# FOREWORD

## Managing Knowledge for Sustainability

Welcome to the 18th International Forum on Knowledge Asset Dynamics (IFKAD 2023) co-hosted by the University of Basilicata and the University of LUM Giuseppe Degennaro in the inspiring city of Matera, Italy. We are delighted to have you here.

The current IFKAD edition is a major milestone as it marks the event's 18th year since its establishment. IFKAD is recognized as a significant international event that emphasizes the importance of knowledge as a driver of innovation, performance improvement, and value creation at the individual, organizational, and territorial levels. This achievement results from the dedication, interest, and involvement of the entire IFKAD community, including the chairpersons, organizers, delegates, scientific committee, keynote speakers, and journal editors and publishers.

We can be happy about achieving our goal but are also motivated to continue improving the conference's overall mission and impact. This includes enhancing the content's quality, increasing journal publication rates, and improving event management.

IFKAD is bringing together world thought leaders, academicians, young researchers, practitioners, and policymakers from different fields to discuss and debate new approaches, models, tools, and practices of knowledge and innovation management. This year's conference will focus on addressing growing pressures and emerging opportunities related to the "sustainability agenda", with high-quality and extensive participation guaranteed, as always.

Knowledge management is now widely recognized as critical for maintaining and improving an organization's competitive advantage. Recently, there has been a renewed emphasis on the significance of knowledge-based strategies and factors in promoting sustainability. This involves various environmental, political, economic, and socio-cultural issues. These aspects are essential in enabling managerial and policy approaches towards sustainability.

The growing focus on sustainability means that organizations need to adapt their business models and values to prioritize social and environmental responsibility alongside economic success. As a result, knowledge management is becoming a key factor in meeting the new standards for economic, environmental, and social sustainability.

We aim to improve how we measure the impact of sustainability-focused projects by using better processes and practices that consider environmental, social, and economic factors.

At the 18th edition of IFKAD, we wish to elaborate, extend and improve theories and discuss and share findings, practices and experiences to inform academic, managerial and policy debates about the role of the knowledge drivers in stimulating and supporting the organisational capacity to address the emerging challenges of the sustainability, by

developing and implementing new products and services, re-thought operations, new ways to conceive and use technology and digitalisation, renewed relationships with customers and stakeholders, and new business models.

We invite you to join us in making IFKAD 2023 the premier forum for advancing academic understanding of how knowledge-intensive organizations can address sustainability challenges at all levels of investigation - micro, meso, and macro. Our goal is to provide valuable insights to help leaders, managers, and policy-makers rethink their organizations and develop practical initiatives to move beyond the rhetoric of "greening."

This year's conference program promises to be as informative and engaging as previous IFKAD conferences. With COVID-19 restrictions removed, most attendees will be present in Matera. The conference will feature exceptional keynote speakers who will share their research and practical insights, inspiring new perspectives and avenues of research. Over 200 speakers from 30 countries will present an excellent blend of academic and practical papers.

The IFKAD event in 2023 will demonstrate IFKAD's involvement in Asia through the IFKAD ASIA Chapter, which is led by Prof. Min-Ren Yan from National Chengchi University in Taiwan. In addition, there is a collaboration with Ipàzia, which is a Scientific Observatory on Gender Research led by Professor Paola Paoloni from Sapienza University. The focus of this collaboration is to promote a culture of equality and equal opportunities, while also working to prevent any forms of discrimination or violence.

The IFKAD 2023 conference is a joint effort between the Arts for Business Institute, LUM University, and the University of Basilicata. Our associate partner, the Institute of Knowledge Asset Management, is also involved in organizing this event.

We are honoured for your participation and confident that all the delegates will share insights to help private and public organisations worldwide to face uncertainty, identify opportunities and capitalize on high-level human capital and emerging technologies to improve their value creation capacity.

## Abstract

This paper tests the intellectual capital (IC) framework dedicated to elite athletes proposed by Aprile et al. (2022) on the Italian Paralympic champion Bebe Vio to determine the usefulness of this framework and its components. To do so, the study is based on primary and secondary data from and about Bebe Vio. The findings underline that the IC framework offers a solid approach to determine and learn about the IC of elite athletes (regardless of its type). Additionally, the findings indicate areas that could be added/extended to successfully determine the IC of these persons.

**Keywords** – Intellectual capital framework, Elite athletes, Athletes with Disabilities, Sport, Inclusiveness

## 1 Introduction

In this paper, we apply the IC framework developed by Aprile *et al.* (2022) dedicated to elite athletes, on the Paralympic champion Bebe Vio (in the remainder of this paper called Bebe, since in Italy she is well known with her first name), an Italian elite athlete (wheelchair fencer), to understand if it can be applied also with reference to the Paralympic elite athletes or if it should be further developed/strengthened to capture different types of elite athletes. Thus, the primary aim is to test the usefulness of this IC framework and its components.

Aprile *et al.* (2022)' framework considers the emerging research interests regarding both sports and elite athletes. As far as the latter is concerned, these types of athletes in particular have an intellectual capital (IC) that allows these individuals to generate considerable monetary capital not only for themselves but also for their immediate environment in the course of their careers (Wicker *et al.*, 2012; Puspitasari *et al.*, 2019), making them an interesting subject of investigation. By focusing on elite athletes, Aprile and colleagues have made an attempt to extend the application of IC frameworks that tend to focus on organizations, industries or countries rather than individual persons (Pedro *et al.*, 2018).

To capture the possible IC of elite athlete, Aprile *et al.* (2022) propose three specific dimensions namely Natural Capital, Sports Capital and Media Capital. In view of the fact that the framework is still a conceptual work, further research activities are needed to ensure the robustness of the framework and its components. The present paper aims to contribute to this; namely to apply the framework to Bebe Vio.

Bebe has been chosen since she has a very relevant sports capital (she won two Paralympic gold medals) and an impressive media capital strongly related to her contagious energy and positiveness and to her generosity (e.g., she founded an association aimed at helping young amputee people to practice sport, supplying prothesis and other forms of support). By focusing on professional athletes with disabilities we would also like to contribute to bringing more diversity and inclusiveness to social sciences in general and business and management research in particular.

The remainder of this paper is structured as follows. We first briefly address the theoretical background of this paper. We then explain the methodology of the research. This is followed by the application of the IC framework to the case, and finally the discussion and conclusions are presented.

## **2 Theoretical background**

### ***2.1 The IC framework proposed by Aprile *et al.* (2022)***

The IC framework dedicated to elite athletes proposed by Aprile *et al.* (2022) is based on three IC dimensions namely Natural Capital, Sports Capital and Media Capital. The authors describe Natural Capital as an athlete's natural characteristic; thus, it is assumed that this capital can help the individual to a win and to realize

superior performance not only on the field but also off the field in the form of fame. The sports capital is the sum of sporting success and economic success; i.e., the former leads to the latter while, the media capital aims at increasing the reputation of elite athletes regardless of their sporting successes.

Aprile et al. (2022) argue that elite athletes should invest in these IC dimensions to maximize their success inside and outside the sporting competition zone. According to our knowledge, this framework has not been validated yet, but this would be needed to determine not only the robustness of the framework's dimensions and their elements but also its overall usefulness for determining the IC of highly professional individuals.

## ***2.2 Elite athletes as the focus of studies***

The study of elite athletes has intensified over the years given these persons' impact and influence in different areas of social life (Su et al., 2020). Elite athletes have demonstrated their ability to create enormous incomes from which not only the athlete but also the environment benefits (Puspitasari et al., 2019). The IC of these people is a decisive factor from the beginning of their career to the end, and the more successful the IC, the greater it is (Aprile et al., 2022).

When the studies of elite athletes are examined, it is noticeable that disabled elite athletes are neglected, although they are also very successful on and off the sporting field (Dehghansai et al., 2017a). Erin Popovich (a Paralympic Swimmer), or Esther Mary Vergeer (a former professional wheelchair tennis player) can be named next to Bebe Vio. Important for this study, little is known about the factors that influence the development of athletes with disabilities (Dehghansai et al., 2017b), by taking the perspective of IC and arguing that IC determines and supports the development and maintenance of a successful career, this paper is believed to contribute to this gap in the literature.

A review of the relevant literature reveals that the study of elite athletes from an IC perspective is underdeveloped to date, the focus is still on organizations, and here primarily on private organizations. Thus, the present paper is an attempt to address this situation.

## **3 Methodology**

We used the case study methodology (Yin, 1994; Stake 1995; Miles and Huberman 1994). More precisely, this paper is based on a single case study which

was considered suitable for reaching our aim to test the usefulness of the IC framework. The case of inquiry in this study is Bebe Vio.

To make the testing possible, we collected primary and secondary data. Primary data have been collected through a questionnaire given to Bebe Vio by her father (Ruggero Vio), who is also her manager. To complement and also validate the primary data and vice versa we used the books published by Bebe (2017, 2019) as well as other sources about her publicly available on the internet and traditional media.

The questions were sent by email, following after a conversation with Ruggero Vio that took place in February 2023. The questionnaire was divided into three parts. The first part contained questions aimed at developing a better understanding of the context (e.g., the indication of the victories achieved considered as the most important, Bebe's charitable activities, the main sponsorships and advertising activities, some social networks' data, like number of followers). The second part asked to fill tables containing the three dimensions (natural, sports and media capital) and elements as defined in the IC framework. We also asked for a rating of the individual elements on a scale from 0 to 10. Finally, the third part included some questions about Bebe's opinion on possibly missing elements of the model and others aimed at better understanding the aspects that have mainly contributed to Bebe's success and whether a certain order can be found in the development of the different IC dimensions. The focus of this paper is primarily on the assessment of the individual elements of the three IC dimensions.

### **3.1 The case: Bebe Vio**

#### *3.1.1 The choice of Bebe Vio.*

Bebe Vio is the name used by Beatrice Maria Adelaide Marzia Vio Grandis, a wheelchair fencing, specialised in the discipline of foil, born in Mogliano Veneto on 4 March 1997. She has achieved several and continuous sports successes, starting at the age of 15 with the gold medal at the Italian Championship. She started emerging at an international level in 2014, finishing second at the World Cup and at the European Championship. Since 2015, that means since the age of 18, she collected substantially all most important victories in her discipline: from 2015 to 2019, winner of the World Cup, Winner of the European Championships 2016 and 2018, winner of the World Championships 2015 and 2017, and most of

all, gold medal at the Paralympic Games 2016 and 2021. She received important honours such as 'Cavaliere della Repubblica', 'Collare d'Oro Paralimpico' and 'Collare d'Oro' that represent the best Italian awards.

Her notoriety, anyway started before such successes, in fact, since her dream was to participate to Paralympic games, but when she was 15, she hadn't achieved enough sports results to grant the participation at the competition, a journalist, Claudio Arrigoni, indicated to her family that there was the possibility to be candidate to participate at the Ceremony as torchbearer. It was necessary to register on the website of the International Paralympic Committee (IPC) and become the most voted one (Vio 2015, reprinted 2021, p. 21). She was helped to achieve this result from journalists working for an important national Journal (Corriere della Sera) and by the diffusion of the information on several blogs and websites (Vio, 2015, p. 21). Her result was defined 'Overwhelming', since more than 1.000 e-mails were sent to support her application.

She is also notorious for all the charity initiatives that her and her family put in place, in particular by the Association Art4Sport, and for the initiatives aimed at fostering the inclusiveness of athletes with disabilities and able-bodied athletes, in particular with the project 'Wembrace Sport', and with the Bebe Vio Academy, founded in 2021 with the support of the brand Nike. Bebe has some important sponsors – for some of them she is global ambassador – and she connects such partnerships to social projects (diffusion of sport for disabled and integration, diffusion of sustainability with the project 'Beyond 0' of Toyota for cars with no emissions, and with Sorgenia, supporting the green energy and the safeguard of women). She is also sponsored by L'Oréal, Barilla, Disney, Unilever.

With reference to the social dimension, she is active in particular on Instagram. Considering all socials in which she is involved, she collects about 2.000.000 followers. She hasn't any social manager. Despite all these aspects, she is reserved, trying to avoid interviews and gossip. She also has some institutional roles and she has had the opportunity to meet the Pope Francesco, the President of the European Commission Ursula von der Leyen, the Italian President Mattarella, and the former President of the US, Obama. She also collected a lot of selfies with famous artists. Her popularity is strongly related to the fact that she is a symbol of correctness, energy, vitality, passion for life, solidarity and other values (defence of the weakest, women and the environment).

Against this background, Bebe was considered an interesting case to be studied, since she combines to an enormous mental strength, a long history of

sports successes (even if she is still very young), and a great mediatic impact, in particular in Italy, but also in several other countries. In other words, one would expect an enormous IC, articulated in each of the three dimensions of the IC framework for elite athletes to be tested in this paper.

#### 4 The application of the IC framework on Bebe Vio

In the following sections, we apply the IC framework for athletes to the case of Bebe Vio. Table 1 displays the framework's three dimensions and their components.

Table 1. Components of IC framework for elite athletes

<b>Natural Capital (Adapted from human capital)</b>	<b>Sports Capital (Similar to organisational capital)</b>	<b>Mediatic Capital (A sort of specific adaptation of relational capital)</b>
Natural aspects Native characteristics Mental strength/fragility Talent Technical skills Aesthetic qualities  Improving elements Training activities Experience	Professional choices Technical choices Other aspects Results  Competitions choice Technical staff Professional management Training (place, type, etc.) Coach Team selection  Place of training Rest period  Lifestyle Relationships with teammates  Wins Sport success	Natural aspects Professional choices Other Aspects  Reputation Public relations Sponsors (technical and others) Relationships with journalists  Social media Media exposition Popularity  Sympathetic Empathy Charisma  Looks Gossip

Next, we report the assessment of each element of the IC dimensions with reference to the Bebe Vio case. These assessments have been retrieved from the interview.

#### **4.1 Natural Capital**

Table 2. Assessment of the elements of Bebe Vio's Natural Capital

<b>Natural Capital Elements</b>	<b>Degree of importance (0 - 10)</b>
Native characteristics	3 (25% of importance)
Mental strength	10 (75% of importance)
Talent	9
Technical skills	8
Aesthetic qualities	8
Training activities	9
Experience	6

#### **4.2 Sports Capital**

Table 3 reports the assessments of the elements making the Sports Capital dimension.

Table 3. Assessment of the elements of Bebe Vio's Sports Capital

<b>Sports Capital Elements</b>	<b>Degree of importance (0 - 10)</b>
Competitions choice	4
Technical staff	9
Professional management	10
Training	10
Coach	9
Team selection	6
Place of training	4
Rest period	4
Lifestyle	10
Relationships with teammates	9
Wins	10
Sport success	10

#### **4.3 Media Capital**

Table 4 reports the assessments of the elements of the Media Capital dimension.

Table 4. Assessment of the elements of Bebe Vio's Media Capital

<b>Media Capital Elements</b>	<b>Degree of importance (0 - 10)</b>
Reputation	10
Public relations	10
Sponsor	10
Relationships with journalists	6
Social media	7
Popularity	10
Published Books and other publications	5
Other activities/elements	8

## 5 Discussion

The analysis of the individual dimensions and element suggests that in terms of Natural Capital, the most important characteristic is mental strength, whereas native characteristics are less important. This is due to the fact that facial disabilities, especially severely debilitating disabilities, require a lot of mental strength. Such disabilities can, of course, reduce many of the physical native features that might characterise an athlete. Talent is important and during the interview it became clear that passion and extreme competitiveness can help to develop sports capital. Technical skills are important and training activity has a high value in the given context. Aesthetic qualities can be important in gaining self-confidence and making the person (athlete) feel comfortable with him/herself and in human relationships.

Referring to the Sports Capital, no great importance has been attributed to the choice of the competition. Bebe focuses only on the most important ones. This is also important to preserve the athlete from injuries. Victories and sports results are considered extremely important. The other elements that are considered most important are (i) having a professional manager, in this case her father, i.e., one who respects the human needs of the athlete without putting economic objectives first. (ii) Training is very important to achieve sports results and absorbs a very relevant part of the athlete's life. Finally, (iii) lifestyle is important both for having the necessary energy for sporting success (those who are happy and motivated can achieve better results) and for Bebe's popularity. The findings suggest that her love for life, the energy that she transfers during her relationships with the people that belongs to her 'squadra', and to other people,

and all her charity initiatives, contribute constantly to Bebe's media capital. Her popularity is the sum of these aspects and enforced by her sports successes. Important is also the choice of the coach, technical staff, and teammates, that means people strictly related to the athlete. Other aspects are considered less important.

As far as media capital is concerned, many of the elements that make it up are closely interrelated. Reputation and popularity are very important. They allow to become the representative of attractive brands. Bebe seems to be a natural when it comes to public relations, since she is at ease with everyone and put at ease people in relationship with herself. Meeting important people increases her popularity even further. Other aspects like publishing books, having relationships with journalists, and social media are not considered as important. Important are, on the contrary, all the charity activities she has put in place because they became one of her distinguishing features.

The result of the interview also enabled a ranking of the three IC dimensions. First and foremost is the Natural Capital, Bebe's mental strength and personality enable her to circumvent significant difficulties and achieve sporting and media success. In 2nd place is the Media Capital, as she became famous before sporting success, as in the case of her participation in the London 2012 Olympics as a torchbearer. Finally, the sports capital has become important and supports the continuous development of her Media Capital.

The analysis of the primary and secondary data also highlighted the important role of the family for the athlete and her development. This is also related to the fact that living with a disability, especially at a young age, requires a great presence and effort from the family. The family, but also friends, are important to cope with this circumstance in order to be able to develop self-confidence as well as the necessary energy, which is important for sporting success. This element was not considered in the tested IC framework. However, it can be considered as another important element that can complement and complete the other IC dimensions. The role of the family also appears important when looking at the careers of other athletes, e.g. Steffi Graf or Raphael Nadal.

## **6 Conclusions**

In this paper, we applied the recently proposed IC framework dedicated to elite athletes by Aprile et al. (2022) on Bebe Vio, an Italian elite wheelchair fencer. The

study helped us to validate the framework and its components. By testing it on an elite athlete with disability we were able to demonstrate that it can also be applied on other types of athletes. Additionally, we could expand the framework by adding the family as a further critical element for determining the IC capital of professional athletes. This supplement opens discussions for comparing elite athletes and their operations with those found in family businesses where the role of the family on the firms' success has been studied for many years (e.g., Gomez-Mejia et al., 2001; Salvato & Melin, 2008).

In our view, this study has contributed to a better understanding of the IC framework and its usefulness for determining the IC of individuals (here professional athletes). This was of course only a first step and more research should follow.

### Abstract

Considering the relevance of leadership to sustainable business development (Hind et al., 2009; Kurucz et al., 2017; Pham and King, 2019), in this paper, we examine the relationship between leadership and organizational performance. More precisely the focus is on ethical leadership which has been defined as “the demonstration of normatively appropriate conduct through personal actions and interpersonal relationships, and the promotion of such conduct to followers through two-way communication, reinforcement, and decision-making” (Brown et al., 2005, p. 120). Ethical leadership has found to be relevant in situations of change, as followers appear more satisfied with ethical leaders, which in turn motivates them to perform better, engage in more organizational citizenship behaviours, and also enjoy higher job satisfaction (Sharif and Scandura, 2014). A recent study by Ali et al. (2022) has also shown the positive relationship between ethical leadership and organizational learning. At the same time, empirical research on the impact of ethical leadership on organizational performance, however, is still limited (Dey et al., 2022).

Acknowledging the role of knowledge for sustainable business development (Abbas and Sağsan, 2019; Durst and Zieba, 2020), we argue in this paper that ethical leaders will emphasize and promote continued knowledge creation and knowledge networks to

contribute to the firms' organizational performance (Rhee et al., 2022; Li et al., 2009) and thus their sustainable development.

The remainder of this paper is structured as follows. We first briefly address the literature background of this paper. We then explain the methodology of the research. This is followed by the presentation and discussion of the results before we terminate the paper with a conclusion.

**Keywords** – Ethical leadership, Knowledge management, Knowledge creation, Knowledge networks, performance

**Nature of proposed paper** - Academic Research Paper

## **1 Literature background**

### **1.1 Ethical leadership**

There is a believe both among practitioners and academics that ethical leadership is crucial, both for increasing the organizational performance of companies (Neubert *et al.*, 2009; Mayer *et al.*, 2009; Treviño *et al.*, 2014) and acting sustainably and responsibly (Islam et al., 2021). It is assumed that ethical leaders are honest and trustworthy (Sosik *et al.*, 2019). Moreover, these persons are described as fair as possible, sound decision-makers and as persons who behave ethically in their professional life (Sharma *et al.*, 2019). Ethics, value, rewards and discipline have been determined as important issues for ethical leadership (Sosik *et al.*, 2019; Koay and Lim, 2019). Such explicit behaviours and traits help ethical leaders to be more reliable, and gets better attention of their team members and motivate them for the common target of companies (Treviño *et al.*, 2000; Treviño *et al.*, 2003).

Moreover, ethical leaders are more human centered and pay more attention on issues such as human rights, self-respect, creativity and they are also motivated to build capacity of employees by providing opportunities and giving them right positions in which they can be successful (Ciulla, 2004; Zhu *et al.*, 2004). They also motivate their team members by providing the right channel to them to build their capacity for better performance. This eventually helps employees to gain knowledge, skills, ability and creativity and to perform better with regard to R&D and knowledge creation activities in return (Al Halbusi *et al.*, 2021). Different works (e.g., Zacher and Rosing, 2015; Jiang and Chen, 2018) revealed that this type of leadership is important for improved knowledge creation performance;

and mainly the ethical leadership promotes this because it supports creativity not only at the individual level but also at the team level (Černe *et al.*, 2013; Chughtai, 2016; Dhar, 2016; Javed *et al.*, 2018) which eventually affects organizational performance (Tu *et al.*, 2018).

Regarding the workplace context, since ethical leaders are critical for employee motivation to gain successful results in the workplace (Dust *et al.*, 2018), they are also considered as the main developer and provider of an innovative atmosphere by motivating and encouraging employees to include learning and creativity activities in companies. Ethical leadership also makes sure that employee's opinions and views are considered during the organizational decision-making process (Piccolo *et al.*, 2010) that increase both the motivation and dedication of employee for the companies. Therefore, we propose the following research proposition:

*P1: Ethical leadership has a positive effect on company performance.*

### **1.2 Knowledge management**

Knowledge management has been described as a crucial function to contribute to organizations continued and sustained business development (Durst and Zieba). Having access to relevant and updated knowledge is vital not only for ethical leaders (Le and Nguyen, 2023) but also for the employees to make sure that current and coming business opportunities and challenges can be addressed (Reinholt *et al.*, 2011).

### **1.3 Knowledge creation**

Nonaka *et al.* (2000, p. 8), have defined knowledge creation as "a continuous, self-transcending process through which one transcends the boundary of the old self into a new self by acquiring a new context, a new view of the world, and new knowledge." Ongoing knowledge creation is relevant to support firm's organizational performance (Li *et al.*, 2009), given that one can also assume that forward-looking leaders will emphasize this process (von Krogh *et al.*, 2011). Goswami and Agrawal (2023) have shown in a recent study the impact of ethical leadership on knowledge creation. Thus, the following propositions are posed:

*P2: Ethical leadership has a positive effect on knowledge creation.*

*P3: Knowledge creation has a positive effect on performance.*

#### **1.4 Knowledge networks**

It is known that not all knowledge can be developed in-house (Nonaka & Toyama, 2003) and organizations actively enter into networks to get access to new and other knowledge to continuously broaden and deepen their knowledge domains (Durst *et al.*, 2020). Leaders who understand the importance of having access to internal and external knowledge actively promote the creation and maintenance of knowledge networks among employees (Hansen, 2002). Thus, it is assumed that also ethical leaders will actively promote the use of knowledge networks to support the organizations' development and thus their performance (Zhang *et al.*, 2020).

Consequently, the following propositions are raised:

*P4: Knowledge creation has a positive effect on knowledge networks.*

*P5: Knowledge networks have a positive effect on performance.*

## **2 Methodology**

### **2.1 Sample and Data collection**

The companies contacted for this research came from the Technology Transfer Office (TTO) company database of Ege University in Turkey. The Ege University TTO was established in 2013 in order to create a link between university and industry as well as help researchers to commercialize their research results. The TTO also has been providing services to companies such as accessing university infrastructures, research capacity and patents. The TTO is playing a key role specially to bring together companies and researchers for contracted research and access to government funds. For these reasons, there is a strong link between the TTO and companies and the TTO has a large company database. To provide sustainable services the TTO registers each company that asks for support into its database. The database contains several contact details of the companies, such as their representatives, sector and company size.

For this study, companies that approached the TTO between 2018 and 2020 for different reasons were selected. There were 1053 companies in total that were contacted. To gather information a questionnaire was developed and sent to the managers of the companies via email. This email was accompanied by a letter that explained the aim of the research. The data were collected between May and

September 2021. Of the 1053 companies, 416 responded to the survey. We excluded missing and non-useful information, i.e., 75 responses were removed that left 341 full responses. This means a response rate of 23%, which can be deemed as good.

## **2.2 Measures**

We used the following measures in our study.

### **2.3 Independent variables**

Ethical leadership: Ethical leadership variable was created by using the 10-item ethical leadership scale developed by Brown et al. (2005). Example items are “my manager listen to what employees have to say”, “discipline employees who violate ethical standards”. A 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree) was used.

#### *2.3.1 Knowledge creation:*

To measure knowledge creation four questions were used; example “acquire new/more market knowledge”, “acquire new technological knowledge”. As before a 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree) was utilised.

#### *2.3.2 Knowledge networks:*

To measure knowledge networks items such as “we form ecosystems” and “generate knowledge together” were used. Again a 5-point Likert was used.

#### *2.3.3 Dependent variable*

For measuring performance, we used five indicators namely growth, sustainability, innovativeness, profitability and success. Items were also measured on a 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree).

#### *2.3.4 Statistical Methods*

Structural equation modelling was carried out test our proposed propositions using the software ADANCO.

### 3 Results

We conducted several tests in order to assess our measurement model. We checked for the indicator loadings which should be  $> 0.7$  each, which was fulfilled. We checked for reliability / internal consistency using Cronbach Alpha which should be  $> 0.7$ , which was fulfilled for each of our variables. We tested convergent validity using the Average Variance Extracted (AVE), scores above  $> 0.5$  are considered as desirable. This was received for all variables but one, knowledge creation obtained a score of slightly below 0.5, namely 0.4805; which, however, was considered still ok by us. Discriminant validity test was also performed to evaluate the level of deviation that possibly exists among the constructs. All indicators had loadings in the accepted thresholds.

We also investigated collinearity among our indicators and found that all variance inflation factor (VIF) values were below 5 which indicates that there is no indication of problematic multicollinearity. The values for the indicators ranged from 1.2188 to 2.2568.

In order to evaluate the structural model, we examined the overall fit of the estimated model, the path coefficient estimates, their significance and, the effect sizes ( $f^2$ ) and the coefficient of determination ( $R^2$ ) (Benitez *et al.*, 2020). The results show a good SRMR index (0.0725), a measure of approximate fit, below the suggested threshold of 0.08. The path coefficient estimates for our proposed relationships range from 0.093 to 0.589, and are significant at a 5% significance level except the effect of the relationships between knowledge creation and performance and knowledge networks and performance. The evaluation of the effect size ( $f^2$ ) revealed values ranging from 0.0063 to 0.5313. Values larger or equal to 0.350 indicate large effect size, in our case reached for the relationship between knowledge creation and knowledge networks while values below 0.150 indicate weak effect size (Benitez *et al.*, 2020), which was obtained in our study for the relationships between ethical leadership and performance, knowledge creation and performance, and knowledge networks and performance. Finally, we evaluated the  $R^2$  and learned that our model explains 14.54% of knowledge creation, 34.70% of knowledge networks and 11.56% of performance.

The results of the propositions testing are presented in Table 1.

Table 1 Propositions testing results

Effect	Path coefficient	Mean value	Standard error	t-value	p-value (one-tailed)	Interpretation
Ethical leadership -> Performance	0.2013	0.2144	0.0912	2.2061	0.0138	Accepted
Ethical leadership -> Knowledge creation	0.3813	0.3949	0.0764	4.9900	0.0000	Accepted
Knowledge creation -> Performance	0.1381	0.1351	0.1149	1.2022	0.1148	Rejected
Knowledge creation -> Knowledge networks	0.5890	0.5905	0.0785	7.4991	0.0000	Accepted
Knowledge networks -> Performance	0.0925	0.0951	0.1285	0.7200	0.2359	Rejected

#### 4 Discussion and conclusion

Our findings allow us to better understand the link between ethical leadership and performance. The findings confirm recent research that stressed the pivotal role of ethical leadership for organizational performance (Tu *et al.*, 2018; Dey *et al.*, 2022). Additionally, the findings suggest that ethical leadership significantly influences both knowledge creation and knowledge networks in organizations. We provide empirical evidence about the impact of knowledge creation and knowledge networks on performance and thus add to recent research in these areas (e.g., Zhang *et al.*, 2020; Goswami and Agrawal, 2023).

