anjum[1], W. Akram[2]
[1]Agricultural Sciences, [2]Punjab University, Lahore, Pakistan

This study was planned to investigate an ecological safe method to manage soil borne diseases in crops. We used two indigenous *Bacillus* strains including *B. fortis* 162 and *B. subtilis* 174. The bacterial strains were primed with tomato plants and the soil was made sick using active cultures of *Fusarium oxysporum* f. sp. Lycopersici, the causal agent of Fusarium wilt. Both the strains significantly supported plant growth and helped in decreasing soil

© 2014 The Authors. FEBS Journal © 2014 FEBS

borne disease. However, a little variation was observed in this and *B. subtilis* showed more effective results in comparison to the *B. fortis*. The studies were extended to the evaluation of the total phenolics and defence related enzymes in treated plants to have an idea for the physiological changes after defence induction. Overall findings depicts that the tested bacterial strains forced the plant to activate their defence system. In the next step fractions from *B. subtilis* 174 metabolites were investigated for potential ISR (Induced systemic resistance) determinant/s. Intracellular metabolites and cell free culture filtrates of selected bacterium were analyzed for their capability to induce systemic resistance in tomato under greenhouse conditions. In contrast to intra-cellular metabolites, cell free cultural filtrates (CFCF) elicited ISR in tomato plants as they showed significant reduction in disease index. These CFCF were then fractionated by a series of organic solvents and purified. These fractions were then tested for inducing systemic resistance in tomato using test tube bioassay. ISR determinates were found to retain in ethyl acetate fraction that was then subjected to column chromatography and portioned into ten sub-fractions by step wise elution method. GCMS (Gas Chromatography Mass Spectroscopy) analysis of ISR active sub-fraction confirmed the presence of four compounds including Eugenol, 3-methoxy Butylacetate; Pentachloroanilin and Phthalic acid Dimethyl ester. On analysis of ISR activity of these pure compounds in different concentrations, Phthalic acid Dimethyl ester proved as ISR determinant of B. subtilis IAGS174.

Influenza A virus affects the expression of nmda receptor subunits in mice

M. Egorova[1], M. Plotnikova[1], K. Sergey[1], Z. Yana[1], G. Angelica[1], E. Vladimir[1], Z. Vladimir[1], V. Andrey[2]
[1]Research Institute of Influenza, [2]Research Institute of Influenza, St. Petersburg State Polytechnic University, St.-Petersburg, Russian Federation

Influenza is an acute respiratory infection caused by (-)-RNA influenza viruses. Seasonal epidemics of influenza result in about 3–5 million cases of severe illness and up to 0.5 million deaths annually. Among various complications of influenza are neurological. Particularly according to the clinical observations it was suggested that individuals exposed to maternal influenza A virus infection are at increased risk of developing schizophrenia later in life. Since schizophrenia is in part associated with the dysfunction of N-methyl-D-aspartate receptors (NMDARs) and influenza virus infection is among the affecters of NMDARs we evaluated the impact of influenza A virus infection on the expression of mRNAs encoding the NR1, NR2(A-D) and NR3(A-B)) of NMDARs in mice. We analyzed the mRNA levels of NMDAR subunits, in brain of mice, infected with influenza A/WSN/1933 (H1N1) and A/Aichi/2/1968 (H3N2) viruses at 0,2 LD_{50}, on the 1, 3, 5 and 10 days post infection using real-time PCR method. All seven NR mRNAs were detected in brain of mock animals. The infection with influenza A virus led to the changes in the expression levels of NR2A, NR2B, NR2D and NR3B mRNAs. We also evaluated the influence of A/H7N9 virus on the expression of NMDARs. Further we are going to make the more detailed analysis of NMDARs expression on the mRNA and protein levels during influenza A infection in mice, and also to study other genes, that are up- or down-regulated during schizophrenia.

Keywords: Influenza A virus, NMDA receptor, gene expression.

Interaction of *C. perfringens* epsilon toxin with biological and model membranes

M. Manni, J. Sot, F. Goñi
Biochemistry and Molecular Biology, Unidad de Biofisica, Leioa, Spain

Epsilon toxin (ETX) is a powerful toxin produced by strains of *C. perfringens* classified as types B and D, and is responsible for enterotoxemia in animals. ETX belongs to the heptameric β-pore-forming toxin family that includes aerolysin and *C. septicum* alpha toxin. These toxins are characterized by the formation of a pore through the plasma membrane of eukaryotic cells, consisting in a β-barrel of 14 amphipatic β-strands. ETX shows a high specificity for a few cell lines, like Madin-Darby canine kidney (MDCK) the first sensible cell line identified and the most studied one, G-402 (Human Renal Leiomyoblastoma cell line) and mpkCCDc14 (Mouse cortical collecting duct cell line). The molecular mechanism of ETX has been well characterized *in vitro* using MDCK cells. It is known that ETX induces permeabilization to different ions, organelle alterations and vacuolization, it is internalized in cells and colocalizes with endosomes and lysosomes. Moreover pore formation requires binding and heptamerization of the toxin in cholesterol-rich microdomains. Depletion of cholesterol by inhibitors of cholesterol synthesis damage ETX heptamerization, reducing its cytotoxicity. The aim of our project was to establish the role of lipids in the toxicity caused by ETX and the correlation of its activity in model and biological membranes.

In MDCK cells, using cell counting and confocal microscopy, we have seen that the toxin causes cell death mediated by toxin binding to plasma membrane. However little effect is observed in large or giant unilamellar vesicles.

Keywords: cell death, model membranes, toxin.

WED-390
Isolation of immunoglobulin Y from hen egg and determination of its efficiency against *Salmonella* species

E. M. Guler[1], M. Kesmen[1], S. Polat[2], R. Ayas[2], B. Aksu[2], A. S. Yalcin[1]
[1]Medical Biochemistry, [2]Medical Microbiology, Marmara University School of Medicine, Istanbul, Turkey

The World Health Organization recommends not to use the new age antibiotics on animals, plants and aquaculture because of their antimicrobial resistance mechanisms. It further recommends to restrict the use of existing antibiotics. The misuse of antibiotics causes a problem of antibiotic residual in the food chain. It also causes an increase in health problems of individuals, a decrease of effectiveness and reduces low public budgetary. On the other hand, passive immunotherapy that counteracts pathogens helps destroying antimicrobial residual and resistance mechanisms. It can be used even in the presence of infection so it is a good alternative for antibiotic therapy, especially in hazardous periods. In our study we have used a Salmonella-free Ross 308 parent stock. Immunization was achieved using *Salmonella gallinarum, Salmonella pullorum, Salmonella gallinarum* + *Salmonella pullorum* and *Freund's Adjuvant*. Two doses of immunization was given for 21 days. Eggs were collected daily and saved. The amount of total protein was measured by Bradford method. Ammonium sulfate precipitation and dialysis methods were used for IgY purification and proteins were identified by SDS-PAGE. Subsequently in vitro activity of all fractions in inhibiting microbial growth was determined. Especially *Salmonella gallinarum* + *Salmonella pullorum* antibodies were observed to have high activity. In conclusion, we have devel-

© 2014 The Authors. FEBS Journal © 2014 FEBS

oped a method and process whereby egg yolk antibodies can be obtained in a short time and can be produced as specific antibodies against other antigens than *Salmonella*.

Keratins 8 and 18 are required for Listeria invasion of mammalian cells

R. F. Cruz, M. T. Almeida, D. Cabanes, S. Sousa
Molecular Microbiology, IBMC, Porto, Portugal

To promote infection pathogens interfere with crucial host intracellular pathways. In particular, host cytoskeleton components are preferential targets of infecting bacteria. The study of the cell biology of infection provided insights in the way bacteria manipulate the host cytoskeleton and revealed unsuspected functions of cellular proteins, leading to a deeper understanding of eukaryotic basic cellular processes. *Listeria monocytogenes* is a facultative intracellular gram-positive pathogen adapted to thrive in diverse environments. In humans, *Listeria* is capable to cause listeriosis, a pernicious foodborne disease, largely usurping cytoskeleton functions during host cell infection. Keratins are major components of the cytoskeleton of epithelial cells with structural and regulatory functions. Although keratins were reported to be targeted by pathogens, the molecular and functional details behind keratin involvement in bacterial pathogenesis remain largely elusive.

In this work we studied the importance of Keratin 8 (K8) and its preferential binding partner Keratin 18 (K18) in *Listeria monocytogenes* pathogenesis. Our results demonstrate that both K8 and K18, together with actin and cMet, a major *Listeria* receptor, are found enriched in the vicinity of *Listeria* invading HeLa cells. Depletion of K8 and K18 by an RNAi approach revealed that both keratins are required for *Listeria* entry in Hela cells. Likewise, InlB/c-Met-dependent internalization of *Listeria* is found to be impaired in cells depleted for K8 and/or K18. Strikingly, we found that K8/K18 depletion results in the down-regulation of cMet levels and impaired cMet signaling. Additionally, using beads coated with the InlB invasin, we found that actin recruitment precedes K18 enrichment during InlB-mediated internalization in HeLa cells, suggesting that keratins may be relevant in later stages of *Listeria* uptake.

Together our results point out keratins as important players in *Listeria* pathogenesis. The molecular details of their involvement in *Listeria* infection and cMet signaling are under investigation.

Keywords: Infection, Keratins, *Listeria monocytogenes*.

WED-392
Malaria parasite responds to unfolded protein stress using a novel mechanism

S. Chaubey, M. Grover, U. Tatu
Biochemistry, Indian Institute of Science, Bangalore, India

To establish a successful infection, *Plasmodium falciparum* has to competently remodel erythrocytes, its host compartment. The infected erythrocytes harbor several parasite induced membranous structures. Most importantly, pathogenesis related structures termed knobs which impart cytoadherence appear on the cell surface of the infected erythrocytes. In order to do so, the parasite exports 8% of its genome (around 400 proteins) to various destinations in the host cell. In other words, the parasite heavily relies on secretory functions for its pathogenesis. Additionally, this parasite also experiences significant amount of redox stress during its growth in human erythrocytes. As a result, it is predisposed to unfolded protein or endoplasmic reticulum stress during its life cycle.

Eukaryotes possess a fairly conserved mechanism known as unfolded protein response (UPR) to deal with ER-stress which restores the cellular homeostasis. However, when we looked for the UPR components in *P. falciparum*, we found that this parasite completely lacks the canonical UPR machinery. In accordance with that, our biochemical analysis established that malaria parasite indeed fails to mount a response as it was unable to up-regulate ER chaperones or ER associated degradation (ERAD) components when subjected to DTT mediated ER stress. However, an exported chaperone, PfHsp70-x, otherwise exported to erythrocyte cytoplasm, was found to be retained in the ER, increasing the local availability of this BiP homologue upon DTT-stress and thereby could provide a temporary relief. High throughput transcriptomic and proteomic analysis in response to ER stress, revealed a network of AP2 transcription factors and their targets being activated. Interestingly, a set of sexual stage specific genes became up-regulated when the parasites were subjected to DTT mediated ER-stress. Intrigued by this observation, we looked at the ability of ER stressors to induce stage transition by undergoing gametocytogenesis in response to ER-stress. We indeed found that ER-stress results in a greater than 2 fold induction in the numbers of gametocytes formed suggesting that this parasite makes use of a novel strategy of stage transition to cope with ER-stress.

In conclusion, our study not only highlights lack of a canonical UPR pathway in malaria parasite but also suggests that this parasite utilizes stage transition as an alternate means to escape ER stress.

Keywords: Gametocyte, *Plasmodium falciparum*, Unfolded Protein Response.

WED-393
Mapping Rig-I Like Receptors protein partners upon Chinkungunya virus infection

R. Y. Sanchez David, C. Combredet, F. Tangy, A. Komarova
Virology, Institut Pasteur, Paris, France

The host innate immune response to chikungunya virus is type-I interferon dependant. Today, our knowledge on the molecular players recognizing this virus during infection is still a matter of research. It is known that there are two different mechanisms of recognition, one is IPS-1 (Interferon-b Promoter Stimulator 1) dependent and the other is IPS-1 independent (Schilte et al, 2012). We study the IPS-1 dependant pathway of chikungunya virus recognition via the cytosolic Rig-I Like Receptors (RLR): Rig-I, Mda5 and Lgp2. The role of these cytosolic receptors in chikungunya virus detection is currently controversial.

To clarify our knowledge on the mechanisms of action of RIG-I, MDA5 and LGP2 during infection, we have established HEK293 cell lines that express tagged RLRs. These cell lines have been characterized for:

(i) their capacity to overexpress the respective tagged-RLRs, (ii) the capacity to purify tagged RLRs by affinity chromatography of cell lysates, (iii) their efficacy to produce type-I interferon after in vitro transfection of synthetic RNA (iv) the efficiency of chikungunya virus replication in these tagged RLR cells.

Further, our aim will be to map the protein partners of RLRs upon viral infection. For this we will perform affinity purification of tagged-RLRs and mass spectrometry analysis.

The role of RLRs during chikungunya infection has been shown to be essential for controlling virus dissemination and initiating adaptive immunity against other RNA viruses. Thus it is essential to elucidate the protein complexes that are being formed and that are at the origin of this response.

Keywords: chikungunya virus, innate immunity, Rig-I Like Receptors.

MEG-14: an intrinsically disordered protein

D. Orcia[1], J. L. S. Lopes[1], A. P. Araújo[1], B. A. Wallace[2], R. DeMarco[1]
[1]Departamento de Física e Informática, Universidade De São Paulo (USP), São Carlos, Brazil, [2]Institute of Structural and Molecular Biology, University of London, London, UK

MEG-14 is a protein encoded by a micro-exon gene (MEG) from the parasite S. mansoni, a causative agent of schistosomiasis. The MEGs are capable to produce a pool of variant secreted proteins by alternative splicing of micro-exons. Bioinformatics analysis of MEG-14 protein sequence suggested the presence a signal peptide in the N-terminus, a transmembrane helix at the C-terminus and a central soluble portion which is mainly disordered. This soluble portion (sMEG-14) was expressed in a heterologous system and used for analysis of the effects of a range of physical-chemical factors of the structure this protein The synchrotron radiation circular dichroism (SRCD) spectroscopy spectrum of sMEG-14 in aqueous solution exhibits a strong minimum at 198 nm and a small positive band at 182 nm, corresponding a high content of disordered structure (>80%). However, disorder-to-order transitions that lead to the induction of a alfa-helix structure in sMEG-14 were noted by the addition of trifluoroethanol (≥50%) with negative peak at 208 and 222 nm and a stronger positive peak at 192 with a shoulder at 175 nm. This ordering effect was also produced by increasing temperature (in a reversible process) and in the presence of negatively charged lipids (like POPG and SDS). Furthermore, dynamic light scattering measurements demonstrate that sMEG-14 protein promoted fusion of vesicles formed by negatively charged lipids, the same effect was not observed for vesicles with zwitterionic or positive charged lipids. Taken together, these results support the classification of MEG-14 as good model of an intrinsically disordered protein, and suggest its interaction with different partners.

Keywords: intrinsically disordered proteins, micro-exon gene proteins, *Schistosoma mansoni.*

Membrane destabilization and amyloid oligomers formation by influenza A virus protein PB1-F2 are dependent on bilayer composition

J. Vidic[1], C. Chevalier[1], S. Mazaret[2], C.-A. Richard[1], B. Delmas[1]
[1]VIM, INRA, Jouy en Josas, [2]VIM, Université Paris-Sud, Orsay, France

Influenza is an acute respiratory infection which most severe manifestations are caused by Influenza A viruses of the *Orthomyxoviridae* family. The precise mechanism of Influenza A mediated pathogenicity is still being investigated and it appears that the virulence of the virus can be influenced by each of virus proteins. PB1-F2 is small accessory protein of 75-90 amino acids displays a strong polymorphism and is expressed in most human and avian influenza A strains. PB1-F2 was shown to increase morbidity and mortality though cell-type and viral-strain dependent manner. The protein C-terminal containing a non-canonical mitochondrial targeting signal is believed to be essential for the protein reactivity.

PB1-F2 is an intrinsically disordered protein in aqueous solutions but can adopt α-helical or β-sheet secondary structure depending on the environment hydrophobicity. In a membrane mimic environment or within infected cells PB1-F2 was shown to adopt β-sheet conformation and oligomerize to amyloid fibres.

To further understand the interaction of PB1-F2 with cellular membranes we sought to investigate PB1-F2 domains involved in the protein binding to membrane bilayers and to characterize PB1-F2 conformational changes and self-association occurring upon bindings. For this, we tested interactions of the full length and C- and N-terminal domains of PB1-F2 with liposomes of various lipid compositions and different net charges. We show that recombinant PB1-F2 aggregates and forms amyloid like structures upon binding membranes of negative net charge and that the conversion process depends on the lipid composition. Our results confirm the high reactivity of C-terminal part of PB1-F2 to impair membrane integrity but reveal also the enhancing role of the protein N-terminal domain in membrane structure destabilization. Finally we tested the cytotoxicity of monomeric and oligomerized PB1-F2.

Microarray-based molecular assay for rapid identification of tuberculosis causative agent, analysis of its pathogenicity and drug susceptibility testing

A. Leinsoo, D. Zimenkov, E. Kulagina, D. Gryadunov
Russian Academy of Sciences, Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

Fast spread of Multidrug-resistant and Extensively drug-resistant strains of *Mycobacterium tuberculosis* (TB) is one of the greatest threats to the global control of TB. Multidrug resistance (MDR) is resistance to at least isoniazid and rifampin. Extensively drug-resistant (XDR) TB is MDR TB plus resistance to any fluoroquinolone and at least one of the three injectable second-line drugs (amikacin, kanamycin or capreomycin). Annual growth of XDR TB cases estimated as 28000 worldwide (~9% of MDR TB) and almost all of them cause death. The actual incidence of XDR TB could be underestimated, because second-line drug susceptibility testing is not availible in many countries. To avoid a progressive development of drug-resistant TB worldwide, rapid identification of resistant *M. tuberculosis* complex strains is necessary.

A molecular assay based on original Russian technology of hydrogel microarrays (biochips, www.biochip.ru) has been developed for fast identification of MDR and XDR tuberculosis.

The microarray comprises immobilized oligonucleotides based on the corresponding sequences of IS6110 region that is typical for *Mycobacterium tuberculosis* complex and the sequences of *rpoB, katG, inhA, ahpC, gyrA, gyrB, rrs, eis, embB* genes with the mutations that act as markers for identification MDR and XDR TB as well as the sequences of single nucleotide polymorphisms that identify different TB genotypes such as Beijing, Beijing B0/W148, Haarlem, LAM and Ural which differ from each other by their pathogenicity.

The procedure includes multiplex amplification of analyzed fragments of mycobacterial genome with simultaneous fluorescent labeling of PCR-products followed by hybridization on the developed microarray. The assay allows to identify 104 genetic determinants of TB resistance to rifampin, isoniazid, fluoroquinolones, aminoglycosides/capreomycin and ethambutol. Compared to conventional drug susceptibility testing (Bactec MGIT 960, Becton Dickinson, USA), the sensitivity and specificity of the assay were 97.4% and 96.2% for rifampin; 98.0 and 91.5% for isoniazid, 94.1% and 85.2% for fluoroquinolones; 95.1% and 86.4% for aminogycosides/capreomycin; and 67.4% and 90.5% for ethambutol correspondingly. All analyzed samples defined as Beijing B0/W148 were extensively drug-resistant that confirms

© 2014 The Authors. FEBS Journal © 2014 FEBS

clinical significance of identification of this strain. Application of the developed method in clinical practice will lead to the coincident medication of tuberculosis with the timely therapeutic correction and will promote prevention of the expansion of extensively drug resistant *M. tuberculosis* strains.

Mixed proteome analysis using a long monolithic column for elucidation of mechanisms of *Candida albicans* infection

H. Morisaka[1,2], N. kitahara[1], M. Ueda[1,2]
[1]Kyoto University, [2]KIST-BIC, Kyoto, Japan

Candida albicans is an opportunistic pathogen that causes disease if the host immunity is compromised. The mortality rate of systemic candidiasis is very high because of the lack of effective diagnoses and therapy. Host resistance against pathogenic fungus relies on the ingestion and elimination by macrophage. However, *C. albicans* can escape from attack by macrophage. Therefore, further analysis of the mechanisms of *C. albicans* infection is required for development of treatment protocol.

On the other hand, proteome analysis is an important approach for comprehensive characterization of biological process. Separation technique such as liquid chromatography takes very important role in development of high-efficiency analysis system. Therefore, a long monolithic column which showed excellent performance has been applied to nano-LC/MS system for proteome analysis [1].

In this study, we performed mixed proteome analysis using a long monolithic column for direct analysis of the response of *C. albicans* to phagocytosis without isolation of cells. Proteins directly extracted from cells in co-cultivated mixture with *C. albicans* and macrophages were subjected to reduction, alkylation, and tryptic digestion. Tryptic fragments were injected to high-efficiency proteome analysis system (nano-LC/MS) using a long monolithic column (500 cm long, 0.1 mm ID) [2]. Collected data were used for protein identification and pathway analyses for elucidation the mechanisms of *C. albicans* infection. From these results, phenomena during the interaction of *C. albicans* with macrophage were comprehensively suggested. In *C. albicans*, proteins related to the glyoxylate cycle and hypha formation, etc were up-regulated. In macrophage, proteins related to the immune response were down-regulated [3].

More Jaz in plant defense response

M. Zhou
Leiden University, Leiden, The Netherlands

Plants are exposed to many forms of stress, including biotic and abiotic factors. Due to their sessile life style, plants defend themselves via physiological adaptations. Jasmonates (JAs) are important hormones involved in plant defense responses. JAs-dependent defense reactions form two major branches. In one branch against insect herbivores, the JAs receptor F-box protein COI1 triggers degradation of JAZ proteins, which in the absence of JAs bind to the transcription factors AtMYC2/3/4 and repress its activity. In Arabidopsis the JAZ family counts 12 members, 10 of which interact with AtMYC2 in yeast. In the other branch of JAs-dependent defense against necrotrophic microbial pathogens, JAs interact with the defense hormone ethylene (ET). We previously identified the AP2-domain transcription factor ORA59 from Arabidopsis, which regulates the JAs- and ET-responsive expression of a set of defense genes, including the plant defensin gene PDF1.2. Interestingly, this branch also depends on the F-box protein COI1, since a coi1 mutant does not express this branch. It is speculated in the plant defense field that JAZ repressors may also control the activity of ORA59. However, ORA59 does not appear to interact directly with members of the JAZ protein family. Recently, we identified a protein interacting with ORA59 via yeast two-hybrid screening of an Arabidopsis cDNA library (ORA59-binding protein 1, OBP1). In the ORA59 activity assay, OBP1 has a moderate repressing activity. Interestingly, even more recently we discovered that OBP1 interacts in the yeast two-hybrid assay with a member of the JAZ family. Biochemical and molecular results showed that OBP1 forms the bridge between ORA59 and the JAZ protein and that this complex represses ORA59 activity in the absence of JAs.

Multivalent Adhesion Molecule 7 clusters act as signaling platform for host cellular GTPase activation and facilitate epithelial barrier dysfunction

A.-M. Krachler
Institute of Microbiology and Infection, University of Birmingham, Birmingham, UK

Vibrio parahaemolyticus is an emerging bacterial pathogen which colonizes the gastrointestinal tract and can cause severe enteritis and bacteraemia. During infection, *V. parahaemolyticus* primarily attaches to the small intestine, where it causes extensive tissue damage and compromises epithelial barrier integrity. We have previously described that Multivalent Adhesion Molecule (MAM) 7 contributes to initial attachment of *V. parahaemolyticus* to epithelial cells. Here we show that the bacterial adhesin, through multivalent, high-affinity interactions between surface-induced adhesin clusters and phosphatidic acids in the host cell membrane, induces activation of the small GTPase RhoA and actin rearrangements in host cells. In infection studies with *V. parahaemolyticus* we further demonstrate that adhesin-triggered RhoA activation is sufficient to redistribute tight junction proteins, leading to a loss of epithelial barrier function. Taken together, these findings show an unprecedented mechanism by which an adhesin acts as assembly platform for a host cellular signaling pathway, which ultimately facilitates breaching of the epithelial barrier by a bacterial pathogen.