Our study contributes to both the body of knowledge concerning leadership and KM; empirical research on ethical leadership in conjunction with KM has only started recently and is still rather fragmented (Le and Nguyen, 2023). Having a better understanding of the link between ethical leadership and performance has important managerial implications for decision-makers in organizations too as it can help them to make better (i.e., more informed) decisions regarding the training of ethical leaders and their role in improving KM and thus ultimately organizational performance.

### Abstract

This conceptual paper aims to identify and analyse knowledge risks resulting from digitalization. Additionally, the paper tries to present factors influencing knowledge risks arising from digitalization and ways of handling them.

The study is a continuation of the research by Durst and Zieba (2019) related to knowledge risks and their potential outcomes. This present study makes an update on the literature on knowledge risks arising from digitalization.

The paper offers new insights for researchers dealing with the topic of knowledge risks in the context of digitalization and ways of handling them.

The study provides insight for each of us, as the issue addressed concerns us all. By becoming aware of the potential consequences of such knowledge risks, people may meet and cope with digitalization in a better, more enlightened way.

The presented paper is based on prior literature and the authors' reflections, experience, and analysis. Thus, to check for the suitability of the risks proposed, there is a need for empirical studies. Such studies are planned by the authors in the near future.

**Keywords** – Knowledge risks, risk management, knowledge management, digitalization

**Nature of proposed paper** - Academic Research Paper

## 1 Introduction

The dynamic development of the past (the recent one in particular) has made the importance of knowledge for organisations and people in general even more evident. From the beginning of the study of knowledge management (KM), knowledge had been both presented and examined as something positive that has to be collected, stored, transformed and broadly shared within organisations (Nonaka and Takeuchi, 1995; Massingham, 2010; Durst and Edvardsson, 2012). Only recently, this approach has been questioned by the increasing focus on factors that can potentially bring negative risks and challenges related to knowledge. The whole plethora of so-called knowledge risks has been identified (Durst and Zieba, 2019) and organisations too have started to consider them in their regular activities related to knowledge management (Durst et al., 2019; Marabelli and Newell, 2012; Sarigianni et al., 2015). In the taxonomy proposed by Durst and Zieba (2019), there are three main categories of knowledge risks namely human knowledge risks, technological risks and operational risks. Among the technological risks, one can find risks related to cybercrime, old technologies, digitalization, or social media (Durst and Zieba, 2019). In this paper, the authors are going to examine in more detail one type of those risks, namely knowledge risks resulting from digitalization. As the world becomes increasingly interconnected - a development that started even before the pandemic but accelerated it - it is crucial for all types of organisations to also address the possible negative impacts of this development. To the best knowledge of the authors, however, there are no studies examining knowledge risks related to digitalization, thus there is a clear need for rigorous research on the topic.

To fill this knowledge gap, this conceptual paper identifies and analyses knowledge risks resulting from digitalization. The paper develops in the following way. In the second part, it presents the concept of knowledge risks. In the third section, digitalization and risks related to it are described. In the fourth section,

knowledge risks arising from digitalization are presented, alongside with factors influencing them and ways of handling them. The last section concludes the paper.

## **2 The concept of knowledge risks**

Perrott (2007) defined knowledge risk as the likelihood of any loss resulting from the identification,

storage or protection of knowledge that may decrease the operational or strategic benefit of a company. While Durst and Zieba (2017) in order to highlight the possible origin of knowledge risks divided them into internal and external knowledge risks. According to these authors, internal knowledge risks are primarily connected with an organization's internal environment and cover risks such as knowledge attrition, knowledge waste or knowledge hoarding, while external knowledge risks can emerge due to an organization's interactions with its external environment, examples of these risks are knowledge leakage or knowledge spillover. Durst and Zieba (2019) developed a powerful taxonomy of knowledge risks, realized in the form of a knowledge risk map, that classifies knowledge risks according to three categories: operational, human, and technological. Human knowledge risks are connected with the employees, organizational culture, social and psychological factors. Possible knowledge risks are knowledge hiding, unlearning, or missing competencies. Technological knowledge risks are related to the usage of different information and communication technologies (ICTs), and their consequences. It covers cybercrime, digitalization or social media risks. While the last category operational knowledge risks is about the organization's functioning and its daily operations. It includes knowledge acquisition and application risks, or risks related to the knowledge gaps.

Major knowledge risks if not addressed properly can result in several negative consequences, such as failing to offer high-quality solutions (Demian & Fruchter, 2009), costly disruptions of performance or operations (Martins & Meyer, 2012) or reduced capacity to innovate (Durst et al., 2018).

## **3 Digitalization and risks related to it**

Digitalization is more than just technical development or digital transformation. It is defined as "socio-technical phenomena and processes of adopting and using

digital technologies in broader individual, organisational, and societal contexts.” (Legner et al., 2017). It originated as the automation of routine work, the next wave of digitization gave rise to e-commerce, and the Internet became a global communication infrastructure. Today the vision of universal computerization is no longer distant, it is very close to being realised. The current wave of digitalization is affecting human lives at all levels (Legner et al., 2017). Certainly, it brings people many benefits every day, it improves the company's results, reduces costs, strives for new products, and provides ever-new customer experiences (Savic, 2019). Nevertheless, organisations and societies have not mastered the ability to follow and adapt to digital changes. Pearce (2020) reveals that even boards of directors are not well prepared and lack the competencies to govern digitalization incentives, especially as it brings ever newer challenges and risks. Additionally, the pandemic in 2020 had accelerated the digitization process and brought additional challenges. Not all companies were ready in terms of financial resources or simply time to properly adopt and use digital technologies in the organisational context (Almeida et al., 2020). At that time, companies and societies felt tremendous pressure to digitise quickly, but the obstacle faced was the inexperience of many. The challenge was not just buying technology, digitization is about introducing new technology in such a way that it is adopted and becomes an integral part of the new reality that increases efficiency. Not all companies had the right conditions to successfully carry out this process (Almeida, 2021).

The adverse effects of accelerated digitization are being felt by everyone. Concerns have begun to arise that a less educated population unfamiliar with digital technology will begin to lose their jobs. Even those with skills may begin to fear that they will soon be replaced by intelligent machines. This harms society, arousing a kind of negative emotions, and an aversion to rapid digitalization. People are afraid of losing their autonomy, and thus their motivation to work may decrease (Gimpel & Schmied, 2020). Another side effect could be a deterioration in interaction and cooperation between people, whether friends, family, or co-workers. In a way, people are isolating themselves, hiding behind the screens of digital devices, while cyberbullying is gaining momentum. Another risk or side effect associated with digitalization is an increase in vulnerability to cybercrimes and thus their more frequent occurrence. National reports are sounding the alarm about this phenomenon. For example, Denmark, a leading country regarding the level of digitalization, is at the same time facing a very high risk of cybercrime and cyber espionage (Danish Centre for Cyber Security, 2021). Polish companies have

also increased digitization initiatives in recent years. The driver for the change was the need to reorganise the workforce in the pandemic. As a consequence, more than half of Polish companies noticed an increase in vulnerability to cyber-attacks, and as many as 64% of them reported at least one cyber security incident in 2021 (Cyfrowa Polska, 2021). This example discloses that the pressure to keep up with technological changes is high, but to have pressure or even awareness of cybercrime is not enough for companies and societies to be adequately prepared. It seems that the pace of digitalization is faster than the pace of spreading the necessary knowledge and skills to cope with it. Moreover, this lack of competencies does not only affect individuals but also small and large companies. Even though the larger companies often have specialised IT departments, it was reported that 55% of large companies worldwide are unable to effectively stop cyber-attacks (Cyfrowa Polska, 2021). To sum up, although digitalization brings many positive phenomena, it also has some negative consequences and causes some risks for organizations and individuals. Deloitte has prepared a framework that covers 10 areas of digitization risk which are present in every digital environment (Deloitte, 2018). Additionally, Gimpel and Schmied (2020) identified and described 11 types and 35 subtypes of risks and side effects of digitalization. It can be said that the general risks associated with digitization are well described in the literature. However, there are many knowledge risks arising from digitization, while literature linking digitalization and knowledge risks is very scarce. Durst and Zieba (2019) have only generally mentioned digitalization as one of the knowledge risks in their previous studies. This constitutes a research gap, and there is a need to take a closer look at knowledge risks arising from digitalization.

#### **4 Knowledge risks arising from digitalization – factors influencing them and ways of handling them**

In this section, the authors of this paper list potential knowledge risks resulting from digitalization followed by factors influencing these risks and potential countermeasures for dealing with them.

The first potential knowledge risk resulting from digitalization are related to **mental health issues**. Digitalization can adversely affect individuals' mental health and contribute to knowledge loss/unlearning. Employees might feel overwhelmed with digitalization and as a result, not cope with it in their everyday

work. Employees not being in their best mental state might have problems with motivation to work, take sick leaves more often and manifest some negative phenomena related to knowledge, such as knowledge hiding or knowledge hoarding.

The second potential linked knowledge risks connected with digitalization is **the loss of autonomy** and **lack of empowerment**. Digitalization can lead to a loss of the ability to make one's own decisions, a feeling of lacking power among employees and as a result, a reduced engagement in activities related to knowledge sharing and creativity. Empowerment is a vital element of an organizational culture of trust and learning (Caniëls *et al.*, 2017) and when it is missing, employees are less eager to admit to mistakes or come up with innovative ideas.

The third potential knowledge risk related to digitalization is **the dehumanisation of work**. For example, digitalization brings job losses and the need for new occupations, which can lead to the dropout of some valuable employees and their knowledge from organizations. Possible consequences of this situation could be a motivation problem among workers across generations and their tacit knowledge is also likely to suffer.

The fourth knowledge risk is the **overreliance on technology** leading to wrong or improper decisions - based on automatization without the human factor inclusion trivial and biased decisions might be made.

The fifth knowledge risks is **vulnerability**. Companies of all sizes run the risk of having nothing to defend themselves against possible cyber-attacks. In the worst case, there is a threat of the cessation of business activities.

A last but not least knowledge risk is **acting rashly**. The fast and increasingly unpredictable development can lead to rash actions out of fear of missing something / losing the connection. Digitalization brings the pressure on organizations to adapt quickly and with the use of new technologies. Those technologies might not be suitable or stable enough to use in an organization, but organizations might feel pushed to implement them.

There are several factors that may potentially influence the knowledge risks described above. Those factors can be divided into two groups: human factors and technical factors.

Human factors:

1. ways of implementing digitalisation solutions and skills in change management manifested by the management staff (e.g., leadership

- support) - for example, if employees are trained, involved in the process of digitalisation process from the beginning, supported, etc., they may more easily accept it and the knowledge risks like mental health issues can be reduced;
2. part/share of the processes that are substituted with digitalisation - to which extent the regular routines and habits of employees will be affected by digitalisation and how well this is explained/justified to employees – if employees understand why it is necessary and how it will help in their work, they will feel more empowered;
  3. creating organizational culture of trust – if employees trust their supervisors and peers, they will be more eager to accept digitalization process and its consequences;
  4. faith in technology – if employees have faith in technology and are aware of both the positive and negative benefits it may bring, they will be more open to the whole digitalization process.
  5. skills and competences of the organization members – if the organization members are constantly being trained or educated with regard to risk management, knowledge management and digital transformation, the likelihood that they will approach the topics in a more informed and reflective way increases.

Technical factors:

1. solutions and their suitability for the organisation/industry/sector – if the solution is suitable and adjusted to the needs of an organization, it can boost the operations and gain the acceptance of employees, otherwise, it is more probable to be a failure;
2. necessary upgrade of the solutions - how often, how it is going to be handled technically, etc. – the more complicated and frequent the updates need to be, the more difficult it will be to sustain the solution in the organization and get the support of employees;
3. digital readiness of the organization – if the organization is not ready technically and organizationally, implementing digitalization process will be hindered.

To sum up, there is a variety of knowledge risks arising from digitalization that may potentially hinder the operations of an organization. Their consequences might be negative for the organization and its individuals. Essential knowledge risks if not addressed can terminate the business. All in all, knowledge risks arising

from digitalization should be taken into consideration and their consequences should be minimized as well as possible. Otherwise, they risk significantly reducing the performance/well-being not only of the organisation but also of the people.

Apart from these above knowledge risks resulting from digitalization, there are many risks in general. For example, there is a threat of even stronger discrimination against minorities. There is clear evidence that the programming of the algorithms is significantly influenced by the person behind it (Orwat, 2020). Since these jobs are still run by men, there can be considerable negative effects in different areas of life, e.g., in granting loans, in the job application process, etc. Digitalization can also lead to marginalised social groups. The changes risk exacerbating the digital divide, and people with low education and from poorer countries will suffer even more (Vasilescu et al., 2020). The above discussion also shows how important education, training and continuous professional development are. This must begin as early as possible, for employees to be trained and understand the whole digitalization process better. The state, but also each individual, has a decisive role to play here.

## **5 Conclusions**

This conceptual paper has identified and presented different types of knowledge risks arising from digitalization. Focusing on knowledge risks analysed in the context of digitalization, the taxonomy proposed by Durst and Zieba (2019) has shown again its powerful usefulness for different settings and challenges. From a practical point of view, the study provides useful insight for each of us as the issue addressed concerns us all. Becoming aware of the potential consequences of such knowledge risks, people may meet and cope with digitalization in a better, more enlightened way.

The limitations of this paper are similar to those of theoretical or conceptual papers. The presented paper is based on prior literature and the authors' reflections, experience, and analysis. Thus, to check for the suitability of the risks proposed, there is a need for empirical studies. Such studies can be conducted in the near future.

### Abstract

The purpose of this paper is twofold: (1) to understand how knowledge management failed to fulfil its promises and became a blurred field of research that gets increasingly diluted in adjacent fields, a catch phrase referring to an eclectic group of intangible phenomena related to learning and roughly to any organizational situations using the word 'knowledge'; (2) to explore how the use a meta-theoretical analysis may suggest a way forward that moves away from eclectics to unity and highlight the potential KM holds for organizations striving to manage organizational knowledge within turbulent times. Considering the persistence of the conventional rational-cognitive obsession with recipes and the slicing and dicing of organizational knowledge in well-defined, circumscribed, and quasi-observable sub-domains, is timely. This widely spread inclination in objectifying and reifying knowledge fails to help organizations navigate the complex business environment of this first quarter of the 21st Century. Contemporary organizations are compelled to manage knowledge within a VUCA or BANI world. More than ever, firms must consider holistic perspectives enabling the management of an ambiguous and elusive organizational knowledge, while acknowledging the complexity or crisis state of our current world. Practitioners and scholars must go beyond the simplified assumptions currently available in mainstream literature. The following research question guides the study: What does a meta-theoretical study about the evolution of knowledge management reveal on its inherent ontological and epistemological assumptions, and how can this support scholars and practitioners to make most of a VUCA context? Through a meta-theoretical analysis, this paper endeavours to highlight how the field has come to this situation. It attempts to refocus the audience attention on the kernel of organizational knowledge, mechanisms, and dynamics. Meta-theoretical analyses on knowledge management are rare provided that the field is taken for granted and that trends seems to define the field and how it evolves.

**Keywords** – Knowledge management, Metatheory, Positivism, Social Constructionism

**Paper type** – Academic Research Paper

## 1 Introduction

The purpose of this paper is twofold: (1) to understand how knowledge management failed to fulfil its promises and became a blurred field of research that gets increasingly diluted in adjacent fields; (2) to explore how the use a meta-theoretical analysis may suggest a way forward that moves away from eclectics to unity and highlight the potential knowledge management holds for organizations striving to manage organizational knowledge within turbulent times. In other words, this study attempts to highlight some problems that may jeopardize the future of knowledge management and provide some prompts for a much-needed philosophical discussion.

Although, questions may arise on the importance of knowledge management, it is unquestionably viewed as part of the organizations' picture today (O'Leary, 2016). Practitioners identify knowledge management, the activity of identifying and leveraging the collective organizational knowledge helping an organization to improve its competitive advantage (von Krogh, 1998), as one of the top three domain affecting companies' success. This role has become even more prominent since the last pandemic as employees work from different locations (Behme and Becker, 2021). In research, knowledge management has become a full-fledged field of research (Bedford, 2013) despite its many eclectic definitions (Alavi and Leidner, 2001). In 2018, an international standard on knowledge management has been published by the International Standards Organization (ISO), giving knowledge management the legitimacy the field deserves as 'a distinct, strategic and influential management practice' (Loon, 2019: , p. 433). Thus, knowledge management has achieved a certain maturity and a substantial body of knowledge has accumulated for the last 30 to 35 years allowing a sound reflection of the paradigmatic evolution of this science.

However, the field has not really achieved its potential and is crippled by a lack of conceptual robustness (Serenko and Dumay, 2015b; Tzortzaki and Mihiotis, 2014). Rather, knowledge management has evolved into a convenient phrase, gathering different processes (Gaviria-Marin et al., 2019; Alavi and Leidner, 2001). Adding to the confusion, KM is sometimes combined with the resource-based view of the firm theory (Audretsch (Audretsch and Belitski, 2021). Looking back at the consolidation of knowledge management since inception, it is worth considering the times where knowledge management emerged and developed or when its overall reason of being and future are questioned. Such complicated

business contexts have been labelled as a world characterized by volatility, uncertainty, complexity, and ambiguity (VUCA) (Bowman, 2019; Bennet and Lemoine, 2014). Some argue that the Covid-19 pandemic and its aftermath made VUCA an insufficient descriptor and use an alternative acronym to refer to the present turbulent time: BANI. (B) B stands for Brittleness and the ideas that business stand on fragile foundations that can collapse anytime and overnight. (A) Anxiety characterises our society at large and a sense of urgency guide decision-making. (N) Detailed and long-term planning organizations depends on, is no longer possible in a Non-linear world where events appear disconnected and disproportionate. (I) The final letter underscores an Incomprehensible world where individuals seek for answers, but these answers do not makes sense; so at the end, actors must understand that the don't have to control everything (Cascio, 2020; Adam, 2023). While the 1990s introduced the game changing Internet and workflow software (Friedman, 2006), the 2020s brought about the trend that has been building for subsequent 30 years at full speed with the Covid-19 years, the Artificial Intelligence (AI) being the new disruptive technology (Akinsola et al., 2022).

Against a backdrop of 'turbulent times' acknowledging the complexity or crisis state of our current world (Bratianu, 2020), this paper aims to underscore the need to restart or rather engage in a metatheoretical discussion about knowledge management, and how it has consolidated over the last 30 years. Metatheory can be viewed primarily as "the study of theory, including the development of overarching combinations of theory, as well as the development and application of theorems for analysis that reveal underlying assumptions about theory and theorizing"; in short the central subject of study is theory (Wallis, 2010, p. 78). Any piece of research builds on a particular ontology (i.e., the reality out there), epistemology (i.e., ways of knowing or the relationship of the knower with that reality, and a methodology (i.e., what method the knower is using). Beyond, one must look at the bigger picture and reflect on the techno-economic paradigm (i.e., the economic, social, and technological context) (Perez, 2010) within which a theory is born and evolves. Provided that every researcher's production holds somehow to these assumptions, they adopt a specific metatheory or philosophy of science (Sousa, 2010). The following research question leads the paper: *What does a meta-theoretical study about the evolution of knowledge management reveal on its inherent ontological and epistemological assumptions, and how can this support scholars and practitioners to make most of a VUCA context?*

An attempt to answer this question called naturally for a literature review analysis that would have focused on identifying existing ontologies and epistemologies and see how the field had evolved since inception, or rather the 1990s. However, such an attempt revealed of limited interest for two reasons. First, several recent literature review studies have been recently executed in the field of knowledge management (Durst et al., 2023; Farooq, 2021; Serenko, 2021; Agostini et al., 2020). These studies covered many dimensions of the knowledge management literature. Second, the pointed to the very limited contributions to metatheories (Serenko and Dumay, 2015a; Agostini et al., 2020; Serenko, 2021). Instead, to provide a better account of the emergence of the philosophy underpinning knowledge management, we relied on Barley et al. (2018) bibliometric study published in the *Academy of Management Annals*, a highly ranked journal.

Hereafter, we provide background information on Barley et al. (2018) approach. The authors made the choice to start the study of papers with the year 1996, the year when the special issue from *Strategic Management Journal* on Knowledge and the firm was published (Spender and Grant, 1996). Their study focussed on knowledge management at large and used key terms (e.g., “knowledge management”, “knowledge sharing”, “knowledge transfer”, etc.) encapsulating diverse dimensions of knowledge management, view that is in line with what this paper seeks to address. Then, Barley et al. (2018, p. 281) identified the papers that were the most cited per year and retained the top 10 ones; the sample expresses a primary interest “in examining the processes by which knowledge flows within organizational contexts.”) Within the groups of papers selected for the year 1996, the ones including a discussion on epistemology and that are highly cited, are retained for points of reference (e.g., Grant, 1996; Spender, 1996; Kogut and Zangler, 1996). Other papers such as Mowery et al. (1996) or Sanchez and Mahoney (1996) are discarded as they do not engage in metatheoretical discussion. To provide a fuller picture, other highly cited texts such as Nonaka and Takeuchi (1995) are considered. This paper is laid out as follow. First, against a techno-economic backdrop, we discuss how knowledge management emerges around the mid-1990s and we put forwards the needs for a knowledge-based view of the firm theory for the 2020s. Second, we provide a critical review of positivism and social constructionism, two favoured approaches in knowledge management. Then, considering the techno-economic context of the 2020s, we suggest some possible ways forward.

## **2 Some considerations about knowledge management in recent history**

Although the last three decades seemed to be an epoch marked by a succession of extraordinary (as in out of the ordinary) events, the 1990s (Friedman, 2006) and the current times, the early 2020s (Loon, 2019) as two interesting milestones that can be characterized as 'turbulent times'. These dates are not proposed as the ultimate turning points of modern socio-economic history and its impact on organizations, but these years coincide with maturity points for knowledge management.

Although Simons'(1947) critique of economic rationality and Edith Penrose's work may be considered as the origin of knowledge management, the first manifestations can be traced back to the early 1970s with Henry (1974) introducing the central role knowledge principles play in public policy and major companies such as Chaparral Steel (Leonard-Barton, 1995) and Digital Equipment Corporation putting actually setting and implementing knowledge management (Wiig, 1997). But, as bibliometric studies show (Farooq, 2021; Mariano and Ykika, 2016), momentum for knowledge management is gathered when the substance of our modern economies changed at the turn of the 1990s and the advent of the knowledge societies (Bell, 1973; Drucker, 1993; OECD, 1996). A new techno-economic paradigm (Perez, 2010) emerges signalling the importance of the world of intangibles over the tangible (OECD, 1996). The previous industrial age is a brick-and-mortar era where land, capital and labour represent the core elements of value creation. Large corporations, such as major car manufacturers, big banks, and the likes, constitute formidable pillars on which our modern world is built. Progress is made in academia and a humanistic approach of organizations take form (Cohen et al., 1972; March, 1978; Schein, 1985; Weick and Roberts, 1993).

In the 1990s, the emergence of disruptive technologies such as the Internet and workflow software, the advent of geopolitical upheavals such a globalization and the rise of BRIC countries (Dicken, 2015; Friedman, 2006; Reich, 2002), and the acknowledgement of knowledge-intensive firms (Sveiby and Lloyd, 1988; Starbuck, 1992) signalled a profound change in the nature of business contexts. The convergence of different forces indicate the emergence of a new era, an era where the intangible became the main source of organizational performance (Carlucci and Schiuma, 2006). This VUCA world set the tone for the rising knowledge age. Against this backdrop, scholarly contributions on knowledge

management emerged and formed the base of the field that was to develop in the three following decades. In the same period, some key contributions to knowledge management are published, for example Kogut and Zander (1992); Nonaka and Takeuchi (1995). For example, Grant (1996) seminal paper introduced knowledge integration mechanisms for organisations while Spender (1996)'s conducted an epistemological inquiry about knowledge differentiation and its dynamics; Nonaka (1994) gifted the field with the most complete theory of knowledge so far (Krogh et al., 2013). Knowledge management was then celebrated with the special issue of Strategic Management Journal on Knowledge and the Firm (Spender and Grant, 1996).

The 2020s are the years where knowledge management is part of the International Standard Organization benchmarks. This period is also marked by intense social (i.e., global social movements against inflation, authoritarian political orientations; development of working from home), technological (i.e., advent of AI since November 2022; cybersecurity issues), and economic turmoil (i.e., near bankruptcy of Credit Suisse; bankruptcy of Silicon Valley Bank, inflation). Thus, both the 1990s and 2020s two periods conveniently represent two points of references allowing us to engage in a meta-theoretical study of knowledge management. Indeed, while the 1990s trumpeted the need for a knowledge-based view of the firm, the 2020s renew this imperative.

Wallis (2010) argues that the traditional approach existing in social sciences consists in committing expensive resources to the problem studies and that this led to the emergence of thousands of theories and vast amounts of data. The author blames this on the imitation attempts made after physical sciences where scientists became mostly concerned with gathering objective facts (see also Tsoukas, 2016) through empirical research, downplaying the importance of delineating or identifying a clear theory. For example, a study shows that 61% of academic papers published between 1997 and 2009 did not apply any theory (Serenko and Dumay, 2015a), trend that should be worrying. This metatheoretical 'noise' is clearly present within knowledge management. Recent studies provide a mapping of knowledge management and give an account of the many facets of the discipline encountered in the literature in the last decades. For example, Barley et al. (2018) reviewed 20 years of scholarly contribution and uncovered a bias towards knowledge integration over knowledge differentiation and its processes. A bibliometric analysis conducted by Farooq (2021) over 35 years of literature shows that knowledge management is at the centre of knowledge

management itself, innovation, performance and learning. We can see that each different bibliometric study provides an interesting account of what is going on in the field and what aspects of knowledge management is occupying researchers' minds, which seems to shy away from metatheoretical concerns.

While some scholars strive to bring unity in the field suggesting more nuanced understanding of knowledge management (Agostini et al., 2020; Akbar, 2022), others simply propose to abandon any notion of interdisciplinary cohesion and consistency and that knowledge management should be viewed as an overarching umbrella that gather divergent schools of thought (Serenko, 2021; Schultze and Stabell, 2004). In this paper, we lean against the former and rather support the idea that knowledge management is crippled with a lot of confusion, disintegration, and sharp divides (Spender, 2013; Spender, 2015; Pereira and Bamel, 2021). There is little efforts to address this unfortunate situation based on the small number of papers addressing these paradigmatic issues, number that seem to be decreasing further (Serenko, 2021; Spender, 2015).

The way KM exists and how it has evolved, does not allow a holistic nor integrative view of organizational knowledge-related activities as this was originally suggested (Spender, 1996; Nonaka and Takeuchi, 1995). Instead, KM became like a Swiss knife and resembles a collection of recipes made available to organizations to fix punctual problems. This presents the advantage of diversity of options and of the easy use quick fixes provide. The problem with this, is that managing knowledge remains superficial and does not transform the organization in depth, or at least does not affect the way managers are thinking about organizational knowledge. Indeed, the Newtonian philosophy within which our organizations and management studies are based is deeply rooted in practitioners and scholars' minds alike (Tsoukas, 2016). We argue that the lack of uniformity in the field is rooted on the lack of metatheoretical discussion that is too often the case in management and organizational studies (Sousa, 2010; Tsoukas, 2016), and that the knowledge management as a field is crippled by prevailing positivist and social constructionist epistemologies (Reihlen and Ringberg, 2013; Ringberg and Reihlen, 2008).

### **3 Consolidation of the knowledge management paradigm**

#### ***3.1 Few words on positivism and its limitations***

The favoured philosophy in research in general and in the field of knowledge management in particular pertain to positivism (Sousa, 2010). This perspective is the at the centre of knowledge-based view of the firm (Grant, 1996; Kogut and Zander, 1992; Conner and Prahalad, 1996) and the resource-based view of the firm (Barney, 1991; Wernerfelt, 1984). Ontologically, knowledge is considered an external and objective entity, an object that can be transmitted or exchanged outside any human intervention (Orlikowski, 2002; Nag and Gioia, 2012). More recently, Foss (2003) extended the transaction cost economies to knowledge management and likened knowledge to information and a commodity one could exchange outside any cognizant mind. Around 2000, this trend was strengthened by the rise information technology and the myth that human knowledge could be traded and shared outside the knower. Moreover, Alvesson and Kärreman (2001, p.1007) argue that "it is assumed that stored knowledge provide templates for thinking as well as acting". This means that positivist researchers make sense of the word or symbol independently from the mind of the one perceiving it (Ringberg and Reihlen, 2008). At this point, one must take in consideration the domination of positivism in management and organization studies (Tsoukas, 2016) and in the field of knowledge management. Afterall, the knowledge-based view of the firm concept is seen as an 'outgrowth' of the resource-based view of the firm (Grant, 1996).

At the turn of the 1990s and the call for handling intangible knowledge, many scholars expressed critical views about a positivist approach of knowledge management. For example, Spender (1996), in his influential paper entitled 'Making knowledge the basis of a dynamic theory of the firm', has presented several limitations of such a metatheoretical approach and an objectification of knowledge. Nonaka and Takeuchi (1995), Blackler (1993) among others had underscored that knowledge cannot be separated from the knower (Alavi and Leidner, 2001; Tuomi, 1999) and called for a different philosophy. In a study on computer-mediated knowledge management systems, Reihlen and Ringberg (2006) showed that individuals' understanding and interpretation always determine knowledge artefacts. Interestingly, positivists blame people's "limited absorptive capacity rather than divergent interpretative frameworks" (Ringberg

and Reihlen, 2008: , p. 915). For positivists, texts is a mean that carries objectified meaning (Boland et al., 1994), statement that lead Whorf (2012) to argue that positivists choose to ignore the beautiful intricacies composing complex systems of linguistic patterns and classification two ends of a communication must share prior adjusting to each other's assumptions. Thus, positivists view knowledge as a product that can be easily stored, accessed, and widely disseminated (Sousa, 2010). This raises some questions then: can we share knowledge without creating it beforehand? Can we create knowledge without some kind of pre-existing repository? Can we disseminate (for whatever this entail) knowledge without any of these steps? Although the practitioners' concern attached to any of these knowledge slices is understandable, it merely shows that assumptions are made that knowledge issues can be approached in a compartmented manner like an object that can be decomposed, laid bare into its basic components, ignoring the knower.

### **3.2. Few words on social constructionism and its limitations**

Other philosophical approaches are found in knowledge management, approaches that strove to best embrace the intangible resources organizations needed to harness. For social constructionists for example, knowledge emerges from socially constructed processes and is expressed or enacted through practice, approach used to understand knowledge transfers of organizational conflicts (Brown and Duguid, 2001; Orlikowski, 2002; Tsoukas and Mylonopoulos, 2004) or collective knowledge (Paraponaris and Sigal, 2015; Brown and Duguid, 2001). In other words, for social constructionists, knowledge is formed and transferred through practice. In their seminal text, Nonaka and Takeuchi (1995) made clear that tacit knowledge should be made explicit in to be transferred to the rest of the organization and participate in setting the tone for knowledge management.

This approach also presents issues. Some argue that social constructivism follows a pattern that is very similar to positivism and that practice instead of texts are the carriers of objectified meaning. At the end, both knowledge production and knowledge transfer are codified and are separated from the knower (Ringberg and Reihlen, 2008). This obsession viewing knowledge as an object is an odd contradiction. While knowledge is viewed as the most strategic resource a firm possess (Quinn, 1992), resource that is idiosyncratic, not easily

transferable or replicable (Grant, 1996), knowledge management researchers strive to make this strategic asset explicit (Schultze and Stabell, 2004).

#### **4 Discussion and conclusion**

Two popular metatheories in research were briefly introduced, both presenting different world view but ending with similar outcomes, the objectification of knowledge and its Newtonian treatment (e.g., Van den Berg, 2013, Akhavan et al., 2018). We argue that such approaches do not help knowledge management progress or make for its own name. We argue that the field is in danger of disappearing or being absorbed by neighbouring fields such as organizational learning (Akbar, 2022; Castaneda et al., 2018; Trigo, 2013; Massingham, 2020). No matter the statements made influential scholars (e.g., Spender, 1996, Nonaka and Takeuchi, 1995, Cook and Brown, 1999), the philosophical principles underpinning positivism and social constructivism alike, the separation between knowledge and the knower, still prevail like the many papers on knowledge-sharing or knowledge transfer show (Haas et al., 2015; Zhou and Li, 2012; Akhavan et al., 2012). Knowledge management has been introduced as a new specialty that should have helped us better handle the information age (Spender and Scherer, 2007). Have we lost our way since the inception of the field? Are we equipped to approach the new turn of the knowledge age or digital age artificial intelligence promises? Do we have an academic 'language' to address the managerial challenges coming ahead?

VUCA is used to describe a socio-economic reality that started after the Second World War; this term is replaced now by BANI to describe 'turbulent times. The knowledge management language adopted so far fails to free itself from a metatheory that sees knowledge in terms of input-output process. Already complicated business contexts are to get even more complicated. Artificial intelligence, as a tool, is the new tidal wave that will give the knowledge/digital paradigm that started at the end of the last century, its full dimension. Organizations and society alike are to be impacted the way the Industrial Revolution transformed the traditional agricultural economy. In line with BANI, the relatively stable environment on which organizations relied is changing at an increasing speed, making long-term planning a myth. Companies are to be under constant pressure as they must make important decisions while seeking organizational answers they cannot get. For example, firms face shaky banking

system that undermine the trust in the global financial system, aging workforce and attached future knowledge losses, global labour shortages that worsened since Covid-19, and new working patterns (i.e., Stocker et al., 2021).

Moving forward, some call for socio-cognitive style metatheories that can reconcile the complex role of cultural and private mental models, and how “how these are applied categorically and/or reflectively by the person in response to socio-cultural feedback mechanisms, and subsequently, how this leads to (and explains) very different meaning (knowledge transfer) outcomes” (Reihlen and Ringberg, 2013; Ringberg and Reihlen, 2008: , p. 919). While such an approach looks inclusive and holistic, it remains at the surface and consider disjunctive items and attempts to decompose these in a linear manner. An alternative worth considering is one that focused to the level of mechanisms and dynamics triggering knowledge emergence or creation (Blackler, 1995). The 2020s like the 1990s are complex and turbulent times; any attempts to describe and idealised knowledge creating / transfer / storage process is not going to help organization nor the progress of knowledge management.

### **Abstract**

Numerous scholars and scientific areas are investigating sustainability. Usually, it is drawn up by specific reporting which describes the economic, environmental, and social impacts of the organizational activities.

One of the main approaches for drawing up this report has been developed by Global Reporting Initiative (GRI). It defines a list of standards useful for the description of the impacts; however, these standards rarely address business management through performance measurement and management systems.

Through a pilot case study, the paper aims to represent the GRI standards and the stakeholders' needs through performance measurement and management systems.

The findings describe a useful approach to represent the GRI standards and the stakeholders' needs to illustrate economic, social, and environmental performance suggested by the GRI Standards and stakeholders' needs.

**Keywords** – Sustainability report, GRI standards, Performance measurement, Performance management, Performance measurement and management system.

**Paper type** – Academic Research Paper.

## 1 Introduction

Climate change is one of the effects that are changing people and companies by increasing general interest in the sustainability of the actions carried out. Sustainability is increasingly at the centre of debate on how to realize a sustainable world (Kalender & Vayvay, 2016). Over the last two decades, companies are writing sustainability reports (Kolk, 1999). The sustainability report is a reporting document that companies write to inform stakeholders of the impact of their activities on the business area (Blacconiere & Patten, 1994; Patten, 1992). Sustainability reporting is also important for the company from a management point of view as it should guide the governance and strategic choices of organizations.

To use the information collected on sustainability, companies should have a Performance Measurement and Management System (PMMS) to monitor the economic, social, and environmental impacts. The main model identified in the literature for performance measurement is the Balance Scorecard (BSC) (Kaplan & Norton, 1992), furthermore, it is a useful model to represent the organization's strategy (Sardi et al., 2020). According to the recent scientific literature, the BSC model has been integrated and modified based on the control needs of the companies; for example, it is integrated with new perspectives and key performance indicators related to the Global Reporting Initiative (GRI) standards (Kalender & Vayvay, 2016; Nikolaou & Tsalis, 2013). The integration of these aspects allows having a PMMS useful for controlling the organizational strategy toward more sustainable management of the company.

The research aims to represent the GRI Standards and stakeholders' needs through PMMS. The paper carries out a pilot case study in a key business sector from an economic, social, and environmental point of view, that is the disposal of

special, dangerous, and non-hazardous waste. The paper investigates the following research question "How can GRI standards be represented in a PMMS?".

The paper is organized as follows. Firstly, it highlights the research background. Secondly, it describes the research methods used to collect and analyze the data case study. Thirdly, it presents the main results of this study. The last section discusses and summarizes the contributions, implications, and limitations of this research.

## **2 Research background**

From the 1990s, following Kaplan & Norton's Balance Scorecard, many PMMS models have emerged to offer innovative solutions (Taticchi et al., 2010). Kaplan and Norton identified the Balance Scorecard as a model "balanced" that combines financial and non-financial measures, dividing them into four perspectives: financial, customer, internal process, and learning and growth (Kaplan & Norton, 1992). Scholars highlight the key integration between performance measurement and performance management to improve the engagement between employees and performance (Sardi et al., 2020, 2021; Smith & Bititci, 2017). *The interplay between performance measurement, performance management, employee engagement and performance remains poorly understood in literature* (Smith & Bititci, 2017) (p. 2). However, according to Bititci and Smith, a good PMMS allows the creation of a link between performance measurement and performance management (Smith & Bititci, 2017).

PMMS is defined as *a holistic, balanced and dynamic system able to support the decision-making process through a set of performance measurement activities* (Sardi et al., 2019; Smith & Bititci, 2017). Performance measurement identifies what to measure and performance management how to use the measures to manage organization performance (Bititci et al., 2012). Performance measurement is defined as the process of quantifying the efficiency and effectiveness of action (Bianchi et al., 2015) including data gathering, data analysis and data interpreting about performance to achieve a specific goal(s) (Melnyk et al., 2014). Performance management is defined as the cultural and behavioural routines used to define performance measurement to manage the performance of the organization (Bititci, 2015). It is a process(es) to evaluate the difference between actual and desired outcomes, intending to identify and report the critical differences to can adopt strategy by management to improve the organization's performance

(Melnyk et al., 2014). According to Smith and Bititci (2017), performance measurement and performance management *"have not been conceptualised as two separate but interdependent dimensions of organisational control"* (Smith & Bititci, 2017) (p. 3).

Since the 1990s, numerous companies published a voluntary document where organizations explained the strategies for a sustainable environment called Corporate Environment Report (Cerin, 2002; Cormier & Gordon, 2001; Gray et al., 1995; Kolk, 1999; Roberts, 1991; Stittle et al., 1997). Subsequently, Corporate Environment Report was in doubt about its aim following the use by companies more to show good action to have an approval social than to join the aim of the document (Hedberg & Von Malmborg, 2003). Corporate Environment Report was turned into Corporate Sustainability Report (Kolk, 2004) including sustainability reports such as environmental, social, and economic activities, but also organization decision-making and potential conflicting goal (Godemann & Michelsen, 2011). The aim of Corporate Sustainability Report was to inform companies' stakeholders about their sustainability activities and to evaluate the impact of development sustainability of the companies (Godemann & Michelsen, 2011).

Scholars began to study the Corporate Environment Reports (CER) (Kolk, 1999) following two disasters involving the environment and/or people. Firstly, it has been a chemical disaster in Bhopal (India) (Blacconiere & Patten, 1994) and, secondly, has been Exxon Valdez oil spill disaster (Patten, 1992). CER has been studied and integrated by scholars and practitioners. In 1997, the British economist and entrepreneur John Elkington described the triple bottom line theoretical model which highlighted the importance of economic, social, and environmental performance reporting for all stakeholders through the report (Elkington, 1998). At the end of the 1990s, there was continuous interest by companies in sustainability reporting. This contest created the condition to founded Global Reporting Initiative on 27th September 1997 in Boston. The aim of GRI was *"to create the first accountability mechanism to ensure companies adhere to responsible environmental conduct principles, which was then broadened to include social, economic and governance issues"* (GRI, 2023). Following the mission *"GRI envisions a sustainable future enabled by transparency and open dialogue about impacts. This is a future in which reporting on impacts is common practice by all organizations around the world. As provider of world's most widely used sustainability disclosure standards, we are a catalyst for that change"* (GRI,

2023). GRI published the first guideline in 2000. Subsequently, GRI published the second, third and the fourth version of the GRI Guideline in 2002, 2006 and 2013. Guidelines highlight the importance to have a report to communicate the organization's action for *"a sustainable future enabled by transparency and open dialogue about impacts. This is a future in which reporting on impacts is a common practice by all organizations around the world"* (GRI, 2023). GRI are guideline reviewed *"to ensure they reflect global best practice for sustainability reporting, helping organizations respond to emerging information demands from stakeholders and regulators"* (GRI, 2023). The aim of the first guideline provided the first global framework for sustainability reporting. Today, GRI Guidelines are recognised such as GRI standards. GRI standards are the base of sustainability reporting and a model for any organization – large or small, private or public – to reporting their impacts on the economy, environment, and social point of view. GRI standards allow to compare and give credibility to the company increasing transparency on their contribution to sustainable development. Stakeholders are also more interesting to GRI standards such as investors, policymakers, capital markets, and civil society (GRI, 2023).

### **3 Methodology**

The research adopted a qualitative method, i.e. a case study methodology (Yin, 2018). The case study was carried out from February to September 2022. This is a pilot case study, i.e. an initial study to assess its use for more in-depth studies in the future. It tests the feasibility on the full-scale study by allowing different phenomena to be observed from different angles and attempts to identify problems or obstacles that might arise. The results of the pilot study can be used to make adjustments or to decide not to proceed with a full-scale study (Yin, 2018).

Data gathering. The authors collected data from documents and semi-structured interviews. The authors collected the following documents:

- sustainability report
- financial statements.

These documents allow the definition of the GRI standards according to the BSC perspectives.

The authors carried out semi-structured interviews with the company's stakeholders to identify the main interests in the company's economic, social, and

environmental impacts according to the BSC perspectives (Yin, 2018). The interviews focused on the research topic. The questions were carefully worded to allow the interviewee to answer freely following the guideline suggested by Kallio et al., 2016 to realize a rigorous semi-structured interview.

The questions were:

1. What is the role of the company in the territory?
2. What are the activities and results of the company that you would like to know?
3. What are the main economic, environmental and social impacts you would like to know about the company's activities?

The authors interviewed the following stakeholders' categories:

- Personnel
- Public Administration
- Investors
- Shareholders
- Community (e.g. students, citizens).

Subsequently, the authors gathered information from both documents and interviews in an electronic file divided by each interview question.

Data analysis. The authors analyzed data through a within case study analysis. This analysis highlights the number of GRI standards subdivided for each BSC perspective. Furthermore, this analysis describes the GRI standards used for sustainability reporting according to the stakeholder's answers.

#### **4 Findings**

The findings of the research highlight the GRI standards used by the organization to write sustainability reporting. It describes 117 GRI standards used for the sustainability reporting divided into 36 for general disclosures, 13 for economic standards – GRI 200, 32 for environmental standards – GRI 300 and 36 for social standards – GRI 400.

The authors subdivided the GRI standards adopted by the organization to write the sustainability reporting in the BSC perspectives; various GRI standards are associated with at least two BSC perspectives.

The authors describe the number of GRI standards present in each BSC perspective (see Table 1). The results recognized the internal processes perspective as the main perspective. This perspective includes several GRI

standards such as GRI 306: "Effluents and waste", which is compatible with the business sector in which the company operates. Learn and innovation and financial perspective are enough equal. Lower importance for customer perspective.

Table 1: Number of GRI standard associated for each BSC perspective.

BSC perspective	GRI standards		
	Economic	Environment	Social
Financial	9	0	6
Customer	0	1	3
Internal process	3	26	17
Learn and Innovation	4	7	10

The finding also represents the GRI standards into the BSC perspectives according to the interests of the stakeholders with respect to the economic, environmental, and social impacts of the organization. It indicates that the stakeholders' interests are directed more for the internal process perspective (over 60%). Learn and innovation perspective is also enough directed by stakeholders' interests (over 20%). Finally, the interest of the customer and financial perspectives have minor stakeholders' interests. As in the first step, some GRI standards are associated with different perspectives (see Table 2).

Table 2: GRI standard cited for each BSC perspective by stakeholders.

BSC perspective	GRI standards		
	Economic	Environment	Social
Financial	13	0	12
Customer	0	5	6
Internal process	3	87	25
Learn and Innovation	7	14	18

The results obtained allowed the construction of the integrated PMMS with the GRI standards (see Figure 1).

Figure 1: PMMS developed from GRI standards

Financial perspective		Customer perspective		Internal process perspective		Learn and innovation perspective	
N.	GRI standard	N.	GRI standard	N.	GRI standard	N.	GRI standard
201.01	Direct economic value generated and distributed	307.01	Non-compliance with environmental laws and regulations	204.01	Proportion of spending on local suppliers	201.02	Financial implications and other risks and opportunities due to climate change
201.02	Financial implications and other risks and opportunities due to climate change	416.01	Assessment of the health and safety impacts of product and service categories	205.01	Operations assessed for risks related to corruption	202.01	Ratios of standard entry level wage by gender compared to local minimum wage
201.03	Defined benefit plan obligations and other retirement plans	416.02	Incidents of non-compliance concerning the health and safety impacts of products and services	205.03	Confirmed incidents of corruption and actions taken	203.01	Infrastructure investments and services supported
201.04	Financial assistance received from government	418.01	Substantiated complaints concerning breaches of customer privacy and losses of customer data	301.01	Materials used by weight or volume	205.02	Communication and training about anti-corruption policies and procedures
202.01	Ratios of standard entry level wage by gender compared to local minimum wage			301.02	Recycled input materials used	301.03	Reclaimed products and their packaging materials
203.01	Infrastructure investments and services supported			301.03	Reclaimed products and their packaging materials	302.03	Energy intensity
203.02	Significant indirect economic impacts			302.01	Energy consumption within the organization	302.05	Reductions in energy requirements of products and services
204.01	Proportion of spending on local suppliers			302.02	Energy consumption outside of the organization	303.03	Water withdrawal
206.01	Legal actions for anti-competitive behavior, anti-trust, and monopoly practices			302.04	Reduction of energy consumption	305.04	GHG emissions intensity
401.02	Benefits provided to full-time employees that are not provided to temporary or parttime employees			302.05	Reductions in energy requirements of products and services	305.05	Reduction of GHG emissions
401.03	Parental leave			303.01	Interactions with water as a shared resource	305.06	Emissions of ozone-depleting substances (ODS)

403.08	Workers covered by an occupational health and safety management system			303.02	Management of water discharge related impacts	403.01	Occupational health and safety management system
403.10	Work-related ill health			303.03	Water withdrawal	403.05	Worker training on occupational health and safety
413.01	Operations with local community engagement, impact assessments, and development programs			303.04	Water discharge	403.06	Promotion of worker health
415.01	Political contributions			303.05	Water consumption	403.07	Prevention and mitigation of occupational health and safety impacts directly linked by business relationships
				305.01	Direct (Scope 1) GHG emissions	404.01	Average hours of training per year per employee
				305.02	Energy indirect (Scope 2) GHG emissions	410.01	Security personnel trained in human rights policies or procedures
				305.03	Other indirect (Scope 3) GHG emissions	412.02	Employee training on human rights policies or procedures
				305.04	GHG emissions intensity	413.01	Operations with local community engagement, impact assessments, and development programs
				305.05	Reduction of GHG emissions	414.01	New suppliers that were screened using social criteria
				305.07	Nitrogen oxides (NOx), sulfur oxides (SOx), and other significant air emissions	414.02	Negative social impacts in the supply chain and actions taken
				306.01	Water discharge by quality and destination		
				306.02	Waste by type and disposal method		
				306.03	Significant spills		

				306.04	Transport and hazardous waste		
				306.05	Water bodies affected by water discharges and/or runoff		
				307.01	Non-compliance with environmental laws and regulations		
				308.01	New suppliers that were screened using environmental criteria		
				308.02	Negative environmental impacts in the supply chain and actions taken		
				401.01	New employee hires and employee turnover		
				403.02	Hazard identification, risk assessment, and incident investigation		
				403.03	Occupational health services		
				403.07	Prevenzione		
				403.09	Work-related injuries		
				403.10	Work-related ill health		
				404.02	Programs for upgrading employee skills and transition assistance programs		
				405.01	Diversity of governance bodies and employees		
				406.01	Incidents of discrimination and corrective actions taken		
				407.01	Operations and suppliers in which the right to freedom of association and collective		

					bargaining may be at risk		
				408.01	Operations and suppliers at significant risk for incidents of child labor		
				409.01	Operations and suppliers at significant risk for incidents of forced or compulsory labor		
				411.01	Incidents of violations involving rights of indigenous peoples		
				412.01	Operations that have been subject to human rights reviews or impact assessments		
				413.02	Operations with significant actual and potential negative impacts on local communities		
				414.02	Negative social impacts in the supply chain and actions taken		
				416.02	Incidents of non-compliance concerning the health and safety impacts of products and services		

## 5 Discussion and conclusions

Since the founding of GRI, the number of companies adopting the guidelines to publish sustainability reporting has been steadily increasing (GRI, 2023). Almost 80 % of big companies use GRI standards to write their sustainability reporting (KPMG International, 2022) because they adopt continuous improvement with constant revisions to “reflect global best practices for sustainability reporting, helping organizations respond to emerging information demands from

stakeholders and regulators" (GRI, 2023). Furthermore, these standards can be used for each size of an organization.

Since its first publication, sustainability reporting has been a document used by companies to describe their actions on the environment (UNEP, 1994). The main target groups are the stakeholders, either as an individual or groups or organisations, as they have an influence, or are influenced, on the organisational activities of a company to achieve a specific aim (Freeman, 1984).

In the case study described, the stakeholders' interest is that the company's strategies avoid a natural disaster for humans and the environment.

The increased interest in sustainability reporting has also involved Institutions. The European Commission presented the European Green Deal in 2019 and Directive 2264/2022 or 'Corporate Sustainability Reporting Directive' increased the number of companies that have to write sustainability reporting from 2023 (European Commission, 2022). In this context, PMMS becomes an important tool for any organization (Bititci et al., 2012; Franco-Santos et al., 2012) to represent the GRI standards and improve the transparency of the economic, social, and environmental impacts, especially in a business sector such as the case study analysed by the authors considered hazardous.

Sustainability reporting for many companies is a voluntary decision such as for the company in the case study. Having a reference tool for organisations to write sustainability reporting becomes important. The basis of reference can be the GRI standards although a guideline to be applied for the writing of the sustainability reporting is not yet present (La Torre et al., 2018). However, the GRI standards are the most globally known (KPMG International, 2022). The literature confirms this assumption even though other emerging organisations have defined different standards for reporting a sustainability report such as the International Financial Reporting Standards (de Villiers et al., 2022).

The research fills the lack of a representation of GRI standards through PMMS of an organisation operating in a business considered "hazardous" to the community, i.e. the management of the disposal of special, dangerous, and non-hazardous waste, especially in a historical context in which sustainability is increasing public attention.

The method used allowed representation of the economic, social, and environmental impacts in a PMMS of an organisation by combining GRI standards on the one hand and stakeholder interests on the other.

The results showed the division of the GRI standards in each perspective of the BSC (from financial statements data and semi-structured interviews) allowing the organisation to adopt the best strategies to can write sustainability reporting following the GRI standards.

The main limitation of this research is the study of a unique organization. The case study refers to a single organization that allows on the one hand, to provide a better contribution; on the other hand, it is not able to compare with other organizations.

The practical and theoretical contributions of the research are to describe a PMMS able to represent economic, social, and environmental impacts according to the scientific literature and practitioners' needs.

The practical and theoretical implications can compare and/or improve the PMMS of the selected organization with other companies. The social implications consist of making stakeholders aware of the organization's strategy in terms of sustainability.

Future opportunities concern the possibility to improve and compare the findings obtained with other organizations. The research area needs other case studies to integrate the methodology for drawing up the sustainability report following the GRI standards through the PMMS.

### **Abstract**

In today's competitive environment, measuring and managing the sustainability performance of supply chain is fundamental as organizations are considered responsible for their harmful impact as well as for their contribution to sustainable development beyond corporate boundaries. The purpose of this paper is to investigate if and how organizations embed SDGs and their targets in their supply chains and how the impacts on SDGs can be measured and assessed. To this aim, a multiple case study involving four

Italian companies is adopted. Our insights show the main supply chain practices implemented across the entire supply chain in order to achieve sustainability and SDGs. Furthermore, the preliminary findings show that performance measurement practices are critical enablers to instil a sustainability and SDGs oriented culture closing the knowledge gap with the various actors of the supply chain, especially those who exhibit a lower awareness of environmental and social issues. However, some barriers to the measurement of supply chain impacts on SDG targets are identified. In so doing, this paper contributes to prior studies on sustainability supply chain literature by providing empirical evidence on supply chain strategies and measurement practices to contribute to sustainability performance and realize a positive contribution towards the achievement of SDGs.

## 1 Introduction

During the past few years, the issue of sustainability supply chain has gained considerable momentum in academic literature (e.g., Beske and Seuring, 2014; Dubey et al., 2017; Geissdoerfer et al., 2018; Luthra et al., 2017) and many organizations have started to integrate sustainability principles in their supply chains (Spence and Rinaldi, 2014; Rajeev et al., 2017). In today's competitive environment, supply chains play a key role in enhancing economic performance and they have an important impact on sustainable development (Ahi and Searcy, 2015). Thus, measuring, monitoring and managing the sustainability performance of supply chains is fundamental as organizations are considered responsible for their harmful impacts - as well as for their contribution to societal well-being - beyond corporate boundaries (Beske-Janssen et al., 2015; Qorri et al., 2018; Schaltegger and Burritt, 2014).

In response to growing concerns about evaluating and monitoring supply chain impacts (e.g., Burritt and Schaltegger, 2014; Maestrini et al., 2017), scholars have started to explore methods and tools for sustainability performance measurement and management along the supply chain. Some scholars have explored how existing tools or frameworks can be adapted by integrating the sustainability dimension (e.g., Bai and Sarkis, 2014; Yakovleva et al., 2012), while other scholars have proposed new approaches (e.g., Azevedo et al., 2017; Goyal et al., 2018). Specifically, the most popular tools are Life Cycle Assessment (Crenna et al., 2018; Del Borghi et al., 2014), Supply Chain Operations Reference (SCOR) model (Bai

and Sarkis, 2012; Taticchi et al., 2013), Balanced Scorecard for supply chain (Bhattacharya et al., 2014; Ferreira et al., 2016). Instead of addressing specific tools and approaches, some scholars have focused on the identification and selection of ad hoc sustainable performance metrics in supply chains (e.g., Ahi and Searcy, 2015; Calzolari et al., 2022), focusing primarily on environmental indicators (Bai et al., 2012).

More recently, studies have suggested that supply chains may have a fundamental role in improving economic, social and environmental benefits and particularly in the achievement of Sustainable Development Goals (SDGs) (e.g., Agrawal et al., 2022; Kayikci et al., 2022). In so doing, these studies have acknowledged that focal companies can address the 17 SDGs through specific supply chain strategies and practices. For example, Teixeira et al. (2022) have demonstrated the importance of education and training offered by the focal companies to the members of the supply chain to provide skills and knowledge crucial for the implementation of SDGs. Similarly, other scholars have emphasized the role of supplier evaluation and selection (Mina et al., 2021) or the importance of partnerships, information sharing and knowledge integration (Chauhan et al., 2022; Zhou et al., 2020).

Despite the growing attention on sustainability performance measurement of supply chains and on their role in achieving SDGs, a thorough understanding of performance measurement practices for the alignment with SDGs across supply chains is still lacking (Chauhan et al., 2022). Therefore, the aim of this article is to investigate if and how organizations embed SDGs and their targets in their supply chains and how the impacts on SDGs can be measured and assessed. In doing so, this paper explores supply chain strategies and practices devised to achieve SDG targets and performance measures to quantify the impact of the supply chain on specific SDGs. To achieve this aim, a multiple case study involving four Italian companies which have implemented sustainability practices in their supply chains has been conducted. By combining theoretical insights and empirical findings this paper offers contributions to literature on sustainability supply chains.