NMR study of the structure and interactions of two cofactors of the polymerase of human respiratory syncytial virus

S. Lassoued[1], N. Pereira[1], M. Galloux[2], F. Bontems[1], J.-F. Eleouet[2], C. Sizun[1]

Respiratory syncytial virus (RSV) is a member of the Paramyxoviridae family of non segmented, negative sense single-stranded RNA viruses. Bovine and human respiratory syncytial virus (bRSV and hRSV) are major causes of respiratory diseases in calves and children, respectively, and are prioritized vaccine targets. Our aim is to get answers about the structure and dynamics of different components of the RSV RNA dependent RNA polymerase complex (RdRp) and about their interactions either with other components of the RdRp or with cellular partners, by using Nuclear Magnetic Resonance, as a prerequisite to rational drug design. We are focusing on two RSV proteins: the phosphoprotein, which is the main polymerase co-factor and necessary for both viral transcription and replication, and M2-1. We are aiming at characterizing the structure of P. Indeed, it has been predicted that P contained an oligomerization domain and large disordered N-and C-terminal extensions.

NMR is a unique tool to investigate intrinsically disordered proteins and regions (IDRs).

We have shown that these regions display transient helices which form potential sites for binding partners of P, among which the M2-1 and N proteins. The M2-1 protein of hRSV functions as an essential transcriptional cofactor of the viral (RdRp) complex by increasing polymerase processivity. M2-1 is a modular RNA binding protein that also interacts with the viral phosphoprotein P. These binding properties are related to the core region of M2-1. After solving the structure of the corresponding domain, we showed that partial overlap of the RNA and P interaction surfaces, determined by NMR on the monomeric M2-1(58-177) fragment, accounts for the previously observed competitive behavior of RNA versus P in M2-1 binding.

Keywords: respiratory syncytial virus, polymerase, transcription.

Novel mode of action in plant defense peptides

A. A. Slavokhotova[1], T. A. Naumann[2], N. Price[3], E. A. Rogozhin[4], Y. A. Andreev[4], A. A. Vassilevski[4], T. I. Odintsova[5]
[1]Plant Genetics, Vavilov Institute of General Genetics, Moscow, Russian Federation, [2]Foodborne Pathogens & Mycology Research Unit, [3]Renewable Product Technology Research Unit, USDA-ARS-NCAUR, Peoria, USA, [4]Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, [5]Vavilov Institute of General Genetics, Moscow, Russian Federation

The multilayered plant immune system relies on rapid recognition of pathogen-associated molecular patterns followed by activation of defense-related genes that results in the reinforcement of plant cell walls and production of antimicrobial compounds. To suppress plant defense, fungi secrete effectors including a recently discovered Zn-metalloproteinase from *Fusarium verticillioides*, named fungalysin Fv-cmp (Naumann, T.A. (2011) Modification of recombinant maize ChitA chitinase by fungal chitinase-modifying proteins. *Mol Plant Pathol*, 12, 365-372). This proteinase cleaves class IV chitinases, plant defense proteins that bind and degrade chitin of fungal cell walls. In this work, we studied plant response to such pathogen invasion and discovered novel inhibitors of fungalysin. We produced several recombinant hevein-like antimicrobial peptides named WAMPs containing different amino acids (A, K, E, and N) at the non-conservative position 34. An additional serine residue in the site of fungalysin proteolysis makes the peptides resistant to the protease. Moreover, approximate equal WAMP-1b, -2 concentration to chitinase concentration was sufficient to block the fungalysin activity and keeping the chitinase active against fungi. Thus, WAMPs represent a novel type of protease inhibitors being active against fungal metalloproteases. According to *in vitro* antifungal assays WAMPs demonstrated direct inhibition of hypha elongation suggesting that fungalysin is playing an important role in fungi development. A novel molecular mechanism of dynamic interplay between host defense molecules and fungal virulence factors is suggested.

AAS and AAV are recipients of the stipend of the President of Russian Federation.

Oligandrin and β-aminobutyric acid-induced resistance to *Oidium neolycopersici* in tomato plants

P. Moricová[1], T. Starý[2], M. Pečinková[2], J. Lochman[2], L. Kubienová[1], B. Mieslerová[3], L. Luhová[1], T. Kašparovský[2], M. Petřivalský[1]
[1]Department of Biochemistry, Faculty of Science, Palacky University, Olomouc, [2]Department of Biochemistry, Faculty of Science, Masaryk University, Brno, [3]Department of Botany, Faculty of Science, Palacky University, Olomouc, Czech Republic

Oligandrin, a 10 kDa elicitin molecule secreted by *Pythium oligandrum*, was demonstrated to share biochemical similarities with other elicitins, however fail to provoke a visible HR-associated necrotic response on leaves of treated tomato plants [1]. Treatment of tomato plants with oligandrin confers enhanced resistence against *Phytophthora parasitica, Fusarium oxysporum* f. sp. *radicis-lycopersici and Botrytis cinerea*. Oligandrin is known to trigger the expression of PR-proteins and to stimulate the activity of the defense related enzymes. Oligandrin might induce signal pathways of salicylic and jasmonic acid and ethylene in parallel. A non-protein amino acid β-aminobutyric acid (BABA), has previously been shown to effectively induce plant resistance against many different oomycetes and against various downy mildews. It has been shown that callose deposition as well as defense mechanisms depending on the phenylpropanoid and the jasmonic acid pathways contributed to BABA-induced resistance [2]. Expression of PR-proteins after treatment with BABA is dependent on used plant species, applied BABA concentrations and the on the application mode. In our study, as a working model we used two *Solanum* genotypes differing in their susceptibility to *O. neolycopersici* pathogen: *S. lycopersicum* cv. Amateur as a susceptible and *S. habrochaites* as a highly resistant genotype [3]. We analysed the expression of 45 defense genes after treatment of oligandrin and BABA with tomato leaves or after inoculation with *O. neolycopersici*. We evaluated germination and growth of pathogen and detected the effect of oligandrin or BABA on pathogen development. Our results showed that the expression of defense genes was increased after inoculation by *O. neolycopersici* in *S. habrochaites* (resistant genotype) comparison with *S. lycopersicum* cv. Amateur. By contrast, BABA slightly induced expression of genes in susceptible genotype but not *in S. habrochaites*. Expression of defense genes was similar after treatment with oligandrin in both genotypes. Data obtained from gene expression

Outer membrane proteins, lipopolysaccharide and morphological alterations of starved *Shigella* isolated from wastewater

K. Chourabi[1], J. A. Rodriguez[2], F. Torrella[3], S. Campoy[4], A. Chatti[5]
[1]*Water Research and Technology Centre, Technopole of Borj-Cédria, Soliman, Tunisia,* [2]*Genetics and Microbiology, Faculty of Biosciences, University Autonoma, Barcelona,* [3]*Genetics and Microbiology, University of Murcia, Murcia,* [4]*Genetics and Microbiology, Faculty of Biosciences, University of Autonoma, Barcelona, Spain,* [5]*Water Research and Technology Centre, Technopole Borj Cedria, Soliman, Tunisia*

Bacteria living in habitats of frequently changing conditions like nutrient starvation have evolved very sophisticated responses to adapt to environmental changes. To survive prolonged periods of starvation, many bacteria have developed starvation-survival strategies enabling them to persist in the environment until conditions become favorable for growth. One of the most frequently observed behaviors in the nutrient starvation response of Gram negative bacteria is the size reduction and cell morphology conversion from rod to coccoid shape.

The aim of this work was to evaluate the starvation effect (30 days incubation in laboratory microcosms) on the survival, morphology, Lipopolysaccharide (LPS) and outer membrane proteins (OMPs) profiles of *Shigella* sp. (isolated from wastewater).

Our results showed that *Shigella* sp. is able to adapt and survive under starvation conditions, owing to gradual changes in cellular physiology and morphology. Untreated cells are rod shaped presenting a very clear cell wall and membrane surrounding an expended cytoplasm. Whereas, the starved cells present a coccoid form with condensed cytoplasm. In addition, our data indicate that starvation induced changes in the OMPs and LPS profiles of *Shigella* sp.

These results point out that *Shigella* may sustain their adaptation to changes of external environment by changing their morphology, LPS and OMPs profiles.

Keywords: LPS, OMP, Morphology, *Shigella*, Starvation.

WED-404
Palmitoylation of HIV-1 Tat regulates its capacity to inhibit neurosecretion

C. O. Chopard[1], A. Tu[2], N. Vitale[2,3], P. Tryoen-Tóth[2], B. Beaumelle[4]
[1]*UMR5236, Université Montpellier, CNRS, Montpellier,* [2]*Institut des Neurosciences Cellulaires et Intégratives, CNRS UPR3212, Université de Strasbourg,* [3]*CNRS, Strasbourg,* [4]*UMR 5236, Université de Montpellier, CNRS, Montpellier, France*

HIV-1 infected cells release the transactivating Tat protein. This small (86 residues) and basic proteins owns seven cysteine residues and is recruited to the inner leaflet of the plasma membrane by a strong and specific interaction with phosphatidylinositol(4,5) bisphosphate (PIP_2). Tat is then directly exported through the plasma membrane using an unconventional secretion process that remains poorly characterized, although Tat secretion is very efficient since about 2/3 of this protein is exported. Tat concentration reaches the nanomolar range in the serum of infected patients. Tat can be endocytosed by target cells and escapes from endosomes by translocation through their membrane to reach the cytosol. It can then trigger various cell responses, depending on cell types.

Here we shoed that Tat, once endocytosed by PC12 cells and translocated to the cytosol, is able to bind PIP_2 at the plasma membrane with which it remains stably associated. Tat thereby prevents the PIP_2-mediated recruitment of proteins involved in neurosecretion and strongly inhibits this process. Why does Tat stays on PIP_2 in neurosecretory cells and is apperently not exported? It seems that it is because Tat is palmitoylated in these cells. Indeed we found, using two independant approches that transfected Tat can be palmitoylated in PC12 cells but not in T-cells that release Tat. We identified the modified cysteine as well as the enzyme that enables Tat acylation among the 23 DHHC mammalian protein acyl transferases. Non-acylable Tat poorly inhibits neurosecretion and is more cytosolic than the WT. Similar data were obtained using 2-bromopalmitate, a palmitoylation inhibitor. Hence, palmitoylation stabilizes the association of Tat with PIP_2 and enables Tat to strongly impair neurosecretion.

Keywords: HIV-1, Palmitoylation, Tat protein.

WED-407
Phylogenetic and three-dimensional analysis of endoxylanases of two races of *Colletotrichum lindemuthianum*, pathogenic and saprophytic, with endoxylanases of *Colletotrichum* sp.

U. Conejo-Saucedo[1], H. Cano-Camacho[1], E. López-Romero[2], M. G. Villa-Rivera[1], A. Lara-Márquez[3], M. G. Zavala-Páramo[1]
[1]*Centro Multidisciplinario de Estudios en Biotecnología, Universidad Michoacana de San Nicolás de Hidalgo, Morelia,* [2]*Departamento de Biología, División de Ciencias Naturales y Exactas, Universidad de Guanajuato, Guanajuato,* [3]*Escuela Nacional de Estudios Superiores, Universidad Autónoma de México, Morelia, Mexico*

The genus *Colletotrichum* includes a number of plant pathogens of major importance, causing diseases of a wide variety of mono and dicots plants. *C. lindemuthianum* is an intracellular hemibiotrophic pathogen of bean. After penetration of a host epidermal cell, an infection vesicle is formed and the fungus extends into adjacent cells by large primary hyphae, which invaginate without penetrating the host cell membrane, thus persisting as a biotrophic interaction. Once a large area of the plant tissue has been colonized, necrotrophic hyphae develop and this event closely correlates with the production of a battery of host cell wall-degrading. Among these, xylanases are thought to play a major role in pathogenesis.

Deduced amino acid sequences of xilanases reported for twenty two *Colletotrichum* species, xilanases Clxil1 from a pathogenic (race 1472) and a saprophitic (race 0) race of *C. lindemuthianum* isolated in this study, and a xylanase sequence from *Lentinula edodes* as an external group, were used to generate distance trees. Phylogenetic analysis showed that the xylanases are grouped into four clades, where Clxil1 xylanase from *C. lindemuthianum* Race 1472 and R0 were grouped with xilanase from *C. orbiculare* (goup I) and in another clade with *C. gloeosporioides Nara_gc5_ xil1 and C. gloeosporioides Cg_14_xil1*.

© 2014 The Authors. FEBS Journal © 2014 FEBS

Results showed an interesting separation of xylanases from *C. graminicola M1_xil2* and *C. higginsianum_xil1* (Group III), both pathogens of monocotyledoneus.

Apparently there is a different source for these enzymes, those from pathogens of monocotyledonous on one side and on the other side enzymes from dicotyledonous pathogens hosts (group I and II) followed by a diversification of these enzymes in more recent evolutionary process (group II).

The results show an basal separation mostly integrated whith xilanases from *C. gloeosporioides Nara_gc5* and *C. gloeosporioides Cg_14,* these enzymes show patterns with larger sequences and carbohydrate-binding modules.

Interestingly, for fungi that have more of a xylanase in their repertoire, these enzymes are not in the same group, as in the case of *Colletotrichum gloeosporioides, C. graminicola* and *C. higginsianum*.

We believe that these xylanases of *Colletotrichum* sp. evolved independently according to its host (mono or dicotiledons), life style and that might have influence on small changes in the tridimensional structure and these perhaps generate more efficient enzymes.

Keywords: *Colletotrichum lindemuthianum*, Endoxylanases, Phylogenetic relationships.

Plasmodium falciparum products affect human erythrocyte membrane-bound glycohydrolases activity

L. Massaccesi[1], N. Papini[2], S. Parapini[3], D. Taramelli[3], G. Goi[1], N. Basilico[1]

[1]Department of Biomedical, Surgical and Dental Sciences, [2]Department of Medical Biotechnology and Translational Medicine, [3]Department of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, Milano, Italy

Background: *Plasmodium falciparum* (*Pf*) malaria causes about 600,000 deaths each year, mostly African children, because of complications including cerebral malaria and severe anemia. Pathogenesis of anemia is due to different factors including parasite induced hemolysis, diserythropoiesis and reduced deformability, accelerated senescence and removal of uninfected red blood cells (RBC). Modifications of RBC membrane's properties can be ascribed to increased oxidative stress caused by parasite heme products such as Fe(III)-protoporphyrin IX (hematin) or hemozoin, present at high concentration in the plasma of malaria patients.

Several plasma membrane-bound glycohydrolases of human RBC were recognized to have a role in signaling early membrane alterations both in pathologies related to oxidative stress and in physiological conditions as ageing, suggesting their use as new markers of cellular oxidative stress. However, an association between RBC glycohydrolases alteration and malaria infection has not been previously described.

The aim of the present work was to investigate the ability of malaria parasite products to alter RBC membrane by affecting glycohydrolases activity.

Methods: RBC from human donors were incubated for 24 hours in the presence of supernatants, derived from *Pf* cultures, containing heme products released during parasite growth. RBC were then treated with different concentrations of hematin (20-10-5 μg/ml) or hemozoin (10-5-2.5 μg/ml) purified from *Pf* cultures. Hexosaminidase, β-D-Glucuronidase, α-D-Glucosidase and acidic Sialidase activities were evaluated by fluorimetric assays; membrane fluidity by fluorescence anisotropy method.

Results: A decrease in the activity of the tested enzymes was observed after incubation of RBC in the presence of culture supernatants from different *Pf* strains. Moreover, a significant dose dependent inhibition was observed after treatment with either hematin or hemozoin. At the highest dose used, hematin induced a decrease in the activity of the examined enzymes between 65% and 55%. Likewise a decrease of RBC membrane fluidity was observed following treatment with hematin or hemozoin.

Conclusions: The decrease of glycohydrolases activity and the increase in membrane rigidity are in agreement with accelerated RBC senescence observed in malaria infection and the parasite heme products seems to be the main contributors to these membranes damages. Glycohydrolases alterations could be indeed promising candidates as early markers of RBC damage in malaria infections.

Pleiotropic role played by the PDZ domains in neuronal signaling pathways

N. Wolff [1], P. Maisonneuve[1], C. Caillet-Saguy[1], E. Terrien[1], F. Delhommel[1], M. Lafage[2], F. Cordier[1], C. Préhaud[2], H. Buc[3], M. Delepierre[1], M. Lafon[2]

[1]Biologie Structurale et Chimie, [2]Virologie, [3]Institut Pasteur, Paris, France

The human tyrosine phosphatase PTPN4 and the Ser/Thr kinase MAST2 are two enzymes expressed in neurons. While PTPN4 is an anti-apoptotic protein, MAST2 inhibits neurogenesis and neuroprotection. The PDZ domain of these two enzymes is specifically targeted by the cytoplasmic domain of the envelope glycoprotein (G protein) of the rabies virus (RABV) during neuron infection (Préhaud et al., 2010). We have solved the NMR structures of the complexes formed by MAST2-PDZ and PTPN4-PDZ with their respectives endogenous and viral ligands. As a result, the complexes formed by the PDZ of the two enzymes and their respective ligands are disrupted, triggering drastic effect on cell signaling and cell commitment either towards death or survival. By targeting MAST2-PDZ, the G protein of virulent RABV alters the intracellular trafficking of PTEN (Terrien et al., 2012) and promotes survival, whereas the G protein of attenuated RABV induces neuronal cell death by targeting PTPN4-PDZ (Babault et al., 2011). We recently demonstrated that the catalytic activity of PTPN4 is regulated by its PDZ domain and that the viral sequence interfered with this allosteric regulation.

We provided structural and biological evidences that the RABV proteins act as competitors endowed with specificity and sufficient affinity in a vital cellular process. The disruption of critical endogenous protein-protein interactions by viral protein altered drastically intracellular protein trafficking and catalytic activity controlling the cellular homeostasis.

Rapid preparation of frequently mutated-proteins of influenza viruses and construction of screening system to discover novel inhibitors

J. Yamada[1], N. Miura[1], T. Shigemori[1], T. Katsuragi[2], S. Yongkiettakul[3], K. Kuroda[1], M. Ueda[1]
[1]*Graduate School of Agriculture, Kyoto University, Kyoto,* [2]*Nara Institute of Science and Technology, Nara, Japan,* [3]*National Center for Genetic Engineering and Biotechnology, Pathum Thani, Thailand*

Recently, many of new mutants of influenza virus, such as H5N1 subtype, have occurred. Hemagglutinin (HA) and neuraminidase (NA), which are membrane proteins of influenza virus, are the main factors that determine the pathogenicity. It has been reported that some NA mutants have tolerance to oseltamivir and zanamivir which are NA inhibitors for effective treatments. It is necessary to develop a novel treatment for the disease caused by new mutants of influenza virus. In order to solve such problems, we focus on yeast cell surface engineering (1). Using this system, it is possible to construct mutant protein library on yeast cell surface easily and comprehensively, because various inconvenient and troublesome steps for protein preparations could be avoided. In addition, it can be easily evaluated whether oseltamivir and zanamivir could be effective against mutant proteins. We succeeded in displaying HA derived from H1N1 subtype and NAs derived from H9N2 and H1N1 subtypes on the yeast cell surface (2). The activity of displayed HA was detected by hemagglutination assay. It was confirmed that displayed mutant NAs which are known to be tolerant to oseltamivir and zanamivir maintained the tolerance. Moreover, the NA- and HA-displaying yeasts constructed in this research can be considered to be useful tools in high-throughput screening of inhibitors toward frequently mutated-influenza viruses. Using the displaying yeasts, a new screening system could be constructed for developing new NA inhibitors (3). Our advantageous system will contribute to prevention against pandemic by influenza viruses.

Review on malaria in Saudi Arabia, current status and future prospects

N. A. Al-Zanbagi
Biology, King Abdulaziz University, Jeddah, Saudi Arabia

Malaria is atimeworn illness as the mankind itself, in many countries, it discompose a dangerous hurdle to economic advancement, furthermore Malaria is arduous to exterminate and its monitoring is conceivable only with consistent efforts of the governmental agencies, general publicandhealthcare personnel. Malariosis is caused by*Plasmodium* spp., a protozoan parasite which make it is responsible for an over of one million people death annually, mostly are children. The demonstrationsof malaria disease are conductedthrough the erythrocytes infection by the parasite asexual stages, so it is believedto be apossibility multisystem disease, as every body's organ is reached by the blood. The essential mode of malaria infection transmission is via the female *Anopheles* mosquito bites, while the other modes of infection include the transplacentally route, infected blood transfusion and very rarely cases by needle-stick injuries. Saudi Arabia is the only country that hosts annually and throughout the year large numbers of pilgrims of different nationalities, that may pose a significant burden in tackling the spread of epidemic diseases. In Saudi Arabia, *Plasmodiumfalciparum* is the predominant species, as well as the *P. vivax* is also reported. The malaria incidence performedalong the Southern Region of the Red Sea coast, down to the border with Yemen. In 2004 Saudi Arabia took the decision to remove this disease especially in the border villages by mapping the malaria foci and the investigation of all infected cases using the clinical diagnosis which based on the patient's sign and symptoms, then by making the free laboratory diagnosis and giving the suitable medication.

HIV-1 agent of the AIDS pandemic is a RNA virus that requires an intermediate DNA phase via reverse transcription (RT) step in order to establish productive infection in the host cell. Within cells retroviral assembly requires thousands of structural Gag proteins and two copies of genomic RNA (gRNA) as well as cellular factors to converge to the assembly sites at the plasma membrane in a finely regulated timeline. In this process, the nucleocapsid domain of Gag (GagNC) ensures gRNA selection and packaging into virions. Then, budding and virus release require the recruitment of cellular ESCRT machinery. Interestingly, mutating GagNC results into the packaging of DNA instead of gRNA by promoting a late occurring step of reverse transcription of the gRNA into DNA. Generally, RT takes place early after entry of wild-type viruses in cells. Late RT occurs in producer cell prior to virus release through an unknown mechanism and is reminiscent of the detection of DNA-containing particles in HIV-1-infected people. In order to decipher the molecular mechanisms involved in controlling late RT, we explored the biogenesis of DNA-containing particles in cells, combining live-cell total internal reflection fluorescence microscopy, electron microscopy and *trans*-complementation assays. Our study reveals that DNA virus production is the consequence of HIV-1 budding defects with large patches of Gag aggregation at the plasma membrane. Targeting Tsg101, a key component of the ESCRT-I machinery, to virus assembly sites restores virus budding and decreases DNA levels in cells and particles in favor to RNA packaging. Altogether, our results highlight the role of

Role of a two-component system, AcsS/R, in expression of acetyl-coA synthetase of *Vibrio vulnificus*

M. J. Kim, N. Lee, S.-J. Park
Department of Environmental Medical Biology and Institute of Tropical Medicine, Brain Korea 21 PLUS Project for Medical Science, Yonsei University, Seoul, Korea

VarS/VarA is a master regulator involved in diverse aspects of bacterial metabolism. An experiment to identify VarS/VarA target gene(s) in *Vibrio vulnificus* revelaed a putative LuxR-type transcriptional regulator as a down-regulated protein in *ΔvarA* mutant. Comparative transcriptome analysis of this *ΔluxR* mutant versus wild-type, indicated that the *acsA* gene encoding acetyl-CoA synthetase was down-regulated in the renamed *ΔacsR* mutant (response regulator for acetyl-CoA synthetase). A putative histidine kinase gene, *acsS* (sensor kinase for acetyl-CoA synthetase) was found upstream of the *acsR* gene. Luciferase activities of the *acsA::luxAB* transcriptional fusion indicated that expression of *acsA* was decreased in *ΔacsR* or *ΔacsS* mutant than wild-type. In addition, expression of the *acsA::luxAB* was repressed by the presence of glucose, which occurs in a CRP-cAMP-independent manner. *ΔacsA* mutant *V. vulnificus* was retarded in bacterial growth in minimal acetate medium. In the same manner, *ΔacsR* and *ΔacsS* mutant strains grew slower than wild-type in the same medium. Growth retardation of *ΔacsR* strain in minimal acetate medium was restored when wild-type *ascR* gene was added to the mutant as a complementation plasmid. Binding of AcsR recombinant protein to the *acsA* promoter was shown by *in vitro*-gel shift assays. These results indicated that AscS/AscR plays a role in controlling acetate metabolism by positively regulating the expression of acetyl CoA synthase.