The remainder of this paper is structured as follows. Section 2 reviews prior literature on supply chain, sustainability performance measurement and SDGs. Then, following the description of the research design provided in section 3, the preliminary findings of the study are presented in section 4. Finally, section 5 briefly summarises the main contributions and provides some concluding remarks.

## **2 Literature review**

### ***2.1 Sustainable Development Goals and supply chain practices***

In the last few years, issues related to climate change, air and water pollution, resource waste, socioeconomic inequalities and population growth have increased pressure on organizations for pursuing sustainable development. The SDGs have been proposed as possible solutions for addressing these challenges and achieving a higher level of sustainability (Bebbington and Unerman, 2018; Mio et al., 2020). Specifically, the SDGs have been first proposed by the United Nations General Assembly within the UN 2030 Agenda in order to “stimulate action over the next 15 years in areas of critical importance for humanity and the planet” (UN, 2015: 3). They include 17 goals focused on economic, social and economic issues (see Zimon et al., 2020 for a classification) oriented towards improving well being, education, reducing inequalities and promoting peace and prosperity.

The achievement of SDGs requires coordination and collaboration at various levels, i.e. countries, companies and society. As far as companies are concerned, according to the UN Global Compact (2015), supply chains represent the most important levers for businesses to create a positive impact on people and the environment. With the advancement of the UN 2030 Agenda, businesses are called to play an active role and take a broader view in society, explore how they can support their suppliers and use their value chains to contribute towards the sustainable development (UNGC, 2015).

Scholars have recently recognized that the issuance of SDGs provides a new area of research in supply chain management (Cai and Choi, 2020; Kayikci et al., 2022; Mina et al., 2021). Nevertheless, it requires a new level of companies’ commitment towards the implementation and the innovation of sustainable supply chain management (van Zanten and van Tulder, 2018; EY & UNGC, 2016).

In this regard, scholars have recently devoted their attention to the role of focal companies (i.e. “those companies that usually (1) rule or govern the supply chain, (2) provide the direct contact to the customer, and (3) design the product or service offered”; Seuring and Müller, 2008: 1699) in pursuing the 17 SDGs along their supply chain, calling for more understanding of specific supply chain strategies and practices (Agrawal et al., 2022). For instance, Teixeira et al. (2022) highlight the importance of training sessions held by the focal company for its

suppliers. In their case study, the Authors show that training suppliers by addressing topics such as eco-design or sustainable procurement was relevant for advancing and implementing SDGs in the supply chain. Likewise, Pohlman et al. (2020) suggest that collaboration and partnerships between the focal company and the main actors of a Brazilian food supply chain facilitated the promotion of SDGs and specifically the fulfilment of SDG 12 “responsible consumption and production”. In turn, other scholars have explored the role of knowledge management and information sharing for promoting sustainability in supply chains reaching mixed results. Albeit not specifically focused on SDGs, Zhou et al. (2020) recognize knowledge sharing as a critical factor to push green innovation within the supply chain, while Yu et al. (2020) argue that information sharing does not always benefit the supply chain towards sustainable development. Moving towards a broader view, by adopting a grounded approach based on literature analysis, Zimon et al. (2020) identify a map of supply chain practices for an alignment with UN SDGs, including among others waste management, green product design, green purchasing, reverse logistics, green shipping and distribution.

All in all, the literature reviewed has highlighted the role of the focal company in addressing sustainability and SDGs through supply chain strategies and practices. However, resonating with recent calls, more studies on the supply chain sustainable practices for attaining SDGs are needed (Agrawal et al., 2022; Pohlman et al., 2020). Specifically, researchers have focused attention primarily on specific actors of the supply chain, i.e. suppliers (Mina et al., 2021; Teixeira et al., 2020), overseeing other fundamental stages such as manufacturing, transportation and distribution (Agrawal et al., 2022). Furthermore, “the main difficulties for the implementation of SDGs in supply chains” (Teixeira et al. 2022: 13) merit further investigations. Finally, scholars investigated among others knowledge sharing, training and green procurement practices while there is a lack of understanding about measurement and monitoring practices as we will see in the next paragraph.

## ***2.2 Sustainability performance measurement of supply chains for an alignment with SDGs***

In relation to SDGs and supply chain debate, a critical factor is represented by the performance measurement systems (Alexander and Delabre, 2019; OIBR,

2023; Zimon et al., 2020). Supply chains are considered fundamental forces driving organizational sustainability goals and commitment (EY & UNGC, 2016) and nowadays measuring and assessing supply chain sustainability performance appears urgent to determine the environmental and social effects for which organizations are held responsible (Beske and Seuring, 2014; Seuring and Gold, 2013). In response to these challenges and the growing concerns about the negative impacts occurring beyond the companies' boundaries, scholars have started to devote attention to the strategies, purposes, approaches and frameworks of supply chain sustainability performance measurement.

Academic literature has acknowledged that measuring the sustainability performance of supply chains has several purposes. First, measurement allows the improvement of the overall supply chain sustainability performance by addressing the different dimensions of sustainability (Beske-Janssen et al., 2015; Schaltegger and Burrit, 2014). Second, supply chain sustainability performance measurement consents to manage sustainability supply chain risks that may undermine company's reputation related for example to particular working conditions or excessive levels of pollution (Schaltegger and Burrit, 2014). Another key goal of sustainability performance measurement of supply chain is providing transparency about environmental and social impacts (Beske and Seuring, 2014).

Measuring and managing the sustainability performance of supply chains can be guided by three main strategies (Schaltegger and Burrit, 2014): the efficiency approach (i.e. focused on reducing waste and resource consumption along the supply chain), the consistency approach (i.e. based on the substitution of unsustainable materials with more sustainable ones) and the sufficiency approach (i.e. focused on eliminating or reducing products or parts of a product which are not strictly necessary).

However, measuring and managing sustainability along the supply chain may present various complexities because it requires suitable tools for capturing information at each stage across the entire supply chain (Qorri et al., 2018). In order to address these challenges, several scholars have first relied on existing performance measurement frameworks adding the sustainability dimension. The most popular examples are represented by the Balanced Scorecard for assessing the sustainability performance of supply chains (e.g., Bhattacharya et al., 2014; Thanki and Thakkar, 2018), the Life Cycle Assessment with its modification (Arcese et al., 2017; Kulak et al., 2016) and the SCOR framework (Bai et al., 2012). Some scholars have proposed new approaches aimed at assessing the sustainability

performance of supply chains, combining different methodologies (e.g., mathematical modelling, sensitivity analysis) (Lee and Wu, 2014) and within specific industries (Goyal et al., 2018).

Instead of investigating specific performance measurement systems, other scholars have devoted attention to metrics' identification. As conventional indicators are primarily focused on economic issues (Beske-Janssen et al., 2015), several authors have proposed indicators that span various topics. However, these indicators are predominantly focused on environmental issues and circular economy (Calzolari et al., 2022) and they are mostly focused on measuring harmful environmental impacts (Bai et al., 2012b). The most frequently used metrics are carbon emissions or the energy consumption. Conversely, social issues are often disregarded and limited to fair trade, health and safety (Ahi and Searcy, 2015; Beske-Janssen et al., 2015).

In sum, different approaches and metrics for sustainability performance measurement have been proposed, however previous studies have focused on specific dimensions of sustainability and on particular stages of supply chain i.e. suppliers and manufacturers (Qorri et al., 2018) and few insights have been provided on comprehensive approaches to measure all three dimensions of sustainability across the entire supply chain.

Importantly, while these studies generally recognize the importance of measuring sustainability performance of supply chains, they do not provide clear insights on how performance measurement of supply chains may support sustainability improvement strategies (Beske-Janssen et al., 2015). Specifically, scholars question how to develop and implement performance measures able to assess the impact and the achievement of SDG targets in the long-term period and in the particular context of supply chains (Agrawal et al., 2022; Muñoz-Torres et al. 2018; Zimon et al. 2020). Investigating this issue seems important considering that 169 targets and 232 indicators in total underpin the 17 SDGs, providing performance measures against which the recipients of the targets are expected to be monitored. Furthermore, literature and policy makers have recognized the potential of the SDGs framework to become leading not only for governments and society but also for business (Alexander and Delabre, 2019), thus it is important to investigate whether SDGs might be integrated and guide organizations' sustainability performance measurement and management practices.

### **3 Research design**

This paper builds on a multiple case study approach (Yin, 2014) to investigate if and how organizations embed SDGs and their targets in their supply chains and how the impacts on SDGs can be measured and assessed. The multiple case study method has been chosen for several reasons. First, the case study method has been widely recognized to be particularly suitable for an in-depth investigation of contemporary phenomena not yet explored (Eisenhardt, 1989). Second, this method is considered particularly appropriate for answering “how” questions; by providing holistic and systemic thinking, case study research is encouraged when there is the need to understand the factors influencing a phenomenon and the relations between the phenomenon itself and its context (Yin, 2014). Additionally, it has been argued that case studies allow for gathering rich information and are suitable for exploring the difficulties of implementing new accounting procedures and techniques and for evaluating the benefits or derived challenges (Scapens, 1990). For these reasons, the use of multiple case study seems to be relevant for capturing the complexities and nuances of sustainability supply chain measurement practices (Agrawal et al., 2022).

The case companies were selected through purposeful sampling (Patton, 1990); the companies involved in the study have implemented sustainability practices in their supply chains and they are engaged in measuring sustainability performance. Also, these organizations have been selected because they have implemented over the years several initiatives to align themselves with the SDGs and they are committed to measure their SDGs performance. Finally, the selection of the case studies was guided also by considerations about accessibility to relevant and internal information. The four resulting companies investigated in this study included medium and large Italian organizations from different industries (i.e., manufacturing, wholesale and retail distribution, public transportation).

The primary data sources were semi-structured interviews. 12 interviews were conducted with management accountants and sustainability managers, each interview lasted from 45 to 90 minutes and each one was recorded and immediately transcribed. The main topics covered during the interviews can be grouped into three categories. The first group of questions refers to general information about the structure and the characteristics of the supply chains of the analysed organizations. The second group inquires about the practices to align

the supply chain to sustainability and SDGs. The third group of questions examines the performance measurement systems employed by the organizations to measure sustainability performance and to pursue SDG targets. Finally, the last group of questions concerns the benefits and drawbacks of measuring sustainability performance with regard to supply chains. To allow data triangulation, semi-structured interviews were supplemented with documental analysis both of official documents (e.g., website, non financial reports) and internal documents provided by the organizations. For confidentiality reasons, the data collected about the companies have been anonymized and when presenting detailed information, we will refer to the organizations investigated as A, B, C and D.

All the data collected were analysed through a within-case analysis and cross-case analysis, which allow to look for common patterns shared between the case studies to elaborate the main findings. In our preliminary analysis, the data retrieved from the data collection were progressively coded according to the insights provided by the literature reviewed in section 2. This allowed to identify the main supply chain practices and strategies employed by the companies to extend SDG targets to their supply chains. Importantly, this allowed to identify specific management accounting practices of supply chain sustainability performance measurement.

It is important to underline that data collection and analysis of the selected cases are still ongoing and we are also adding other cases to reach saturation of evidence. Thus, in this paper we present the first insights of the analysis so far conducted.

#### **4 Preliminary findings**

The four Italian companies involved in the study play a strategic role in governing and influencing their supply chains. Although they present different levels of adoption and standardization of sustainability supply chain practices, they are all committed to integrate sustainability and SDGs within their downstream and upstream operations. The observed companies have launched several initiatives aimed at pursuing two main goals. On the one hand, initiatives are aimed at integrating the environmental and social aspects in their supply chain. On the other hand, they are aimed at obtaining information and monitoring the impact of their supply chains on sustainability issues.

The practices employed involve all the stages of the supply chain, with a specific focus on suppliers. Regarding upstream practices and particularly the procurement stage, the most implemented practice regards sustainability supplier qualification and selection (Tab. 1). The companies adopt approaches based on questionnaires which are aimed at gathering information related to the candidate suppliers, with informative purposes, or ranking eligible suppliers in tender procedures according to specific sustainability criteria. In this latter case, the criteria primarily employed concern environmental issues such as the use of materials and components which can be recyclable or reused directly at the end of their life with little or no further processing or on the possession of specific certifications and ratings like ISO 14001 or EcoVadis.

Table 1 – Examples of sustainable supply chain practices within the observed companies

<b>SUPPLY CHAIN PRACTICES</b>	
<b>UPSTREAM</b>	<b>DOWNSTREAM</b>
<ul style="list-style-type: none"> <li>• Sustainability supplier qualification and selection</li> <li>• Carbon footprint of purchased products and services</li> <li>• Compliance with environmental standards and certifications</li> <li>• Training on sustainability and SDGs</li> <li>• Partnerships with suppliers for sustainability initiatives</li> </ul>	<ul style="list-style-type: none"> <li>• Green packaging</li> <li>• Green transportation</li> <li>• Raising awareness of sustainability issues</li> <li>• Compliance with environmental standards and certifications</li> </ul>

In company A the suppliers' compliance with environmental standards, certifications and ratings is not mandatory to participate in tender procedures but it is associated with a score that allows to reward the most virtuous supplier in terms of sustainability. The attribution of a score linked to ESG ratings allows to motivate suppliers towards sustainable practices, without excluding from tender procedures those who are not compliant. As highlighted by company A:

*"The possession of ESG ratings or certifications is not mandatory but is just a 'nice to have' at the moment. In this way, we avoid penalising small and medium suppliers and, by giving them a score, we motivate at the same time the implementation of sustainable practices towards reaching SDGs. Maybe in the future the possession of ESG ratings will be mandatory, but we want to support our suppliers throughout this process".*

Other practices employed in the procurement stage are: calculating the carbon footprint of products and services, measuring the suppliers' carbon emissions, implementing eco-design initiatives with suppliers' and developing joint projects to promote emerging technologies that enable to increase the use of renewable energy. Furthermore, company B has started to train its employees - and specifically its buyers - about sustainability and SDGs in order to involve suppliers in partnerships or support those with fewer competences on environmental and social issues. As highlighted by company B:

*"We have started to train our buyers on sustainability and SDGs in order to develop fruitful relationships with suppliers. Some suppliers are very virtuous, so when we discuss about environmental or social issues we must speak the same language, so we know each other what we are doing. Other suppliers show a low awareness of SDGs and they need to be helped and supported, clearly it's our job".*

Similarly, company D encourages its suppliers to pursue SDG 13 "climate action" by establishing appropriate corporate governance to make initiatives aimed at combating climate change and reducing emissions. Specifically, the company supports its suppliers along the transition path, providing its experience, know-how and valid approaches to sustainability issues.

Downstream supply chain practices include green packaging, i.e. packaging with recycled, reused or easily disposable materials, green transportation, i.e. using low-emission vehicles and implementing the rationalisation of transport or full-load transport. These practices are more likely to be adopted when they are connected to cost reduction and to economic sustainability, as emphasized by company C:

*"Some initiatives have a dual impact on both the economic and social dimensions. They have allowed us to obtain cost reduction and this drives us to implement further initiatives".*

Another common practice concerns initiatives aimed at increasing awareness among customers, for instance through public communication campaigns, about company's sustainability initiatives. Moreover, company C - operating in a business-to-business sector - invites its customers to get environmental and social ratings.

The supply chain practices so far described are predominantly aimed at contributing to and attaining at the following SDGs identified by the investigated organizations: "clean water and sanitation" (SDG 6), "affordable and clean energy"

(SDG 7) “decent work and economic growth” (SDG 8), “industry, innovation and infrastructure” (SDG 9), “sustainable cities and communities” (SDG 11), “responsible consumption and production” (SDG 12), and “climate action” (SDG 13).

In-depth interviews allowed us to understand also the current managerial accounting practices within organizations in relation to the advancement and implementation of sustainability and SDGs at a supply chain level. At this stage, a particular focus was given to the supply chain performance measurement and management systems currently in use within the organizations. All the interviewees recognized the significance of supply chain sustainability performance measurement and all the organizations use internal information systems to track the sustainability performance of upstream and downstream supply chains. Regarding environmental sustainability, the monitoring process and the relative audits are related to the measurement of emissions of the procurement and logistics processes; to this aim, as aforementioned, carbon footprint assessment of purchased goods and services is conducted and scope 3 emissions are monitored. Concerning social sustainability, indicators like the number of local suppliers, the revenues from local suppliers as well as indicators about safety procedures and gender diversity are periodically collected. In the observed cases, measurement practices are considered critical enablers to sustainability supply chain management. Particularly, they are deemed relevant to instil a sustainability and SDGs oriented culture in the main actors of the supply chains pushing them to embrace sustainability practices when their performance on the sustainability issues measured is low. This helps reduce the knowledge gap particularly with small suppliers.

However, while companies recognize that measurement practices allow to integrate SDGs principles along the supply chain, they find several barriers to assess the impacts of supply chains on SDG targets. First, the lack of common measures and difficulties related to information sharing between the focal company and external actors might hinder the monitoring process. Second, the companies find difficulties in using the SDGs framework for planning and controlling as SDGs are considered too generic and primarily referred to countries and governments. The SDGs framework is deemed relevant for communication purposes and for creating a “common ground” with the various actors of the supply chain but is considered less useful for monitoring purposes, as highlighted by company A:

*“The main benefit of the SDGs framework is that it facilitates communication with those who may not know the GRI standards by heart but instead they know the colour of SDG 12. It is very simple and clear, it represents a common ground. However, it is more complicated to translate that colour into a specific goal for the organisation, because it can be very different from organization to organization and it is difficult to adapt the specific targets to a business, as they are often too focused on a national and governmental level”.*

## **5 Conclusions**

Prior studies on supply chains and sustainability have highlighted the need for companies to commit under a supply-chain perspective for promoting sustainability and the achievement of SDGs (Alexander and Delabre, 2019; OIBR, 2023; Pohlmann et al., 2022). More specifically, this paper has explored if and how organizations embed SDGs and their targets in their supply chains and how the impacts on SDGs can be measured and assessed. To reach this aim a multiple case study research has been conducted.

The preliminary findings show that the analysed companies recognize their role in realizing the challenges linked to the United Nations Sustainable Development Goals by undertaking specific initiatives in their supply chains. Moreover, the observed companies have well-structured processes and procedures for assessing the sustainable performance within their supply chains and especially with reference to their suppliers. This focus on the upstream supply chain confirms what Qorri et al. (2018) have already highlighted. Worthy of note is the fact that all companies, during the interviews, expressed their awareness about the role they play in promoting initiatives to help suppliers embrace a sustainability strategy. Similarly, the companies expressed the importance of playing the same role also towards customers to make them understand the importance of buying sustainable products. In this regard, specific actions are being undertaken (e.g. public communication campaigns or inviting customers to get social and environmental ratings and certifications).

If we consider our research questions “if and how companies embed SDGs and their targets in their supply chains and how impacts on SDGs can be measured and assessed” we can say that companies embed SDGs in their supply chain thus contributing to their achievement. Nevertheless, companies do not use the 17

SDGs and their targets and indicators for envisaging, implementing and measuring their sustainable strategies. SDGs and their targets are used *ex post*, to communicate or disclose the companies' sustainability strategy. *Ex ante*, when planning, and *in itinere*, when controlling the implementation of their sustainable strategy, the SDGs framework is absent. Interestingly, when talking about sustainability strategies and their measurement the analysed companies referred to the ESG framework.

This paper contributes to studies on sustainability supply chains by shedding light on sustainability performance measurement and management of supply chains. In so doing, this paper responds to wide calls to strengthen both theoretical and empirical evidence on this topic (Beske-Janssen et al., 2015; Qorri et al., 2018) and contributes to the emerging call for guidance on how to measure and improve companies' sustainability performance across supply chain to realize a positive contribution towards the achievement of SDGs (Agrawal et al., 2022; EY & UNGC, 2016). Furthermore, this paper contributes to previous studies that have investigated the purposes of supply chain measurement systems (e.g., Beske and Seuring, 2014; Schaltegger and Burrit) by showing their role in closing knowledge gaps about sustainability with actors that exhibit a low awareness of sustainability.

Second, this study provide contribution to extant research that has started to explore the role of supply chains in the achievement of SDGs (Kayikci et al., 2022; Zhou et al., 2020), by showing the relevant role and some of the practices and strategies that focal companies may embrace to extend SDG targets across each stage of supply chains. Previous studies have focused on practices implemented primarily in the procurement stage (e.g., Teixeira et al., 2022); this paper adds to this literature by providing empirical evidence about downstream practices involving distribution, transportation and customers. Furthermore, this study contributes to this literature by showing the barriers that hinder the measurement of supply chain impacts on SDGs such as the lack of common measures and common methods of calculating indicators between the focal company and the various actors of the supply chain.

This research has practical implications as it suggests strategies and practices that may facilitate the attainment of SDGs and guide managers towards the improvement of the sustainability performance of the supply chain.

It is important to underline that the research is still ongoing and that some insights emerged from the preliminary findings have to be further investigated. To this aim, we are conducting further interviews in the case organizations and we

are also adding other cases to reach saturation of evidence. This paper provides only a glimpse of the role of performance measurement as a “social and moral practice” that supports the transition path of the different actors of the supply chain towards sustainability. This topic could be explicitly addressed in the continuation of the study.

### Abstract

Economic well-being within a society will ultimately depend on the productivity increases that occur at industry level. Digitalization and the use of ICT are tools of capital importance in this process. However, in order to scale up to industry level, they should first appear at an individual level. Having or not having ICT skills will therefore be crucial both for the individual (not to be left behind due to his/her digital divide) and the society (to keep up with the economic development of other regions). In this research we study the existing relationship between ICT skills and the free market orientation, both in its political and economic component. We find that ICT skills is a complex measure, that can interact with free market in some aspects and be independent in others. The use of on-line banking, communication technologies and the access to databases are not linked to free market orientation. But the ability to buy on-line is found to be positively correlated with free market orientation, which could speak of the existence of trust in the markets as a

facilitator of on-line purchasing. Contrarily, on-line selling is negatively correlated with free market orientation.

**Keywords** – Digital skills, Sustainable development, ICT, libertarianism, statism.

**Paper type** – Academic Research Paper

## 1 Introduction

Innovation and knowledge go hand in hand with sustainable economic growth and development. The former will produce the productivity increases that are the ultimate reason of a healthy and sustainable economic growth. However, the extent to which a sustainable economic growth can be leveraged with innovation and knowledge depends to a great extent of the forces affecting from the environment.

And 2023 finds the world on the so-called “VUCA environments”, where VUCA stands for Volatile, Uncertain, Complex, and Ambiguous environment. This concept, originally coined to describe the world after the fall of the Berlin Wall (1989), was taken up again with more emphasis after the attacks of September 11 (2001), and is now experiencing a third youth as the world is getting closer to what the “new normal” should be. We should now face that turbulent times are here to stay.

An example of how the VUCA environment affects the economic, business and public policy spheres is the appearance in 2021 of the Great Resignation, a term that gives its name to the process of voluntary resignation of millions of workers in all parts of the world. More than 24 million American employees left their jobs in 2021 (Sull et al., 2022).

In spite of the effects coming from the environment, the acquisition of ICT skills is a process that occurs at an individual level. Therefore, it is of the greatest importance to understand what are the drivers behind the possession of ICT skills. In this research we posit free market orientation can be linked to some extent to ICT skills at individual level. We look into this issue through a survey instrument.

## **2 Literature review**

### **2.1 ICT skills**

A crucial component of education today is the access and use of information and communication technologies (ICT) (Castells, 2002). The lack of access to ICT can be conceptualized as the "digital divide". This concept has changed over time, from focusing on connectivity (first level of digital divide) to worrying about the development of skills and abilities required to use ICT (second level of digital divide), and to measuring the tangible results of the use of the Internet (third level of digital divide) (Scheerder et al., 2017). Its study remains of the biggest importance, as highlighted by OECD (2016), that points out that the labor market demands new skills and digital capabilities as a result of the growing use of ICT in the workplace, either in the production of ICT goods and services or the need for workers with generic or complementary ICT skills (such as the management of social media or ecommerce platforms).

The digital divide can impact at two different levels. First, at a society level: it limits the economic development due to its negative impact in productivity. And second, it can create inequalities at individual level: workers with lower ICT skills will be unable to access to well paid jobs.

In this research we look at this effect at an individual level. Previous results point towards several factors affecting use and capabilities on the Internet, such as age, educational level, and employment status (Blank and Groselj, 2014; van Deursen and van Dijk, 2014).

According to the results from Hidalgo et al. (2020), the main predictor of digital skills is the education level. From their results obtained from the main socioeconomic digital skills drivers of the Spanish population, it is concluded that there is an education level threshold that splits the society in the two first groups, in terms of their ICT capabilities: below and above secondary education. In fact, 77.8 percent of the cases with education level corresponding to the first secondary stage (primary or illiterate cases) have no or a low level of digital skills, compared to 22.2 percent of the population with this education level who have basic or above basic digital skills.

This result contrasts with the digital skills level of the population with higher education levels (university, vocational training and secondary education), for which 73.3 percent have basic or above digital skills level, compared to 26.7

percent with low or no digital skills levels. In this study, the second variable in importance is age: 90.6 percent of the sample with lower studies and an age above 44 have low or no digital skills.

## **2.2 Free market orientation**

In opinion of the authors, the discussion between left- and right-winded policies is outdated. Contrarily, the discussion which is relevant today at economic, social and political level is whether an individual is a supporter of the free markets or a supporters of state intervention, which we will name "statism" in the following.

Free market orientation can be linked with the concepts of libertarianism or liberalism. These are philosophical perspectives that can be narrowed down to political or economic decisions. A common definition of liberalism is the one by Alberto Venegas Lynch, "the unrestricted respect for the life project of others". Also in the words of David Boaz (2010), it is "the only fundamental human right is the right to live your life as you choose, as long as you do not infringe on the equal rights of others."

As found by Boudreaux et al. (2019), those people who reside in environments that enjoy higher levels of economic freedom have a greater probability of creating a company. In this way, economic freedom is linked to business action and precedes economic growth (McMullen, Bagby, & Palich, 2008).

On the contrary, the perception of economic-administrative barriers that hinder the creation of new companies, such as financial and credit difficulties, administrative obstacles and lack of institutional support, play the opposite role: it discourages entrepreneurship (Lüthje & Franke, 2003).

That is to say, the orientation towards free market or towards statism has proven to be relevant in different domains. We believe it can also play a role in the development of ICT skills.

## **2.3 Research question**

The thesis of this paper is that those individuals who are more critic with state intervention and have a higher orientation towards free markets will develop higher ICT skills. Therefore, the research question that drives this research is "To what extent university students perceive themselves as well skilled in ICT?". As a

sub-question, we wonder how the orientation of the individual towards the free market, both in its political and economic components affect their ICT skills perception.

### 3 Methodology

The abovementioned research question speaks of a study of an explanatory nature, which calls for a quantitative methodology. For this reason, the study has been conceptualized as a survey.

The instrument for data gathering is a self-administered questionnaire set into the Google Forms platform. The questionnaire is composed of 4 different sections, of which three are used for obtaining the variables analysed in the present study, and the other provides with demographic statistics of the sample. This first section accounts for demographic variables, such as age, gender, and nationality. The three sections that define the variables of this study follow, and are (i) the ICT skills section, (ii) the political orientation section, and (iii) the economic orientation section.

The ICT skills section is composed of 5 items that have been extracted from the "Survey on Equipment and Use of Information and Communication Technologies in Households", from the Spanish National Institute of Statistics (INE), which is developed following the recommendations of the Statistical Office of the European Union (EUROSTAT). These items have been expressed into a 7 points Likert scale, to make them homogeneous with the rest of the questionnaire. The ICT skills items are summarized in Table 1.

Table 1. Items used for the ICT skills variables.

Variable	Item
S1	How often have you sold goods or services online in the last 3 months (transaction or deal made online, for example, Vinted, Amazon, Wallapop...)?
S2	How often have you purchased goods or services over the Internet in the last 3 months (online transaction or deal, e.g. Vinted, Amazon, Wallapop...)?
S3	How often have you carried out Internet banking activities (including via mobile) in the last 3 months?
S4	How often have you communicated with professors or students through online audio or video tools such as Zoom, Microsoft Teams or Google Meet?
S5	How often have you accessed databases or public records (subsidies, health, work life, fines, availability of books in public libraries, cadastral registers, company registers, electoral census) through a public administration website in the last 12 months?

NB: In the scale, 1 calls for "almost never" and 7 for "very often".

For the free market orientation of the individual, we relied on the very popular dual-axis Nolan plot (Anania, et al., 2019). That is, Nolan's graph depicts the free market orientation in two axes: political orientation and economic orientation. In order to do that, ten items are set to represent personal liberty from a political stand-point and another ten from an economic point of view. In its original setting, this plot allows to differentiate respondents into four categories: libertarian, liberal, conservative, and authoritarian. The original formulation of the items has been changed to be expressed into a 7 points Likert scale. The items used can be seen in Tables 2 and 3.