Role of hydrogen peroxide and peroxiredoxins in the resistance of cowpea (*V. unguiculata* [L]. Walp.) to *Colletotrichum gloeosporioides*

F. D. Albuquerque, I. M. Vasconcelos, K. D. D. C. Saraiva, J. H. Costa, J. T. A. Oliveira
Biochemistry and Molecular Biology, Federal University of Ceara (UFC), Fortaleza, Brazil

C. gloeosporioides is a major hemibiotrophic pathogen with a broad host range that causes substantial crop losses. Recent data have shown that the hypersensitive response (HR) is an event involved in the resistance of cowpea against *C. gloeosporioides*. Several studies have been undertaken on the defense mechanisms of plants to pathogens, but overall they remain poorly understood. Previously, we have compared changes in protein expression induced in resistant cowpea leaves after infection with *C. gloeosporioides* using a proteomic approach. Based on these results, in this present study we evaluated whether *PRXIIBCD* and *PRXIIE*, genes which encode for peroxiredoxins and are involved in HR, are responsive in cowpea leaves challenged with *C. gloeosporioides* using qRT-PCR analysis. Increase of hydrogen peroxide (H_2O_2) generation was detected in cowpea leaves 2 h after infection (HAI) using DAB-staining. However, spectrophotometric measurements showed that the amount of H_2O_2 increased 12 HAI. Enhanced lipid peroxidation was also observed, but at 2 HAI. qRT-PCR analysis showed that the quantitative level of *PRXIIBCD* transcript expression was up-regulated at 2 HAI and remaining elevated up to 72 HAI. Contrarily, *PRXIIE* transcript did not alter at the early hours after inoculation, but showed increased expression levels at 48 and 72 HAI. The present study indicates that H_2O_2 has an important function in the early defense strategies of cowpea *preventing* the *spread* of *C. gloeosporioides Infection* and possibly as a signaling molecule. Furthermore, *PRXIIBCD* and *PRXIIE* seem to be involved, in combination with other molecules, in the regulation of H_2O_2 levels toward preventing cell death and regulating the cell redox homeostasis, important events in the resistance mechanisms of plants to pathogens.

Keywords: *Colletotrichum gloeosporioides*, Hydrogen Peroxide, Peroxiredoxins.

Role of oligomannose-rich apoptotic membranous vesicles in *Escherichia coli* infections

T. Dumych[1], J. Bouckaert[2], N. Yamakawa[2], S. Gouin[3], J. Bernard[4], R. Bilyy[1]
[1]*The Department of Regulation of Cell Proliferation and Apoptosis, Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine,* [2]*Unité de Glycobiologie Structurale et Fonctionnelle, Université Lille 1, Villeneuve d'Ascq,* [3]*Chimie Et Interdisciplinarité, Synthèse, Analyse, Modélisation, UMR CNRS 6230, LUNAM Université, Nantes,* [4]*Ingénierie des Matériaux Polymères, Université de Lyon, Lyon, France*

Escherichia coli (*E. coli*) are known infectious agents in *cystitis* and Crohn's disease by utilizing the same mechanism of binding with receptor molecules on the epithelia of oropharyngeal, gastrointestinal and urinary tracts – the oligomannose-specific lectin (adhesin) FimH on the tip of type 1 fimbriae. Thus, bacteria utilize the sugar decoration of cells, the glycocalyx, to colonize the cell surface, wherever cells are in contact with the outside environment, as for example in the case of epithelial cells. *E. coli* are more prone to infect patients having a disease with an increased apoptotic rate. Recently we demonstrated [R.Bilyy, T. Shkandina, et al, JBC, 2012] that apoptotic cells release two distinct types of apoptotic cells-derived microvesicles (ACMV): either derived from endoplasmic reticulum (ER), or from the plasma membrane (PM). Both exhibited an altered glycoprofile: desialylated glycotopes resulting from surface-borne sialidase activity on PM-derived ACMV, while surface exposure of oligomannose glycoproteins results from surface exposure of internal ER membranes.

Here we studied the possibility of *E. coli* to utilize mannose-rich ACMV for host cell colonization and studied the application of a new class of monovalent mannosides for preventing binding of AIEC towards host cells. (i) We have developed an ELISA-based method for testing affinity of synthetic inhibitors towards FimH using oligomannose glycans of RNAse B proteins as substrate. This test enables quick evaluation of the intensity of lectin binding to the substrate, as well as a fast test of compounds that inhibit this process [Brument S; at all J Med Chem, 2013]. In this way specific FimH inhibitors acting in the nanomolar range have

© 2014 The Authors. FEBS Journal © 2014 FEBS

been selected. (ii) Co-incubation, of bacteria that expose FimH lectin, with host cells led to formation of oligomannose-positive ACMV and these ER-derived ACMV were bound by FimH lectin. Also by using a combination of fluorescent and DIC microscopy we demonstrated the direct binding of *E. coli* with mannose-rich ACMV of human *HeLa* cell after co-incubation period of 2 h. Changes of surface oligomannose-rich glycans of epithelial cells after influence of FimH adhesins were confirmed by MALDI TOF MS/MS screening of ACMV glycans in the untreated conditions and after the action of bacterial FimH lectin. (iii) We used *Jurkat* human T-cells and human intestinal epithelia *Caco-2* cells in co-culture models with *E. coli* and demonstrated that thiazolylmannoside-based inhibitors can effectively abrogate FimH-induced apoptosis. Moreover, addition of thiazolylmannoside-based inhibitors prevented binding of *E. coli* towards host cells in bacteria-cells co-cultures at 500 nM concentration.

Salmonella co-opts host cell chaperone-mediated autophagy for intracellular growth

V. Singh, J. Finke, P. Scwerk, K. Tedin
Centre for Infection Medicine, Institute of Microbiology and Epizootics, Freie University, Berlin, Germany

Salmonellosis is one of the most common food borne diseases in humans and presents a major public health and economic burden worldwide. *Salmonella* serovars are facultative intracellular pathogens which are invasive for host cells where they establish an intracellular, membrane-bound replicative niche known as the *Salmonella*-containing vacuole (SCV).

The SCV has been regarded as a nutrient deprived compartment. However, despite apparent nutrient limitation within the SCV, *Salmonella* is still able to replicate in the SCV. Here, we provide evidence for a unique mechanism whereby intracellular *Salmonella* gains access to the host cell cytosol from within its membrane-bound compartment to acquire nutrients. Our study shows that *Salmonella* Typhimurium acquires small peptides by co-opting the host cell chaperone mediated autophagy (CMA)-dependent cytosolic protein turnover pathway. CMA is a selective host cell protein turnover pathway active in all cell types and w is involved in the transport of cytosolic proteins into lysosomes for degradation. An estimated 30% of all cytosolic proteins are turned over through this mechanism. Here we show for both intracellular *Salmonella* and in purified SCVs that the SCV is associated with the key components of the CMA pathway, and inhibitors of CMA affect the intracellular growth of peptide-dependent mutants of *Salmonella*. Furthermore, we show that acquisition of the key CMA components is selective, with recruitment of only one isoform of one host protein component, and exclusion of other lysosomal proteins.

These results reveal a novel means whereby an intracellular pathogen can access the host cell cytosol to acquire nutrients from within its membrane-bound compartment. We suggest these results may provide an explanation for relapse infections resulting from persistent *Salmonella* infections, and suggest a possible means of targeting antibacterials against intracellular pathogens.

Salmonella enterica cells accumulate RND-family efflux pump inhibitor Phenylalanyl-arginyl-beta-naphthylamide

R. Daugelavicius, V. Mikalayeva, S. Sutkuviene
Biochemistry, Vytautas Magnus University, Kaunas, Lithuania

Increased activity of efflux pumps is one of the major reasons of bacterial resistance to antibiotics. Prevention of the efflux of administered antibiotics using the pump inhibitors could increase effectiveness of the treatment. Interaction of RND-family efflux pump inhibitor phenylalanyl-arginyl-b-naphthylamide (PAβN) with *Salmonella enterica* ser. Typhimurium cells was assayed using a novel PAβN-selective electrode. We showed that PAβN has a high affinity to lipopolysaccharide (LPS), the major constituent of bacterial outer membrane. EDTA stimulates binding of PAβN to *S. enterica* cells and *E. coli* LPS. Because of the membrane voltage, like other lipophilic cations, PAβN accumulates also in the cytosol of EDTA-treated bacteria. However, energization of the cells by addition of glucose does not induce efflux of PAβN. Polycationic antibiotic Polymyxin B releases both the accumulated and the LPS-bound inhibitor.

Screening of Kazakhstani wheat varieties for the presence of Lr-genes and their effectiveness

N. Aitkhozhina[1], A. Chirkin[1], E. Maltseva[1], Y. Skiba[1], O. Blokhina[1], G. Ismagulova[1], S. Rsaliev[2], M. Esimbekova[3]
[1]Genome Lab, M. Aitkhozhin Institute of Molecular Biology and Biochemistry, Almaty, [2]Laboratory of Phytosanitary Safety, Research Institute for Biological Safety Problems, Gvardeiskiy, [3]Laboratory of Gene Fund, Kazakh Scientific and Research Institute of Land Farming and Plant Growing, Almalybak Village, Kazakhstan

Leaf rust caused by *Puccinia recondita* Desm. is very harmful for wheat yield and widely expanded in many cereal-producing countries. A search for effective Lr-genes and their introduction into culture are necessary to create new varieties with high level of resistance to pathogen.

The goal of the research was to analyze the collection of commercial bread wheat varieties and isogenic lines of Thatcher variety for the presence of *Lr* genes and their effectiveness against local pathotypes of *P. recondita*. The analysis was carried out on 45 commercial varieties and 39 lines of Thatcher variety, using four *Lr* markers: *Lr*1, *Lr*9, *Lr*10 and *Lr*19. The experiment was conducted on DNA markers associated with Lr-genes and phytopathological tests in greenhouse and in the field.

For each marker the frequency of occurrence in the research group was defined. The least occurring and least effective of the four markers was *Lr*19 gene. Varieties with the given gene were susceptible to three pathotypes of *P. recondita*, which are widely distributed on the territory of Kazakhstan, and revealed low level of resistance in field experiments. The same result was shown for the varieties with *Lr*1 marker in their genome. The only exclusion was the resistance of this gene towards low virulent pathotype KHP/F (South-Eastern Kazakhstan). Varieties with *Lr*10 gene were also slightly resistant. In monogenic condition this gene was effective only for pathotype KHP/F. The most effective of all analyzed genes was *Lr*9 gene. Varieties with this gene were characterized by high level of resistance to all three pathotypes; they also showed high resistance during field

© 2014 The Authors. FEBS Journal © 2014 FEBS

experiments. It is important to mention varieties that combine *Lr*9 and *Lr*10 genes in their genome. When evaluating plant lesions in points according to Mains and Jackson scale, the varieties that contained both *Lr*9 and *Lr*10 genes, were characterized by higher level of resistance in comparison with the plants with only *Lr*9 gene. Kazakhstan varieties with these characteristics are Yegemen and E-792.

Secreted aspartic proteases of *Candida parapsilosis*, SAPP1 and SAPP2, deregulate the major systems of host homeostasis, including the complement cascade, the fibrynolysis pathway and the kallikrein-kinin system

G. Braś, A. Kozik
Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland

Candida yeasts are causative agents of human disorders (candidiases) of variable severity, ranging from relative mild superficial infections to life threatening systemic diseases. Although one species, *Candia albicans*, is responsible for most cases of candidiasis, the role of "non-albicans" *Candida* species has progressively increased in last decades. The major pathogen from this latter group is *Candida parapsilosis* which is frequently isolated from blood cultures, especially in neonates, transplant recipients and patients receiving parenteral nutrition. The major virulence factors of *C. parapsilosis* are secreted aspartic proteases (SAPPs) which can help the pathogen to acquire nutrients, disseminate and also to evade the host defense mechanisms, e.g., by deregulating the major homeostatic systems of the host which are based on triggering the proteolytic cascades.

The current study aimed at characterizing the influence of two major secreted aspartic proteases of *C. parapsilosis*, SAPP1 and SAPP2, on three proteolytic systems of the human host, including the complement cascade, the fibrinolysis pathway and the kinin-generating system. It was shown that SAPP1, but not SAPP2, degraded the complement C3 protein in a non-specific manner to form small inactive peptides. On the other hand, both SAPP1 and SAPP2 seemed to specifically digest the component C5. The products of C5 degradation appeared to be similar to the C5a and C5b fragments, although their activity had still to be confirmed. The analysis of plasminogen digestion excluded the contribution of SAPP1 and SAPP2 in the activation of fibrinolytic pathway. We showed that SAPPs degraded not only plasminogen but also its active form, plasmin, thereby definitively inhibiting the fibrinolysis. In the current study it was also found that SAPP1 non-specifically digested the components of the kallikrein-kinin system, i.e., the plasma prekallikrein and its active form, kallikrein, suggesting that at sites of infections caused by *C. parapsilosis* the production of kinins, the universal mediators of inflammation, can be effectively ceased.

The results of the current study confirm the hypothesis that the deregulation of major homeostatic systems of the host by fungal proteases is an important mechanism of *C. parapsilosis* virulence.

Sequence-structure-function relationships in the GmrSD family of Type IV restriction enzymes

M. A. Machnicka[1], K. H. Kaminska[1], S. Dunin-Horkawicz[1], J. M. Bujnicki[1,2]
[1]*Laboratory of Bioinformatics and Protein Engineering, International Institute of Molecular and Cell Biology in Warsaw, Warsaw,* [2]*Institute of Molecular Biology and Biotechnology, Faculty of Biology, Adam Mickiewicz University, Poznan, Poland*

GmrSD belongs to the Type IV restriction systems. It constitutes the first-discovered modification-dependent restriction endonuclease which specifically targets and digests glucosylated hydroxymethylcytosine (glc-HMC) DNA. Nuclease activity was first reported to be dependent upon the presence of two proteins: GmrS and GmrD which can form a double (in *Escherichia coli* CT596 strain) or single-polypeptide (in *E. coli* UT189 strain) structure. GmrS was initially predicted to act as an endonuclease and NTPase while GmrD was proposed to bind DNA. Enzyme activity requires also nucleoside triphosphates (NTPs) hydrolysis (favors UTP) and is stimulated by calcium [1,2]. However, the two GenBank entries for *E. coli* CT596 proteins have been recently replaced with a single record, suggesting that GmrSD system has the single-polypeptide structure in both *E. coli* strains.

We present the results of an extensive bioinformatics analysis of sequence - function - structure relationships in the GmrSD protein family. We show that the GmrS and GmrD proteins are composed of DUF262 and DUF1524, respectfully and thus we propose the assignment of function to this uncharacterized domains. In contrast to previous reports, our protein fold-recognition analysis revealed the GmrD to possess the HNH endonuclease fold, while GmrS to be an NTPase. For both proteins, we have constructed three-dimensional models of the catalytic cores which revealed residues potentially important for structure and/or function. We have also found that the GmrSD system exists in its single-polypeptide form rather than as a heterodimer but still in some organisms the GmrS and GmrD domains are separated. Our genomic context analysis of GmrSD homologs proved them to be encoded in regions enriched in defense and gene mobility-related elements. Finally, phylogenetic reconstructions of GmrS and GmrD proteins suggests strong co-evolution of these two domains. Altogether, our results provide a stepping stone towards understanding of the GmrSD mechanism of action.

Single cell measurements of intracellular signaling, and motility, in activated macrophages

E. Cammarota[1], J. Sakai[2], C. Bryant[2], P. Cicuta[3]
[1]*Transpol Cavendish Laboratory,* [2]*Veterinary Medicine,* [3]*Cavendish Laboratory, University of Cambridge, Cambridge, UK*

Macrophages are cells of the vertebrate innate immune system. They are the only cells able to eat colloidal scale particles and bacteria. Macrophages move around the body to explore the environment and with their receptors they are able to detect the presence of pathogens. When this happens a complex net-

© 2014 The Authors. FEBS Journal © 2014 FEBS

work of signal pathways is triggered on. In this particular state the macrophage is "activated". The aim of our research is the characterization of the activation process in macrophages, via the investigation of both the NF-kB intracellular signaling pathway and the observation of motility and morphological cell phenotypes.

Regarding the intracellular signaling we propose a single cell approach to a better understanding of the TLR4 receptor and its role in the activation of the NF-kB pathway inside macrophage cells. We developed custom-build image segmentation software that enables the detection of NF-kB translocation within the cell. This method allows us to have quantitative direct measurements and to discriminate common trends and differences between different individual cells. On a bigger scale, from the point of view of cell motility, we investigate if the migratory behavior of macrophages changes de- pending on the different activation agents in order to fulfill specific biological needs. With this aim we conducted experiments to observe cells behaviors after stimulation from LPS (a molecule present on the outer membrane of gram-negative bacteria) and IFN-γ (used by macrophages for intercellular communication).

Keywords: Cell motility, NF-kB pathway.

Singlet molecular oxygen generation by light-activated DHN-melanin of the fungal pathogen *Mycosphaerella fijiensis* in Black Sigatoka disease of bananas

M. J. Beltran-Garcia[1], P. Di Mascio[2], M. H. Medeiros[2], F. M. Prado[2], M. Oliveira[3], A. Pessoa Jr[4], D. Ortiz[5], J. F. White Jr[6]
[1]*Chemistry, Universidad Autonoma de Guadalajara, Zapopan, Mexico,* [2]*Biochemistry, Universidade de Sao paulo, Sao Paulo,* [3]*Unidade Universitária de Ciências Exatas e Tecnológicas, Universidade Estadual de Goiás., Anápolis-Goiás-Brasil,* [4]*Faculdade de Ciencias Farmaceuticas, Departamento de Tecnologia Bioquımico-Farmaceutica, Universidade de Sao paulo, Sao Paulo, Brazil,* [5]*Instituto de Ingenieria, Universidad Autonoma de Baja California, Mexicali, Mexico,* [6]*Plant Biology and Pathology, Rutgers, NJ, USA*

In pathogenic fungi, melanin contributes to virulence, allowing tissue invasion and inactivation of the plant defence system, but has never been implicated as a factor for host cell death, or as a light-activated phytotoxin. Our research shows that melanin synthesized by the fungal banana pathogen Mycosphaerella fijiensis acts as a virulence factor through the photogeneration of singlet molecular oxygen O2 (1**D**g). Using analytical tools, including elemental analysis, ultraviolet/infrared absorption spectrophometry and MALDI-TOF mass spectrometry analysis, we characterized both pigment content in mycelia and secreted to the culture media as 1,8-dihydroxynaphthalene (DHN)-melanin type compound. This is sole melanin-type in *M. fijiensis*. Isolated melanins irradiated with a Nd:YAG laser at 532 nm produced monomol light emission at 1270 nm, confirming generation of O2 (1**D**g), a highly reactive oxygen specie (ROS) that causes cellular death by reacting with all cellular macromolecules. Intermediary polyketides accumulated in culture media by using tricyclazole and pyroquilon (two inhibitors of DHN-melanin synthesis) were identified by ESI-HPLC-MS/MS. Additionally, irradiation at 532 nm of that mixture of compounds and whole melanized mycelium also generated O2 (1**D**g). A pigmented-strain generated more O2 (1**D**g) than a strain with low melanin content. Banana leaves of cultivar Cavendish, naturally infected with different stages of black Sigatoka disease, were collected from field. Direct staining of the naturally infected leaf tissues showed the presence of melanin that was positively correlated to the disease stage. We also found hydrogen peroxide (H2O2) but we cannot distinguish the source. Our results suggest that O2 (1**D**g) photogenerated by DHN-melanin may be involved in the destructive effects of *Mycosphaerella fijiensis* on banana leaf tissues. Further studies are needed to fully evaluate contributions of melanin-mediated ROS to microbial pathogenesis.

Keywords: Melanin, *Mycosphaerella fijiensis*, singlet oxygen.

Structome analysis of rapid freeze-substituted *Mycobacterium tuberculosis* cells on serial ultra-thin sections by transmission electron microscope

H. Yamada[1], K. Chikamatsu[1], A. Aono[1], S. Mitarai[1], M. Yamaguchi[2]
[1]*Department of Mycobacterium Reference and Reserch, Research Institute of Tuberculsis, Japan Anti-Tuberculosis Association, Kiyose, Tokyo,* [2]*Medical Mycology Research Center, Chiba University, Chiba, Japan*

Introduction: Structome is a coined word by combining 'structure' and '-ome', and defined it as the quantitative and three-dimensional structural information of a whole cell at the electron microscopic level. We've performed transmission electron microscopy (TEM) of *Mycobacterium tuberculosis* (MTB) cells processed through rapid freeze-substitution (RFS), in which can preserve exquisite ultrastructure comparable to live cell. In this report, we quantitatively examined structural properties of MTB cells by RFS and serial ultra-thin section (SUS) and performed Structome analysis.

Materials and methods: MTB, H37Rv strain was cultured and freeze-substituted as described (2, 3). The SUSes were cut to a thickness of 55 nm, mounted on a grid with formvar support film, stained and examined with JEOL JEM-1230 and the images were analyzed with Fiji (ImageJ) software.

Results: Five MTB cells were cut into 24, 35, 69, 55 and 63 SUSes. Cell profiles were measured and the average data were as follows, length: 2.71 ± 1.05 μm, diameter of cell and cytoplasm were 0.345 ± 0.033 μm and 0.293 ± 0.025 μm, respectively. Cross section area of cell and cytoplasm were 0.115 ± 0.030 μm^2 and 0.092 ± 0.024 μm^2, respectively. Surface area of outer membrane (OM) and plasma membrane (PM) were 3.04 ± 1.26 μm^2 and 2.64 ± 1.18 μm^2, respectively. Volume of cell, OM, periplasm, PM, and cytoplasm were 0.286 ± 0.113 fl (=μm^3), 0.006 ± 0.002 fl, 0.057 ± 0.021 fl, 0.018 ± 0.008 fl and 0.204 ± 0.085 fl, respectively. Total ribosome number was $1,313 \pm 841$ (ranging from 49 to 1,997) and density was 597.9 ± 361.7 / 0.1 fl.

Conclusion: This is the first report of structome analysis in MTB cells prepared with RFS and examined SUS by TEM. These data must contribute to understanding of structural properties relating to the antigenicity, acid-fastness, and the mechanism of drug-resistance relation to the ratio of the targets to the corresponding drugs.

Structural and functional insights into ObcA

S. Rhee, J. Oh, E. Goo, I. Hwang
Agricultural Biotechnology, Seoul National University, Seoul, Korea

Bacterial quorum sensing (QS), a cell-to-cell communication in many *Proteobacteria*, coordinates the gene expression for population-wide characteristics. Recently, a novel concept of QS was recognized, in which QS provides further benefits at the population level by regulating the production of public goods. The function of public goods could be beneficial to all members of the group including QS-deficient, exploitative individuals. In the genus *Burkholderia*, oxalate was identified as an excreted public good for the group. Particularly, its acidity regulates the pH of the environment, avoiding a possible sudden collapse of the bacterial population caused by an alkaline pH in the stationary phase of their growth. Therefore, QS-mediated oxalogenesis is a cellular event indispensible for the survival of bacteria in the stationary phase. ObcA is the first of two enzymes in oxalate biosynthetic component (obc) in *B. glumae*. ObcA-dependent catalysis presents several interesting and unexpected features. It uses oxaloacetate and acetyl-CoA as substrates, metabolites also utilized by citrate synthase in the TCA cycle, and produces an anionic tetrahedral oxaloacetate-CoA adduct, which differs from the formation of the citroyl-CoA intermediate catalyzed by citrate synthase. The proposed CoA adduct from ObcA is degraded into oxalate, acetoacetate and CoA in ObcB-dependent catalysis. These structural features are absent in other structurally irrelevant but functionally related acetyltransferases, in which an acetylated substrate and CoA are commonly produced as product via a tetrahedral intermediate. Our structural and functional analyses revealed an unprecedented mechanism of oxalogenesis.