Table 2. Items used for the political freedom variables.

<b>Variable</b>	<b>Item</b>
<b>Opening sentence for all the items</b>	<b>It is the individual, and not the State, who should decide whether you...</b>
PF1	...wear a seatbelt
PF2	...own a gun
PF3	...serve in the military
PF4	...smoke marijuana
PF5	...use a risky medical treatment
PF6	...engage in a homosexual relationship
PF7	...buy a pornographic video
PF8	...buy a sexist book
PF9	...send your child to a particular school
PF10	...have uncensored access to the Internet

NB: In the scale, 1 calls for "the State" and 7 for "the individual".

Table 3. Items used for the economic freedom variables.

<b>Variable</b>	<b>Item</b>
<b>Opening sentence for all the items</b>	<b>It is the individual, and not the State, who should decide whether you...</b>
EF1	...buy a foreign car
EF2	...put your retirement savings in Social Security
EF3	...give money to help the poor
EF4	...drive a taxicab without a license
EF5	...hire a worker of another race
EF6	...build a home without a permit
EF7	...pay subsidies to farmers
EF8	...work for less than minimum wage
EF9	...set up a mail-delivery company to compete with Postal Service
EF10	...purchase flood or earthquake insurance

NB: In the scale, 1 calls for "the State" and 7 for "the individual".

The data has been analysed with the correlations technique and with the principal components methodology. First, correlation matrices are obtained for each group of variables, namely (i) ICT skills, (ii) political freedom, and (iii) economic freedom. Following, variables of each group are further studied through the principal component analysis. Lastly, a correlation analysis for the complete gathering of 25 variables is performed. The results obtained are presented in the next section.

## 4 Results

### 4.1 Descriptive statistics

The questionnaire was administered in two public Spanish universities, namely Universidad Politécnica de Madrid and Universidad Rey Juan Carlos, in February 2023. Researchers visited the room at the beginning or the end of the lesson, and asked the students to respond the survey anonymous- and voluntarily. The questionnaire was made accessible through a QR code and a link so that each student could respond it on his/her own phone.

A total of 257 responses were gathered, of which 155 were men (60%) and 102 women (40%). The average age is 20.3 years old, with a standard deviation of 2.93 years.

The first set of variables are the digital skills (S1 – S5). Their descriptive statistics are summarized in Table 4. Noteworthy, highest means are for S3 (4.88, “Internet banking activities”) and S2 (3.94 “purchased goods or services over the Internet”), and the lowest is S1 (1.98, “you sold goods or services online”).

Table 4. Descriptive statistics for the ICT skills variables.

Variable	Mean	Std. Deviation	N
S1	1.98	1.521	256
S2	3.94	1.765	256
S3	4.88	2.098	256
S4	3.46	1.851	256
S5	2.88	1.719	256

NB: In the scale, 1 calls for “almost never” and 7 for “very often”.

The second group of variables of this study are the metrics of political freedom (PF1 – PF10), see Table 5 for their descriptive statistics. Highest values are obtained for PF9 (5.02, “It is the individual, and not the State, who should decide whether you send your child to a particular school”) and PF10 (5.89, “It is the individual, and not the State, who should decide whether you have uncensored access to the Internet”), while the lowest appears for PF2 (2.05, “It is the individual, and not the State, who should decide whether you own a gun”).

Table 5. Descriptive statistics for the political freedom variables.

<b>Variable</b>	<b>Mean</b>	<b>Std. Deviation</b>	<b>N</b>
PF1	4.61	2.493	248
PF2	2.05	1.852	248
PF3	3.83	2.591	248
PF4	3.43	2.364	248
PF5	3.78	2.544	248
PF6	4.37	2.851	248
PF7	4.46	2.370	248
PF8	3.72	2.534	248
PF9	5.02	2.466	248
PF10	5.89	1.722	248

NB: In the scale, 1 calls for “the State” and 7 for “the individual”.

The third and last set of variables is the one used to capture the economic leaning towards free markets (EF1 – EF10), for which Table 6 summarizes the results obtained. The highest values are obtained for EF5 (5.47, “It is the individual, and not the State, who should decide whether you hire a worker of another race”), EF1 (5.12, “It is the individual, and not the State, who should decide whether you buy a foreign car”), EF3 (5.10, “It is the individual, and not the State, who should decide whether you give money to help the poor”), while the lowest is for EF4 (1.96, “It is the individual, and not the State, who should decide whether you drive a taxicab without a license”).

Table 6. Descriptive statistics for the economic freedom variables.

Variable	Mean	Std. Deviation	N
EF1	5.12	2.374	239
EF2	4.56	2.298	239
EF3	5.10	2.164	239
EF4	1.96	1.696	239
EF5	5.47	2.180	239
EF6	2.53	1.909	239
EF7	3.30	2.100	239
EF8	2.69	2.172	239
EF9	3.86	2.315	239
EF10	4.89	2.332	239

NB: In the scale, 1 calls for "the State" and 7 for "the individual".

#### 4.2 Findings

From the descriptive statistics of the variables presented above, the respondents can be described as averaged-skills in terms of ICT, being the average of the 5 independent means of the variables equal to 3.43, just below half of the scale. They are more skilled in banking activities and buying through the Internet, but less prone to sell on-line.

A correlation matrix was obtained for the ICT skills, but all the correlation coefficients are below 0.35 between S1 – S5 variables. For this reason, the correlation matrix is not presented here. This result speaks of the ICT skills variables measuring concepts that are different from each other, at least when focus is solely put into ICT skills variables. As it will be shown later, the ICT skills will correlate better when analysed together with the rest of the variables of the study. When principal components are obtained for the ICT skills variables, the 5 variables group around a single component, that explains 31.88% of variance, see Table 7.

Table 7. Principal components for the ICT skills variables.

Variable	Component 1
S1	.294
S2	.428
S3	.539
S4	.693
S5	.744

Regarding the political freedom measures, the results obtained point towards a shortly above-average sample leaning towards political freedom (average of 4.11 over 7). The respondents support that the State decides who can own a gun, but not the schooling of children nor censoring Internet. The correlation matrix depicts a link between PF3, PF4, PF5, PF6, PF7, PF8 and PF9.

This link is further confirmed by the principal components obtained (see Table 8), for which a first principal component account for all these variables, explaining 49.91% of variance. A second component is composed by PF10 ("It is the individual, and not the State, who should decide whether you have uncensored access to the Internet"), with 10.78% of variance explained, and a third component driven by PF2 ("It is the individual, and not the State, who should decide whether you own a gun"), with another 10.7% of variance explained. All in all, these three components explain a 71.39% of variance. These last two components account for the highest and the lowest average values obtained in this part of the survey.

Table 8. Principal components (rotated matrix) for the political freedom variables.

Variable	Component 1	Component 2	Component 3
PF1	-.670	.158	.297
PF2	.097	-.041	.940
PF3	.820	-.190	.077
PF4	.709	.009	.234
PF5	.835	-.066	.086
PF6	.919	-.037	-.046
PF7	.770	.239	.072
PF8	.825	.136	.146
PF9	.736	.013	-.005
PF10	-.007	.966	-.033

Last but not least, the economic freedom variables present an overall average of 3.94 (over 7). Again, over the half of the scale but slightly lower than the result obtained for political freedom (4.11). The correlation matrix shows that EF1, EF2, EF3, and EF10 are correlated. On the other hand, also EF4 ("It is the individual, and not the State, who should decide whether you drive a taxicab without a license") and EF6 ("It is the individual, and not the State, who should decide whether you build a home without a permit") appear to be correlated.

In this case, two components are formed after the principal components analysis is performed. The first component accounts for the abovementioned factors EF1, EF2, EF3, and EF10, together with EF5 and EF9. This component accounts for 34.43% of the variance. A second component, explaining another 19.12% (being therefore the accumulative variance explained of 53.55%), gathers the variables EF4 and EF6.

Table 9. Principal components (rotated matrix) for the economic freedom variables.

<b>Variable</b>	<b>Component 1</b>	<b>Component 2</b>
EF1	.770	.173
EF2	.801	.088
EF3	.835	-.011
EF4	.018	.810
EF5	.603	.098
EF6	.027	.853
EF7	.427	.290
EF8	.225	.520
EF9	.557	.353
EF10	.777	.035

A last analysis has been performed, with the aim of understanding how the variables from one section of the survey impact on the variables of a different section. To that end, a correlation analysis that includes the 25 variables under study has been performed, as detailed in Table 10.

From these correlations, three main conclusions can be driven. First, variables S3 ("Internet banking activities"), S4 ("communicated with professors or students"), and S5 ("accessed databases or public records") correlate positively with each other and with S2, and only one correlation is found with the complete set of variables PF1 – PF10 and EF1 – EF10. This is a far-reaching result, as it proves that certain ICT skills are independent from political and economic orientations. Second, S1 ("sold goods or services online") does not correlate with any of the rest of variables from ICT skills, but correlates negatively with PF3, PF6, PF7, PF8 and EF2. And third and last, S2 ("purchased goods or services over the Internet") correlates positively with S5 and also with PF5, EF3, EF5 and EF10.

Table 10. Correlation analysis for the ICT skills, the political freedom, and the economic freedom variables.

## 5 Conclusions

Economic development and economic well-being are very dependent on economic growth. And economic growth is ultimately driven by productivity

increases, especially in developed countries in which population demographics are shrinking. In this setting, the ICT skills of the members of the society can be of the greatest importance. In this study we look into ICT skills and their link to free market orientations of the individuals. We do so by means of a questionnaire answered by 257 respondents.

The results obtained speak of a young sample (20.3 years of age), composed of university students, and skewed towards men (60% male, 40% female). In this sample, respondents find themselves as averaged-skilled in terms of ICT (3.43 in a 7 points scale). The respondents are particularly prone to the use of on-line banking and on-line purchasing, but do not lean towards on-line selling.

The individuals of the sample are in the middle of the scale between libertarianism and statism, but slightly leaning towards the former. They are, both for political and economic freedom in the upper-middle range of the scale (4.11 and 3.94, respectively). From a political or personal freedom standpoint, respondents feel that choosing the school of their offspring and accessing Internet without censorship are their more valued freedoms. Contrarily, they feel that the State should decide who can have access to guns. In terms of economic freedom, respondents support the ability of hiring workers independently of their race, but are less flexible with the existence of taxi drivers operating without a license.

When ICT skills and free market orientation are sought after together, we find that on-line banking, the use of on-line meetings and the access to personal data bases seem to be skills purely independent of free market orientation. Contrarily, selling on-line is negatively correlated with free market orientation, while buying on-line is positively correlated.

We hypothesize that individuals with a more critical view of State intervention in the economy are individuals with higher human capital, better informed and prepared, and possibly from wealthier environments. For this reason, they are more prone to develop trust in the markets, and therefore decide to buy on-line. They would be following the pro-trade ideas of Spanish thinker Antonio Escotado: "the only alternative to trade is violence". Somehow, respondents that purchase on-line are hoping for a honest person on the other side of the market, who just wants to trade and make a profit.

Contrarily, selling on-line in our sample may come from a necessity rather than the search of a business opportunity. This could probably mean that on-line

sellers in the sample have a lower income level, and are more favourable to the intervention of the State, and less prone to free markets.

In spite of its contributions, this study is not free from limitations. The sample in use is limited to university students from Spain. More data would be needed to dig deeper in the results presented here.

Last, as an avenue for further research, we call for the gathering of data from different settings, both in age and in cultures.

### **Abstract**

Since the late 20th century, the introduction of digital technologies has revolutionized the way people interact with the world. This has led to the mass diffusion of the Internet, smartphones, global computer networks and virtual reality, which have become an integral part of people's daily lives. This digital transformation has had a significant impact on all spheres of human activity, including work. In addition, unexpected events such as the COVID-19 pandemic forced organizations to digitize rapidly to conduct business, despite social restrictions. This has contributed to the emergence of new paradigms in the world of work. In manufacturing sectors, the industry 4.0 model using automation, robotics, artificial intelligence, the Internet of Things and additive manufacturing has enabled manufacturing companies to optimize processes, reduce costs and improve service efficiency.

While digital tools have a positive impact on economic and environmental aspects, they also force organizations to reconceive the role of human activity in the workplace. This

revolution in the world of work can, however, have both positive and negative implications for an organization's human resources. It is the responsibility of organizations to choose whether to adopt a sustainable approach that balances economic, environmental, and social factors.

Specifically, to preserve social sustainability, organizations should adopt human resource management practices that place human capital at the centre of the transition to digital workplaces. This requires providing employees with digital skills for decent and rewarding employment.

This paper aims to provide an analysis on the topic of digitization and social responsibility, where humans are at the centre of interest for organizations. Conflicting views on the effects of digital transformation on social sustainability make this an important topic for research. To investigate this gap, we adopted a two-stage methodology. In the first stage, we conducted a systematic literature review to understand the most widely discussed research topics on the topic to date. Then, based on these findings, we conducted an exploratory case study. Specifically, this paper analyses a San Marino company operating in the medical sector. This case is particularly interesting in that it highlights the effects of social sustainability related to digital transformation, both from the perspective of the organization and the beneficiaries of the product/service. The case study will allow for feedback and empirical validation of what is known in the scientific literature.

## 1 Introduction

The World Wide Web was created in the 1980s and within 21 years it had become a central element of the global economy, used by nearly 40% of the world's population. The number of digital devices has reached 100 million users and in 12 years the Internet has gathered its first billion users (Castells, 1996). This marked the beginning of a digital revolution: the emerging world adopted mobile phones, and therefore increased use of the Internet. Mobile connectivity enabled socio-economic growth and increased commercial opportunities (Digital Evolution Index, 2015). The 1990s saw a shift towards digitization in the field of information storage and transmission, which marked a departure from previous analogue technologies. This shift towards digitization has brought people together around the world, providing a common platform and language for sharing ideas and experiences (Castells, 1996). The rapid development of digital technologies has led to a profound transformation of society and the economy,

with significant impacts on businesses, workers, and consumers (Grigorescu, Pelinescu, Ion, & Dutcas, 2021).

In the industrial sector, the integration of advanced digital technologies such as the Internet of Things, cloud computing and artificial intelligence (industry 4.0), has opened new opportunities for innovation and growth. (Almeida, Santos & Monteiro, 2020). As a result, the production of new knowledge-based products and services and more efficient production processes have been developed (Bigliardi, Filippelli, Petroni, & Tagliente, 2022). There is no doubt that this new digital age has brought about disruption to existing industries and markets, creating both opportunities and challenges for businesses and workers. This concept is summed up in the term "digital disruption", which attributes to digital technologies the merit of being bearers of innovation and growth on the one hand but a source of inconvenience and uncertainty for workers and companies on the other (Nyagadza, 2023).

The theme of digitization has assumed an even more important role in the wake of the Covid 19 Pandemic. Indeed, the COVID-19 pandemic has had a profound impact on the world of work, accelerating the adoption of digital technologies and changing the way many companies operate (Almeida, Santos & Monteiro, 2020). As a result of the pandemic, many companies have been forced to make a rapid transition to remote working and digital collaboration tools, leading to a significant increase in the use of digital technologies such as video conferencing, cloud computing and digital project management tools (Sima, Gheorghe, Subić, & Nancu, 2020).

While the rapid adoption of digital technologies has allowed many businesses to stay operational during the pandemic, it has also highlighted the digital divide between those with access to digital technologies and those who don't (Sima, Gheorghe, Subić, & Nancu, 2020). Additionally, the shift to teleworking has raised concerns about the impact of digitalisation on job security, work-life balance, and mental health. Collectively, the COVID-19 pandemic has demonstrated the importance of digitization in enabling businesses to adapt to change and continue operating despite disruptions (Nyagadza, 2023). However, the pandemic has also highlighted the need for policies and initiatives to promote digital inclusion and ensure that the benefits of digitization are shared equally across society (Nyagadza, 2023).

From the workers' point of view, there are situations in which digitization offers opportunities, as it improves, speeds up and facilitates specific activities and

processes. On the other hand, workers also face the risk of job loss, when some activities become obsolete and digitally replaceable, and the difficulty of learning new technologies and adapting to new work processes (Harteis, Goller, & Caruso, 2020). To overcome these challenges, workers need to develop new skills and competencies, such as digital literacy, data analysis and critical thinking, which can be supported through comprehensive training programs and educational initiatives (Harteis, Goller, & Caruso, 2020). Furthermore, HR departments play a crucial role in this process by providing workers with the support and resources they need to develop these skills (Kuzior, Kettler, & Raab, 2022). While digitization can lead to job displacement in some sectors, it also creates new opportunities for job creation in others. This is because digital technologies can enable the creation of new products and services, leading to the emergence of new sectors and business models (Aksin-Sivrikaya, & Bhattacharya, 2017).

As found during this analysis, the upheavals brought about by digitization have both positive and negative effects on the community (Aksin-Sivrikaya, & Bhattacharya, 2017). For this reason, it is essential to consider the issue of digitization in relation to that of sustainability and specifically, to social sustainability. Indeed, social sustainability refers to the ability of a society to meet its current needs without compromising the ability of future generations to meet their own needs (Bigliardi, & Filippelli, 2022). It involves ensuring that social, economic, and environmental systems are aligned in a way that promotes long-term well-being and prosperity for all members of society (Bigliardi, & Filippelli, 2022).

Digitization can contribute to social sustainability in several ways. First, digital technologies can improve access to education, healthcare, and other essential services, particularly in underprivileged communities (Senbekov et al., 2020). For example, telehealth can allow patients in rural areas to access medical care remotely, while online educational platforms can provide educational opportunities for people who may not have access to traditional educational institutions.

Secondly, digitalisation can promote social inclusion by reducing barriers to participation in the economy and society (Şerban, Moxon, Potočnik, Pasic, & Ştefan, 2021). For example, digital platforms can enable people to participate in the gig economy, offering new opportunities for income generation and entrepreneurship. Digital technologies can also facilitate the participation of

marginalized groups in the political process by providing a platform for their voices to be heard (Moutafidou, & Bratitsis, 2018).

Digitalisation has the potential to contribute significantly to social sustainability by improving access to essential services, promoting social inclusion, and enabling more sustainable production and consumption patterns. However, realizing these benefits requires a concerted effort to ensure that digitization is implemented responsibly and sustainably, considering the social and environmental impacts of these technologies (Aksin-Sivrikaya, & Bhattacharya, 2017).

The intent of this paper is to provide a systematic literature review to identify key themes and issues related to digitization and social sustainability. By reviewing the existing literature, we will develop a comprehensive understanding of research trends on the topic. Furthermore, to provide a more practical illustration of the concepts and ideas discussed in the literature review, we will also present a case study of a company that has successfully integrated digitalisation and social sustainability into its business model and vision. Through this case study, we will demonstrate how digitization can contribute to social sustainability and provide guidance for companies seeking to integrate these concepts into their operations.

Overall, this document aims to provide comprehensive and practical guidance for businesses and organizations seeking to leverage digitalisation to promote social sustainability, while also addressing the challenges and risks associated with this process. By combining theoretical insights with practical examples, we hope to provide a valuable resource for researchers, practitioners and policy makers seeking to navigate the complex and rapidly changing landscape of digitalisation and social sustainability.

## **2 Methodology**

This section describes the methods used by the authors to achieve the objectives.

First, a systematic literature review (SLR) was conducted to provide a comprehensive overview of the academic research on digitisation and social sustainability. The SLR analysis was conducted using the cloud platform MySLR (My Systematic Literature Review) by implementing the principle outlined in (Ammirato, Felicetti, Rogano, Linzalone, & Corvello, 2022). We opted to utilize

Elsevier's Scopus as the scientific database for our search because it is a robust tool for measuring science (Bhimani, Mention, & Barlatier, 2019). Additionally, various materials that offer direction for systematic reviews of literature indicate that Scopus is a suitable database for this type of review (Bhimani, Mention, & Barlatier, 2019). The initial search query for Scopus was as follows ( TITLE-ABS-KEY ( "Digit\*" ) AND TITLE-ABS-KEY ( "sustainab\*" ) AND TITLE-ABS-KEY ( "Human resourc\*" ) AND TITLE-ABS-KEY ( "social\*" ) ). The research yielded 116 articles. Then, the search string was refined by incorporating the following criteria to align with the objectives of our review: the articles had to be written in English and published in journals indexed in the subject areas "Business, Management and Accounting," "Economics, Econometrics and Finance," "Computer Sciences," "Social Sciences," and "Decision Sciences." We thus obtained a dataset of 85 papers.

After the systematic literature review, a case study was considered to show possible links between digitalisation and social sustainability. The case study is based on a detailed survey instruments and interview on the topics covered in the paper, as better discussed in section 4.

### **3 SLR Analysis**

The initial findings from the analysis highlight a growing interest in the investigated topic over time in research. Specifically, as shown in Figure 1, there was a 71.4% increase in literature on the topic in 2020. This is likely due to the Covid19 pandemic, which, as noted in the introduction section, has forced rapid digitalization processes. The interest in the topic continues to grow, with the latest complete data from 2022 showing almost double the number of publications from 2020 and 2021. This trend over time underscores the importance of digitalization and social sustainability today.

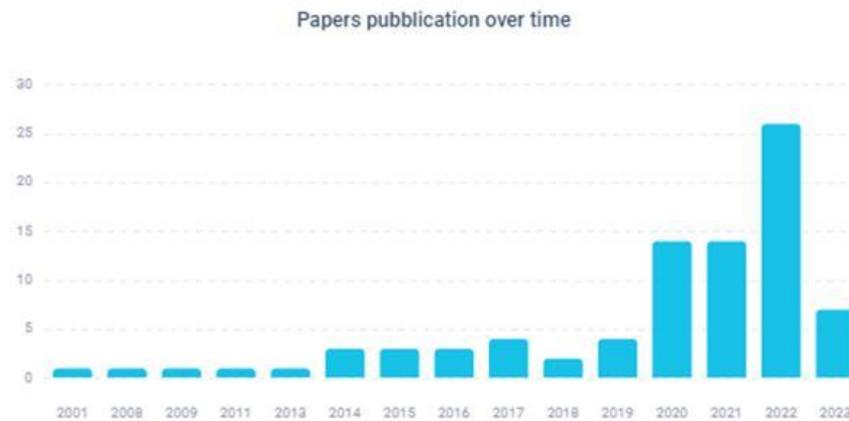

Figure 1. Published articles by year.

Through the MySLR platform, we analyzed the sample of papers to identify the main literature topics related to the theme of digitalization and social sustainability. Specifically, we utilized the "Latent Dirichlet Allocation (LDA)" technique, which outputs a set of  $k$  topics and a matrix that measures how much each article in the sample is linked to a specific topic ( $k$ ) (Ammirato, Felicetti, Rogano, Linzalone, & Corvello, 2022). Figure 2 shows the LDA curve in blue as a function of the topics  $k$ . In the specific case at hand, we determined  $k=2$ , where the coherence value  $u_{mass}$  was  $-1.70$  (Röder, Both, & Hinneburg, 2015) for the Gensim LDA algorithm. This value is indeed high enough to ensure the coherence of the topics (Chen and Liu, 2014) and to make the interpretation clear to the reader.

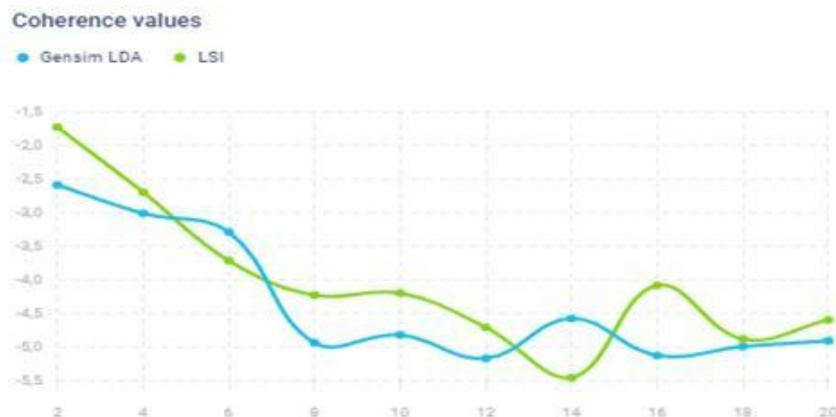

Figure 2. Coherence scores

Once we determined the correct number of topics, we analyzed each of the two clusters, assigning a name to the topics based on the relevant terms and documents associated with them by the MySLR platform. Table 1 reports the topic name, the relevant terms associated with it, and a list of sample documents that that we have established most representative for the topic.

A brief overview of the topics that emerged is shown below:

Table 1. Topic analysis

### **3.1 Digitalization and human resources processes**

The ongoing digital transformation is impacting various sectors and functions within organizations, including Human Resources (HR) (Bigliardi, Filippelli, Petroni, & Tagliente, 2022). The integration of digital technologies into HR processes has become essential for organizations to improve efficiency, accuracy, and cost-effectiveness. The use of digital technologies in HR processes, also known as digital HR, has the potential to transform the way organizations manage their workforce (Sotnikova, Nazarova, Nazarov, & Bilokonenko, 2020).

Digital HR includes a wide range of technologies, such as cloud computing, big data analytics, artificial intelligence, and social media, which enable organizations to automate and streamline HR processes, improve data accuracy, and reduce costs (Sotnikova, Nazarova, Nazarov, & Bilokonenko, 2020).

Digitalization has had a significant impact on various HR processes, such as recruitment and selection, onboarding, training and development, performance management, and employee engagement (Sotnikova, Nazarova, Nazarov, & Bilokonenko, 2020). For example, digital HR tools such as applicant tracking systems and online assessments have improved the efficiency of recruitment and selection processes. Online onboarding programs have reduced the time and costs associated with new employee orientation. Digital learning platforms have enabled organizations to provide personalized and on-demand training to employees at a lower cost (Guragain, 2016).

The integration of digital technologies into HR processes offers several benefits to organizations (Fenech, Baguant, & Ivanov, 2019). First, digital HR can improve the speed, accuracy, and efficiency of HR processes. Second, digital HR can reduce costs associated with HR processes, such as recruitment, training, and performance management. Third, digital HR can improve the quality of data and analytics available to HR professionals, enabling them to make more informed decisions about their workforce. Finally, digital HR can enhance the employee experience by providing personalized and on-demand services (Fenech, Baguant, & Ivanov, 2019).

Despite the benefits of digital HR, organizations face several challenges in implementing digital HR). These challenges include resistance to change, lack of digital skills among HR professionals, data privacy and security concerns, and the need for significant investment in digital technologies (Zavyalova, Sokolov, Kucherov, & Lisovskaya, 2022). Addressing these challenges requires a strategic

approach to digital HR implementation, which includes assessing the organization's digital readiness, providing training and support to HR professionals, and ensuring compliance with data privacy regulations (Zavyalova, Sokolov, Kucherov, & Lisovskaya, 2022).

In conclusion, digitalization has transformed various HR processes, offering organizations the potential to improve efficiency, accuracy, and cost-effectiveness. However, the implementation of digital HR requires careful planning and management, as well as addressing several challenges. Organizations seeking to leverage digital technologies to enhance their HR processes should adopt a strategic approach, which includes assessing their digital readiness, providing training and support to HR professionals, and ensuring compliance with data privacy regulations. By doing so, organizations can realize the benefits of digital HR and stay ahead of the competition.

### ***3.2 Innovation and Social Responsibility***

The fourth industrial revolution, also known as Industry 4.0, is characterized by the integration of advanced technologies such as artificial intelligence, the Internet of Things (IoT), and big data analytics into manufacturing processes. Industry 4.0 represents a significant opportunity for businesses to innovate and improve their operations. Advanced technologies such as AI and IoT can help businesses streamline their processes, reduce costs, and improve product quality (Bigliardi, & Filippelli, 2022). However, while Industry 4.0 promises significant benefits for businesses, it also raises important questions about the role of technology in society and the responsibility of businesses towards the community. That is because these technologies also have the potential to displace workers and exacerbate social inequalities. To address these challenges, businesses need to adopt a socially responsible approach to innovation (Scavarda, Daú, Scavarda, & Goyannes Gusmão Caiado, 2019).

Businesses can demonstrate social responsibility is by engaging with the government and other stakeholders to ensure that the benefits of Industry 4.0 are shared across society. This can include investing in training programs and other initiatives to help workers adapt to the changing nature of work, as well as collaborating with policymakers to develop regulations that promote innovation while also protecting workers' rights (Scavarda, Daú, Scavarda, & Goyannes Gusmão Caiado, 2019).