Keywords: bacterial quorum sensing, oxalogenesis, Structure Determination.

Structural basics for complex formation between HIV-1 integrase and its cellular co-factor Ku70

A. Anisenko, E. Knyazhanskaya, A. Bolbat, M. Gottikh
A.N. Belozersky Research Institute of Physico-Chemical Biology, Moscow State University, Moscow, Russian Federation

Today, the treatment of HIV infection mostly relies on a combination of inhibitors of viral enzymes (HAART) and as a result, drug resistant viral strains are eventually generated. However, a new approach for HIV drug design is being currently developed that is focused on the disruption of functional interactions between viral enzymes and their cellular co-factors. This approach has been proven to be applicable when compounds that specifically disrupt the interaction between HIV-1 integrase (IN) and its cellular co-factor LEDGF inhibited viral replication in cell culture.

Recently, a few reports showed that Ku70, which is a part of the DNA-PK complex, prevents HIV-1 IN from degradation potentially by a direct interaction. It is known, that in cells depleted of Ku70 levels of viral replication are significantly lowered. Thus, the inhibition of Ku70-IN interaction might affect viral replication. A detailed structure of Ku70/IN complex would greatly facilitate drug design. Unfortunately, only single domains of IN can be effectively crystallized. In this regard, it is important to estimate the minimal subdomains within IN and Ku70 that are required for complex formation.

A full-size N-His_6-tagged HIV-1 IN was purified form *E. coli* as well as its C-terminal domain (IN_220-270 a.a.). At first, two versions of Ku70, Ku70_wt and a protein carrying the first 430 amino acids of Ku70 (Ku70_430), were purified also from *E. coli* both carrying a GST-tag on their N-termini. Ku70_wt and Ku70_430 both formed stable complexes with IN with Kd approximated at 80 nM as determined by GST and His6 pull downs. Ku70_wt and Ku70_430 undergo proteolysis during expression with formation of one major N-terminal product (1-319 a.a., identified by mass-spectrometry). Interestingly, this proteolytic product when individually purified interacts with IN_wt as strongly as do larger proteins with Kd approximated at 70 nM. This deletion mutant of Ku70 also equally binds the C-terminal domain of IN. The X-ray structure of Ku70 shows that Ku70_430 contains the N-terminal domain and the DNA-binding ring stabilized by a β-barrel formed by N- and C- terminal a.a., while Ku70_319 contains just the N-terminal domain and a part of the DNA-binding loop. To investigate the function of DNA-binding loop in complex formation we constructed and purified additional Ku70 deletion mutants: Ku70_309, Ku70_294, Ku70_273 and Ku70_250, where the later comprised the sole N-terminal domain of Ku70. All of them co-precipitated with IN_wt. Therefore, the DNA-binding ring in Ku70 is not an essential structure for IN/Ku70 complex formation. Also, we successfully minimized the fractions of Ku70 and IN that are required for complex formation.

Perfringolysin O (PFO) is a toxic protein produced by *Clostridium perfringens* that binds to cholesterol-containing membranes.

© 2014 The Authors. FEBS Journal © 2014 FEBS

The interaction of perfringolysin O with cholesterol-rich membranes initiates a series of structural changes which result in the formation of a ring-shaped-barrel pore, leading to cell lysis. The pore formation mechanism is a three-step process consisting of binding of water-soluble monomers to the membrane, assembly into oligomeric prepore complex on the membrane surface and finally insertion of monomer amphipathic β-hairpins into the membrane, resulting in conversion of a prepore complex into a β-barrel pore.Previous studies have uncovered the scenario of events in this multistage structural transition to a considerable detail, but the underlying molecular mechanisms are not fully understood yet.

Using hydrogen-deuterium exchange coupled with mass spectrometry (HDX-MS) method we have obtained a detailed list of all regions which undergo structural changes caused by the interaction with lipid membranes and oligomerization, thus providing a new experimental constraints for molecular modeling of the pore formation process.

Obtained results indicate that HDX-MS can be useful method applied for study of structural changes of PFO derivatives during interaction with lipid membranes. Structural insight into the properties of PFO mutants can bring a new information helpful to elucidate the role of particular domains in conformational changes during formation of lytic pores.

Keywords: HDX-MS, pore-formation, toxin.

Structure-function relationship of the first strand transfer in human immunodeficiency virus type 1 (HIV-I)

O. Maskri[1], Y. Chen[1], F. Chaminade[1], B. René[1], Y. Mély[2], O. Mauffret[1], P. Fossé[1]

[1]CNRS UMR8113, LBPA, ENS de Cachan, 94235 Cachan Cedex, [2]CNRS UMR7213, Université de Strasbourg, 67401 Illkirch Cedex, France

HIV-1 can develop resistance to antiretroviral therapies and escape to the host immune system because it is prone to recombine via strand transfers occurring during the reverse transcription process. Reverse transcription of the HIV-1 genome consists in a succession of steps allowing the conversion of the single-stranded RNA genome into a double-stranded DNA molecule. An obligatory step of reverse transcription is the first strand transfer. Characterization the molecular mechanisms governing the first strand transfer would contribute to a better understanding of the reverse transcription process and of the strand transfers that are responsible for HIV-1 recombination. The first strand transfer relies on the annealing of the minus-strand strong-stop DNA (ssDNA) (the first DNA's part synthesized during reverse transcription) to the 3′ end of the viral RNA (3′ UTR RNA). This annealing reaction is facilitated by the HIV-1 nucleocapsid protein (NC) that destabilizes the nucleic acids secondary structures and promotes their association. Note that the annealing process of the full-length ssDNA to the 3′ UTR RNA is not known at the molecular and structural level. The main aim of this study is to better understand the NC-mediated annealing process. First, we use structural probes (potassium permanganate, kethoxal, dimethyl sulfate, DNase I, mung bean nuclease and RNase V1), to determine the secondary structures of the full-length ssDNA and the 3′ UTR RNA in the absence or presence of NC. Second, we investigate the structural changes in ssDNA and 3′ UTR RNA during the annealing process in order to identify the initiation and destabilization sites of hybridization. Finally, our results will be confirmed by site-directed mutagenesis.

Structure-functional study of PHL lectin from *Photorabdus asymbiotica*

G. Jancarikova, M. Wimmerova

National Centre for Biomolecular Research, Ceitec, Masaryk University, Brno, Czech Republic

Lectins are a very important group of proteins and glycoproteins, which specifically recognize and reversibly bind glycoconjugates. Due to this interaction, lectins play a crucial role in many physiological and pathophysiological processes including immunological reactions or interactions between tissue's cells. They also play a very important role in interactions between a pathogen and its host as they can mediate the first step of an expansion of infection. Currently, lectins become essential tools in the biological and medical research, i.e. to follow agglutination of erythrocytes, detection and characterization of different saccharide composition of glycoconjugates, mitogenic stimulation of lymphocytes, inhibition of fungal, bacterial and viral growth, etc. [1].

Our project is focused on study of a new lectin from the *Photorabdus asymbiotica* bacterium. It belongs to the *Photorabdus* genus together with *Photorabdus luminiscens* and *Photorabdus temperata*. The latter 2 species are characterized as strictly virulent insect pathogens. In contrast, *P. asymbiotica* is also a human pathogen, which causes locally invasive soft tissue and disseminated bacterimic infections. We have identified a new putative lectin in the *P. asymbiotica* genome with the predicted structure similarity to the lectins from so-called AAL family, which are specific for fucosylated oligosaccharide. The AAL family contains AAL from *Aleuria aurantia* which inhibits a repair of epithelia [2] or the RSL lectin from *Ralstonia solanaccearum* predicted as one of the key virulent factors of this plant pathogen [3].

A wide range of methods was used for structural a functional studies of PHL including surface plasmon resonance, isothermal titration calorimetry, analytic ultracentrifugation, hemagglutination, and X-ray structural analysis.

Analytical ultracentrifugation confirmed that PHL forms a dimer. The crystal structure of PHL revealed a presence of fourteen potential binding sites per monomer. PHL lectin belongs to seven beta-propellers, which makes this protein unique compared to proteins from AAL family, which share the six beta-propeller fold. Crystal structures of PHL with different saccharides demonstrated two types of binding sites, which could bind ligands with different polarity. PHL lectin showed highest affinity to fucose among studied monosaccharides. SPR revealed a strong multivalent effect when binding to the high-density fucosylated surface on a chip. Binding properties of PHL will be further studied with more complex saccharides.

Keywords: lectin, *Photorabdus asymbiotica*.

Study of the interaction of proline-rich antimicrobial peptides of caprine leukocytes with bacterial and mammalian cells

O. Shamova[1,2], A. Artamonov[2], V. Yukhnev[2], M. Zharkova[2], T. Pazina[2], E. Romanovskaya[1], V. Kokryakov[1,2], D. Orlov[1,2]

Antimicrobial peptides (AMPs) of the innate immune system play an important role in anti-infective host defense. Proline-rich peptides (PRPs) comprise a special group of AMPs whose members have a potent antimicrobial activity predominantly towards Gram-negative bacteria and negligible toxicity towards host cells

© 2014 The Authors. FEBS Journal © 2014 FEBS

and therefore can be considered as promising templates for development of new antibiotic drugs.

We explored an interaction of two proline-rich peptides ChBac3.4 and ChBac5, that we previously have isolated from goat leukocytes, with bacterial and mammalian cells. It was found that despite these peptides belonged to the same structural family of bactenecins, they displayed differences in the biological activity. Both peptides exhibited broad-spectrum antimicrobial action under low salt conditions and possessed similar lipopolysaccharide-neutralizing activity. In the presence of physiological concentration of NaCl the peptides retained the high activity towards Gram-negative bacteria including drug-resistant strains of *Acinetobacter baumannii, Pseudomonas aeruginosa, Klebsiella pneumonia*. While the activity of ChBac5 against staphylococci upon this condition was significantly decreased, the antibacterial action of ChBac3.4 was inhibited to a much lesser degree. Typically for most PRPs, antimicrobial action of ChBac5 was not accompanied by marked damaging of bacterial membranes; in contrast, ChBac3.4 caused relatively increased outer and inner membrane permeability of *E. coli* ML35p.

ChBac5 demonstrated the low toxicity for mammalian cells; ChBac3.4 exerted an unusual for PRPs cytotoxic activity towards cultured cells (human erythroleukemia cells K562, hystiocytic lymphoma cells U937, promyelocytic leukemia HL60 but not for normal human skin fibroblasts). The cells K562 or U937 treated with the peptide (10-20 μM) demonstrated the features of apoptosis; upon the higher peptide concentration (>40 μM) – necrosis. The differences in biological activity of two studied peptides might be partly due to higher hydrophobicity of ChBac3.4 in comparison with ChBac5 and other peculiarities of ChBac3.4 primary structure.

The obtained data contribute to understanding of the molecular mechanisms of the interaction of proline-rich peptides with bacterial and host cells and provide valuable information for the future structural-activity relationship study of PRPs synthetic variants directed to a design of novel anti-infective pharmaceuticals.

Study on S-nitrosoglutathione reductase from plant pathogens

L. Kubienová[1], M. Kopečná[2], D. Kopečný[2], L. Luhová[1], M. Petřivalský[1]
[1]Department of Biochemistry, [2]Department of Protein Biochemistry and Proteomics, Centre of the Region Haná for Biotechnological and Agricultural Research, Palacky University, Faculty of Science, Olomouc, Czech Republic

Nitric oxide (NO) and NO-related molecules such as *S*-nitrosothiols (*S*-NOs) play a central role in the regulation of plant physiological processes and host defence. The enzyme *S*-nitrosoglutathione reductase (GSNOR) participates in the control of *S*-NOs cellular homeostasis and in the metabolism of reactive nitrogen species. GSNOR has emerged as a key regulator of protein denitrosylation in plant defence to pathogens [1]. GSNOR has been recently characterized from several organisms like human, *Arabidopsis* or *Solanum* spp. [2]. This study represents the first detailed biochemical and structural characterization of GSNOR from plant pathogen, oomycete *Phytophthora infestans*, the causative agent of potato late blight. Corresponding gene (*PiGSNOR*, GenBank XM_002998982, 1160 bp) was sequenced, cloned and expressed in T7 *E. coli* cells as a N-terminal 6xHis tagged recombinant protein. We showed previously that in comparison to hGSNOR plant enzymes exhibit different composition of the anion-binding pocket, which negatively influences the affinity for w-hydroxyfatty acids [2]. GSNOR from *P. infestans* also differs in the anion-binding pocket composition and carries Ser113 in place of Gln112 found in human GSNOR and Gly114 found in plant GSNOR. PiGSNOR shows 63% sequence identity with SlGSNOR (GenBank GU296438) [2] and 67% identity with human (EMBL M30471). Detailed biochemical study of purified PiGSNOR was performed to characterize its stability, substrate affinity, cofactor preferences and sensitivity to known GSNOR inhibitors like a novel, first-in-class drug N6022 [3]. The obtained results will be used to get further insight on the role of S-nitrosylation and GSNOR both in pathogen and host cells during various stages of *Phytophthora* pathogenesis.

This work was supported by Ministry of Education, Youth and Sports of Czech Republic (LH11013), Czech Science Foundation (GACR P501/11/1591) and IGA 2014_020 of Palacký University in Olomouc.

WED-433
Substrate Protein interaction plays key role in microbial adhesion

S. Dutta
Department of Physics, Jadavpur University, Kolkata, India

Biomaterial-associated-infections remain a major cause of failure of biomaterial implants.

Microbial adhesion to a biomaterial surface is determined by ability of a pathogen to form a **biofilm** on it, which is again significantly dependent on the physicochemical properties of the implant surfaces. **Biofilms** are surface-associated microbial communities, which can form on a variety of surfaces in natural conditions and hospital niches.

But what are the controlling factors of **biofilm formation** on the surface of implant materials? That is the primary question that drives my research.

My research is focused on bacteria which are responsible for device-associated infections. Bacterial biofilms arise from microcolonies that become embedded in an extracellular matrix (or extrapolymeric matrix EPS), which is a glue, holding microbial cells together. The biofilm matrix contributes to the overall architecture and the phenotype of biofilms. Uncovering roles played by EPS matrices in biofilm formation will be beneficial in controlling **biofilm formation**. *In vivo*, biomaterials are rapidly covered with layers of adsorbed proteins from plasma, saliva, tear fluid, or other bodily fluids, depending on the implant site. Hence, adsorbed protein films play a vital role in microbial or tissue adhesion to the implant surface.

My experiment initiates with study of adsorption of fibrinogen, fibronectin and albumin from solutions of the respective proteins singly, on a variety of specimens of implant surfaces with varying degrees of hydrophilicity and thrombogenicity. This was studied with the help of a UV-Visible spectrophotometer and the respective data was plotted with requisite software. Adsorption behavior and hence adhesion shows a strong dependence on surface properties. All surfaces show a preference for fibronectin

© 2014 The Authors. FEBS Journal © 2014 FEBS

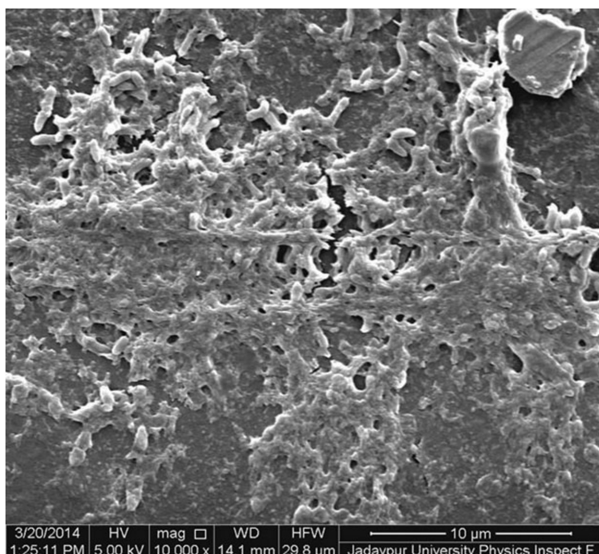

Fig. 1. Biofilm of *Pseudomonas aeruginosa* on polypropylene having fibronectin adsorbed on its surface.

and fibrinogen, and the degree of preference appears to correlate with thrombogenic tendency.

Next, biofilms of Pseudomonas aeruginosa were grown on these specimens of biomaterials by placing them in 24 well microtiter plates with bacterial culture and supplied with nutrient broth. These were kept inside a BOD incubator at 37 °C for 1 week. The biofilms were provided with nutrient broth for the whole period of growth. There was a control experiment in each case to observe the contribution of the adsorbed protein layers.

Finally each specimen of biomaterial was taken out of the microtiter plate, washed with distilled water and PBS. The biofilms were then fixed using glutaraldehyde and all samples were studied under a scanning electron microscope. The variation of the nature of biofilms and the EPS matrices in the differentt cases were worth noting and could be related primarily to the thrombogenicity of the adsorbed proteins and hydrophobicity of the biomaterial surfaces.

The bacterial cytolethal distending toxin: a nuclease inducing indirect DNA double-strand breaks into eukaryotic cells

E. Bezine[1,2], Y. Fedor[2,3], J. Vignard[2], E. Boutet-Robinet[2,3], B. Salles[2,3], G. Mirey[2,3]
[1]Institut National Polytechnique, UMR1331, Toxalim, Université de Toulouse, F-31000 Toulouse, [2]Toxalim Research Centre in Food Toxicology, INRA UMR1331, F-31027 Toulouse, [3]Université Paul Sabatier, UMR1331, Toxalim, Université de Toulouse, F-31062 Toulouse, France

The cytolethal distending toxin (CDT) is produced by many pathogenic Gram-minus bacteria like *Escherichia coli, Helicobacter hepaticus, Haemophilus ducreyi, Salmonella typhi* and others. *In vivo*, the production of CDT by *Helicobacter hepaticus* induces the development of dysplastic liver nodules, thus defining CDT as a potential carcinogen. *Ex vivo*, CdtB, the catalytic sub-unit of CDT, is relocated into the eukaryotic cell nucleus. There, CDT induces DNA double-stranded breaks (DSBs), leading to cell cycle arrest and cell death. However, after years of study, the CDT mode of action only begins to be unrevealed and many aspects remain to be studied.

To better characterize the CDT-induced DNA lesions, we are studying the biochemistry of CDT, specifically regarding its catalytic nuclease activity and relate these aspects to the overall cellular effects of the toxin. Based on the literature and on the structural homology of CdtB with the DNase I, we developed several CDT mutants for specific residues involved in the catalytic activity. The DNA binding and the nuclease activities of CdtB are studied by *in vitro* tests, like Supercoiled DNA cleavage and DNA binding assay. *Ex vivo*, CDT-induced DNA damages and the activation of specific DNA damage response (DDR) pathways have been characterized. Thanks to comet assay and immunofluorescence staining, we have shown that, depending on the CDT dose, DSBs (high doses) or SSBs (moderate doses) will be induced, the later degenerating into DSBs following the replication. In fact, after a treatment with moderate doses, CDT-induced DNA damages leading to the activation of the DDR involving the RPA, ATR and CHK1 proteins, characteristic of a replicative stress. The DSBs DDR involving the ATM pathway, occurs later during CDT treatment.

The importance of the S-phase passage for the CDT cytotoxicity suggests that proliferating cells are more sensitive to CDT than quiescent cells. The presence of unrepaired damage can lead to cell death, whereas effective repair will allow cells to resume cell cycle. However, improper repair of DNA damage can induce genetic instability and lead to cancer. Bacterial niches containing CDT producing strains are located at epithelia that are quick renewal tissues. Understanding the effects of CDT at the cellular level is an essential step in order to understand these effects at the tissue and/or organism level as well as CDT's involvement in bacteria pathogenicity.

The epizootic hemorrhagic disease virus (EHDV) induces and benefits from cell stress, autophagy and apoptosis

B. Shai, M. Ehrlich
Cell Research and Immunology, Tel Aviv University, Tel Aviv, Israel

The mode and timing of virally-induced cell death withhold the potential of regulating viral yield, viral transmission and the severity of virally-induced disease. Orbiviruses such as the epizootic hemorrhagic disease virus (EHDV) are nonenveloped and cytolytic. To date, the death of cells infected with EHDV, the signal transduction pathways involved in this process and the consequence of their inhibition have yet to be characterized. Here, we report that the Ibaraki strain of EHDV2 (EHDV2-IBA) induces apoptosis, autophagy, a decrease in protein synthesis and the activation of c-Jun N-terminal kinase (JNK) and the phosphorylation of its substrate c-Jun. Inhibition of: (i) apoptosis with the pan-caspase inhibitor Q-VD-OPH, (ii) autophagy with 3-methyladenine or via the knockout of the autophagy regulator Atg5, and (iii) c-Jun phosphorylation with the JNK inhibitor SP600125 or with the cyclin-dependent-kinase (cdk) inhibitor roscovitine, independently attenuated the increase in viral titer in the course of infection. Moreover, SP600125 and roscovitine attenuated the EHDV2-IBA-mediated induction of autophagy. Taken together, our results imply that EHDV induces and benefits from the activation of signaling pathways involved in cell stress and death.

Keywords: Apoptosis, Autophagy, EHDV.

The impact of phosphate limitation on bacterial pathogenicity of *T. thermophilus* HB8

A. A. Pantazaki[1], E. G. Andreadou[1], T. Choli-Papadopoulou[2]
[1]Department of Chemistry, [2]Aristotle University, Thessaloniki, Greece

Environmental inorganic phosphorus constitutes the growth limiting nutrient for aquatic microorganisms. When starved for phosphate, bacteria adapt to their environment to increase their ability to take up inorganic phosphate. Example of an adaptation is the bacterial morphogenesis ending in the elaboration of long, filiform tubular extensions of the cell envelope of certain aquatic bacteria called stalks. Clinical isolates of *P. aeruginosa* formed stalks induced by phosphate limitation, which contain a DING protein named from the first 14 amino acids. This protein is an alkaline phosphatase. Bacteria, for motility and phosphate acquisition, develop also flagella, where the principal substituent is flagellin. They secrete also rhamnolipids as virulence factors. The formation of flagella is enhanced after prolonged cultivation time where phosphate and other nutrients were depleted; thus it seems likely that these organelles have a role in the virulence of pathogenic organisms.

The non pathogen bacterium *T. thermophilus* when cultivated in low phosphorus showed after dyeing stalks and produced rhamnolipids in contrast to those cultivated in rich medium. The length of the stalks was inversely related to phosphate concentration. Stalks were isolated and an alkaline phospatase activity was found to be localized on stalks. This activity was purified with a gel filtration chromatographic Sephadex G-150 superfine column and a band of 40 kDa molecular weight was immuno-stained in Western blot using antibody against DING protein. To elucidate the possible co-localization on the stalks of flagellin, DING and rhamnolipids, a stalks preparation was also tested by Dot blot immunoassay using three antibodies against these constituents. All antibodies immuno-cross reacted suggesting the presence of these three constituents in the stalks structure and the immunosignal was affected by the phosphate concentration. Moreover, a Western blot analysis of stalks after SDS-PAGE, with the same three pre-referred polyclonal anti-sera, was also performed. This analysis resulted in a band of the same molecular weight with all three antibodies suggesting that DING protein, flagellin and rhamnolipids probably form a complex.

The intestinal Muc2 mucin can influence on the binding, swarming and chemotaxis processes in *Vibrio cholerae* along the gut

R. L. Galvez Rojas, G. Saavedra, N. Favi, J. I. Vasquez, J. Santander
Center for Genomics and Bioinofrmatics, Universidad Mayor, Santiago, Chile

To successfully infect and colonize the human intestine, *Vibrio cholerae* must penetrate the intestinal mucus layer system and express virulence genes. The first line of defense against the microbes is the intestinal mucus layer system that covers and protects the intestinal epithelial cells. The intestinal mucus system of both the small intestine and colon is organized around the highly glycosylated Muc2 mucin, that forms large net-like polymers that are secreted by the goblet cells. Recent knowledge suggests that mucin-sensing signaling systems are required for the bacterial pathogen colonization of the mammalian intestine. *V. cholerae* activates a colonization mechanism towards the mucus layers which has been correlated with the pathogen′s competence in penetrating the mucus and reaching the small intestine, but the precise role of this process during infection has not been clearly established. We have established an In vitro system where we have purified mouse Muc2 mucin from different regions along the intestinal tract and we expose it to the presence of *V. cholerae* in order to evaluate the growth, binding, the swarming and the chemotaxis process. Our results shows that *V. cholerae* can growth to the presence of intestinal Muc2 mucin obtained from different regions along the gut, and binds preferentially to Muc2 mucin from ileum, proximal and distal colon. The chemotactic responses to the presence of Muc2 mucin are predominantly found from the jejunum, ileum and middle colon. Intriguingly, high *V. cholerae* swarming activity to the presence of Muc2 mucin was found on the jejunum and the whole large intestine. Taken together, these data suggests an interesting scenario where *V. cholerae* might sense the gut environment through the presence of Muc2 mucin.

Keywords: intestinal colonization, Intestinal Muc2 mucin, *Vibrio cholerae*.

The periplasmic binding protein AccA from the plant pathogen *Agrobacterium tumefaciens*

A. El Sahili
LEBS UPR CNRS 3082, Gif Sur Yvette, France

Agrobacterium tumefaciens is a soil bacterium that is pathogenic for several plants causing the crown gall disease, which is characterized by tumour formation at the infection site. The virulence of the bacteria is brought by the presence of the virulence plasmid pTi. The infection mechanism is well known and composed of 4 steps:

1. The wound on the plant activates *A. tumefaciens*' virulence plasmid.
2. T-DNA, a piece of the pTi is then transferred to the plant's cell and integrated to its genome.
3. The plant secretes hormones, triggering the tumour formation, tumours which are colonized by *A. tumefaciens*. The plant also secretes Agrocinopine that is used as energy source by the bacterium.
4. Agrocinopine also activates quorum sensing mechanisms in *A. tumefaciens* leading to spreading of the pTi to non-virulent bacteria.

Agrocinopine is imported in the bacteria by Acc system. Acc is composed of an ABC transporter and a periplasmic binding protein. The PBP AccA that recognize Agrocinopine. Genetic studies showed that AccA also was responsible for the import of Agrocine 84, a lethal toxin, produced by another bacteria A. radiobacter K84. The subject of my thesis is the understanding of the interaction specificity of the PBP AccA with Agrocinopine and Agrocine 84, thus combining structural and biochemical studies of the complexes formed by AccA with its ligands.

In order to understand these interactions, we determined the first 3D structure of a PBP with its opine ligand. We also determined the structure in complex with the toxin Agrocine 84 allowing us to characterize the interaction with each ligand. Combined with biochemical studies, our findings revealed the interactions involved in the binding of the two antagonist ligands leading to their import by the corresponding Acc ABC transporter.

The prevalence of *Leucocytozoon toddi* in bird blood samples in Aras-Iğdır and evaluation of its phylogenetic relationships

Ö. Akbaba[1], Ç. H. Şekercioğlu[2,3], S. İnak[2,4], R. Bilgin[1]
[1]Boğaziçi University Institute of Environmental Sciences, Istanbul, [2]KuzeyDoğa Derneği, Ortakapı Mah. ehit Yusuf Cad, Kars, Turkey, [3]Department of Biology, University of Utah, Salt Lake City, USA, [4]Deparment of Biology, Faculty of Science, Kafkas University, Kars, Turkey

Today biological diversity is faced with high risks of extinction due to the overuse of natural resources. Studies of bird species constitutes a central theme in ecological investigations and for conservation of biological diversity. The identification of parasitic infections encountered in birds provide contributions to ecological studies with regards to the persistence of species. The aim of this study is the detection of the prevalance of *Leucocytozoon toddi* infection in birds of Aras-Iğdır region, using genetic methods. 401 blood samples belonging to 58 bird species of 25 different families were investigated. *L. toddi* infection was detected in 41 samples and five distinct haplotypes were obtained from six sequences. Phylogenetic trees were constructed using these five haplotypes along with 265 sequences of 76 species taken from GenBank and MalAvi databases. Four out of five haplotypes of Aras-Iğdır positive samples were distinct from those in literature. Again four of the five Aras-Iğdır haplotypes clustered very closely together, potentially suggesting some genetic isolation in this migratory pathway. The phylogenetic comparisons made using all sequences also support the idea of the presence of two cryptic species of *L. toddi*.

Keywords: Avian haemosporidians, Host-switching, *Leucocytozoon toddi*.

WED-441
The RfaH in *Yersinia enterocolitica* O:3 is a high specificity regulator

K. Knapska[1], M. Varjosalo[2,3], Z. Li[1,4], C.-M. Li[1,2], M. Skurnik[1,5]
[1]Bacteriology and Immunology, [2]Institute of Biotechnology, [3]Biocentrum Helsinki, [4]Neuroscience Center, University of Helsinki, [5]Helsinki University Central Hospital Laboratory Diagnostics, Helsinki, Finland

RfaH is a regulatory protein functioning as antiterminator for long operons. In some bacterial species like *Escherichia coli* and *Salmonella enterica* it promotes the expression of selected operons encoding extracytoplasmic cell components, such as lipopolysaccharide (LPS), capsule, hemolysin, exotoxin, hemin uptake receptor and F pilus. Due to the fact that these structures are required for bacterial virulence, loss of RfaH usually attenuates virulence. We report that in *Yersinia enterocolitica* O:3 it acts as a highly specific regulator that enhances the transcription of O-antigen and outer core encoding operons, yet does not affect the expression of enterobacterial common antigen (ECA). The luciferase promoter reporter analysis confirmed the decrease in transcription of these two oprerons upon the inactivation of RfaH. Furthermore, the transcriptomic analysis of $\Delta rfaH$ strain and a spontaneous rough mutant revealed similarities in the gene expression patterns indicating that the $\Delta rfaH$ mutation triggers via the loss of O-antigen indirect responses, including changes in the outer membrane and Cpx pathway stress response. Moreover, decrease in the amount of LPS on the cell surface results in stress response and lower resistance to such compounds as sodium dodecyl sulfate and polymyxin B. Interestingly, loss of RfaH resulted in marginally higher resistance to normal human serum. It may be speculated that RfaH might have *in vivo* role in controlling tissue-specific expression of bacterial surface oligo/polysaccharides.

WED-442
The RNA chaperonne activity of Vif is mainly contained in its C-terminal domain

D. Sleiman[1], B. Serena[2], J.-C. Paillart[2], C. Tisné[1]
[1]University Paris Descartes, CNRS, Paris, [2]University of Strasbourg, CNRS, Strasbourg, France

The viral infectivity factor (Vif) is essential for the productive infection and dissemination of HIV-1 in non-permissive cells, containing the cellular anti-HIV defense cytosine deaminases APOBEC3 (A3G and A3F). Vif neutralizes the antiviral activities of the APOBEC3G/F by diverse mechanisms including their degradation through the ubiquitin/proteasome pathway and their translational inhibition. In addition, Vif appears to be an active partner of the late steps of viral replication by interacting with $Pr55^{Gag}$, reverse transcriptase and genomic RNA. In this study, we expressed and purified full-length and truncated Vif proteins, and analyzed their RNA binding and chaperone properties. First, we showed by CD and NMR spectroscopies that the N-terminal domain of Vif is highly structured in solution, whereas the C-terminal domain remains mainly unfolded. Both domains exhibited substantial RNA binding capacities with dissociation constants in the nanomolar range, whereas the basic unfolded C-terminal domain of Vif was responsible in part for its RNA chaperone activity. Second, we showed by NMR chemical shift mapping that Vif and NCp7 share the same binding sites on $tRNA^{Lys}{}_3$, the primer of HIV-1 reverse transcriptase. Finally, our results indicate that Vif has potent RNA chaperone activity and provide direct evidence for an important role of the unstructured C-terminal domain of Vif in this capacity.

Keywords: HIV-1, RNA, vif.

The *Salmonella* effector SteA contributes to the control of membrane dynamics of *Salmonella*-containing vacuoles

J. Mota[1,2], D. W. Holden[3], L. Domingues[1,2]
[1]Centro de Recursos Microbiológicos (CREM), Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, [2]Infection Biology Laboratory, Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, [3]MRC Centre for Molecular Bacteriology and Infection, Imperial College London, London, UK

Salmonella enterica serovar Typhimurium (*S.* Typhimurium) is a bacterial pathogen causing gastroenteritis in humans and a typhoid-like systemic disease in mice. *S.* Typhimurium virulence is related to its capacity to multiply intracellularly within a membrane-bound compartment, the *Salmonella*-containing vacuole (SCV), and depends on type III secretion systems that deliver bacterial effector proteins into host cells. Here, we analyzed the cellular function of the *Salmonella* effector SteA. We show that, compared to cells infected by wild-type *S.* Typhimurium, cells infected by $\Delta steA$ mutant bacteria displayed less *Salmonella*-induced filaments (SIFs), an increased clustering of SCVs, and morphologically abnormal vacuoles containing more than one bacterium. The increased clustering of SCVs and the appearance of vacuoles containing more than one bacterium were suppressed by inhibition of the activity of the microtubule motors dynein or

© 2014 The Authors. FEBS Journal © 2014 FEBS

kinesin-1. Clustering and positioning of SCVs are controlled by the effectors SseF and SseG, possibly by helping to maintain a balanced activity of microtubule motors on the bacterial vacuoles. Deletion of *steA* in *S.* Typhimurium Δ*sseF* or Δ*sseG* mutants revealed that SteA contributes to the characteristic scattered distribution of Δ*sseF* or Δ*sseG* mutant SCVs in infected cells. Overall, this shows that SteA participates in the control of SCV membrane dynamics. Moreover, it indicates that SteA is functionally linked to SseF and SseG, and suggests that it might contribute directly or indirectly to the regulation of microtubule motors on the bacterial vacuoles.

The three Serine Rich proteins encoded in the secA2Y2 system of the human commensal bacterium *Streptococcus salivarius* promotes binding to different targets of the host

B. Couvigny, E. Guedon
Micalis, INRA, Jouy en Josas, France

Bacterial adhesion to host and bacterial surfaces is a crucial step for colonization, development of microbial communities and the establishment of a bacterial-host cross-talk. To characterize molecular mechanisms underlying adhesion of commensal bacteria, we used *Streptococcus salivarius* (SSAL) as a model. SSAL is among the most important pioneer colonizers of neonatal oral mucosal surfaces, and later becomes a predominant component of the human adult oral microbiota with pre-eminent ecological role and a sub-dominant bacterium of the human gastro-intestinal tract.

We identified, through phenotypic screening assays, genes involved in SSAL adhesion to host surfaces. In particular, we showed that the SecA2Y2 system, which comprises genes devoted to glycosylation and export of surface Serine Rich repeat Proteins (SRPs), participates to bacterial aggregation, biofilm formation, *in vitro* adhesion and potential colonization of mice. While all bacteria containing a similar system possess only one SRP, the SSAL *secA2Y2* locus comprises three SRPs with complementary role in line with the previous phenotypes. Interestingly, SrpB is specifically involved in the binding to epithelial cells, while SrpC to the extracellular matrix proteins. We showed that these interactions require glycosylation of both bacterial SRPs and host surfaces.

This work is the first report showing the presence in a bacterium of three SRPs, which display complementary roles in bacterial-host interaction. It also underlines the role of glycosylation of both host and bacterial components in these processes. Finally, while the SecA2Y2 system is mostly associated to virulence in pathogenic bacteria, it appears to be involved in the expression of commensal traits in SSAL, such as its colonization and its resilience to oral and intestinal niches. This work may offer new insights into the mechanisms of niche establishment (host, microbial communities) of commensal bacteria.

Keywords: adhesion, commensal-host, interaction.

Transcript and metabolite analysis of *Vitis vinifera* cv. Trincadeira berries infected with *Botrytis cinerea* reveals a suppression of developmentally activated defenses

S. P. Agudelo-Romero[1], A. Erban[2], C. Rego[3], T. Nascimento[3], P. Carbonell-Bejerano[4], L. Sousa[5], J. M. Martínez-Zapater[4], J. Kopka[2], A. M. Fortes[1]
[1]*Center for Biodiversity, Functional & Integrative Genomics, Universidade de Lisboa, Lisbon, Portugal,* [2]*Max-Planck-Institut für Molekulare Pflanzenphysiologie, Potsdam-Golm, Germany,* [3]*Instituto Superior de Agronomia, Universidade de Lisboa, Lisbon, Portugal,* [4]*Instituto de Ciencias de la Vid y del Vino (ICVV), Consejo Superior de Investigaciones Científicas-Universidad de La Rioja-Gobierno de La Rioja, Logroño, Spain,* [5]*Centro de Estatística e Aplicações, Universidade de Lisboa, Lisbon, Portugal*

Vitis vinifera berries are sensitive towards infection by the necrotrophic pathogen *Botrytis cinerea* leading to important economic losses worldwide. The combined analysis of the transcriptome and metabolome associated with fungi infection has not been previously performed in grapes or in another fleshy fruit.

In an attempt to identify the molecular and metabolic mechanisms associated with the infection, pepper-corn size fruits were infected in-field. Green berries and *véraison* berries were collected following infection for microarray analysis. These transcriptome analyses were complemented with metabolic profiling of primary and other soluble metabolites and of volatile emissions.

The results provide evidence of a reprogramming of carbohydrate and lipid metabolisms towards increased synthesis of secondary metabolites involved in plant defense, such as *trans*-resveratrol and gallic acid. The response is already activated in infected green berries with the putative involvement of jasmonic acid, ethylene, polyamines and auxins whereas salicylic acid does not seem to be involved. Genes encoding protein kinases, WRKY transcription factors, pathogenesis-related proteins, glutathione S-transferase, stilbene synthase and phenylalanine ammonia-lyase were up-regulated in infected berries. However, salicylic acid signaling is activated in healthy ripening berries along with the expression of proteins of NBS-LRR superfamily suggesting that ripening berries have defenses that are absent in infected berries. Furthermore, this study provided metabolic biomarkers of infection such as azelaic acid, a substance known to prime plant defense responses, arabitol, ribitol, 4-amino butanoic acid, 1-O-methyl- glucopyranoside and several fatty acids that alone or in

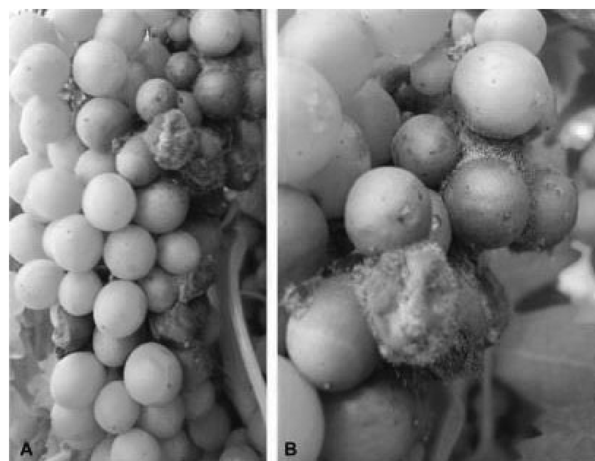

Fig. 1.

WED-446

Transcription activator-like effectors (TALEs) are effective modulators of transcription in *Leptospira* spp.

C. Pappas[1,2], M. Picardeau[1]

[1]Unité des Spirochetes, Institut Pasteur, Paris, France, [2]Biology, Manhattanville College, Purchase, NY, USA

Objective: Leptospirosis is a neglected zoonotic disease that affects approximately one million people annually with a mortality rate greater than ten percent. While an important global disease, there is a deficiency of effective genetic manipulation tools available for targeted mutagenesis in pathogenic *Leptospira* spp. Transcription Activator-Like Effectors (TALEs) are a recently described group of proteins which modify transcriptional activity in prokaryotic and eukaryotic cells by directly binding to a targeted sequence of repeat variable di-residues responsible for transcriptional control. This study aims to elucidate the efficiency of TALEs within *Leptospira* spp. for targeted repression.

Methods: To determine the function of TALE within *Leptospira* spp., three distinct TALE constructs were designed: a *tale* specific for the *lacO*–like region in the saprophyte *Leptospira biflexa* (pTALE$_{\beta\text{-}gal}$); a *tale* specific for the promoter for *ligA* and *ligB* in the pathogenic strain *Leptospira interrogans* (pTALE$_{lig}$); and a *tale* specific for the promoter of *loa22* in the pathogenic strain *Leptospira interrogans* (pTALE$_{loa22}$). Prior to *tale* insertion in each genome, respectively, the TALE repressors were placed distal to *flgB*, a constitutively expressed promoter, and inserted into suicide vector pSC189ColE1 carrying the *Himar1* mariner transposon system, which then randomly inserts the *flgB-tale* construct into the bacterium's genome.

Results: RT-PCR analysis demonstrated β-galactosidase was not transcribed in pTALE$_{\beta\text{-}gal}$ in vitro; Miller ONPG enzymatic assay revealed pTALE$_{\beta\text{-}gal}$ produced 0 mU of β-galactosidase, while wild type produced 3.36 mU β-galactosidase. Cells grown on solid media supplemented with 100 μM IPTG and 80 μg/ml X-gal revealed wild type produced blue colonies, while pTALE$_{\beta\text{-}gal}$ produced white colonies. pTALE$_{lig}$ showed a 6-8 fold reduction in expression of LigA and LigB by Western blot analysis when grown under osmotic stress (120 mM NaCl). pTALE$_{loa22}$ showed a 3 fold reduction in expression of Loa22 by qRT-PCR and Western blot analysis.

Conclusion: TALE effectively reduces expression of targeted genes within saprophytic and pathogenic strains of *Leptospira* spp., which provides an additional genetic manipulation tool for this genus. Future work includes testing pTALE$_{lig}$ and pTALE$_{loa22}$ for reduced virulence in vivo, and testing additional TALE constructs that have been designed for attachment to distinct promoter regions of *ligA*/*ligB*, and *loa22* to determine if TALE can further repress expression of these genes.

This work was supported in part by National Science Foundation grant IIA-1159099.

Keywords: *Leptospira*, TALE, Transcription Repression.

Understanding the cellular function of SAMHD1: from HIV restriction to tumor suppression

T. Louis[1], R. Clifford[2], F. Sigaux[3], J.-G. Judde[4], M. Rotger[5], A. Telenti[5], Y.-L. Lin[1], P. Pasero[1], A. Schuh[2], M. Benkirane[1]

[1]Institute of Human Genetics, CNRS UPR1142, Montpellier, France, [2]Oxford National Institute for Health Research Biomedical Research Center/Molecular Diagnostic Center, University of Oxford, Oxford, UK, [3]Laboratory of Molecular Hematology, Centre Hayem, Hôpital Saint Louis, INSERM U462, Paris, [4]Xentech SAS, Genopole, Evry, France, [5]Institute of Microbiology, University Hospital Center and University of Lausanne, Lausanne, Switzerland

SAMHD1 was identified as a deoxynucleoside triphosphate (dNTP) triphosphohydrolase and a potential nuclease that acts as an HIV-1 restriction factor in noncycling cells. Germline mutations in the corresponding gene have been described in 17% of the patients suffering from Aicardi-Goutières syndrome, a disease mimicking congenital infections.

We investigated the role of SAMHD1 outside the context of HIV-1 infection and we showed that (i) This protein is expressed at low levels in proliferating transformed cell lines. (ii) Overexpression of wild-type SAMHD1 slows down cell proliferation and promotes cell death after induction of DNA double strand breaks (DSB). (iii) SAMHD1 was specifically regulated and recruited to DSB sites after DNA damaging treatment.

Considering the importance of cell proliferation, DNA damage response and dNTP metabolism in tumorigenesis, we looked at SAMHD1 expression in several cancer types. We provided evidence that SAMHD1 expression is decreased in patients suffering from various hematopoietic cancers and breast cancers. Moreover, in the specific case of Chronic Lymphocytic Leukemia, in addition to reduced SAMHD1 expression at both mRNA and protein levels, we observed mutations in the corresponding gene. This mutation rate is increased in treatment-resistant tumors.

Taken together, this data strongly suggest that SAMHD1 loss during tumorigenesis may not only favor cancer development by promoting DNA instability and cell proliferation, but also confer a drug-resistant phenotype to tumor cells. More studies will be needed to further characterize SAMHD1 roles in resistance to chemotherapy and DNA damage repair.

Virulence and resistance markers in foodborne bacteria isolated in Bucharest, Romania

A. L. Mateescu[1], T. V. Dimov[2], M. M. Mitache[3], M. C. Chifiriuc[1], C. Bleotu[4], V. Lazar[1]

[1]Microbiology, [2]Departament of Genetics, Faculty of Biology, [3]Nosocomial Infections, Division of Public Health, [4]Department of Antiviral Therapy, Stefan S. Nicolau Institute of Virology, Bucharest, Romania

Objective: The aim of this work was the assessment of the microbiological risk for consumers health, by evaluating virulence and resistance determinants of food borne bacteria isolated from food products in Bucharest, Romania.

Methods: A number of 144 bacterial strains belonging to *Enterobacteriaceae*, *Listeriaceae* and *Micrococcaceae* families were isolated and identified, according to the updated ISO standards concerning food safety. Phenotypic assays: (i) adherence to eukaryotic HEp-2 cells (Cravioto's adapted method); (ii) biofilm development on the inert substratum (slime production assay);

© 2014 The Authors. FEBS Journal © 2014 FEBS

(iii) soluble enzymatic factors expression; (iv) antibiotic susceptibility testing (disk diffusion method). PCR detection of virulence and resistance genes: (i) virulence associated genes in enterobacteria (eaea, bfpA, eaf, AggR, EAggE, afa, pap, sfa, VT1,VT2, EAST1, pldA, helD, spvC, invA); in *Listeria* sp. (hlyA, prfA); and in strains from the genus *Staphylococcus* (cna, icaA, tst, eta, fnbB, fib, clfA, clfB) (ii) antibiotic resistance genes (fox, mox, blaTEM, blaCTX-M, cit, dha, accm, ebcm, tetA, tetB, tetC, tetD, dfrD).

Results: Most of the analyzed strains showed the ability to adhere to both eukaryotic cells and inert substratum. Also, many of the analyzed strains produced proteases, glucidases and iron-chelating agents. We identified 9 multidrug resistant strains (beta-lactams, tetracyclines, folate pathway inhibitors/aminoglycosides), ESBL and AmpC producing strains being also detected. The Gram-positive strains belonging to *Staphylococcus* and *Listeria* genera were susceptible to most of the tested antibiotics. The molecular assay revealed the presence of multiple virulence and/or resistance genes in the analyzed strains.

Conclusions: The ability of food borne bacteria to adhere to eukaryotic cells is indicating the potential of these strains to initiate an infection in the human or animal host, while adherence to the inert substratum and biofilm formation on the food processing surfaces is the main method through which strains of different genera persist in the food chain. The presence of ESBL and AmpC producing strains in food products is a cause of concern, because these phenotypes are usually accompanied by a low susceptibility to other classes of antibiotics. These results are of major importance not only for the health of Romanian consumers, but also for those in other countries that import food products from Romania.

Keywords: foodborne bacteria, resistance, virulence.

WED-449

Yeast as a tool to unravel the mode of action of bacterial effectors from *Bartonella* spp. and *Brucella* spp.

S. Siamer[1], H. M. Vasquez[2], C. Mistl[1], A. Conzelmann[2], C. Dehio[1]

[1]Infection Biology, University of Basel, Basel, [2]Department of Biology, University of Fribourg, Fribourg, Switzerland

Many intracellular bacteria ensure their survival and proliferation within host cells by secreting effector proteins that modulate various cellular functions. Among these, we focus on two closely related alpha-proteobacterial pathogens: *Bartonella* spp. and *Brucella* spp. Both pathogens cause chronic infections in mammals including humans using distinct strategies. Several virulence factors allow them to adhere, invade, proliferate and persist within various host-cell types. Among these virulence factors, type IV secretion systems (T4SS) are essential to these bacteria by injecting effector proteins inside host cells. Once into the cells, these proteins modulate cellular processes to the benefit of the bacteria. Thus, defining the role of these Type IV effector proteins is a key to understand pathogenesis. The use of *S. cerevisiae* as a surrogate host is emerging as an efficient strategy to study bacterial effectors. As a first approach, we used the yeast model to establish a genetic screen and look for mutants hypersensitive or suppressor to the expression of effector proteins from *Bartonella rochalimae* and *Brucella abortus*. This genetic screen led to the identification of mutants affected in transport from endosome to vacuole, for several bacterial effectors tested and mutants affected in actin organization and regulation, for one effector tested from *B. rochalimae*. Now, we would like to validate the results of the genetic screen by expressing these bacterial effectors in human cells.