Another important aspect of social responsibility in Industry 4.0 is community engagement. Companies need to be aware of the impact their operations have on the communities in which they operate and take steps to mitigate any negative effects. This can include investing in local infrastructure, supporting community initiatives, and engaging with local stakeholders to understand their needs and concerns (Mayes, McDonald, & Pini, 2014).

Finally, businesses also have a responsibility to ensure that their innovations are designed with social responsibility in mind. This means considering the potential impact of new technologies on society and taking steps to mitigate any negative effects. For example, businesses could prioritize the development of technologies that promote sustainability and reduce environmental impact (Mayes, McDonald, & Pini, 2014).

In conclusion, Industry 4.0 represents a significant opportunity for businesses to innovate and improve their operations. However, this must be done in a socially responsible way, with a focus on engaging with the government, society, and community to ensure that the benefits of innovation are shared across society. This requires a commitment to investing in the development of new technologies that promote sustainability and reduce social inequalities, as well as engaging with stakeholders to understand their needs and concerns. By doing so, businesses can demonstrate their commitment to social responsibility and help to ensure that the benefits of Industry 4.0 are shared across society.

## **4 Case Study**

### ***4.1 Survey and method***

The case study presented was selected as a clear example of how digitalization can have a positive impact on social sustainability. In this section, we refer to social sustainability as the improvement of people's lives (in general, stakeholders) who benefit from the products and services generated by the company, as well as the possibility of creating new job opportunities. The ability to have paid work contributes to improving people's quality of life as it is directly linked to reducing situations of disadvantage and social marginalization.

The purpose of this analysis is to provide an evaluation of the possible impact of new digital business models on social sustainability. Specifically, the case study presented was considered capable of contributing to improving social

sustainability by placing people at the centre of interest, both as beneficiaries of a product/service and as workers.

The study was conducted through an in-depth interview based on a survey of research. The two main themes investigated concern the relationship of the company between digitalization and social sustainability. Through the investigation proposed below, we aim to identify whether there are conditions that allow for the coexistence of digital products and services with a vision of social sustainability that can generate profit for the company.

The following analysis has some main limitations:

1. Evidence derived from a single case can provide some indications but cannot have general validity.
2. The company operates in the Republic of San Marino, a small territory with specific socio-economic characteristics.
3. The economic sector in which the company operates is the healthcare sector, with different characteristics and needs depending on the specific territory.

This case study, therefore, can provide only some initial evidence with respect to the topic under discussion. To be able to attribute general value to the evidence emerging from the analysis, some possible solutions to the limits identified above are proposed in table 2:

Table 2. Case study's limits and solutions

<b>Limits</b>	<b>Solutions</b>
Analysis of a single case	Integrate the analysis with the consideration of multiple companies.
Geographical area	Multiple case study involving countries with different socioeconomic characteristics.
Economic sector investigated	Analyze case studies of companies operating in different economic sectors could be considered.

## **4.2 The Company**

The case study analyzes a company located in the Republic of San Marino operating in the healthcare and social assistance sector. The company, established in 2021, studies and analyzes private and public healthcare realities, therapies, and medical-patient dynamics to find modern solutions to increasingly complex needs through advanced technologies.

The company was founded in response to a collective need, which became even more evident following the Covid-19 pandemic. They develop telemedicine platforms, apps, and software to support doctors and patients. One of the main advantages of using these products and services is the ability to monitor the progress of patients' illnesses remotely and accurately. The company is also involved in interactive training, aimed at helping customers make the most of the proposed innovative digital solutions.

In addition, the firm is classified as a "highly innovative startup" within the business registry, which is issued by a national agency called "San Marino Innovation" which has the task of verifying whether the San Marino companies meet one or more of the following requirements:

1. Development of new technologies, to provide products and/or services (internal development).
2. Adoption of new technologies (i.e., artificial intelligence, machine learning, blockchain, etc.) in business processes (external adoption).
3. Adoption of innovative solutions regarding one's own business model, product, service.
4. The requirement of substantiality is considered satisfied in the event of full compliance with the conditions indicated in the above article.
5. Solidity and consistency of the business plan included in the Certification Program presented by the User.

Another characteristic element of the company is represented by its mission aimed at social sustainability. The founders argue that the latter is one of the main reasons why they have undertaken this type of activity.

#### ***4.3 Evidence and implications of the study***

The company under study presents growing development data. It should be noted that positive profits have been obtained starting from the year of its establishment. Moreover, balance sheet data comparing 2021 and 2022 show a growth in both turnover and profitability of almost 27%. Another point of analysis is the increase in the number of employees (100% from 2021 to 2022). This has had a positive impact on employment opportunities in the area and demonstrates how the company's object is in line with its vision. Specifically, it emerges that a business that produces digital products and services with a mission of social

sustainability can achieve positive business performance results quickly (only two years of activity).

If confirmed by further studies, these indications could be taken into consideration in the creation of new business models. The policies of different countries could also favor the birth of digital businesses with a vision of social sustainability. One possible interpretation emerging from the study is that companies that focus on creating new jobs with products/services that increase collective well-being contribute to a double benefit for social sustainability. This applies not only to new companies but can also be considered for the development or implementation of existing companies that can expand or diversify their business.

The evidence from the case study is summarized in Figure 3:

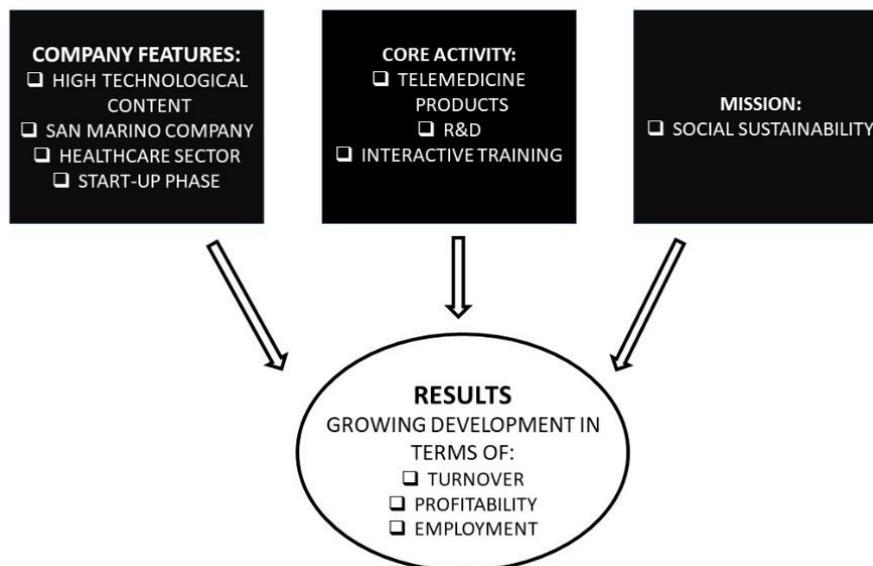

Figure 3. Evidence from the case study

## 5 Conclusion

Our findings highlight the importance of integrating social responsibility into digital strategies to ensure sustainable growth and development. We shed light on two critical research topics related to digitalization and social responsibility. Our systematic literature review identified two current areas of research interest:

1. Digitalization and human resources processes

## 2. Social Responsibility and Innovation.

In addition, our case study analysis confirmed that companies with a strong social sustainability mission that create digital products and services can experience rapid growth in profitability, revenue, and employment opportunities. Therefore, we suggest that managers focus on developing digital strategies that align with their organization's social responsibility mission.

Future research should explore the proposed solutions in table 2. Furthermore, researchers should identify strategies for managing potential risks and challenges associated with digitalization and social responsibility.

## **Collaborative Network Formation in Robotics Digital Innovation Hubs: A Dynamic Capabilities Perspective**

---

Jorge Tiago Martins

VTT Technical Research Centre of Finland  
Tekniikantie 21  
02150 Espoo, Finland

### **Abstract**

The field of robotics has witnessed unprecedented growth in recent years, with emerging technologies such as AI, machine learning, and the Internet of Things (IoT) transforming the industry. To capitalise on this growth, manufacturers are turning to collaboration opportunities with digital innovation hubs, to foster collaboration, experimentation, and learning in the field of robotics. However, the success of such hubs depends not only on individual capabilities but also on their ability to work together as a network. In this context, the constitution of a network of digital innovation hubs operating in the domain of robotics raises important questions about the role of dynamic capabilities in the formation and development and of the network. Dynamic capabilities are traditionally considered to be the ability of organisations to adapt to changing environments and markets by leveraging their resources and capabilities. In the context of a nascent pan-European network of digital innovation hubs focused on robotics in manufacturing, it is proposed that the dynamic capabilities of the network at a system level will play a critical role in the network's development and activities. It is also important to acknowledge that effective knowledge management can enhance dynamic capabilities by allowing the network to leverage existing knowledge and acquire new knowledge to adapt to changing environments. This paper, focusing empirically on the analysis of DIH<sup>2</sup> – a nascent network of digital innovation hubs operating in the domain of manufacturing robotics, examines how dynamic capabilities can be developed and leveraged to contribute to the overall success of the network. Overall, the paper aims to contribute to the growing literature on dynamic capabilities by examining their role in the constitution of a network of digital innovation hubs in the domain of manufacturing robotics. By highlighting the importance of knowledge management in the development of dynamic capabilities, the paper provides insights that can inform the design and management of successful digital innovation hub networks, in cognate domains.

**Keywords** – Digital innovation hubs, Dynamic capabilities, Inter-organisational network

**Paper type** – Academic Research Paper

## 1 Introduction

Regions across Europe have been challenged to deliver digital solutions to small and medium size enterprises (SMEs), through mechanisms that respond to the challenges of complex, multi-layered innovation ecosystems. Under the framework of Digital Innovation Hubs, the configuration for the provision of such services has moved away the establishment of individual initiatives into integrative, regionally grounded hubs that operate as multi-stakeholder entities deploying one-stop-shop services in the form of supporting companies in their technical, business and ecosystem development support needs (Butter et al., 2020).

A key underlying expectation sustaining the operation of digital innovation hubs concerns supporting technology transfer from science to industry, enabling the resource and capacity sharing among firms, and supporting life-long learning of industry workers (Lanz et al., 2020). In this sense, digital innovation hubs support knowledge, technology and competence transfer across European SMEs.

While recent, the development of digital innovation hubs as a policy initiative, corresponds to a structured collaboration environment comprising groups of diverse stakeholders (governmental agencies, industry associations, large companies, SMEs, start-ups, investors, corporations, extension, accelerators, incubators, universities, research centres, specialised experts) that are connected in collaborative and supportive relationships (Zamiri et al., 2021). The collection of collaborative practices is intended to help companies become more competitive vis-à-vis business/production processes and the ability to develop customised products and services.

Crupi et al. (2021) call for further research into how digital innovation hubs act as knowledge brokers (for instance mobilising knowledge to identify performance gaps and assess SMEs level of digitalisation); helping beneficiary firms adopt open innovation practices through overcoming limitations in internal resources; and mediating interactions between previously unconnected actors for the exploitation and exploration of innovation opportunities.

Indeed, the current digital transformation of manufacturing is occurring at an unprecedented rate and manufacturing SMEs are faced with a new set of digital requirements and competitive challenges involving technical transformation, adaptation to customer expectations, environmental sustainability, amongst others. This emerging reality means in practical terms that many regions across

Europe need tailor-made initiatives and policies to take advantage of competitive strengths and expertise. The DIH<sup>2</sup> Network is a pan-European response to this transformation, created to make expertise in robotics and cognitive manufacturing accessible to local industry.

Established under the Horizon 2020 Industrial Leadership programme, DIH<sup>2</sup> is a nascent network of digital innovation hubs. Its core mission is to accelerate sustainable growth in European manufacturing through facilitating access to and development of new robotics solutions to SMEs, who often lack the resources to manage the digital transformation of their businesses. A key role of the DIH<sup>2</sup> Network is therefore to ensure SMEs are able to leverage the benefits of deploying robotics in manufacturing, including working in partnership with technology providers, research and technology organisations and other stakeholders.

While there is a proliferation of manufacturing-focused networks, the DIH<sup>2</sup> Network is unique in its approach to industry transformation through aggregating European digital innovation hubs into a structured collaborative environment. Comparatively, the operationalisation of how such collaborative networks can be designed remains limited, so the approach implemented by the DIH<sup>2</sup> Network exemplifies how the complexity of addressing the knowledge gaps in the transfer of robotics into manufacturing SMEs calls for creative solutions.

Drawing the dynamic capabilities literature and how it intersects with knowledge management, this paper discusses and theorises the key factors that trigger the formation of the DIH<sup>2</sup> collaborative network, the motivations of participating organisations for forming a network, and the sensing, seizing and transforming mechanisms employed to form and develop the DIH<sup>2</sup> collaborative network. The subsequent sections review the literature that forms the conceptual framework, introduce the research methodology, and present the findings of the study. Finally, the paper concludes with a discussion of findings and the identification of practical and managerial implications.

## **2 Conceptual framework**

The concept of dynamic capabilities concerns the mechanisms (sensing, seizing, reconfiguring), through which organisations can adapt and respond to changes in their environments (Tece, 2007). It was initially applied to single organisations, with a focus on the internal processes and resources that enable firms to identify

and exploit new opportunities. Sensing is the ability to detect and interpret changes in the business environment, including market trends, customer needs, technological developments, and regulatory shifts. Organisations with strong sensing capabilities are able to identify emerging opportunities and threats, and to adjust their strategies accordingly. Seizing refers to ability to quickly and decisively capitalise on opportunities, whether by developing new products and services, entering new markets, or acquiring strategic assets. Organisations with strong seizing capabilities are able to move swiftly and confidently, and to take calculated risks in pursuit of strategic goals. Finally, reconfiguring the ability to continuously adapt and reconfigure organizational resources and capabilities to meet changing market and environmental conditions. Organisations with strong reconfiguring capabilities are able to integrate new resources and capabilities, shed those that are no longer useful, and effectively manage organisational change.

However, as the business environment has become increasingly complex and interdependent, the concept of dynamic capabilities has evolved to include the management of networks and network orchestration. Network orchestration (Linde et al., 2021) refers to the coordination and management of a group of firms that collaborate to achieve a common goal. In the context of network orchestration, dynamic capabilities are no longer confined to the individual organisations within the network. Instead, they extend to the network as a whole, and the ability of the network to adapt and respond to changes in the environment. In this way, dynamic capabilities are seen as a critical factor in the success of networked organisations.

Foss et al. (2023) explore the concept of ecosystem leadership as a dynamic capability, and its potential to drive innovation and growth in complex, networked environments. Ecosystem leadership is a key dynamic capability for organisations operating in complex, networked environments. It is defined as the ability to effectively manage and lead a network of partners, suppliers, customers, and other stakeholders to achieve shared goals and outcomes. This typically requires a unique set of skills and competencies, including the ability to collaborate and co-create with partners, manage complex relationships, and drive continuous innovation and learning. Successful ecosystem leadership requires a systemic approach that emphasises the interdependent relationships between different actors and components of the ecosystem. This calls for a deep understanding of the ecosystem, its dynamics, and the different roles and contributions of the

various actors involved. Finally, ecosystem leadership can drive innovation and growth by enabling organisations to access new sources of knowledge, resources, and capabilities, and by facilitating the development of new products, services, and business models.

Relatedly, Linde et al. (2021) argue that the dynamic capabilities framework can be used to develop a capability-based approach to ecosystem orchestration, which involves the coordination of a range of resources and capabilities, including technological, organisational, and institutional resources. They propose four key dynamic capabilities that are essential for ecosystem orchestration: sensing and shaping opportunities, integrating and coordinating resources, learning and adapting, and leading and governing. Such capabilities can be developed through a range of mechanisms, including strategic partnerships, organisational structures, and leadership development. The importance of knowledge management is also emphasised, especially in developing dynamic capabilities for ecosystem orchestration, as knowledge management processes are acknowledged for supporting the development of the sensing and shaping opportunities and learning and adapting capabilities, enabling organisations to identify and respond to changes in their environments.

Adopting a systems thinking perspective, Sunder and Ganesh (2021) call for a more comprehensive understanding of the dynamic capabilities ecosystem, which consists of various components such as knowledge management, learning and innovation, culture, strategy, and leadership. These are interdependent components, which must be managed holistically to develop and sustain dynamic capabilities. Therefore, a framework for identifying and analysing the components of the dynamic capabilities ecosystem is proposed. The framework includes four stages: (1) identifying the key components of the ecosystem, (2) mapping the relationships and interdependencies between the components, (3) identifying the feedback loops and their impact on the ecosystem, and (4) developing strategies to manage the ecosystem and build dynamic capabilities. Crucially, knowledge management processes support learning and innovation, which are critical components of dynamic capabilities. In addition, a culture of knowledge sharing and collaboration is necessary to support the development and implementation of dynamic capabilities. This argument is also put forward by Easterby-Smith and Prieto (2008), who propose that dynamic capabilities and knowledge management are interrelated concepts, and that learning plays a critical role in integrating these two concepts. In that sense, dynamic capabilities involve the

ability of organizations to learn, innovate, and adapt to changing environments. The key dimensions of dynamic capabilities are closely linked to knowledge management, as knowledge management can provide the resources and capabilities necessary for dynamic capabilities to be developed and sustained.

### **3 Methods**

Making use of the DIH<sup>2</sup> network bi-weekly meetings, four ninety-minute focus group (Morgan and Spanish, 1984) discussions provided thirty-seven participants – individual digital innovation hub representatives designated as local evangelists in robotics (LERs) – with a unique opportunity to get acquainted with the other stakeholders involved in the DIH<sup>2</sup> Network, express their needs and what they offer, as well as how they are positioned in relation to each other. Through this, the network had the chance to reflect, justify decisions, question choices and placement of proposed actions. All participants had equal opportunities to ask questions and provide feedback. This reflection encouraged collaborative and iterative development of the network. The focus group discussions were audio-recorded and the qualitative data was analysed using inducting thematic analysis (Braun et al., 2006).

During the focus group discussions, LERs were invited to share snippets from their own experience of the DIH<sup>2</sup> network, focusing on what it should stop doing, what it needs to continue doing, what it needs to do more or less of, and what it needs to start doing that it hasn't already done. Once it was possible to take stock of the challenges impacting what LERs think are the critical activities of the network, the analysis focused on a smaller number of challenges, thinking about them and organising them in terms of their importance and achievability. Finally, there was an opportunity for focused discussion of the root causes of perceived challenges and to brainstorm and propose possible solutions concerning network vision and governance.

### **4 Findings**

The workshops produced a comprehensive and detailed mapping of challenges for the different activities of the DIH<sup>2</sup> Network, as well as a prioritisation of activities, so that the network could attain a more refined focus of action. Table 1 below presents the results outlining role, challenges (and their causes) and solutions the DIH<sup>2</sup> Network is positioned to deliver.

Table 1 – Roles, challenges and solutions the DIH<sup>2</sup> Network is positioned to deliver

<b>Roles</b>	<b>Challenges</b>	<b>Causes</b>	<b>Solutions</b>
Innovating	How to present new technology to SMEs who might be sceptical to new services/ solutions  Engaging with industry needs: taking a listen/ select, take action/ adapt approach	Lack of awareness. No success stories. Lack of technical skills.  Diversity of industrial IoT protocols	Showcase of technology implementation  Adapting the business model of the network to market needs
Connecting	Generating trust  Insufficient visibility of services provided by each digital innovation hub and respective ecosystem	Bureaucracy; security and privacy issues. Staff competences  Distinguishing good/ standardised information. Social interaction to overcome misinformation	Certification of experts and platforms used  Clear and translated to market messages. One-to-one meetings with SMEs
Celebrating	Building follow-up stories of successful use cases  Generating success stories of win-win experiences across network regions	Lack of trust on benefit and applicability of technological solutions  Regional representatives don't know enough about the network and are not necessarily interested in R&D	Appointing ambassadors for clear dissemination. Evaluating technology transfer experiments for demonstration of what was needed and how they succeeded  Engage regional authorities in motivating companies to implement network resources/ practices
Advocating	Lack of clear communication material  Being able to explain the benefits of good practices	Need to establish effective clear and meaningful impact indicators (social, economic, employment)  Lack of meaningful key performance indicators	Fine-tune impact stories to specific target audiences (policy-makers, authorities, industrial associations)  Determining economic and social impact key performance indicators to communicate best practices

Subsequently, conceiving the enactment of the network as a collection of activities, LERs focused their thinking around key challenges (synthesised in Table 2), which they consider to be at the core of the foundational ethos of digital innovation hubs, and by extension, of a pan-European network of digital innovation hubs operating in the domain of manufacturing robotics: funding, sharing knowledge, training, and convening and facilitating.

Funding refers to how to obtain the financing the network needs (operational continuity, membership fee structure, large research grants the network can collectively go for).

Sharing knowledge is about providing and sharing scientific knowledge, technical and practical know-how, information and business intelligence that can lead to enhanced innovation outcomes.

Training for innovation with robotics in manufacturing concerns doing things in new ways – so this requires developing new mindsets and capabilities. Therefore, training and capacity building refers to the technical domain but also to more general business and leadership skills.

Convening and facilitating and involves bringing the members of the network together and facilitating productive, mutually beneficial interactions – this can take the form of working groups, stakeholder workshops, thematic meetings and gatherings.

Table 2 – Enactment of the network as a collection of activities

<b>Roles</b>	<b>Challenges</b>	<b>Causes</b>	<b>Solutions</b>
Funding	Scalable solutions/ business models to attract private funding	Solutions on the market are too focused and are difficult to scale. When scaling up is possible there is insufficient communication	Developing flagship solutions that SMEs can relate to
	Translate knowledge into economic impact	Companies struggle with bridging the gap between low and high technology readiness level	Strengthen digital innovation hubs role in supporting technology transfer experiments, while encouraging companies to collaborate
Sharing knowledge	Emphasising quality and additional services offered	Differentiation difficulties when services in other platforms look similar	Developing service catalogue
	Providing an environment for	Lack of a centralised information platform for	Developing a centralised information platform for

	information exchange between digital innovation hubs	digital innovation hubs	digital innovation hubs, concentrating live news, and opportunities for collaborative work and projects
Training and convening	<p>Make participation in events and coordination of events more accessible</p> <p>Demonstrating results, not documentation. Making more use of media stories and leadership by example</p>	<p>Not many participants are reached. There are too many events on the same topic</p> <p>No real demonstrators. Overuse of presentations and no live demos</p>	<p>Coordinate to develop joint events</p> <p>Develop videos demonstrating technology transfer experiments and live workshops showing results</p>
Facilitating	<p>Getting the right level of information on industrial IoT platforms and services</p> <p>Demonstrating the added value of SMEs obtaining help from digital innovation hubs</p>	<p>Descriptions are in inaccessible language. Insufficient information scares newcomers who have traditionally worked with specific industrial partners</p> <p>SMEs not always recognise the added value</p>	<p>Simplify documentation for end-users. Prepare information for user personals, highlighting what the gains/benefits are, compared to competitors</p> <p>Use technology transfer experiments to present clear return on investment. Act as a consultant to SMEs concerning participation in projects and identification of funding opportunities</p>

## 6 Discussion and conclusions

The identified roles of innovating, connecting, celebrating, advocating, funding, sharing knowledge, training, and convening and facilitating are all closely related to key components of ecosystem dynamic capabilities, especially the systems thinking perspective articulated in Sunder and Ganesh's (2021) construct of dynamic capabilities ecosystem, and the developing stages of identifying the key components of the ecosystem, mapping the relationships and interdependencies between the components, identifying the feedback loops and their impact on the ecosystem, and developing strategies to manage the ecosystem.

For DIH<sup>2</sup>, "innovating" and "connecting" are essential dimensions for identifying the key components of the network. "Innovating" involves identifying new ideas

and technologies that can be integrated into the network, while “connecting” involves identifying the key actors and institutions that make up the network.

“Celebrating”, “advocating”, and “funding” are all relevant dimensions for mapping the relationships and interdependencies between the components of the ecosystem. “Celebrating” involves recognising and promoting the successes of the ecosystem, while “advocating” involves promoting the ecosystem to external stakeholders. “Funding” is also essential for mapping the relationships between the components, as it helps to identify the key sources of financial support for the network.

“Sharing knowledge” and “training” are essential dimensions for identifying the feedback loops and their impact on the network. “Sharing knowledge” involves promoting the exchange of information and ideas within the network, while “training” involves developing the skills and competencies of the actors within the “network”.

“Convening and “facilitating” are relevant dimensions for developing strategies to manage the network. “Convening” involves bringing together actors within the network to collaborate and share ideas, while “facilitating” involves providing the necessary resources and support to enable the “network” to function effectively.

The dynamic capabilities of a network of digital innovation hubs are multidimensional, consisting of a range of interdependent roles that influence each other in complex ways. The implications of these findings for the theory and practice of managing a network of digital innovation hubs are significant. First, the roles proposed in the paper provide a useful tool for managers and policymakers to analyse and manage the dynamic capabilities of a network of digital innovation hubs. Second, the application of systems thinking in the analysis of the network can help to identify and address the feedback loops that exist within the network, which are critical to its sustainability and success. Finally, the findings highlight the importance of effective collaboration and coordination among the various actors and institutions involved in the network.

### **Abstract**

The technological choices facing organisations are increasingly complex and aimed at promoting sustainable development. Recently, the concept of Industry 5.0 has laid the foundations for a digital transformation that drives companies to adopt sustainable approaches. Although there are various contributions investigating the link between sustainable production and digital technologies, there is still a lack of comprehensive research on the role of digital technologies in achieving the three pillars of sustainability in specific areas of supply chain management (SCM). The article aims to assess and understand which digital technologies are the most promising for achieving sustainability standards. Through a systematic literature review, the study analyses 1,720 scientific articles that identify business practices supported by digital technologies such as: 3D

printing, artificial intelligence, blockchain, computing, digital applications, geospatial technologies, immersive environments, Internet of Things, open and crowd-based platforms, proximity technologies and robotics. Such business practices are thereafter associated with specific areas of SCM such as distribution, marketing and procurement. The results show that blockchain technology is promising for different sustainability aspects, whereas computing, 3D printing and immersive environments are less employed for sustainable development. The study also highlights that scholars have paid more attention to environmental rather than economic and social sustainability dimensions. The contribution of this article is to provide a current overview of digital technologies in SCM to clarify the state of the art of research. It also defines a research agenda for academics to conduct further exploratory research. For managers and practitioners, it presents a knowledge base where data on sustainable practices supported by digital technologies in SCM have been collected and organised, providing information to companies on opportunities for implementation in their own business.

**Keywords** – Digital transformation, sustainability, supply chain management, artificial intelligence, blockchain.

**Paper type** – Academic Research Paper

## 1 Introduction

Growing environmental, social and economic threats from pandemics, crises, wars, global warming and increasing poverty are accelerating many significant transformations in society and companies (Ajmal et al., 2022; Mishra and Singh, 2022). To survive in such increasingly complex and dynamic conditions, companies should necessarily innovate and adapt to new standards of efficiency and sustainability (Okorie et al., 2023). To increase and keep their competitive advantage, firms are promoting the adoption and integration of different technologies to ensure more efficient, flexible and agile systems (Felsberger et al., 2022; Latino et al., 2022). Scientific research has identified Industry 4.0 as the phenomenon in which digital technologies are interconnected to automate and optimise industrial processes (Baur, 2015). This paradigm allows companies to have more control over the entire product life cycle, from idea generation, through the development and production phases, to delivery to the final customer, after-sales services and waste management (Corallo et al., 2020). Scholars investigated specific digital technologies related to the Industry 4.0 paradigm - such as Internet of Things (IoT), blockchain, additive manufacturing, artificial intelligence (AI) - and their impact on organisations (Aoun et al., 2021;

Florén et al., 2021). The complexities of the technological choices facing organisations are even greater today because they should take into account the three dimensions of sustainability - environmental, economic and social - and promote sustainable development. In this context, research is converging on integrating the technological principles of Industry 4.0 with sustainability issues in SCM (Bajic et al., 2021; Seyedghorban et al., 2020). Therefore, the European Commission has created the Industry 5.0 agenda, which combines these two theories (Ghobakhloo et al., 2022; Maddikunta et al., 2022).

There are several contributions in literature that combine these two paradigms, however in a fragmented manner. Current studies consider the evaluation of single digital technologies at time, such as blockchain, AI or IoT, in specific SCM case studies or simulations to improve sustainability aspects (Chen, 2023; Tirkolaei and Aydin, 2022). Through literature reviews, other studies have focused on the analysis of the combined use of various digital technologies to improve sustainability in specific sectors (Liu et al., 2023). Other researchers developed conceptual frameworks linking the paradigm of Industry 4.0 and sustainable production by summarising existing research efforts and highlighting research gaps and opportunities (Sharma et al., 2021). Moreover, scientific research is pushing towards the links between Industry 4.0, digital technologies and the circular economy, providing an innovative view of the use of digital technologies (Rosa et al., 2020). Circular economy issues were further investigated by considering collaborative principles that can be developed by combining digital technologies in SCM (Gebhardt et al., 2021). Finally, most studies linking sustainability and digital technologies focus on specific business contexts such as new product development, lean manufacturing or life cycle assessment (Ahmed et al., 2020; Cifone et al., 2021).

Currently, there is still a lack of comprehensive studies investigating different digital technologies in specific business functions in supply chains from the environmental, social and economic perspective. Therefore, the purpose of this article is to increase the body of knowledge on sustainable business practices based on current digital technologies and to classify their use in specific SCM contexts. The gaps in literature led to the development of the following research questions:

1. Which digital technologies are more promising in promoting sustainable practices in SCM?

2. In which specific business functions does the adoption of digital technologies improve sustainability dimensions?

First, the study investigates and analyses which digital technologies are mainly adopted to improve business practices in SCM. To achieve this goal, the study considers eleven digital technologies: 3D printing, AI, blockchain, computing, digital applications, geospatial technologies, IoT, immersive environments, open and crowd-based platforms, proximity technologies and robotics. For each digital technology, business practices supported by their use in SCM were intercepted through a systematic literature review (SLR). Sustainable business practices are therefore identified considering the three sustainability pillars, i.e. environmental, social and economic. Such sustainable business practices were further classified into specific business functions for SCM such as marketing, distribution and procurement. Hence, the study provides a comprehensive overview of digital technologies that promote sustainable practices in SCM. This analysis contributes to the advancement of research on the role of digital technologies in supporting economic, social and environmental sustainability in SCM by providing researchers and academics with insights for future research. The article identified 1,720 peer-reviewed scientific articles featuring business practices based on digital technologies in SCM.

The rest of the document is structured as follows. Section 2 presents the digital technologies and business functions using a conceptual framework. Section 3 shows the research methodology conducted. Section 4 analyses the results. Section 5 presents the discussions, providing insights for future research. Conclusions close the paper.

## **2 Theoretical background**

### ***2.1 Digital technologies for SCM***

There is no rigorous and detailed classification of current digital technologies in literature. The classifications between different studies are conflicting and there are several inconsistencies among the various authors. In 2015, Boston Consulting Group identified nine technologies for Industry 4.0: robots and autonomous vehicles, additive manufacturing, augmented and virtual reality, big data, simulation, IoT, horizontal/vertical systems integration, cloud technologies, blockchain and cybersecurity (Rüßmann et al. 2015). Some researchers divided

technologies into two categories: physical and digital technologies. The former includes sensors, drones, 3D printing and advanced robotics. The latter include information and communication technologies such as big data, blockchain, AI and cloud computing (Liao et al., 2017). Further studies used different taxonomies. For example, Dantas et al., (2021) classify technologies into IoT, cyber-physical systems, big data, Internet of Services, additive manufacturing, augmented reality, cloud computing, systems integration, cybersecurity, simulation and autonomous robots. Bai et al., (2023) identify the following Industry 4.0 technologies: 3D printing, AI, robotics, blockchain, cloud computing, cybersecurity, drones, industrial IoT, mobile technology, nano technology, RFID, simulation, sensors and actuators. With the development of the Industry 5.0 paradigm, other digital technologies were added such as cognitive cyber-physics, cognitive artificial intelligence, intelligent materials, augmented and mixed reality, 5g/6g technology, Internet of Everything, digital twin and adaptive robots (Maddikunta et al., 2022).

Table 1 shows the digital technologies considered in this study with a brief description of each.

Table 1. List of digital technologies considered.

<b>Digital technology</b>	<b>Description</b>
3D Printing	A method of assembling materials in sequential layers to create items from 3D model data to design different products and gain mass-customization.
AI	A system to think rationally and humanly that uses natural language processing, machine learning, and computer vision.
Blockchain	A shared, secure, transparent and distributed ledger in which transactions can be recorded.
Computing	System for providing online storage services on a virtual server.
Digital applications	Technologies that create virtual communication channels.
Geospatial tech	Technologies that geolocate and map objects and things on Earth.
Immersive environments	Technology that simulate elements of the real world, such as machines and people, in a virtual setting with the goal of making system design and live operation easier and more affordable.
IoT	Physical things and devices connected by an information network that allows data to be exchanged among them for interaction and cooperation.
Open and Crowd-Based Platforms	Technologies that favour the power of the crowd using shared digital platforms to achieve a common outcome.

Proximity tech	Technologies that measure the physical condition of systems through sensors.
Robotics	Equipment and machinery that automate operational procedures.

## **2.2 Business functions of SCM**

There are several reference models in literature that classify the different business functions. One of the first models is provided by Porter (2011), where activities are divided into primary (e.g. operations, logistics, services, marketing and sales) and secondary (e.g. technology development, infrastructure, procurement, human resources management). Recently, this model has been further developed into two frameworks: Supply Chain Operations Reference (SCOR) and the Process Classification Framework (PCF). SCOR is based on five business processes - planning, procurement, production, delivery and return - whereas, the PCF model is based on twelve business processes classified into operational and support processes. Both aim to identify the best business practices to be adopted in SCM (Stewart, 1997). Considering these models, the study focuses on three core business functions for SCM, distribution, marketing and procurement. Distribution embraces all logistics activities such as transportation, delivery, inventory, reverse logistics, transportation and warehouses management. Marketing includes customer payment, customer service, after-sales service and sales channel. In procurement are included buyer-supplier relationships, order management, supplier evaluation and selection and supplier payment.

## **2.3 Framework conceptualization**

Digital technologies can be used in different business processes, carrying out specific impacts. In some cases, they can be employed in a single business process; in others, they can be valuable in different business contexts. This research considers the inductive-deductive approach based on a conceptual framework according to Seuring and Gold, (2012). The framework clarifies the key factors that will be examined and the potential relationships between them (Liehr and Smith, 1999). To guide the research findings, the article is based on three elements: digital technologies, business functions and the three dimensions of sustainability. A similar approach was taken by Bai et al., (2023) who conducted a

literature review on the application of digital technologies for social sustainability. The framework proposed in Figure 1 integrates the elements presented above. It supports the understanding of the impact of digital technologies in specific business functions of SCM through sustainable practices. The centre of Figure 1 is the sustainability goal to be achieved by the support of digital technologies in SCM. The second level includes business functions in SCM. The third level identifies the 11 technologies considered. Although these technologies directly address the three pillars of sustainability, they are also explored in different supply chain processes.

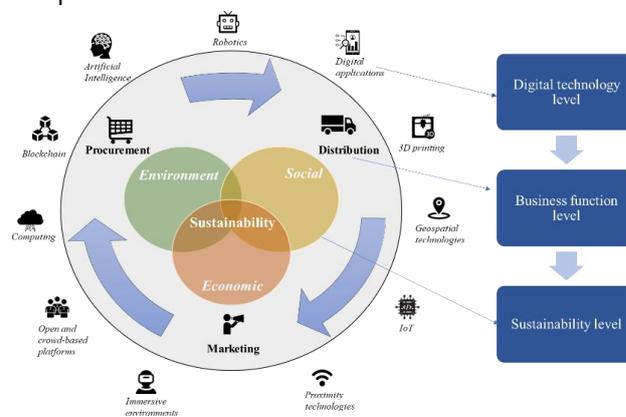

Figure 1. Conceptual framework.

### 3 Methodology

SLR was used in this study since it enables the identification, selection and critical evaluation of data included in scientific studies. It is a transparent, easily replicable and rigorous methodology and enables the selection of the most relevant articles in the field of research to provide a comprehensive view of the state of the art (Tranfield et al., 2003). The SLR involves four steps: problem identification, screening step, selection criteria (inclusion and exclusion criteria), and classification step. Figure 2 presents all the steps for the review.

#### 3.1 Problem identification and screening phase

This work used Scopus as a database because it covers both scientific and humanistic disciplines (Moher et al., 2009). Table 2 shows the keywords used in the Title or Keyword of search string referring to each digital technology analysed. As current digital technologies were considered, the temporal analysis of the

articles is limited to the years 2019-2022. The articles considered belong to the Q1 and Q2 quartiles according to Scimago Journal Ranking and ISI Web of Science. The research area is limited to management, business, accounting, economics, finance and operations research. In the screening phase, 27,288 articles were identified.

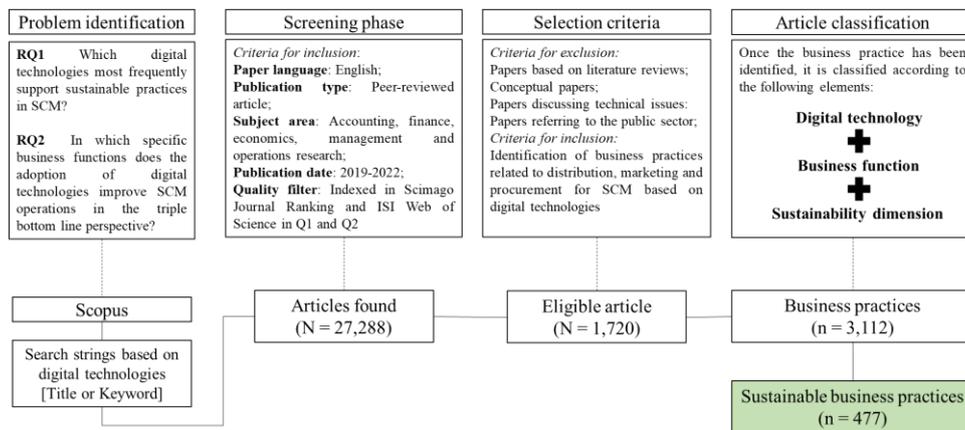

Figure 2. SLR steps.

Table 2. List of keywords.

Digital technologies	Keywords
3D Printing	3D printing; 3D printer; additive manufacturing; rapid prototyping; rapid tooling; bio printing; direct energy deposition; direct metal laser sintering; fused filament fabrication; fused deposition modeling; polyjet; powder bed deposition; selective laser sintering; stereolithography; blinder jetting
Artificial Intelligence	artificial intelligence; machine learning; metaheuristic; unsupervised learning; supervised learning; deep learning; computer vision; natural language processing; cognitive computing; artificial neural network; support vector machine; random forest; decision tree learning; genetic algorithms; reinforcement learning; convolutional neural network; speech technology; speech synthesis; speech recognition; speaker recognition; speaker verification; speech encoding; text-to-speech; speech-to-text; data analytics; data mining; data standardization; advanced analytics; predictive analytics; sentiment analysis; content analysis; text mining; user behavior analytics; user behavior analytics
Blockchain	distributed ledger; blockchain; cryptocurrency; smart contract; non-fungible token
Computing	cloud computing; cloud storage; fog computing, edge computing; quantum computing; cloudlet computing
Digital Applications	digital platform; digital application; digital traces; cron jobs; mobile application; social media; social network; web application; API; web service; robotic process automation; software bots; bots; digital signature; electronic

	signature; digital invoice; electronic invoice; digital contract; electronic contract; certified email; electronic storage; digital storage; substitutive storage; electronic document; digital document; digital certificate; electronic archive; digital archive; dematerialization; digitization; digital conservation; digital preservation
Geo-Spatial Tech	geo-spatial tech; geo-spatial intelligence; geographic information systems; global navigation satellite system; web mapping; remote sensing; global positioning system; spatial modeling
Immersive Environments	Augmented reality; digital twin; extended reality; gamification; mixed reality; virtual reality; metaverse; hologram; digital human
IoT	internet of things; smart sensor; wearable sensor; 5G; wireless sensors; LoRa; mobile sensing; Internet of Vehicles
Open And Crowd-Based Platforms	open science; open source; crowdsourcing; open data; crowd science; open access; crowdshipping; crowdfunding platform; open innovation platform
Proximity Tech	proximity tech; proximity sensor; beacon; RFID; near field communication; QR code; datamatrix; bluetooth; motion detector; biometric; gaze tracking; eye tracking
Robotics	robotic; industrial robot; service robots; cobot; drone; autonomous vehicle; driveless vehicles; autonomous mobile robot; autonomous technology; connected and automated vehicle; modular autonomous vehicles; shared autonomous vehicles; connected vehicle; automated vehicle; wearable robot; bionic robot; exoskeleton; AS/RS; social robot; robot-assisted gait training; robotics parcel lockers; robot-assisted surgery; unmanned ground vehicles; unmanned underwater vehicles; unmanned grounded vehicles

### 3.3 Article classification

Once eligible papers were identified, the team classified them according to the three elements of the research, i.e. digital technology, business function and sustainability dimensions. Figure 3 shows an example of a sustainable business practice where drones can be used in food delivery to improve demand response and reduce pollution (Hwang et al., 2020). Business practices are classified by assessing the technology and business context in which they are used to achieve a specific impact. This is a first classification filter. In this case, in the absence of sustainability-related improvements, they are counted as *business practices* (BP). When the business practice aims for an improvement at the sustainability level, they are counted as *sustainable business practices* (SBP). In this way, business practices are classified into the 11 identified digital technologies, into the three business functions of SCM and finally into the three pillars of sustainability (if any). The number of identified BPs using digital technologies in the SCM is 3,112. Whereas, the number of SBPs found is 477.

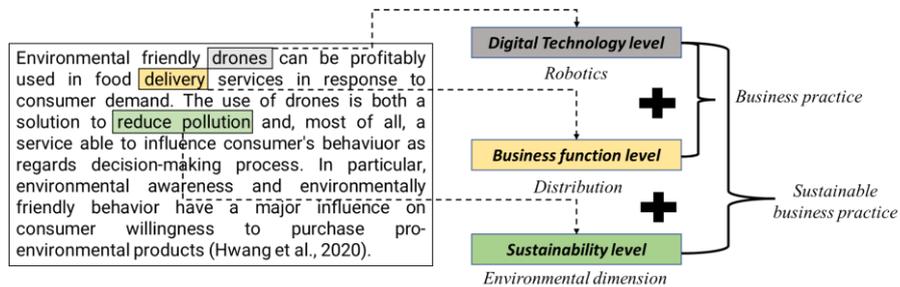

Figure 3. Example of SBP supported by drones.

## 4 Results

This section presents the results of the study. Table 3 shows the overall number of BP and SBP for each technology analysed in the SCM, together with the specific sustainability pillar. Figure 4 reports the overall number of BPs and SBPs: the most widely used digital technologies in SCM for sustainable operations are blockchain, IoT and AI, the least used computing, immersive environments and 3D printing.

Table 3. Distribution of BPs and SBPs for each digital technology.

Digital technology	Total BP	SBP	Economic	Environmental	Social
3D Printing	14	2	-	2	-
Artificial intelligence	728	62	6	46	10
Blockchain	367	85	26	34	25
Computing	119	26	7	12	7
Digital applications	466	44	10	21	13
Geospatial tech	169	51	6	35	10
Immersive environments	231	16	3	9	4
IoT	252	69	22	25	22
Open and crowd-based platforms	135	35	5	22	8
Proximity tech	323	49	15	19	15
Robotics	308	38	3	29	6

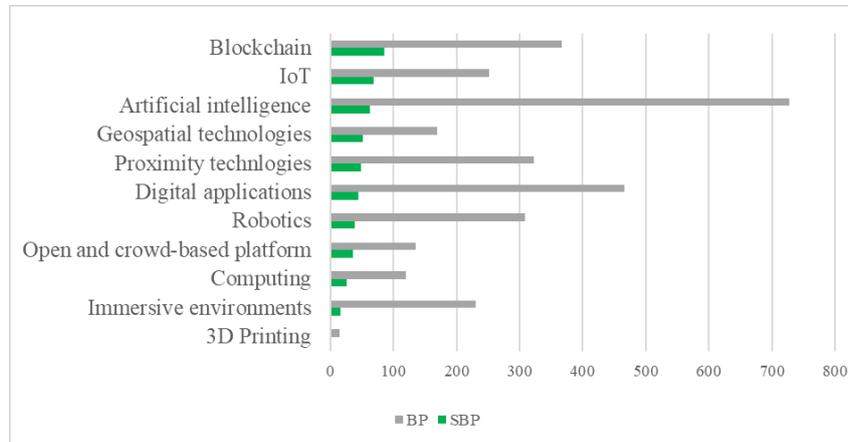

Figure 4. Digital technologies sorted in descending order of SBPs for SCM.

In Figure 5 data are further divided according to the three sustainability pillars. At the top of environmental BPs there are AI, geospatial technologies and blockchain, while in the top three places of social and economic BPs are blockchain, IoT and proximity technologies. At the bottom there are 3D printing, computing and immersive environments.

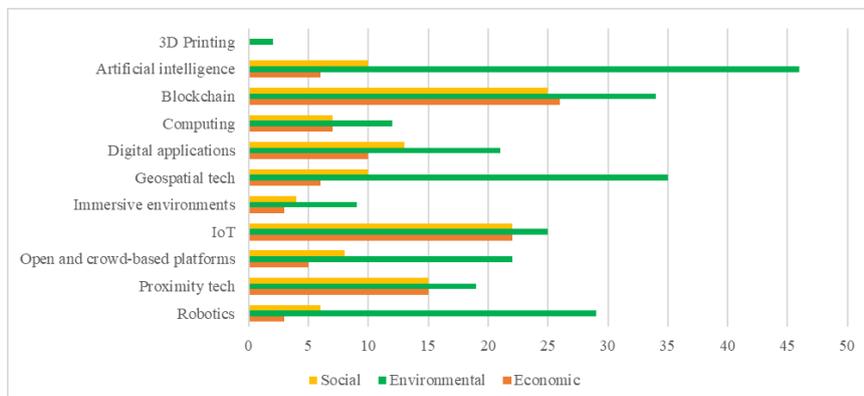

Figure 5. Count of the three dimensions of sustainability for each digital technology.

Table 4 and Figure 6 show how SBPs are distributed in the three SCM processes according to the three sustainability pillars: environmental practices are widely present in distribution, whereas, within procurement, SBPs are relatively evenly distributed across the three sustainability dimensions.

Table 4. Distribution of SBPs for each business function considered.

Business function	Economic	Environmental	Social
Distribution	36	144	42
Marketing	20	60	32
Procurement	47	50	46

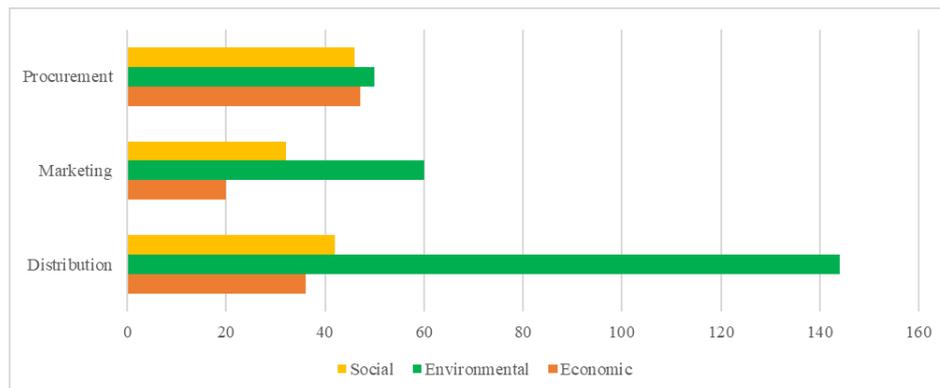

Figure 6. Count of SBPs for each business function considered.

Table 5. Distribution of SBPs for each digital technology and business function

Digital technology	Distribution			Marketing			Procurement		
	Economic	Environmental	Social	Economic	Environmental	Social	Economic	Environmental	Social
3D Printing	-	2	-	-	-	-	-	-	-
Artificial intelligence	3	25	4	2	13	5	1	8	1
Blockchain	7	10	7	3	7	3	16	17	15
Computing	2	6	2	2	3	2	3	3	3
Digital applications	1	7	1	5	12	8	4	2	4
Geospatial tech	1	19	2	1	8	4	4	8	4
Immersive environments	1	5	1	1	2	2	1	2	1
IoT	8	16	8	3	4	3	11	5	11
Open and crowd-based platforms	3	14	4	2	8	4	-	-	-
Proximity tech	7	13	7	1	1	1	7	5	7
Robotics	3	27	6	-	2	-	-	-	-

Table 5 shows the overall number of SBPs distributed according to each digital technology, business function and the three pillars.

Figures 7 to 9 report how SBPs are distributed in the three pillars for distribution, marketing and procurement respectively.

Results for distribution (Figure 7) highlight how the most widely used technologies in environmental practices are robotics, AI and geospatial technologies, while, from both social and economic perspectives, the most widely deployed technologies are blockchain, IoT and proximity technologies. The least employed technologies in distribution are 3D printing, computing and immersive environments. Furthermore, no economic and social BPs have been found for 3D printing.

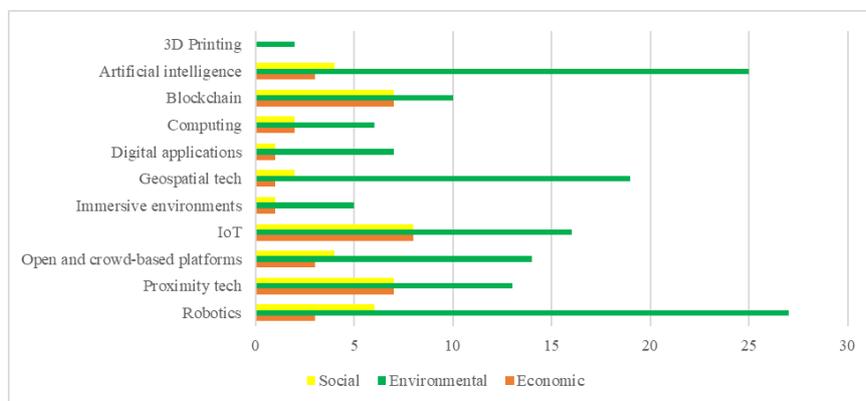

Figure 7. Count of SBPs for each digital technology in distribution.

As to marketing (Figure 8), the most used technologies in environmental and social BPs are AI, digital applications, geospatial tech and open and crowd-based platforms. On the economic side, the most employed technologies are digital applications, blockchain and IoT. At the bottom there are 3D printing, for which there are no SBPs, and robotics, for which there are no economic and social BPs.

In the case of procurement (Figure 9), the technologies most used in environmental practices are blockchain, AI and geospatial technologies. From the economic and social perspective, the most employed technologies are blockchain, IoT and proximity technologies. No SBPs were found for 3D printing, open and crowd-based platforms and robotics.

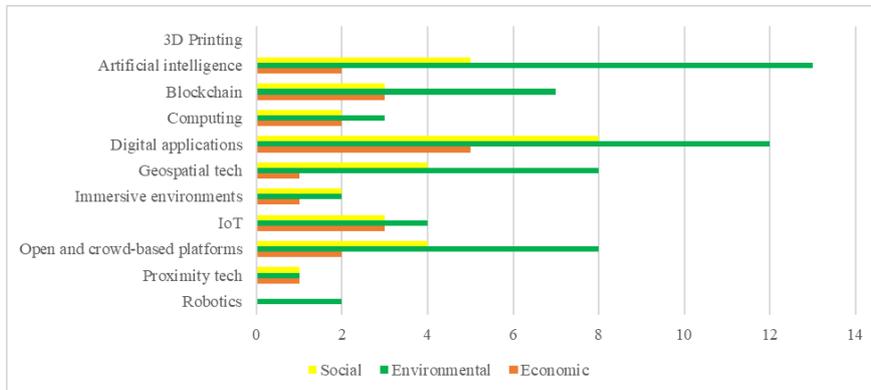

Figure 8. Count of SBPs for each digital technology in marketing.

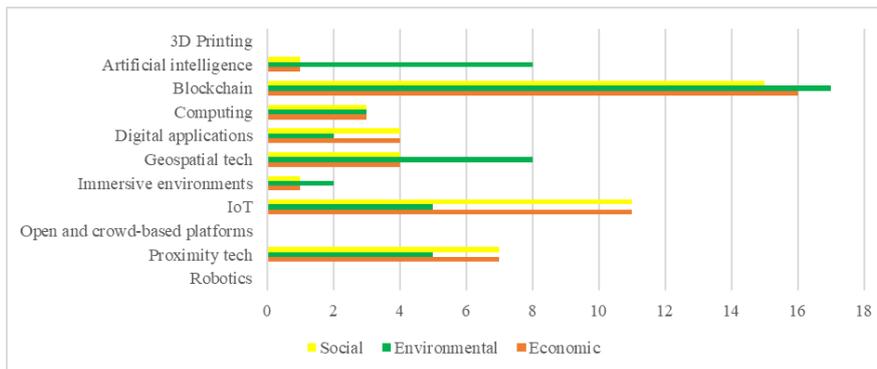

Figure 9. Count of SBPs for each digital technology in procurement.

## 5 Discussions

This section aims to discuss the results achieved by answering the initial research questions and providing further implications for the academic debate. Specifically, the role of digital technologies in sustainable operations management in SCM will be addressed. In addition, further considerations will be carried out regarding the specific business context in which digital technologies are employed. In addition, the article aims to provide a research agenda for academics and researchers. Finally, the study highlights the implications for managers and practitioners and the limitations of the study.

### **5.1 Digital technologies for SCM**

The analysis conducted revealed some interesting insights into digital technologies in SCM in SBPs. Interestingly, blockchain has the highest number of SBPs. Although public blockchain has been severely criticised for its high energy consumption (Alshahrani et al., 2023; Sedlmeir et al., 2020), it has been considerably analysed for sustainable operations management. The results of this study are in line with the high number of articles in the scientific literature demonstrating the importance of this technology in sustainable SCM (Rejeb et al., 2023; Yontar, 2023). In general, blockchain, IoT and AI are considered helpful technologies for sustainable operations management, as they improve transparency, efficiency and security. For example, blockchain can be used to trace the origin and quality of products along the supply chain. This improves transparency and traceability, reducing the risk of fraud and counterfeit products. IoT can monitor the functioning of the supply chain through networks of sensors and data that promotes real-time information on logistics and product distribution, avoiding inefficiencies and issues. The implementation of AI supports distribution planning, optimises stock management and reduces waste of raw materials and energy. Although 3D printing, cloud computing and immersive environments are supportive technologies in many areas of SCM, they have not yet been totally integrated and addressed by scholars in sustainable operations management for several reasons. For example, 3D printing is still a relatively new and expensive technology. It is not yet an efficient solution to produce high quantities of products sustainably. The adoption of cloud computing in SCM may be slowed down by data security and regulatory compliance concerns such as data privacy regulations. Moreover, virtual and augmented reality are considered 'niche' technologies. They may have potential for implementation to improve sustainable aspects of SCM such as efficient warehouse management. However, the complexity and cost of implementation may slow down their use in SCM in the next decade. It should be noted that for some technologies the overall number of BPs is higher such as AI, digital applications, and proximity technologies. However, little scientific research has analysed these digital technologies in SCM from a sustainability perspective. The difference between the overall BPs for blockchain and those are only sustainable in SCM highlights how this technology can be promising for corporate social, economic and environmental responsibility.

Analysing digital technologies in more detail considering the three dimensions of sustainability, it is interesting to note that robotics and geospatial technologies are mainly used for environmental aspects. It is well known that Geographic Information Systems (GIS) aid transport planning and route optimisation through the visualisation and analysis of geographical data. This contributes to reduce costs and greenhouse gas emissions. Instead, robotics support the efficiency and safety of the supply chain for the collection and transport of materials and waste management. In addition, RFID technologies can improve economic and social aspects to identify and monitor objects in real time allowing better processes planning and coordination. Furthermore, from a social perspective, RFIDs can prevent counterfeiting and ensure product safety.

### ***5.2 Digital technologies for marketing, procurement and distribution in sustainable operations management***

The results of the study delve into the second level of the conceptual framework related to business functions. It is evident that SBPs are present more in distribution and less in procurement, indicating that scholars have strongly focused on the use of digital technologies in certain business functions. In distribution, the technologies most used in SBPs, especially environmental ones, are robotics and AI. For example, robots can automate sorting and packaging processes, reducing the time and cost of handling goods. Furthermore, AI can be used to optimise delivery routes and workload, improving efficiency and reducing environmental impact. In distribution, the most adopted technologies are IoT and blockchain to support economic and social BPs. For example, the distributed ledger allows all actors in the supply chain to access information in real time and verify the provenance, quality and product sustainability. IoT supports retailers to better monitor and manage their production and distribution processes, reducing waste and increasing efficiency. However, the results strongly emphasise that the use of digital technologies is mainly used in environmentally oriented BPs and less in social and economic aspects.