Keywords: Type IV effectors, pathogenesis, yeast.

Biosynthesis of wyosine derivatives in tRNAPhe of Archaea: role of a remarkable bifunctional tRNAPhe:m1G/imG2 methyltransferase

J. Urbonavicius[1], R. Rutkiene[1], A. Aucynaite[1], D. Tauraite[1], J. Napryte[1], J. Stankeviciute[1], R. Meskys[1], H. Grosjean[2]
[1]*Department of Molecular Microbiology and Biotechnology, Vilnius University Institute of Biochemistry, Vilnius, Lithuania,*
[2]*Centre de Genetique Moleculaire, CNRS, Gif-Sur-Yvette, France*

The presence of tricyclic wyosine derivatives 3′-adjacent to anticodon is a hallmark of $tRNA^{Phe}$ in eukaryotes and archaea. In yeast *Saccharomyces cerevisiae*, formation of wybutosine (yW) results from five enzymes acting in a strict sequential order. In archaea, the intermediate compound imG-14 (4-demethylwyosine) is a target of three different enzymes, leading to the formation of distinct wyosine derivatives (yW-86, imG, and imG2). Based on our previous experimental data (de Crecy-Lagard et al., Mol.Biol.Evol., 2010) and present comparative genomics analysis, we predicted the existence of a peculiar methyltransferase displaying a dual-specificity (aTrm5a) in several archaeal species. Combining a TLC and HPLC/MS analysis, we confirmed that Trm5a enzyme of *Pyrococcus abyssi* catalyzes two distinct reactions: N1-methylation of guanosine and C7-methylation of imG-14, whose function is to allow the production of isowyosine (imG2), an intermediate of the 7-methylwyosine (mimG) biosynthetic pathway. Based on the formation of mesomeric forms of imG-14, a rationale for such dual enzymatic activities is proposed. This bifunctional tRNA:m1G/imG2 methyltransferase, acting on two chemically distinct guanosine derivatives located at the same position of $tRNA^{Phe}$, is unique to certain archaea and has no homologues in eukaryotes. This enzyme here referred to as Taw22, probably played an important role in the emergence of the multistep biosynthetic pathway of wyosine derivatives in archaea and eukaryotes.

Keywords: Archaea, tRNA, wyosine.

WED-452
Comprehensive analysis of single-nucleotide polymorphisms in major polyadenylation signal (AATAAA) in human genome

Y. Kainov[1], V. Aushev[1], S. Naumenko[2], I. Zborovskaya[1], G. Bazykin[2]
[1]*Oncogene Regulation Department, Institute of Carcinogenesis,*
[2]*Molecular Evolution Department, Institute for Information Transmission Problems of the Russian Academy of Sciences (Kharkevich Institute), Moscow, Russian Federation*

Polyadenylation is an important step of mRNA processing and crucial for mRNA stability and expression. More than a half of human genes have more than one polyadenylation site, resulting in great transcript diversity. These transcript isoforms, generated by a process called "alternative polyadenylation", differ in their stability, translational activity, and even in coding region structure. It is known that cell differentiation and malignant transformation affect the pattern of mRNA polyadenylation. The major polyadenylation signal comprises the AATAAA-hexamer that is recognized by CPSF (Cleavage and polyadenylation specifity factor) multisubunit complex. In this work, we for the first time investigate single nucleotide polymorphisms (SNPs) in the AATAAA-polyadenylation signals (and its variants) in human genome using the data from The 1000 Genomes Project. In about 54000 investigated hexamers we observed about 2400 SNPs. SNPs are depleted in two common hexamer variants (AATAAA and ATTAAA), and enriched in rare signal variants (such as AATATA, AATACA and others). Polyadenylation signals contained SNPs are less likely to be conserved in mouse. Furthemore, SNPs are depleted in signals near "unique" polyadenylation site (one site per gene). Interestingly, we observed that alternative polyadenylation sites (proximal and distal) do not statistically differ in amount of SNPs as well as in its allelic frequencies. Polyadenylation signals carrying SNPs are enriched in mRNA coding regions and depleted in 3′-untranslated regions (3′UTR), suggesting the important role of these signals in 3′UTR alternative polyadenylation and weak participation of AATAAA-hexamers in coding-region alternative polyadenylation. Despite these tendencies, some of the observed SNPs in polyadenylation signals may affect the function of corresponding genes. We found a limited number of investigated SNPs among the pathologic alleles described in OMIM and ClinVar databases. In sum, our work established the trends of SNPs' distribution in polyadenylation signals according to its functional features.

Keywords: mRNA processing, Polyadenylation, single nucleotide polymorphisms (SNP).

Deciphering the nuclear export of Intron-containing mRNA: the model of the murine Leukemia virus

L. Pessel-vivares[1], M. Ferrer-Almirall[1], S. Lainé[1], M. Mougel[1]
[1]*CPBS, CNRS, Montpellier, France*

Eukaryotic cells have evolved stringent proofreading mechanisms to ensure that intron-containing mRNAs do not leave the nucleus. However, all retroviruses must bypass this checkpoint for replication. Indeed, their primary polycistronic transcript

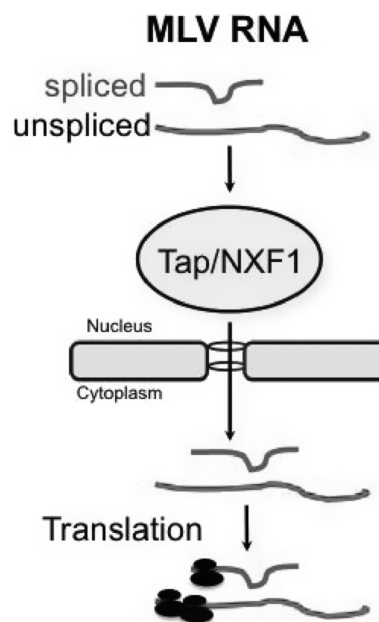

Fig. 1.

© 2014 The Authors. FEBS Journal © 2014 FEBS

(Full-Length) must reach the cytoplasm to be either translated or packaged as genomic RNA in progeny viruses.

Murine leukemia virus (MLV) is a prototype of simple retroviruses with only two well-regulated splicing events that directly influence viral leukemogenic properties in mice. Several *cis*-elements have been identified in the FL RNA that regulate its cytoplasmic accumulation. However, their connection with an export mechanism is yet unknown. Our goal was to identify the cellular pathway used by MLV to export its intron-containing RNA into the cytoplasm of the host cells.

Since other retroviruses use the CRM1 and/or the Tap/NXF1 pathways to export their unspliced RNA from the nucleus, we investigated the role of these two pathways in MLV replication by using specific inhibitors. The effects of export inhibition on MLV protein synthesis, RNA levels and RNA localization were studied by Western blotting, RT-qPCR, fluorescence microscopy and ribonucleoprotein immunoprecipitation assays. Taken together, our results show for the first time that MLV requires the Tap/NXF1-mediated export pathway, and not the CRM1 pathway, for the expression of its spliced and unspliced RNAs and for FL RNA nuclear export.

By contrast to HIV-1, MLV recruits the same pathway for the cytoplasmic expression of its spliced and unspliced RNAs. Thus, MLV RNA expression depends upon coordinated splicing/export processes. In addition, FL RNA translation relies on Tap/NXF1-dependent export, raising the critical question of whether the pool of FL RNA to be packaged is also exported by Tap/NXF1.

Keywords: Intron-containing RNA, Nuclear export, Tap/Nxf1.

Deficiency in Gle1, an mRNA export mediator, inhibits Schwann cell development in the zebrafish embryo

N. Alsomali[1], A. Seytanoglu[2], C. Valori[1,2], H. Rosemary Kim[1,2], K. Ning[1,2], T. Ramesh[1,2], B. Sharrack[1,2], J. D. Wood[1,2], M. Azzouz[1,2]

[1]Department of Neuroscience, The Sheffield Institute for Translational Neuroscience, [2]MRC Centre for Developmental and Biomedical Genetics, University of Sheffield, Sheffield, UK

Background: *GLE1* mutations are associated with Lethal Congenital Contracture Syndrome Type 1 (LCCS1), a severe autosomal recessive foetal motor neuron disease. The gene encodes a highly conserved protein with an essential role in mRNA export. The mechanism linking *GLE1* function to motor neuron degeneration in the human syndrome has not been elucidated, but increasing evidence implicates abnormal RNA processing as a key event in the pathogenesis of several motor neuron diseases. Homozygous *gle1*$^{-/-}$ mutant zebrafish model various aspects of LCCS, displaying multiple developmental abnormalities and embryonic lethality. However, these embryos only show moderate defects in motor neuron specification. A previous microarray study of human LCCS foetuses suggested oligodendrocyte abnormalities may be a feature of LCCS. We have therefore examined the development of myelinating glia in *gle1*$^{-/-}$ mutant zebrafish.

Methods: To analyse stages in the specification of myelinating glia (both oligodendrocytes and Schwann cells), we performed whole mount *in situ* hybridization for *olig2*, *sox10*, *krox20* and *mbp*. Transmission electron microscopy (TEM) was used to examine the differentiation of Schwann cells in the posterior lateral line nerve (PLLn).

Results: We found that *gle1*$^{-/-}$ mutants had a dramatic reduction in *mbp* expression along the PLLn, whereas the expression of *mbp* in hindbrain oligodendrocytes was relatively normal, indicating a specific defect in Schwann cell development. Analysis of *krox20* and *sox10* expression showed a moderate reduction in their expression along the PLLn in *gle1*$^{-/-}$ mutants, suggesting reduced numbers of Schwann cell precursors. TEM revealed a near total absence of wraps of myelinating membranes around PLLn axons in mutant embryos compared with sibling controls. These results suggest a failure in the differentiation of Schwann cell precursors in *gle1*$^{-/-}$ mutants.

Conclusions: These studies suggest an essential role for *gle1* in Schwann cell development. Interestingly, LCCS can also be caused by *ERBB3* mutations, which is essential for Schwann cell development in mice and zebrafish. Schwann cell deficits may therefore be a key factor undermining motor neuron survival in multiple forms of LCCS. Our findings highlight the potential role of myelinating glial cells in the growing number of motor neuron diseases linked to RNA processing defects.

WED-455
Differential targeting of VDAC3 mRNA isoforms influences mitochondria morphology

A.-M. Duchene

Institut de Biologie Moléculaire des Plantes, Strasbourg, France

Intracellular targeting of mRNAs has recently emerged as a prevalent mechanism to control protein localization. For mitochondria, a co-translational mode of protein import is now proposed in parallel to the conventional post-translational model, and mitochondrial targeting of mRNAs has been demonstrated in various organisms. Voltage-dependent anion channels (VDACs) are the most abundant proteins in the outer mitochondrial membrane (OM) and the major transport pathway for numerous metabolites. Four nucleus-encoded VDACs have been identified in *A. thaliana*. Alternative cleavage and polyadenylation generate two VDAC3 mRNA isoforms differing by their 3′ UTR. By RT-qPCR and *in vivo* mRNA visualization approaches, the two mRNA variants were shown differentially associated with mitochondria. The longest mRNA presents a 3′ extension named “alternative UTR” (aUTR) that is necessary and sufficient to target VDAC3 mRNA to the mitochondrial surface. Moreover aUTR is sufficient for the mitochondrial targeting of a reporter transcript, and can be used as a tool to target an unrelated mRNA to the mitochondrial surface. Finally VDAC3-aUTR mRNA variant impacts mitochondria morphology and size, demonstrating the role of mRNA targeting in mitochondria biogenesis.

Keywords: 3′ UTR, mitochondria, mRNA localization.

WED-456
Exploring synthetic biology in Leishmania through auto regulatory RNA elements: a mechanistic perspective

P. R. Bejugam, S. Singh

Computational and Systems Biology Lab, National Centre for Cell Science, Pune, India

Leishmaniasis is a major neglected tropical world disease. Various forms of Leishmaniasis affects nearly 12 Million people worldwide. Genome Sequence has revealed that the genomes of eukaryotes are nearly totally transcribed and generating a vast number of non-coding RNAs having important regulatory functions. Eukaryotic parasite *Leishmania* induces non coding RNA molecules in macrophages upon infection. These Non-coding RNA require a specific secondary and tertiary structure to accomplish the specific function and predicted structure of these RNA elements understudy can be compared with functionally

© 2014 The Authors. FEBS Journal © 2014 FEBS

annotated structural signatures. In this current study we have identified putative regulatory elements from 3′ Untranslated regions (UTR) of several *Leishmania major* genes which can fold to form a Ribozyme like structure. *L. major* transcriptome wide analysis of these 3′UTR was performed. It was predicted based on the observations of these regulatory elements when subjected to secondary and tertiary structure prediction. The tertiary structure validation was done using Interactive Network Fidelity (INF).stability and thermodynamic properties of these predicted ribozymes were calculated using Molecular Dynamic simulations. These MD Simulations helped us to understand the catalytic functions of these modeled synthetic ribozyme. MDS revealed that these ribozymes have a specific stem-loop movements which incorporates a well-defined catalytic site and is highly required for their catalytic activity upon binding to its target RNA sequences.Thus they are essential for possible post transcriptional gene regulation. *In silico* study revealed that almost 70 genes of *L. major* contains these 3′ UTR sequences which may have a possible role in its target gene regulation. Further 2D and 3D structure predictions revealed that 3 critical genes play a vital role in the parasites life cycle viz., DNA dependent RNA polymerase III subunit(LMJF_09_1060),ATP dependent DNA helicase(LMJF_09_0590),pre mRNA Tran splicing factor (LMJF_33_0130).These genes 3′ UTR sequences with higher propensity to form a possible ribozyme structures upon folding. Further these putative sequences can be synthesized *in vitro* using Invitro transcription and validated for their catalytic activity against specific target RNA.Their post transcriptional regulation mechanism can be deciphered using various biophysical and biochemical techniques. Further structure determination can reveal the possible mechanism behind their catalytic activity.These 3' UTRs can even be used along with small molecule metabolites to act as Riboswitches that can be used to knock down the specific gene in post transcriptional manner. Ribozymes and Riboswitches can play critical role in regulating the virulence of leishmanial parasite and may serve as therapeutic agents.

High spatio-temporal resolution study of nuclear mRNPs, from biogenesis to export

D. Guet[1], J. Boulanger[2], C. Nino[1], P. Hersen[3], J. Salamero[2], C. Dargemont[1]

[1]IUH - Saint-Louis, Université Paris Diderot - INSERM U944/ CNRS UMR9212, [2]PICT - IBiSA, Institut Curie, [3]MSC, Université Paris Diderot, Paris, France

Transcripts generated by RNA polymerase II (RNAPII) undergo a precisely orchestrated cascade of processing steps, before being transported to the cytoplasm as export-competent mRNA ribonucleoprotein particles (mRNPs). Although we likely know most of the actors required for the formation of export-competent mRNPs, and some of their roles in separate scenes, we still lack an integrated storyboard of the precise chronology of mRNA biogenesis and its spatiotemporal organization. So far, the results obtained by standard technics used to study mRNA localization, either in fixed conditions (with RNA-FISH or single-FISH) or in live conditions (MS2), have described localization at time and spatial scales which are not compatible with the study of the dynamics of mRNPs export. To understand the coordinated roles of the different machineries involved at the different steps of mRNP formation as well as to decipher their spatiotemporal occurrence, advanced imaging has now become essential. We propose an alternative approach to detect mRNAs in yeast living cells, to analyze the spatiotemporal coordinated cascade leading mRNPs from their site of transcription to their site of nuclear exit. For this purpose, we adapted a recently described system (Paige et al., 2011) where a sequence corresponding to a short RNA aptamer (Spinach) that emits green fluorescence upon binding with a chemical compound (DFHBI) is used to tag the transcript of interest in the yeast *S. cerevisiae*. We focused on both inducible gene transcripts (GAL1, STL1), and genes whose mRNAs display a polarized localization during cell cycle progression (ASH1). Using advanced microscopy and bioimage analysis approaches, we were able to follow the spatiotemporal localization of those mRNAs. As previously described, we found that ASH1 mRNA localization was affected upon deletion of the nuclear pore complex protein Nup60 but also in mutants for post-translational modifications of this Nup. We are also able to follow the expression of STL1 mRNA in timescale consistent with previous data. Interestingly, a specific dot signal corresponding to STL1 transcript was detected within minutes upon osmotic stress, in close relation with the nuclear periphery. To our knowledge, none of the current super-resolution methods in light microscopy has yet been applied to record multiple step transcriptional dynamics and NPC functional imaging in living yeast cell.

Intrinsic disorder mediates secretory protein sorting and targeting

K. Chatzi[1], M. F. Sardis[1], A. Tsirigotaki[1,2], N. Famelis[1,2], S. Karamanou[1], A. Economou[1,2]

[1]REGA institute KU Leuven, Leuven, Belgium, [2]Institute of Molecular Biology and Biotechnology, Iraklio, Greece

Most secretory proteins are synthesized as preforms composed of signal peptides and mature domains. They cross the bacterial inner membrane mainly post-translationally, through the “translocase” that comprises the ATPase motor SecA and the membrane channel SecYEG. Sorting of secretory from cytoplasmic proteins and membrane-targeting of the former is believed to be mediated by signal peptides and facilitated by chaperones, like SecB, that prevent their aggregation and bind to the translocase. Mature domains also possess elusive targeting signals. Signal Peptides and mature domains bind on distinct SecA sites. We now show that most secretory mature domains are *i*ntrinsically *d*isordered *p*roteins (IDPs). They are stabilized in soluble, translocation-competent, non-native states in the absence of any chaperone or signal peptide. Multiple minor evolutionary adaptations establish ID and distinguish secretory mature domain sequences from those of cytoplasmic proteins. A minority of non-native secretory proteins are aggregation-prone due to their mature domains or signal peptides, can associate with chaperones to remain soluble. The ID state also allows targeting signals to remain exposed and guide preproteins to the translocase SecA receptor even in the absence of signal peptides or chaperones. These are short, continuous or discontinuous hydrophobic patches, that can be multiple and interchangeable and are buried in the hydrophobic core after translocation and upon periplasmic folding. This novel mechanism inevitably sorts secretory from fast-folding cytoplasmic proteins and provides molecular understanding of mature domain targeting. Its ramifications are wide, particularly given the increasing evidence of post-translational secretion in eukaryotes.

Keywords: preproteins, targeting, translocase.

Mechanisms of mobile ncRNAs in neural stem/precursor cells

N. Iraci[1], T. Leonardi[1], A. J. Enright[2], S. Pluchino[1]
[1]*Clinical Neurosciences, University of Cambridge, Cambridge,*
[2]*EMBL-EBI, Wellcome Trust Genome Campus, Hinxton, UK*

Neural stem/precursor cell (NPC) transplantation protects the central nervous system from inflammatory damage. While it was first assumed that stem cells directly replace lost/damaged cells, it is now becoming evident that they are able to protect the damaged nervous system also through cell-to-cell communication mechanisms. Importantly, recent reports indicate that the secretion of exosomes is a key player in facilitating horizontal cell signalling. Exosomes secreted from donor cells can capture bioactive molecules, such as ncRNAs, able to affect the biology of recipient cells in various ways from inducing/repressing the immune response, to promoting tissue repair and cancer progression. Employing Next Generation Sequencing on NPCs and NPC-derived exosomes, we have identified a set of miRNAs whose abundance is significantly increased in exosomes, compared to parental cells. This finding suggests the existence of dedicated and selective (but still poorly characterized) cellular trafficking mechanism that selectively exports miRNAs towards exosomes. This observation led us to hypothesise that – similarly to what has been found in other contexts – specific carrier proteins could recognize a 'secretion motif' within the miRNA sequence, bind to it and mediate its export towards exosomes. Therefore, we attempted to identify components of such machinery by analysing the sequence of secreted miRNAs in search for an enriched short motif that could serve as a binding site for a carrier protein. Using a variety of motif enrichment tools available in R/Bioconductor we identified two candidate motifs that are significantly over-represented in secreted miRNAs compared to miRNAs retained in the cell. One of the two motifs matches the binding sequence of the heterogeneous nuclear ribonucleoprotein A2/B1 (hnRNPA2B1), which previous works have already shown to be involved in the trafficking of secreted miRNAs towards vesicles. However, by western blot we found that hnRNPA2B1 is not present within exosomes, suggesting that other proteins could be involved. We are currently investigating the possibility that other proteins and/or other miRNA features (such as the secondary structure of miRNA precursors) might be responsible miRNA secretion in NPCs. Altogether, this work will help to shed light on the molecular mechanism behind inter-cellular miRNA trafficking and on its implication on the therapeutic effect of transplanted NPCs.

Molecular and cellular mechanisms of the Cold-inducible RNA-binding protein (CIRP) nuclear-cytoplasmic shuttling

B. Bourgeois, T. Madl
Chemistry/Structural Biology, Technische Universität and Helmholtz Zentrum München, Garching, Germany

Motifs rich in arginine and glycine residues were recognized several decades ago to play functional roles and were termed RGG motifs. More than 1000 proteins harbor the RGG motif, and these proteins play essential roles in a plethora of physiological processes such as transcription, pre-mRNA splicing, DNA damage signaling, mRNA translation, and the regulation of apoptosis (i). The physiological relevance of the RGG motif is highlighted by its association with several diseases including neurological and neuromuscular diseases and cancer (ii). The Madl group has recently discovered for the protein FUS (fused in sarcoma) that this RGG motif is involved in the regulation of protein nuclear import and that arginine methylation of these motifs plays a key role in the regulation (iii). Misregulation of this novel nuclear import mechanism leads to amyotrophic lateral sclerosis, a severe neurodegenerative disease. Nevertheless, the exact function of RGG motifs in nuclear import and disease is still poorly understood because there is no molecular data allowing to visualize at an atomic level its binding properties with the nuclear import/export machinery. To study these mechanisms the Cold-inducible RNA-binding protein (CIRP) seems to be an excellently suited candidate. Indeed, it's already known that the RGG motifs of CIRP are involved in its cellular localization and contrary to most of all the RGG-containing proteins CIRP possesses only one RGG domain which facilitates this study. By that, CIRP is the best suited model system to study the mechanisms of RGG-mediated nuclear import, its regulation by arginine methylation and link to human disease. For the first time, I show using ITC and NMR that Transportin-1 directly interacts with the RGG region of CIRP with high nanomolar affinity. Thus, the CIRP RGG is sufficient for CIRP nuclear import. I will present preliminary data allowing a better understanding of the molecular mechanism of RGG recognition by Transportin-1 but also its regulation by arginine methylation.

Nuclear mRNA export factor 1 (NXF1) in *Drosophila*: unconventional functions

V. Ginanova, E. Golubkova, A. Prosovskaya, E. Avanesyan, L. Mamon
Genetics and Biotechnology, Saint Petersburg State University, Saint Petersburg, Russian Federation

In eukaryotes mRNAs produced in the nucleus are transported to the cytoplasm by proteins of the nuclear mRNA export factors (*nxf*) family. Dm NXF1 (also known as SBR) mediates the export of mRNAs in *Drosophila*. Previously four *Dm nxf1* transcripts and a protein isoform were identified. Some of them was specific for testes or brain. The determined structures of additional (not ubiquitous) transcripts fail to ensure mRNA export function of the protein coded (Ivankova *et al.*, 2010 // Gene). These data together with various phenotypes of mutant flies let us suggest the other functions of *Dm nxf1* in the cell not reduced to mRNA nuclear export. We analyzed the *Dm nxf1* transcription in testes and heads of the adult flies by qPCR to reveal the transcripts repertoire in these tissues. Both organs contained the transcripts with the retained intron 5-6 and transcripts which included the central region of the same intron. The similar *nxf1* transcripts with corresponding intron retention also exist in *Homo sapiens* and *Mus musculus* and thus this is an evolutional feature (Mamon *et al.*, 2013 // Open Journal of Genetics). Therefore, we propose a regulatory role of these intron-containing transcripts for mRNA metabolism. We further analyzed *Dm nxf1*

Post-translational modifications of Nuclear Pore Complex protein Nup60: mechanisms and functional consequences

C. A. Niño, D. Guet, A. Domingues, C. Dargemont
University Paris Diderot, Sorbonne Paris Cité. INSERM U944, CNRS UMR7212, Hôpital Saint Louis, Paris, France

The nuclear pore complex (NPC) is a multiproteic channel that permits the bidirectional and regulated transport of macromolecules between the nucleoplasm and cytoplasm. With a size of ~50 MDa and composed of ~30 different nucleoporins (Nups), the NPC is one of the largest assemblies in the cell and presents a structural organization highly conserved from yeast to humans. Although extensive research has revealed the molecular architecture and roles of the NPC subcomplexes, little is known about the regulation of NPC functions by post-translational modifications (PTMs). We hypothesized that PTMs such as ubiquitylation and Sumoylation, could participate in the regulation of NPC plasticity and functions. Here we focused on the yeast nucleoporin Nup60, a component of the NPC's nuclear basket subcomplex localized at the nuclear side of the NPC. Our analysis revealed that Nup60 is both mono-ubiquitylated and Sumoylated. Mono-ubiquitylation of Nup60 occurs all along the cell cycle whereas its sumoylation is restricted to G1 and S phases. To carry out functional analyses, we determined the enzymes responsible for these PTM as well as the specific lysine residues that are targets for Ub and SUMO modification. Corresponding mutations (Lys to Arg) were introduced genomically in order to generate Ubiquitin or SUMO-deficient Nup60 proteins. Preventing these PTM did not alter the localization of Nup60 at the nuclear pore. As Nup60 is important for the anchoring of others nuclear basket components (and in particular the Mlps and the SUMO protease Ulp1), we are currently analyzing the role of these PTM in the integrity of the nuclear basket and its associated factors. Nup60 PTM mutants do not present any nuclear protein import and export defect. In contrast, transport of polarized mRNAs to the cytoplasm is significantly affected upon mutation of the modified lysine residues indicating that these Nup60 PTM might regulate specific steps of the export-competent mRNP formation.

Role of RNA-binding protein in MAPK signaling and cell fate regulation

R. Satoh, Y. Ito, A. Kita, K. Hagihara, A. Doi, R. Sugiura
Laboratory of Molecular Pharmacogenomics, School of Pharmaceutical Sciences, Kinki University, Higashiosaka City, Osaka, Japan

Mitogen-activated protein kinases (MAPKs), which are found in all eukaryotes, are signal transducing enzymes playing a central role in diverse biological processes, such as cell proliferation, sexual differentiation, and apoptosis. The MAPK signaling pathway plays a key role in the regulation of gene expression through the phosphorylation of transcription factors. We have utilized the fission yeast, *Schizosaccharomyces pombe* (*S. pombe*) as a model system to elucidate the role of MAPK signaling pathway in cell fate regulation.

Our recent studies based on the functional interaction between protein phosphatase 2B (calcineurin) and Pmk1 MAPK, the *S. pombe* homologue of ERK1/2, identified several RNA-binding proteins (RBPs) as regulators of MAPK signaling. These include *rnc1*$^{+}$ encoding a KH-type RNA-binding protein and *nrd1*$^{+}$ encoding an RRM-type RNA-binding protein. Rnc1 binds and stabilizes the Pmp1 mRNA that encodes a MAPK phosphatase for Pmk1 thus negatively regulates the Pmk1 signaling (1). Nrd1 binds and stabilizes the essential myosin II light chain Cdc4 mRNA in a cell-cycle dependent manner, thereby suppressing the cytokinesis defects of the *cdc4* mutant cells (2,3). Moreover, Rnc1 and Nrd1 also serve as targets of MAPKs because MAPK phosphorylate and regulate the ability of these RBPs to bind and stabilize target mRNAs thus controlling various cellular functions, including cell integrity, cytokinesis and differentiation (1,2,4).

We also found that these RBPs can localize to stress granules in response to various stimuli, including heat shock, oxidative stress and osmotic stress. Notably, deletion of these RBPs leads to defects in stress granule formation, whereas the overproduction promote stress granule assembly, indicating that these RBPs play an important role in stress granules assembly/formation (5).

© 2014 The Authors. FEBS Journal © 2014 FEBS

Moreover, Nrd1 translocates to the stress granule in a phosphorylation- and/or Cpc2/RACK-dependent manner. Combined with our previous findings, these results suggest that these phospho-regulated RBPs are bifunctional proteins that can affect both mRNA stability and stress granule formation.

The binding of TIA-1 to RNA C-rich sequences is driven by its pH dependent C-terminal RRM domain

I. Cruz-Gallardo[1], J. Angulo[2], R. Del Conte[3], M. Gorospe[4], B. G. Karlsson[5], J. A. Wilce[6], M. A. De la Rosa[1], I. Díaz-Moreno[1]

T-cell intracellular antigen-1 (TIA-1) is a key DNA/RNA binding protein that regulates critical events in cell physiology by the regulation of pre-mRNA splicing and mRNA translation [1, 2]. It possesses three RNA recognition motifs (RRM) along with a glutamine-rich domain, with the central domains (RRM2 and RRM3) acting as RNA binding platforms. While RRM2 domain is primarily responsible for the RNA interaction, the RRM3 contribution to the RNA binding, as well as its targets sequences, are still unknown. Here we combine Nuclear Magnetic Resonance (NMR), Surface Plasmon Resonance (SPR) and pull-down assays to elucidate the sequence specificity of TIA-1 RRM3 [3]. We demonstrate that RRM3 significantly binds to those oligonucleotides enriched with cytosines. Notably, in combination with RRM2 or in the context of the full length protein, the RRM3 domain enhances the binding to C-rich sequences. In addition, the binding of RRM3 to RNA is modified by pH conditions, having a significant effect on the overall interaction of TIA-1 protein [4]. Our findings provide a new insight into the role of RRM3 in regulating TIA-1 binding to C-rich stretches, abundant at the 5' TOPs (5' Terminal Oligopyrimidine Tracts) of translationally-repressed mRNAs under stress situations [5].

The human SURF6 protein participates in pre-rRNA processing and HeLa cells proliferation

M. Kordyukova, D. Samoilova, K. Shishova, O. Zatsepina

M.M. Shemyakin and Yu.A. Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation

SURF6 is a specific nucleolar protein that is evolutionarily conserved from human to yeast. The yeast homolog of SURF6, the Rrp14p, takes part in processing of rRNA, ribosome biogenesis and cell budding. However, roles of human SURF6, including its potential implication in processing of rRNAs and proliferation of cells remains still unstudied.

In the current study, we have shown for the first time that experimental knockdown of SURF6 in HeLa cells is not toxic for the cells, but accelerates their proliferation and increases the mitotic index and the number of cells in S period. Furthermore, SURF6 knockdown decreases the number of cells in G1/G0 phase and diminishes the number of apoptotic cells. Taken together, these results demonstrate that depletion of the SURF6 pool renders positive effects on the proliferative status of HeLa cells.

We also examined whether SURF6 knockdown would effect rRNA processing in HeLa cells using Northern blotting and RT-qPCR methods. Both approaches show that diminution of the SURF6 amount results in up-regulation of the synthesis of 47S-45S pre-rRNA and don't decrease the content of 18S, 5,8S and 28S rRNAs. We also observed accumulation of 45S, 41S pre-rRNA, whereas the amount of 26S, 32S, 18S-E, 17S, 12S rRNA intermediates declined. Based on these observations, we concluded that human SURF6, like yeast Rrp14p, is involved in rRNA processing, where the particular roles of SURF6 are participation in degradation of the pre-rRNA transcribed spacers and in regulation of the rRNA processing pathways. In addition to rRNA processing, human SURF6 plays a role in regulation of rDNA transcription, activation of which may stimulate proliferation of HeLa cells in the SURF6 knockdown conditions.

The study has been financed by a grant issued by the President of the Russian Federation (MK-6426.2013.4).

BC44 carcinoma-associated fibroblasts promote stemness of urothelial carcinoma cells in coculture

J. Dobra[1], J. Hatina[2], M. Kripnerova[2], Z. P. Czuba[3], D. Jaworska[3], V. Babuska[1], J. Racek[1]
[1]Department of Biochemistry, [2]Department of Biology, Charles University in Prague, Faculty of Medicine in Pilsen, Pilsen, Czech Republic, [3]Department of Microbiology and Immunology in Zabrze, Medical University of Silesia in Katowice, Zabrze, Poland

According to the cancer stem cells hypothesis tumours like normal tissues are organized in a hierarchical manner. At the top of this intrinsic cellular hierarchy are cancer stem cells (CSC), that are largely responsible for continuous tumour growth and progression, as well as for the development of therapeutic resistance. Consequently, their eradication could lead to the development of novel, curative cancer therapies. We have recently established and characterized an experimental system consisting of a pair of carcinoma (BC44) and carcinoma-associated fibroblast (BC44Fibr) – cell lines derived from the same urothelial tumour [1].

Currently we aimed to understand how carcinoma-associated fibroblast influence stemness of cocultured urothelial carcinoma cells and their sensitivity to anticancer therapies.

Primarily we are focusing on tumor necrosis factor-related apoptosis-inducing ligand (TRAIL). This death ligand belonging to the tumor necrosis factor (TNF) superfamily of cytokines, is known to have the ability to selectively activate apoptosis in cancer cells but not in normal tissues. Thus, TRAIL as well as components of its signalling pathways is considered as promising targets of antitumour therapy. Comparing TRAIL sensitivity of pure culture and coculture with carcinoma-associated fibroblasts indicate a dramatically increased resistence of othewise sensitive SW780 bladder cancer cells. Furthermore co-culture of BC44Fibr and several bladder carcinoma cell lines (BC44, SW780, HT1197) revealed that carcinoma cells strongly positive for putative CSC markers (CK-17, 67 KDa Laminin Receptor, CD44v6) were located in direct contact with co-cultured carcinoma-associated fibroblasts. Therefore we conclude that BC44 carcinoma fibroblasts highly likely promote stemness of urothelial carcinoma cells.

This study was supported by the project of LF UK Plzen no. SVV-2014-260050 and co-financed by the European Social Fund and the state budget of the Czech Republic. Project no. CZ.1.07/2.3.00/30.0022.

Cells with expression of pluripotency marker SSEA-4 are present in adult human skin

J. Borowczyk[1], E. Zimolag[1], A. Waligorska[2], Z. Madeja[1], J. Dobrucki[2], J. Drukaa[1]
[1]Department of Cell Biology, [2]Department of Cell Biophysics, Jagiellonian University, Kraków, Poland

The epidermis is continuously renewed throughout life. Different populations of stem cells can be distinguished that maintain tissue homeostasis by providing a pool of new cells to replace those lost during skin turnover or after injury. Furthermore, several previous studies demonstrated that cells with multipotent character reside in the bulge region of hair follicles and contribute not only to interfollicular epidermis but also to hair follicle and sebaceous gland. Nowadays, keratin 15 and CD200 are considered as the most specific biomarkers for identifying human hair follicular stem cells.

The stage-specific embryonic antigen 4 (SSEA-4) is an epitope on glycosphingolipid widely used as a marker for pluripotent embryonic stem cells, which is down-regulated during their differentiation. Furthermore, it was shown that in human, SSEA-4 is expressed by neural cells and by non-neural cells such as erythrocytes.

In the present study, we show that SSEA-4 positive cells are present in adult human skin. While we were looking for a rare population of pluripotent stem cells in adults called very small embryonic stem cells (VSELs) characterized by small size and expression of specific markers (CD133, SSEA-4, Oct-4), we found distinct population of cells which were SSEA-4 positive, but they did not co-express stem/progenitor marker CD133. Using flow cytometry, we estimated that an average number of these cells constitutes 0.06% of analyzed small nuclear cells both in epidermis and dermis of adult humans. With confocal microscopy we searched for SSEA-4 expressing cells in the commonly known niche for epidermal stem cells - the bulge region of a hair follicle. In our experiments we detected single cells expressing SSEA-4 on their surface (about 20 μm in diameter) localized in the inner root sheath (IRS) of hair follicles. Next, we used immunohistochemical staining to analyze skin tissue sections. We confirmed localization of SSEA-4 positive cells in hair follicles, however, we could also observe these cells within the basal cell layer of the epidermis, with a marked tendency to be localized at the tips of rete ridges, a protective niches of interfollicular epidermal stem cells. Additionally, scattered single SSEA-4 immunoreactive cells were detected within the dermis, especially in the papillary layer.

The obtained data indicate that there is a rare population of cells deposited in human skin demonstrating one of characteristic features of embryonic stem cells. However, further characterization of these cells is needed to establish whether expression of SSEA-4 marker in adult human skin is associated with pluripotency, unipotent epidermal stem cells or neither of them.

Characterization of cancer stem cells derived from pancreatic ductal adenocarcinoma cell lines and generation of three-dimensional culture models

G. Biondani[1], I. Dando[1], E. Dalla Pozza[1], C. Costanzo[1], K. Zeeberg[2], R. A. Cardone[2], M. R. Greco[2], A. Marengo[3], S. Arpicco[3], S. J. Reshkin[2], M. Palmieri[1]
[1]Department of Life and Reproduction Sciences, University of Verona, Verona, [2]Department of Biosciences, Biotechnology and Biopharmaceutics, University of Bari, Bari, [3]Department of Science and Drug Technology, University of Torino, Torino, Italy

Pancreatic ductal adenocarcinoma (PDAC) is a malignant neoplasm with a 5-years survival rate of 3%–5%. Recently, much attention has been addressed to cancer stem cells (CSCs), which possess enhanced tumour-initiation and self-renewal properties, capacity to differentiate into different cellular types, and chemo- and radio-resistance. Their phenotype is generally associated with epithelial-to-mesenchimal transition (EMT) in which epithelial cells lose their characteristics, acquiring stem-like features.

In this study, we cultured different PDAC cell lines, defined parental, in selective growth conditions and derived CSCs forming spheres. Panc1 CSCs were characterized for the expression of the stem and EMT markers E-Cadherin, CD44v6 and EpCAM. *In vivo* studies show that, at the ninth week after injection, 1×10^6 cells/mouse of Panc1 CSCs are significantly more tumorigenic than the correspondent parental cells at the same cell concentration.

Since PDAC is characterized by an intense stromal reaction with a microenvironment rich in extracellular matrix (ECM), the development of three-dimensional cultures appears to be relevant to simulate the *in vivo* conditions. Panc1 and Panc1 CSCs were cultured in matrices composed by collagen I, the major component of ECM, and Matrigel and the differences in morphology have been analysed. In Matrigel, Panc1 CSCs show a tube-like structure, resembling vasculogenic mimicry (VM), while the parental cell line maintained its typical spheroidal-like morphology observed also in 100% collagen I. The VM phenotype is a feature associated with aggressiveness, survival ability and metastatic potential. At the present, we are studying the changes in morphology of cells cultured in a mixture of collagen I and Matrigel.

The microscopy fluorescence analysis of the invasive potential of cells through the formation of invadopodia shows that, unlike the parental cells, Panc1 CSCs did not digest Matrigel, a marker of invasiveness. Since our hypothesis is that low invasive capacity is correlated with high cell migration, we will study the type and migratory ability of CSCs in comparison to the parental cells.

Future experiments will aim to analyse the differences in proteome between CSCs and the parental cells in order to identify specific CSC markers and, then, to selectively target them by using liposome formulations containing anti-proliferative drugs.

Keywords: 3D cell culture, cancer stem cells, migration.

Controlling the communication between brain endothelium and tumor initiating cells as a new therapeutic approach against glioblastoma

E. M. Galan Moya[1,2,3], L. Treps[1,2,3], J. Gavard[1,2,3]
[1]Inserm U1016, Cochin Institute, [2]CNRS UMR8104, [3]Univ Paris Descartes, Paris, France

Glioblastoma multiforme (GBM), is the most common and most aggressive brain tumor in adults. Despite intensive treatment GBM always relapses as an incurable lesion. Recurrence is tightly coupled to increased resistance to radiation and chemotherapy, hallmark features of stem-like glioma cells (GSC). GSC are characterized by self-renewal ability, stem-cell marker expression and tumor initiation capability. Their fate, plasticity and survival are in part regulated by external cues from the immediate adjacent differentiated cell types within the vascular niche, among which are brain endothelial cells (EC). Thus, understanding how niche factors are involved in maintaining aggressive glioma cell phenotypes may help identify novel potential targets for enhancing the efficacy of cancer therapeutics.

We recently demonstrated that the endothelial secretome sustain GSC self-renewal and survival through the Akt/mTor pathway. To further explore the nature of such angiocrine signals, human brain endothelial cell-released factors were identified through an unbiased proteomic approach. Mass spectrometry analysis uncovered 22 endothelial-produced peptides and proteins (8 growth factors, 7 extracellular proteases and 7 extracellular matrix proteins), whose expression was further confirmed by RT-PCR. Interestingly, the use of recombinant peptides was sufficient to support self-renewal and survival, as evidenced by secondary neurosphere formation, Sox2/Nestin expression and trypan blue exclusion, as well as Akt/mTor activation in a panel of 16 patient-derived GSC. Conversely, blocking either the endothelial production of these factors or the activation or expression of their cognate GSC receptor hampered EC-mediated GSC maintenance and signaling. To evaluate the therapeutic potential of our findings *in vivo*, GSC stably expressing interference RNAs targeting angiocrine factors-associated receptors were injected subcutaneously in mice. After 4 weeks, only 30–55% of the shRNA expressing-GSC-derived tumors were palpable in sharp contrast with control tumors, detectable in 100% of the cases. Addition-

ally, receptor-aimed pharmacologic treatment of mice bearing GSC tumors during 6–8 weeks resulted in decreased tumor size, poorer vascularization, lesser proliferation rate and reduced GSC fraction.

Altogether our results reveal that the endothelial-derived factors have an instrumental role in the maintenance of GSC population, controlling self-renewal, tumor-initiating capability and tumor growth. Thus, we propose interfering with the endothelium/GSC dialogue, critical for the integrity of the GSC fraction, as potential therapeutic target to obstruct glioblastoma progression.

Dissecting the role of histone deacetylases 1, 2 and 6 in Eμ-myc driven B cell lymphoma

V. Pillonel[1], N. Reichert[1], C. Cao[1], A. Tzankov[2], P. Matthias[1]
[1]Epigenetics, Friedrich Miescher Institute for Biomedical Research, [2]University Hospital Basel, Institute for Pathology, Basel, Switzerland

Histone deacetylases (HDACs) belong to a family of 18 enzymes that exert their function by deacetylating histones and non-histone proteins. HDACs are predominantly known to play a key role in the regulation of gene expression and abnormal regulation of HDACs is often associated with carcinogenesis and tumor progression. The two major class I; HDAC1 and HDAC2 as well as the cytoplasmic class II; HDAC6 were shown to play important roles in several cancer settings. A variety of broad-spectrum HDAC inhibitors have been developed to overcome the carcinogenic activity of HDACs. However, the function of single HDACs in normal physiology or pathological settings such as cancer remains elusive. In this study, using targeted or conditional deletion of individual HDACs, we have investigated the functional role of these enzymes in the Eμ-myc murine B-cell lymphoma model. Eμ-myc mice overexpress the c-myc oncogene in B-cells and develop aggressive leukemia with circulating leukemic cells in blood and extensive infiltration in lymphoid organs. In order to examine the effect on tumor formation we conditionally deleted HDAC1 and/or HDAC2 specifically in B-cells (using *mb1-cre*) and crossed them with Eμ-myc mice. We found that only dual, but not single loss of HDAC1 and HDAC2 prevents lymphoma development. Likewise, we crossed mice lacking HDAC6 (germ line KO and B-cell KO) as well as mice overexpressing HDAC6 (HDAC6 BAC) with Eμ-myc mice. Interestingly, Hdac6 germ line KO and possibly also B cell specific KO prolong tumor-free development. In contrast, HDAC6 overexpression accelerates lymphoma development. Our findings demonstrate that HDAC1, 2 and 6 play important roles in tumor development of Eu-myc mice.

Gene signature of invading human melanoma cells

G. Restivo[1], G. Kiowski[1], J. Albers[2], I. Frew[2], T. Biedermann[3], E. Reichmann[3], L. Sommer[1]
[1]Institute of Anatomy, [2]Institute of Physiology, University of Zürich, [3]Tissue Biology Research Unit, Kinderspital, University of Zürich, Zürich, Switzerland

Due to its extremely high metastatic capacity, cutaneous malignant melanoma represents the most fatal skin tumor in industrialized countries. Up to date the only possible therapy to cure melanoma patients is surgical excision of localized, non-metastatic primary tumors. Unfortunately, many patients already present micrometastatic disease at the time of diagnosis resulting in a poor 5-year survival probability. Hope for a future therapy might therefore lie in the early identification of metastasizing melanoma cells and the elucidation of the mechanisms governing their dissemination. Melanoma arises in the epidermis from transformation of cells of the melanocytic lineage. Melanocytes originate from neural crest cells (NCCs). During development NCCs delaminate from the neural tube by undergoing an epithelial-to-mesenchymal transition (EMT). Upon EMT NCCs adopt a remarkable migratory capacity, which allows them to disseminate throughout the embryo and to colonize distant sites where they differentiate into specialized cell types. Intriguingly this process is highly reminiscent of metastasis formation during which tumor cells disseminate from the primary neoplasm to establish secondary tumors in distant organs. This raises the question of whether the strong propensity of melanoma to metastasize reflects an intrinsic property of melanoma cells to disseminate by exploiting signaling cues normally active in migratory NCCs. To address this point we performed a microarray analysis of invading melanoma cells using a humanized *in vivo* model able to recapitulate the first steps of melanoma metastasis (Kiowski et al. 2012). With this approach we compared two populations, one positive for a known NCCs marker expressed during neural crest delamination, CD271, and the other negative for this marker. The analysis revealed that genes mostly involved in EMT were differentially modulated in the two populations. Currently we are investigating the mechanisms linking CD271 to melanoma invasion.

Identifying compounds to selectively target glioblastoma stem like cells

E. Harford-Wright[1,2,3], J. Gavard[1,2,3]
[1]Inserm, U1016, Institut Cochin, [2]CNRS, UMR8104, [3]Univ Paris Descartes, Paris, France

Glioblastoma multiforme (GBM) is the most aggressive cancer of the central nervous system, and is associated with extremely poor prognosis due to local recurrence. A subpopulation of cells within GBM has been identified that possess the characteristics of progenitor cells such as self-renewal and multipotency. Glioblastoma stem like cells (GSCs) are a relatively quiescent population of cells that have the potential to evade current treatments, as conventional therapies predominately target rapidly dividing cells. Consequently, it has been suggested that GSCs are responsible for therapeutic resistance and tumour recurrence in GBM. As such, identifying potential therapies that target this resistant population of cells is of great importance.

A chemical screen of 1280 FDA and EMEA approved drugs was performed on patient derived GSCs and to identify potential therapies for the use against GSCs. To assess the efficacy of these compounds cell viability and neurosphere formation capabilities were employed. The neural stem cell line HFT13 served as controls. The most effective candidate was selected for further characterization in a panel of human GSCs.

The initial screen of 1280 compounds resulted in 9 hits with >40% inhibition of GSC viability in two patient derived GSC lines. The hit with the highest inhibition of cell viability was chosen for further assessment on a larger panel of patient derived cells. This natural compound resulted in a significant ($p < 0.001$) reduction in GSC viability at 10uM, with this dose corresponding with impaired neurosphere formation in treated GSC compared to controls.

© 2014 The Authors. FEBS Journal © 2014 FEBS

These preliminary findings indicate that this natural compound has the ability to inhibit GSC growth as well as neurosphere formation, a predictor of rapid tumour progression. Further studies are required to fully elucidate the molecular mechanisms by which this compound is acting to reduce GSC growth. However, our study suggests this compound may represent a novel therapeutic approach to targeting GSC.

Interfering with stem cell-specific p53 gatekeeper functions controls the DNA damage response of hair follicle bulge stem cells and initiates sebaceous skin tumors

K. Reuter[1], M. Petersson[2], C. Niemann[1]

[1]Center for Molecular Medicine Cologne and Center for Biochemistry II, University of Cologne, Cologne, [2]Center for Molecular Biology Heidelberg (ZMBH) Alliance, University of Heidelberg, Heidelberg, Germany

Tumour growth is driven by tumour-initiating cells (TICs) carrying mutations that favor cell expansion by allowing the cells to escape normal growth control crucial for tissue homeostasis. Recently, multiple epidermal cell populations have been tested for their potential to initiate tumour growth in mouse models for different types of skin cancer including squamous cell carcinoma (SCC) and basal cell carcinoma (BCC). These studies have identified the hair follicle (HF) bulge region as one cellular source for SCC and potentially BCC formation. However, a "cell-of-origin" for sebaceous types of skin cancer as well as mechanisms of initiation and progression of sebaceous tumours are not known.

Generating an inducible skin tumour mouse model, which mimics mutations and phenotype of human sebaceous tumours, we have shown that expression of a mutant form of the transcription factor Lef1 leads to sebaceous tumours. *In vivo* lineage-tracing in tumour-whole-mounts demonstrated that bulge stem cells (SCs) contribute to sebaceous tumours and are a "cell-of-origin".

Mechanistically, our data demonstrate that mutant Lef1 interferes with stem cell-specific surveillance mechanisms, including attenuated p53 activation as a consequence of faster DNA repair activity and increased expression of the pro-survival factor Bcl2, protecting SCs from DNA damage-induced apoptosis. Particularly, mutant Lef1 abolishes p53 activity by interfering with important regulators of the DNA damage-induced signaling cascade, like ATM and Chk2, resulting in increased DNA damage. Consequently, DNA damage induces apoptosis of HF bulge stem cells, since mutant Lef1 blocked the Bcl-2 response in HF bulge stem cells. To compensate loss of SCs, proliferation was stimulated within the bulge stem cell compartment, resulting in propagation of cells that escape normal cell cycle control, thereby supporting the accumulation of tumour-initiating mutations within HF bulge SCs.

Thus, normal control of SC proliferation is disrupted by mutant Lef1, representing a new mechanism of tumor-initiating events in tissue SCs and showing the importance of a tight control of these crucial stem cell-specific surveillance mechanisms to prevent tumourigenesis.

Microvesicles secreted from the colorectal cancer cell line HT29 can transfer into cells constituting metastatic niche

M. Sapek[1,2], I. Papiewska-Pająk[1], P. Przygodzka[1], J. Boncela[1], C. S. Cierniewski[1,2], A. M. Kowalska[1]

[1]Department of Cellular Proteomics, Institute for Medical Biology of the Polish Academy of Sciences, [2]Medical University of Lodz, Lodz, Poland

Malignant tumors are complex structures that consist of cancer cells and the surrounding tumor stroma. A continuous cross-talk between cancer cells and local/systemic environment is required for effective tumor growth and dissemination. Studies show that microvesicles derived from activated tumor cells (oncosomes) may participate in cell-to-cell communication and mediate the formation of metastatic niches. Moreover, epithelial to mesenchymal transition (EMT) is crucial in carcinoma metastasis. A key transcription factor involved in EMT is Snail that enhances proliferation, cell adhesion and migration of colorectal cancer cells (CRC).

Important question in above process is the role of CRC microvesicles that may transfer into metastasis niches. Further we would like to clarify the role of Snail in EMT of CRC. In this study we performed the analysis of microvesicles derived from CRC line HT29 and their incorporation into endothelial cells (HUVEC) and monocytes/macrophages cell line (THP-1). We expressed Snail in HT29 line by stable transfection using pcDNA 3.1 vector (HT29/Snail). In this report we show that both HT29 and HT29/Snail produce microvesicles, which can be transferred to the cells constituting metastatic niche (HUVEC and THP-1). We developed protocol and performed isolation of microvesicles from the supernatants of HT29/Snail. The incubation of HT29/Snail in experimental medium did not induce apoptosis and necrosis of the cells. The characterization of the microvesicles was performed by SDS-PAGE and Western blotting. In the purified microvesicles we detected CD63 and CD81, markers of microvesicles, whereas cytochrome c was not detected. Further the microvesicles were labeled using PKH67 Fluorescent Cell Linker kit to examine the uptake into HUVEC and THP-1. The cells with incorporated microvesicles were visualized under a confocal microscopy (Nikon D-Eclipse C1). Localization od microvesicles were confirmed by merging PKH67 fluorescence with Texas Red-labeled antibody against beta-actin and Hoechst dye.

Our study show that microvesicles released by the HT29 and HT29/Snail are internalized by HUVEC and THP-1. This observation is a starting point for our next investigation of the effect of the microvesicles and Snail on the response of cells constituting metastatic niche. It could be important for understanding the induction of immunosuppressive mechanism during cancer progression and inflammatory diseases and also may help to develop the future strategies to block metastasis.

This research was supported by Project DEC-2011/02/A/NZ3/00068 form National Science Centre.

Migrating breast cancer stem-like cells are slowed down by zoledronic acid

H. Bühler, C. Hoberg, P. NguemgoKouam, K. Fakhrian, I. A. Adamietz

Klinik für Strahlentherapie und Radio-Onkologie, Ruhr-Universität Bochum, Bochum, Germany

Rationale: Various effects on tumor cells have been described for zoledronic acid (ZOL). However, only limited data exist

© 2014 The Authors. FEBS Journal © 2014 FEBS

regarding its influence on the motility of tumor cells. Since migration is a decisive step in metastasis, we examined whether ZOL reduces the motility of tumor cells, which may lead to less aggressive metastasis. The hypothesis of tumor stem cells postulates that recurrences may occur from cancer stem cells rather than from "normal," somatic tumor cells. We therefore investigated the effects of zoledronic acid on stem-like progenitor cells obtained from the human breast cancer cell line MDA-MB 231.

Methods: Breast cancer stem-like progenitor cells were obtained via the formation of spheroids from the human breast cancer cell line MDA-MB 231. Stem cell properties were confirmed immunohistochemically by high CD44 and low/no CD24 expression. The motility of cells in the presence of 0, 1, or 10 μM zoledronic acid was documented via time-laps videography over 24 h. The image-stacks were analyzed with the ibidi "chemotaxis and migration tool" as to the motility markers velocity, accumulated and Euclidean distance. The effect of a ZOL gradient on the direction of migration was determined in ibidi μ-slides.

Results: Time-resolved videography showed that zoledronic acid strongly reduced the migration of cancer stem cells. Cellular velocity was reduced by 61% following exposure to 1 μM zoledronic acid, and by 82% after exposure to 10 μM zoledronic acid. Accumulated distance traveled by the cells was reduced by 60% and by 79% after exposure to 1 μM and 10 μM zoledronic acid, respectively. The Euclidean distance was strongly reduced by 48% or by 73% in the presence of 1 μM or 10 μM ZOL respectively. The remaining cellular motility led to very little change in distance, with cellular activity appearing more as "stepping on the spot." A ZOL gradient dislocated the center of mass of migrating cells towards lower concentrations.

Conclusions: The suppression of cancer stem cell motility could potentially contribute to the clinical benefits following the adjuvant administration of zoledronic acid in breast cancer as recently described in clinical studies.

Keywords: breast cancer stem cells, motility, zoledronic acid.

Pancreatic cancer stem cells characterization and secretome analysis

I. Dando[1], G. Biondani[1], E. Dalla Pozza[1], J. Brandi[2], C. Costanzo[1], D. Cecconi[2], M. Palmieri[1]
[1]Life and Reproduction Sciences, [2]Biotechnology, University of Verona, Verona, Italy

Pancreatic ductal adenocarcinoma (PDAC) is generally asymptomatic until the late stage of the disease and it often metastasizes. Cellular dissemination leading to metastasis occurs prior to the formation of an identifiable primary tumour and this event strictly correlates with the presence of cancer stem cells (CSC). These observations render imperative the identification of the specific biological features of CSC, in order to improve PDAC diagnosis and prognosis. We obtained *in vitro* CSC from different pancreatic ductal adenocarcinoma (PDAC) cell lines, named parental cell lines (P), using a selective medium. After the formation of spheres, which represent the first evidence of the staminal traits, cells have been characterized for the expression profile of different markers, e.g. CD44v6, Ep-CAM, E-caderin via FACS or Western Blot (WB) analyses. Furthermore, since CSC have been shown to represent the most threatening and resistant portion of the tumour, we tested their aggressiveness in mice subcutaneously injected with Panc1 P or CSC, at different cell concentrations. At the higher cell concentration ($1*10^6$ cells/mouse), mice injected with CSC displayed a significant higher tumour volume, as well as the tumour cellular morphology appeared to be very different, by histochemical analysis, compared to the mice injected with P cells. We are now performing other analyses, in particular immunohistochemistry on the tumour tissues, WB and real-time PCR on the tumour cells, to evaluate differences in morphology and marker expression between the two cell types. Moreover, to test the capacity of CSC to metastasize, we injected Panc1 P or CSC in the spleen, which was then excised after 5 minutes, with the advantage to follow metastasis formation, without the presence of a primary tumour. The invasive capacity of CSC is still under evaluation, through the monitoring of metastasis formation by MRI.

Since it is known that cells secrete proteins for cell-cell communication and that the specificity of the secreted proteins can direct cells to distinct environments, we analysed the difference in protein secretion between Panc1 P and CSC by iTRAQ, an innovative protein quantification technique. The results showed that 71 proteins were secreted by CSC with an average fold change higher than 1.5 ($p < 0.001$) relative to P cells, and 9 proteins were secreted only by CSC. We are validating these results with other techniques, mainly by WB on the secreted proteins in the culture medium, and by ELISA, using patient serum.

The study of CSC and the analyses of secreted molecules is an approach with the strong potential to improve PDAC biology knowledge and to identify new potential early diagnostic markers.

WED-478
Regulation of actin dynamics by non-muscle tropomyosin and cofilin isoforms

K. Robaszkiewicz, Z. Ostrowska, J. Moraczewska
Kazimierz Wielki Unniversity, Bydgoszcz, Poland

In many cells, directional migration and formation of membrane protrusions depend on regulation of actin filaments by actin-binding proteins: cofilin (Cfl) and tropomyosin (TM). Cfl severs and depolymerizes actin filaments, but it also can facilitate actin polymerization by increasing the number of polymerization-competent ends. Cfl expression level increases in motile cells such as metastatic tumor cells. In contrast, TM is believed to stabilize actin filaments. Increased expression of some non-muscle TM isoforms suppress invasiveness of tumor cells and inhibit mesenchymal migration of multiple cell lines. TM2 and TM5NM1 were previously reported as suppressors of tumor cells motility, whereas TM5a sorted to stable regions of neuronal cells. The goal of this work was to decipher the molecular mechanisms of actin dynamics regulation by cofilin and TM isoforms.

Non-muscle TM isoforms – TM2, TM5a (products of *TPM1* gene) and TM5NM1(a product of *TPM3* gene) were used along with non-muscle isoform of cofilin 1 (Cfl1). TMs and Cfl1 were expressed in *E.coli* BL21 strain and purified using standard methods. Actin was isolated from chicken skeletal muscle. Regulation of actin filaments dynamics by TMs and Cfl1 was analyzed with the use of co-sedimentation and turbidymetric assays.

Binding constant (K_{app}) of Cfl1 to F-actin was reduced about 2-fold by TM2 and TM5a, but was not affected by TM5NM1. Binding of Cfl1 removed TMs from the filament, though with different efficiency. At 1:1 Cfl: actin molar ratio 80% of TM2 and TM5a and only 40% of TM5NM1 were bound to actin. TM2 and TM5NM1 protected the filaments from severing/depolymerization by Cfl1. Surprisingly, TM5a facilitated this activity. The time-course of salt-induced G-actin polymerization was not affected by equimolar concentration of Cfl1. In contrast, all studied TM isoforms slowed down actin polymerization. Cfl1 reversed the inhibiting effect of TM2 and TM5a. However, when polymerization was

© 2014 The Authors. FEBS Journal © 2014 FEBS

conducted in the presence of TM5NM1 and Cfl1, the inhibition was even larger than in the presence of TM5NM1 alone.

A complex mechanism of the thin filaments regulation by Cfl and TM isoforms emerges from the obtained results. On one hand TM isoforms compete with Cfl for binding to actin, but on the other hand the proteins can act in synergy to facilitate filaments dynamics.

The project was supported by National Science Center grant No. 2012/07/N/NZ1/03094.
Keywords: actin filament, cofilin, tropomyosin.

Site specific expression of the Wnt signaling target gene Nkd1 in mouse intestine and liver

B. Fafilek, J. Stancikova, M. Krausova, L. Janeckova, V. Korinek
Cell and Developmental Biology, Institute of Molecular Genetics, V.V.I., Prague, Czech Republic

Wnt signalling pathway is crucial for development and adult tissue maintenance in all metazoans. In adult mammals, the Wnt signalling is required especially for intestinal homeostasis and establishment and preservation of the hepatic zonation. Conversely, aberrant activation of the Wnt pathway in these tissues is linked to development of cancer.

To investigate role of the Wnt pathway in the self-renewal of the intestinal epithelium and its malignant transformation, we employed chromatin immunoprecipitation (ChIP) in combination with DNA microarrays (ChIP-on-chip). As one of the most prominent Wnt signalling target genes, we identified the Naked Cuticle Homolog 1 (NKD1); previously described as a Wnt-induced negative regulator of canonical Wnt signalling. Using the BAC recombineering, we generated mice with CreER^{T2} recombinase produced from the Nkd1 locus (Nkd1-CreER^{T2}). Crossbreeding these mice with ROSA-Lacz reporter strain, we obtained animals with traceable Nkd1^{+} cells. In the small intestine, the expression of Nkd1 overlaps with expression of stem cell and Paneth cell markers, but not exclusively. Moreover, Nkd1-CreER^{T2} expression decreases in proximodistal manner with no expression in illeal stem cells. In the liver, Nkd1-CreER^{T2} marks the Wnt stimulated pericentral hepatocytes and so enables sorting of these otherwise indistinguishable hepatocytes.

In conclusion, gradient zonal expression of Nkd1 in the mouse intestine and liver gives insight into different regulation of Wnt signalling in these tissues.

Keywords: Intestine, liver, WNT signalling.

WED-480
Stem cell plasticity and tumorigenesis: regulatory roles of heparan sulphate in the cancer stem cell niche

R. Baty, A.Pisconti, J. Turnbull
Department of Biochemistry, Institute of Integrative Biology, University of Liverpool, Crown Street, Liverpool, L69 7ZB, UK

Dysregulated stem cell homeostasis is associated with disease and ageing. Sub-populations of cancer cells have been identified in tumours, leading to the cancer stem cell hypothesis, and the potential to target these cells for effective new anti-cancer therapies. Cancer stem cells, also called tumour-initiating cells, are similar to normal stem cells, being capable of self-renewal and differentiation, but the balance between these two processes is highly deregulated in cancer stem cells, leading to tumour formation. Stem cell fate is controlled by intrinsic (genetic information) and extrinsic (microenvironment cues) factors. Changes in either or both these classes of factors could contribute to the carcinogenic process. Heparan sulphate (HS) is a family of multifunctional regulators of different biological processes, including aspects important to cancer cell behaviour such as proliferation and differentiation. HS play important roles in cell growth and development, tissue homeostasis and cell migration, through interactions with a wide variety of proteins such as chemokines, enzymes and growth factors. These activities represent targets for therapeutic or diagnostic approaches. We hypothesise that a targeted modulation of the HS complement in the cancer stem cell niche may lead to reduced cell proliferation, increased apoptosis, and/or loss of malignant properties of the tumour-initiating cells. To study HS involvement in cancer stem cell homeostasis we established an *in vitro* model of cancer stem cells. We used flow cytometry to detect a subpopulation expressing reported markers of breast cancer stem cells (CD44^{+}/CD24$^{-/low}$) in several breast cancer cell lines. Interestingly, only the two most aggressive cell lines, MDA-MB-231 and Hs587-T, contained the CD44^{+}CD24$^{low/-}$ subpopulation described in the literature as a cancer stem cell-like subpopulation. Furthermore, we analysed heparin-treated MDA-MB-231 and Hs587-T cells by flow cytometry and observed that heparin treatment reduced the proportion of CD44^{+}/CD24$^{-/low}$ cells in culture, even at very low doses (1 ng/ml). These preliminary results suggest that HS may play an important role in regulating the homeostasis of breast cancer stem cells. Further investigation is needed to better understand the effects of heparin and other modified heparin compounds on breast cancer cells and their cancer stem cell sub-population and to identify potential therapeutic applications.

Thymosin β4 enhance adhesion to extracellular matrix proteins and reduced adhesion to endothelial progenitor cells

M. Stasiak[1], K. Kusińska[1], A. Selmi[1], K. Bulenger[2], R. Bednarek[1], C. S. Cierniewski[3]
[1]Cytobiology and Proteomics, [2]Medical University of Lodz, Lodz, Poland, [3]Molecular and Medical Biophysics, Medical University of Lodz, Lodz, Poland

After cancer patient's successful treatment the main effort is to inhibit the metastasis. The initial steps of cancer metastasis are: loss of cell polarity in the primary tissue, increased interaction with the extracellular matrix (ECM) through integrins and migration through the ECM towards blood and lymphatic vessels. The paramount significance for anti-metastatic therapy is one of initiating steps - the adhesion of cancer cells to the endothelium.

Thymosin β4 (Tβ4) is a small protein plays an essential role in regulation of actin polymerization. It is also involved in a number of cell functions: adhesion, proliferation, migration, differentiation, directional migration, angiogenesis, wound healing, hair follicle growth, and apoptosis. Tβ4 plays a variety of different roles depending on the cell type and whether it acts extracellularly or intracellularly. Tβ4 peptide, if used after a heart attack, might reactivate cardiac progenitor cells to repair damaged heart tissue but on the other hand Tβ4 is overexpressed in various types of tumors.

We tested the human colon adenocarcinoma cells line HT29 and CX1.1 that differ in integrin β1 level. In our study transient overexpression of Tβ4 in HT29 and CX1.1 cells is correlated with transendothelial cell migration. Tβ4 increased the adhesion of can-

© 2014 The Authors. FEBS Journal © 2014 FEBS

cer cells to the major ECM proteins (fibronectin, vitronectin, collagen and fibrin). Coincidently, the treatment of HT29 and CX1.1 cells with Tβ4 slightly decreased their adhesion to endothelial cells and endothelial progenitor cells. This effect was not observed for Tβ4-treated HT29 cells those adhered to endothelial cells. These observation may indicate that the potential role of Tβ4 in cancer cell adhesion process to endothelial cells is much more complex. In conclusion, our preliminary data suggest a role for Tβ4 in metastasis colon cancer. Further studies are needed in order to shed light on the intimate significance of the expression of this thymosin not only during adhesion and transendothelial migration, but also during the change of polarity in the primary tissue.

Unraveling the mechanism of chronic myeloid leukemia progression by next-generation sequencing of leukemic progenitor and stem cells

M. M. Machnicki[1], J. Niesiobedzka-Krezel[2], I. Solarska[3], P. Stawinski[1], R. Ploski[4], T. Stoklosa[1]
[1]*Department of Immunology, Center of Biostructure,* [2]*Department of Haematology, Oncology and Internal Diseases, Medical University of Warsaw,* [3]*Department of Diagnostic Haematology, Institute of Haematology and Transfusion Medicine,* [4]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland*

Chronic myeloid leukemia (CML) is the first human malignancy in which a genetic abnormality was linked to an oncogenic transformation and a successful targeted treatment was developed. The BCR-ABL1 fusion gene formed by a reciprocal translocation, encodes constitutively active tyrosine kinase effectively inhibited by tyrosine kinase inhibitors (TKI). However, the mechanism of CML progression is relatively poorly understood. TKI therapy induces durable remissions in majority of patients, but leukemic stem cells are never fully eradicated and significant number of patients experience relapse.

Research in the field of cancer genetics accelerated after the introduction of next-generation sequencing (NGS), but there have been only few systemic approaches for CML. Therefore, we have started a study to investigate mechanism of CML progression by sequencing paired diagnosis-progression samples using NGS in order to find new genetic abnormalities responsible for disease progression and/or TKI-resistance. Here we report an analysis of a patient who rapidly developed resistance to imatinib and progressed to acute phase.

Fig. 1.

DNA was isolated from CD34 + cells (containing leukemic progenitor and stem cells), immunomagnetically selected from peripheral blood collected at two time points (at diagnosis and 3 months later when patient progressed to accelerated phase). Exome sequences were acquired by solution-based capture and high-throughput sequencing (Illumina HiSeq1500). Mutational differences between samples were analyzed by Mutect. ABL1 exon 4 was resequenced by NGS and Sanger methods in both samples.

19 and 15 variants were detected exclusively in the diagnosis and progression sample, most of which were uncommon, suggesting an ongoing clonal evolution of the leukemic clone. The most significant mutation discovered exclusively in the progression sample was a G>C transversion in ABL1 kinase domain of BCR-ABL1, which results in p. Q252H substitution in the P-loop, causes resistance to imatinib and is a negative prognostic factor. We verified by additional deep sequencing that this mutation was rapidly acquired by CML progenitor/stem cells, as it was completely absent at the time of diagnosis.

Although results obtained in this particular case revealed previously described mutation as an underlying cause of TKI-resistance and disease progression, we were able to determine with high sensitivity if patient already harbored leukemic clone with mutation at the time of diagnosis and thus evaluate the pace of disease progression at the progenitor/stem cell stage.

Tropomyosin region encoded by alternative exon 2 confers different flexibility to smooth muscle and non-muscle isoforms

M. Sliwinska-Mosson, J. Moraczewska
Department of Biochemistry and Cell Biology, Kazimierz Wielki University, Bydgoszcz, Poland

Tropomyosins (TM) are a family of actin regulators, which determine functional diversity of actin filaments in muscle and non-muscle cells. TM molecules are elongated two-chain coiled coils, which polymerize along actin via end-to-end interactions. The crucial role of TM is the regulation of actin-myosin interactions. It is executed through steric blocking and allosteric mechanisms. It is believed that flexibility is a structural feature of tropomyosin important for TM functions. TM isoforms variety is generated by different genes and selection of alternative exons. Our previous studies show that isoform-specific sequence composition of the N- and C-termini determines functionally important orientation of TM chains on the filament (Śliwińska et al., 2011; Śliwińska and Moraczewska, 2013).

The aim of this work was to check whether alternative sequences of internal region encoded by exon 2 affect positions of TM isoforms on actin. Two TM isoforms: the smooth muscle isoform TMSm, and the non-muscle TM2 were analyzed. Both isoforms are products of α-TM gene and share the same sequence except for the internal region encoded either by exon 2a (TMSm) or exon 2b (TM2). Orientations of both regions were assessed by Förster Resonance Energy Transfer (FRET) between AEDANS attached to Cys^{51} and Cys^{73} of each TM isoform and DABMI bound to actin's Cys^{374}. FRET distances were measured in two activation states of actin filaments – closed state represented by TM-actin complex and open state induced by binding of myosin heads (S1) to TM-actin. In order to introduce reactive Cys residues into alternatively expressed region of TM isoforms site-directed mutagenesis was done.

© 2014 The Authors. FEBS Journal © 2014 FEBS

The obtained results indicated that the analyzed TM isoforms significantly differed in their positions on actin filament. Calculated donor-acceptor distances varied between 36.5 Å and 48.4 Å. Myosin S1 binding to actin filaments induced changes in AEDANS-DABMI distances. It increased FRET distances separating Cys^{51} and Cys^{73} in TM2 from actin by 9.5 and 5.7 Å, respectively. The distance measured from Cys^{73} of TMSm was also increased by 4.3 Å. In contrast, TMSm Cys^{51} was brought closer to actin's Cys^{374} by 2.5 Å. This shows a considerable flexibility of the region encoded by exon 2a. Together the results indicate that alternative TM sequence encoded by exon 2 strongly affects TM orientation on actin filament. Functional importance of the structural differences between TMSm and TM2 are currently under investigation.