In marketing, there is a preponderance of BPs based on digital technologies that support environmental sustainability. However, prominent among these is the use of digital applications and open and crowd-based platforms. The former reduces dependence on traditional marketing activities that require the production of printed materials or the realisation of physical events, which can

have a negative environmental impact. Mobile applications, websites and social media enable more efficient and effective customer engagement by personalising customer communication and obtaining real-time feedback. The latter allows companies to interact with their customers in a direct and transparent manner, promoting dialogue and ideas exchange. In this way, companies can obtain faster feedback on their products and services, co-create new products and services with their customers, and promote sustainable practices through the sharing of information. They can reach a wider, heterogeneous audience by promoting their products and services through digital content and viral marketing campaigns. However, it is evident that some technologies have received less attention such as 3D printing and robotics. Some of these technologies have been less applied in this specific area of SCM and their potential impacts are unknown.

Compared to previous business functions, for procurement there is a preponderance of social and economic BPs in most digital technologies over environmental ones. The reason is that digital technologies can help companies improve transparency and traceability in managing their suppliers. For example, blockchain can enable companies to monitor and evaluate the performance of their suppliers in terms of regulatory compliance, corporate social responsibility, quality of products and services provided. The use of data analytics tools can help companies identify inefficiencies in supplier management and implement corrective actions to improve SCM performance.

### ***5.3 Research agenda***

The analysis conducted reveals several research gaps. For example, not all digital technologies mentioned are useful and available for achieving the three sustainability pillars. Moreover, several digital technologies analysed are not widely used in the business case studies collected. There are several reasons behind them. The first reason is that the digital technologies considered are relatively new and innovative, so their potential impacts on sustainable development in SCM are unknown. In some cases, the implementation of specific digital technologies has little success in managing operations. Probably, they mainly aim at maintaining a competitive advantage but neglect sustainable development issues. Researchers, managers and practitioners have not yet adopted certain technologies in the marketing, procurement and distribution functions and do not study their potential. The study shows that technologies

such as computing and immersive environments are less used for sustainable development. Being relatively new technologies there is limited awareness of their use and effectiveness for sustainable development. Finally, not all business contexts have been identified. For example, the various supporting business functions were not considered in this study.

#### ***5.4 Managerial implications and limitations***

The results of this research are useful for managers and practitioners. Firstly, it indicates which technologies should be used within the company to improve sustainable SCM performance. The article presents a knowledge base in which data on sustainable emerging practices supported by digital technologies in SCM have been collected and organised, providing information to companies on opportunities for implementation in their business. Furthermore, it provides clear and valuable guidelines on what opportunities digital technologies can offer for sustainable supply chains. The article aims to assist managers in increasing the adoption rate of digital technologies in SCM to manage operations from a sustainable perspective.

The SLR has certain limitations. Firstly, the study is based on the analysis of scientific articles for the literature review. Therefore, it is impossible to state that all applications were considered. Furthermore, other research databases such as Web of Science were excluded. A further limitation is the lack of inclusion of grey literature such as web information, reports and conference articles. To support the continuous updating of this knowledge base, a high level of effort is required to read, classify and update sustainable practices by the group of industrial engineers. The challenges and barriers that slow down the adoption of these digital technologies in SCM have not been considered.

## **6 Conclusions**

The study provided a comprehensive overview of the use of digital technologies in SCM to improve BPs from a sustainability perspective. The conducted analysis identified 1,720 articles from which 3,112 BPs and 477 SBPs were extracted. The research provides interesting insights as it investigates the contribution of digital technologies in various areas of SCM and identifies which technologies are particularly focused on the sustainability side of operations management. This paper contributes to the state of the art of the academic

debate by defining the boundaries of current research and proposing potential future research directions. It is crucial a further exploration of these topics to achieve the goals outlined in the UNO 2030 Agenda.

### Abstract

The circular economy (CE) is experiencing increasing attention, as it has the potential to move away from unsustainable production and consumption patterns, such as the linear one. The circular innovation has even more considered an approach to be adopted in pursuing the sustainable development goals, embracing environmental, social and economic nature of sustainability.

Starting from the above premises, our study aims to investigate how inter-organisational collaborations lead to the creation, sharing and exchange of knowledge with potential

benefits for the companies involved, especially in terms of innovation. To achieve this, we observed the circular economy context since, as mentioned above, the interactions between different knowledge areas, as well as the interaction between different actors, are considered strategic keys to support and foster the transition to the circular economy. Furthermore, our paper also aims at contributing to the debate on industrial symbiosis and innovation processes in circular enterprises, focusing on knowledge management (KM), through the integration of different skills provided by local partners. The results underline that the collaborations with local actors are a phenomenon rooted in circular businesses, and that the interconnections between different and complementary knowledge and skills are fundamental to support circular innovation. Implications and suggestions for future studies derive about the knowledge management function both in managing knowledge flows to and from partners and in processing knowledge.

## 1 Introduction

Interactions between different knowledge areas and inter-organisational collaboration are considered the strategic keys to support the transition to the circular economy (Bengtsson et al., 2015; Greco et al., 2019; Bagherzadeh et al., 2021). In fact, interdisciplinarity can be a driver capable of increasing the value of the outputs of innovation processes (Savino et al., 2017).

The circular economy is receiving increasing attention, as it has the potential to move away from unsustainable production and consumption patterns, such as the linear one (Kristensen and Mosgaard, 2020). It is able to reduce the environmental impact, contributing to the ecological transition, while generating economic benefits and meeting social needs, in order to preserve the future generations (Buil et al., 2017). CE is a model that embraces the three dimensions of sustainability, namely the economic sustainability, the environmental sustainability and the social sustainability (Murray et al., 2017) and is aligned to the Sustainable Development Goals (Preston and Lehne, 2017).

The circular economy also plays a very important role for the competitiveness of companies that, through the so-called 4R/9R practices (Kirchherr et al., 2017), can improve the efficiency and effectiveness of their activities, creating new value (Velenturf et al., 2019; Mignacca and Locatelli, 2021). This requires strong and proactive relationships with an extensive network of stakeholders (Bocken and

Ritala, 2022). In this direction, the industrial symbiosis approach recalls the strategic importance of the complex interaction of a network of stakeholders, each with specific and individual identities, to contribute to the co-creation of an ecosystem of shared value (Pera et al., 2016). This approach is based on the involvement of firms located within the same geographical area which become part of a collective approach to competitive advantage involving the physical exchange of materials, energy, water and/or by-products (Chertow, 2000).

Starting from the above premises, our study aims to investigate how inter-organisational collaborations lead to the creation, sharing and exchange of knowledge with potential benefits for the companies involved, especially in terms of innovation. To achieve this, we observed the circular economy context since, as mentioned above, the interactions between different knowledge areas, as well as the interaction between different actors, are considered strategic keys to support and foster the transition to the circular economy.

Furthermore, our paper also aims at contributing to the debate on industrial symbiosis and innovation processes in circular enterprises, focusing on knowledge management (KM), through the integration of different skills provided by local partners. In line with this, the study considers the following research question (RQ):

*Does the management of complementary knowledge and skills from local partnerships fuel business process innovation and foster product innovation in circular businesses?*

We performed an empirical analysis on 117 circular businesses located in the Northern Italy, listed in the Italian Atlas of the Circular Economy, in order to observe their approach and inclination to interact with different actors to produce knowledge and innovation.

The paper has the following structure. Section 2 presents the literature review on the theoretical strands of the circular economy, with a focus on the inter-organisational collaborations, industrial symbiosis and innovation; section 3 illustrates the methods; section 4 describes the results emerging from the empirical analysis; section 5 illustrates discussions, implications and conclusions.

## **2 Literature review**

### ***2.1 Inter-organisational collaboration and knowledge management***

The inter-organisational collaboration - defined as "enduring transactions, flows, and linkages that occur among or between an organisation and one or more organisations in its environment" (Oliver, 1990, 241) - and the resulting exchange of knowledge are considered prerequisites for the creation of new knowledge (Lee and Choi, 2003). It is able to act on the acquisition of organisational skills, through the transfer or sharing of resources (strategic effects) and on increasing the degree of influence on other organisations (political effects) (Hardy et al., 2003). For example, Ngai et al. (2008) show that in the development of a complex innovation, usually based on the integration of different knowledge flows, the cooperation among different categories of actors is needed. It emerges that collaboration and KM within the network is potentially decisive for a successful performance. Pöyhönen and Smedlund (2004) describe three modes of knowledge creation in inter-organisational collaborations based on the network type: (1) the vertical production network, whose flows of money and physical products are the main element, the exchange of information on production enables the dissemination of knowledge; (2) the development network whose actors, while not cooperating in production, exchange knowledge in order to improve themselves and achieve high levels of efficiency; (3) the innovation network, in which the main objective is the creation of new knowledge, seeking solutions to defined problems.

The development of innovation is one of the main objectives of knowledge management (Ben Arfi and Hikkerova, 2021). Indeed, KM practices within a company enable the generation of innovation, through the maximisation of benefits from tacit knowledge and the implementation of collaborative processes (Jones and Mahon, 2012). In this regard, Du Plessis (2007) state that collaboration implements the collection of tacit knowledge, useful for companies to control costs and risks related to innovation (Ashok et al., 2016).

At the same time, KM assumes a crucial role within the relationships, managing information and knowledge flows exchange, through effective coordination and collaboration processes (Gloet and Samson, 2019). Cai et al. (2013) argue that KM is able to improve knowledge sharing, particularly when a feeling of trust is present in relationships.

Within collaborative processes new ideas are generated and the function of KM is to add further value through the development of knowledge and the implementation of good communication between partners (Gloet and Samson, 2019). As concerns this aspect, an interesting contribution is the one provided by Hoegl and Schulze (2005), who provided a description of the main and most useful on knowledge management tools and methods: informal events, experience workshops, communities of practice, project briefings, expert interviews, best practice cases, knowledge broker, experience reports, databases and research services. These methods support the creation of new knowledge in new product development and differ from the four knowledge dimensions (forming the "SECI" acronym): Socialization, Externalization, Combination, and Internalization (Nonaka, 1994).

Knowledge-Based Inter-Organizational Collaborations (KBIOCs) must respond to four factors (Cricelli and Grimaldi, 2010): knowledge application velocity; degree of complementarity of knowledge; participated mission of the KBIOC and coordination degree of the KBIOC. Further aspects such as trust, long-term orientation and commitment are considered fundamental to the free flow of knowledge within collaborative relationships (Mavondo and Rodrigo, 2001). Indeed, in 1994 Morgan and Hunt with commitment-trust theory argued for the centrality of trust and commitment within a network of enterprises, rather than power, assuming a positive relationship between trust and cooperation. Therefore, inter-organisational collaboration seems a necessary element in highly innovative contexts, such as the circular economy, where the need for innovation often encounters capacity and infrastructure problems (Den Hollander, 2018).

## ***2.2 Inter-organisational collaboration in circular business models***

The adoption of circular business models introduces a number of changes in the operating practices of companies, which favour a more responsible use of resources and materials in order to substantially reduce the negative impact on the environment and societies (Luthra et al., 2022). Collaborative practices and the exchange of resources among different industries, with the aim of reusing and recycling by-products to achieve zero waste, underpin the circular economy model (Branca et al., 2020). Recent studies have shown that collaboration with stakeholder groups, suppliers, research institutions and other companies, is an enabling factor for the implementation of circular practices (Eisenreich et al.,

2021). It underpins the creation of new knowledge, which can generate radical innovations, identify new business opportunities and meet the challenges of the CE (Potting et al., 2017; Hettiarachchi et al., 2022).

The CE can be considered an “umbrella” concept based on several principles (Baldassarre et al., 2019): waste design, building resilience through diversity, using renewable energy and converting waste into a new resource for reuse (MacArthur, 2013). In this perspective, the academic debate has brought the concept of industrial symbiosis closer to the circular economy (Kanda et al., 2021).

Industrial symbiosis is based on the identification of symbiotic opportunities between different sectors where geographically close companies can exploit synergistic exchanges with great success (Chertow, 2007) and find innovative ways to source inputs and optimise the value of the residues of their processes (Domenech et al., 2019). This approach has been placed at the centre of strategies to promote the transition to the circular economy (Domenech et al., 2019), since it is able to bring together several companies, apparently distant, to achieve shared goals and find better solutions in a circularity perspective, in which products, by-products and waste circulate between different industries (Batista et al., 2018; Tseng et al., 2020). This approach requires a technical effort based on the exchange of waste, resources and energy (Chertow, 2007), and collaborative effort (Baldassarre et al., 2019) in which stakeholders seek together successful solutions around the elimination of the concept of waste in relation to the supply of virgin materials and energy (Bocken et al., 2014). The improvement of resource efficiency and the implementation of industrial symbiosis partnerships are considered key success factors for the company aiming at developing new sustainable products and processes (Castiglione et al., 2021).

Business innovations dictated by circular economy practices can affect the organisational structure of the company, generating changes within the company structure or production chain (for example, identifying new supply chains and new partners with whom work), and generating process and product innovation (Castiglione et al., 2021; Engez et al., 2021). Process innovation requires the adoption of new production methods and the use of technologies that facilitate environmental and social performance (Pichlak and Szromek, 2022), while product innovation is based on the creation of sustainable, easily disposable and recyclable products (Castiglione et al., 2021).

KM acquires a more strategic relevance in circular enterprises, as it must support the sharing of information both inside and outside the company,

contributing to the construction of networks of interactions capable of positively affecting the creation of innovative process and product practices (Geissdoerfer et al., 2017; Brown et al., 2021), thanks to the adoption of methods and tools as teleconference, video conference, whiteboards and chat rooms, e-mail, forum, groupware calendar, shared information spaces workflow management system, group decision support system and active participation in meetings (Ghani, 2009; Massingham, 2014).

Capturing new knowledge for new highly sustainable products, services and technologies becomes a crucial aspect (Gloet and Samson, 2019), as well as the role played by KM in managing knowledge flows among partners and in processing knowledge to produce organisational, process and product innovation (see figure 1).

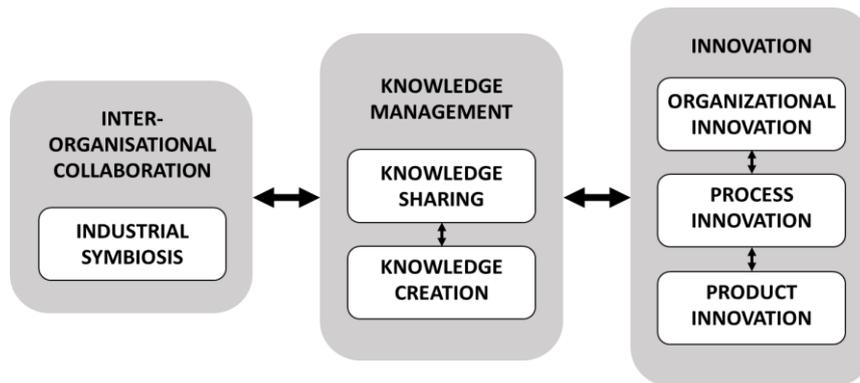

Figure 1 Theoretical framework

### 3 Methodology

Starting from the proposed theoretical framework (figure 1), the empirical research aims to explain KM, within collaborative practices, and how it supports innovation in circular businesses.

The analysis was carried on in two phases. First, we detected information provided by a sample of 117 circular companies of Northern Italy, since this area represents one of the areas with a greater number of companies implementing circular economy practices. Data were extracted from the companies' documents, available on the web platform ([www.economicircolare.com](http://www.economicircolare.com)) and on the companies' official websites; data collection lasted 7 months (from May 2022 to November 2022).

With special reference to the industrial symbiosis, we focused on the presence of actors operating on the same territory with whom the circular practices have been developed; the type of partners and the degree of complementariness of knowledge; the benefits obtained. All these aspects have been analysed in relation to the company profiles. Survey items are illustrated in figure 2.

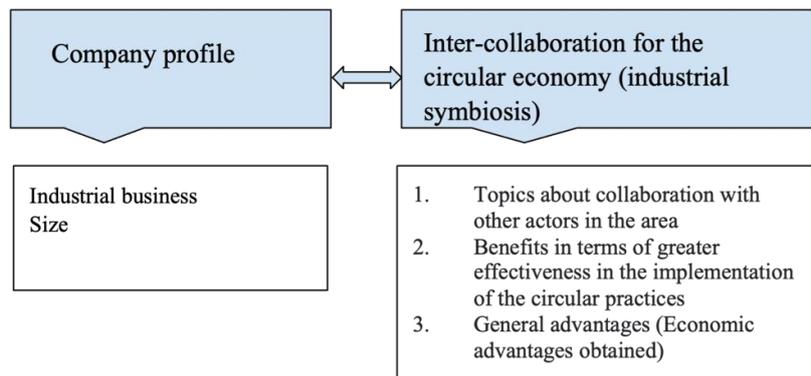

Figure 2 Survey items

In the second phase, we focused on the innovation initiatives implemented by the companies analysed. Only 86 firms have been taken into account in this second phase of the analysis, namely those that declared to collaborate “with local operators”. In addition, we also paid attention to the practices of KM and knowledge sharing. To carry on the second phase of the research process, we performed a content analysis on the documents collected. The table 1 summarises the main characteristics of the dataset. In particular, we selected documents in the same language (Italian) and with a similar length.

The analysis was performed through the software NVivo (Krippendorff, 2012), since it is considered as one of the most suitable tools when carrying on this kind of investigation (Harwood and Garry, 2003; Houghton et al., 2015). In fact, the software gives the opportunity to perform different levels of analysis and to combine results to classify the information obtained and observe linkages among them.

Table 1 Detail of content analysis

Company documents	86
Average length	800 words
Language	Italian
Tool	NVivo
Main topics	Innovation and KM

#### 4 Results

More than half of the circular companies analysed (74%) declared to collaborate with external actors from the surrounding area (figure 3). Of these, 25% declared collaborations with companies in the same industrial sector (namely with actors with the same basic skills); 22% declared to cooperate with research institutions and universities and the same percentage with other companies (from different industrial sector). Smaller percentages are found in collaborations with "other types of actors" 16% and 15% with the combination of several territorial actors included in the previous options (figure 4). This first results highlight the relevance of interconnections between actors with different and complementary skills when dealing with CE initiatives.

Furthermore, it is interesting to observe that most of companies (70%) declared that the inter-organisational collaboration was also due previous relationships with actors located in the surrounding area.

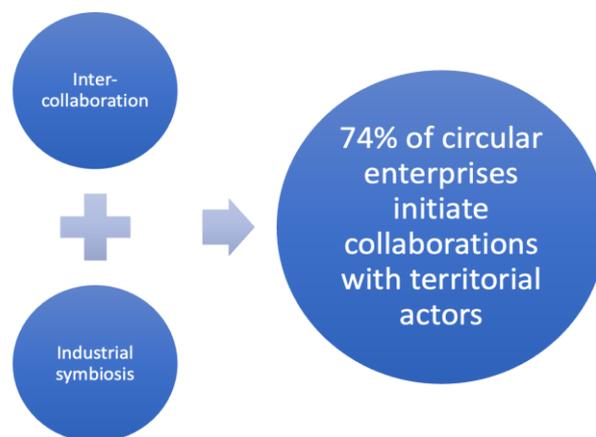

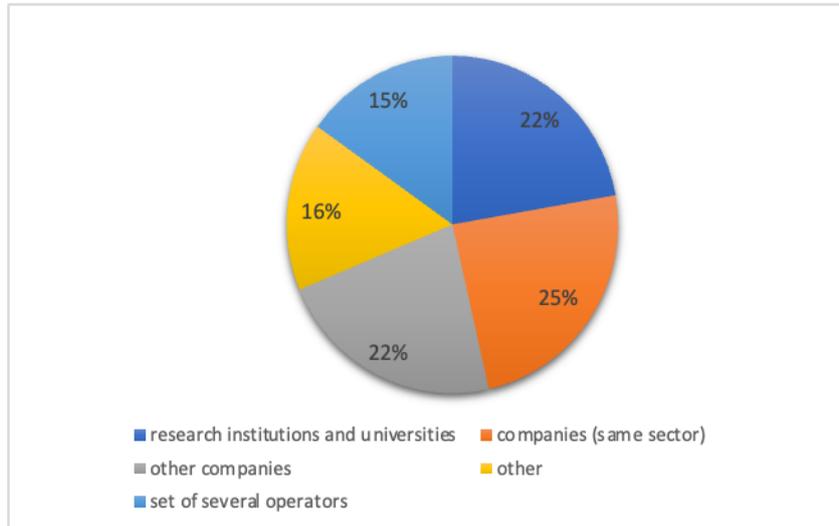

Figure 3 Industrial symbiosis in circular companies

*Figure 4 Degree of complementariness of knowledge*

Another element emerging from the analysis concerns the benefits declared by companies through the cooperation with external actors (Figure 5). 78% of companies collaborating with external partners declared to have obtained benefits. In particular, 52% of companies declared to have achieved benefits in relation to greater effectiveness in the implementation of the circular practices.

However, the majority of companies does not consider the economic benefits as the main goal when establishing collaborations with external actors: in fact, 55% of companies don't mention economic benefits. This is even more interesting if we consider that many of analysed companies are start-ups, born so recently, that they are probably not yet able to illustrate the economic benefits generated by collaborations and circular economy initiatives.

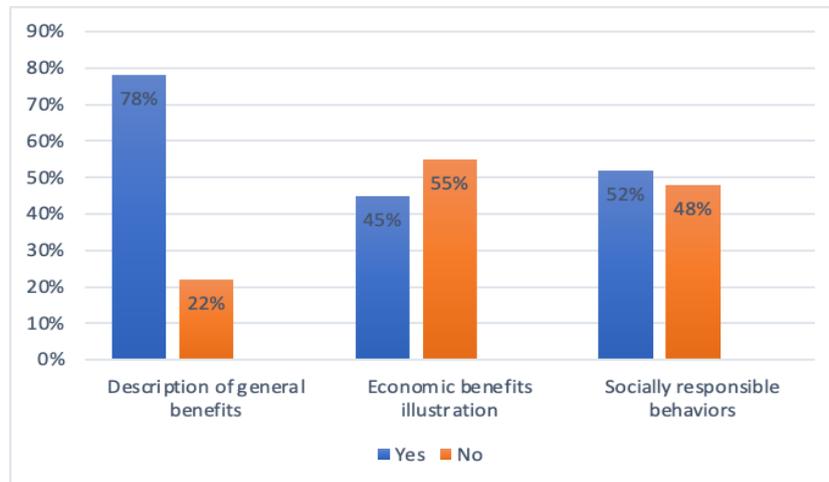

Figure 5 Benefits declared

The results of the content analysis highlight a link between inter-organizational collaboration and circular innovation. First, we detected the most frequently mentioned words (word frequency), in the range of 0.47%-0.10%, with a strong positive connotation and relative frequency of occurrence; the word frequency let us to identify the most mentioned aspects (table 2). It is evident that the content of these words that emerged from the word frequency is mainly of a rational and organizational nature, such as the words politics, products, sustainability, production, services, process and collaboration.

Table 2 Results Word Frequency

Word	Frequency
policies	197
products	179
sustainability	174
production	137
circular	101
services	87
territory	84

reuse	77
process	53
collaboration	43

In order to verify the way each aspect is discussed and taken into account by companies, in the following table we provide a list of quotes (Table 3), that highlights the relevance of the innovation phenomenon within the company documents. In this case, the direct link between innovation and collaboration does not emerge, but it is possible to identify the type of innovation developed by companies. However, it is possible to assume an indirect link, since the content analysis only considered the documents of companies that collaboratively develop circularity practices, although it is believed that this aspect should be further investigated through an analysis of primary data.

In particular, the results of the content analysis highlight the strong innovative capacity recognised by the companies as recipients of various awards; the strategic nature attributed by them to innovation; the importance of the sustainable nature of innovation; the market innovation these companies generate by introducing circular products. Significant elements about KM and knowledge sharing practices don't emerge, although knowledge and knowledge sharing emerge as very relevant phenomena in the literature.

Table 3 Results Text Research

<b>Circular companies</b>	<b>Quotes</b>
Equilibrium (0.75% Coverage)	Environmentally Friendly Innovation Award in 2013; working and investing in innovation, research and development
Ecobnb (0.67% Coverage)	example of tourism business innovation; 1st runner up in the category Business Innovation 2017

SostInnoVi (0.26% Coverage)	Sustainability and Innovation in the Wine Supply Chain
Izmade (0.22% Coverage)	Centre for Art, Innovation and Research dedicated to design
Sumus (0.21% Coverage)	a driver of innovation and a stimulus for improvement

## 5 Discussion, implications and conclusions

Some strong links among the investigated phenomena can be deduced from the research: (1) collaborations with local actors are widespread in circular businesses and are also prompted by the strong interest in the territory. Actors showing a high inclination and propensity to implement CE initiatives also show a strong connection and link to the territory and in their willing to cooperate with local actors and select nearby partners; (2) the industrial symbiosis connects complementary knowledge flows, allowing to obtain advantages with a strong strategic value since they concern the circular practices themselves. In other words, it can be deduced that, without collaborations, the circular companies cannot be created; (3) circular companies have a strong innovative capacity, that can be detected by the declaration of the achievement of various awards, often leading to the creation of new products, concretely contributing to sustainable development.

These findings are in line with previous studies on the strategic value of collaborations in circular economy practices (Cricelli et al., 2021) and on the value of synergistic exchange between actors from the same territory in supporting innovation (Domenech et al., 2019). With regard to the achievable advantages, the literature also underlines the strategic value of collaborations on a territorial scale for the purpose of improving the competitiveness of companies due to the

reduction of the cost of waste disposal, as well as for the costs of procurement of virgin materials (Bocken et al., 2014). This aspect is not sufficiently supported by the results, just as the role of KM and how companies manage knowledge within the collaborations for the development of product, process and organisational innovation does not emerge from the analysis of the secondary data. This brings out the need to conduct further analyses on primary data to better investigate some aspects of the relationship between inter-collaboration, KM and innovation that currently we can only deduce, as they are not directly mentioned by companies.

Further research topics are:

1. the importance of merely intangible aspects in the creation, sharing and management of knowledge. Literature recalls that long-term shared objectives and a relationship based on mutual trust as well as on shared corporate values are fundamental to build profitable collaborative relationships between firms (Mavondo and Rodrigo, 2001), and for there to be a sharing and creation of knowledge that can represent a benefit both for the actors directly involved, and for the other actors of the territory that are not directly involved;
2. the importance of KM in managing and coordinating the exchange of information and knowledge between partners. The theoretical debate underlines that services and technologies are crucial factors (Gloet and Samson, 2019) for the KM, both in managing knowledge flows to and from partners and in processing knowledge. Hence, further aspects to be explored also concern the practical tools used by companies (for example, teleconference, video conference, whiteboards and chat rooms, e-mail, forum, groupware calendar, shared information spaces workflow management system, group decision support system and active participation in meetings) (Ghani, 2009; Massingham, 2014).

In line with the strong linkages that emerged from the analysis, the main implications of this study are above all of an institutional nature; in particular, the role of policies in nurturing the encounter between actors within the same territory emerge as highly relevant, especially in supporting the exchange between complementary knowledge and in stimulating the development of specific skills within territories; these can be useful to the exchange, in a symbiotic approach, among the local actors for the green transition of territories, as well as

promoting the autonomy of local economies, reducing the so-called external resource dependence.

In addition, important managerial implications can also be detected with reference to the relevance of collaboration among local actors, although future research developments on the topics identified are needed.

To this end, future studies will focus on the intangible aspects that affect the creation, sharing and management of knowledge, but whose entity has made their recognition through secondary data complex; therefore, this research will be deepened through semi-structured interviews to key-informants, that are already identified in the previous phase of analysis. In detail, the main aspects the interviews will focus on are: the direct or indirect link between collaborations among local actors and innovation; the direct or indirect link between collaborations among local actors and innovation developed through CE initiatives; how market dynamics are affected by the collaborations among local actors.

In conclusion, our study offers a double contribution: (1) the provided framework will be adopted to advance the present study involving key informants through semi-structured interviews to offer managerial implications and recommendations; (2) the framework represents a contribution to the theoretical debate that can be applied to different research contexts.

### **Abstract**

More and more companies are winking at sustainability through the adoption of circular business models, which are based on resource and waste minimization to establish a renewable closed-loop production and consumption system. Departing from a linear take-make-use-dispose setting, circular economy principles lead businesses' transition toward the development of circular products and processes. Drawing on past studies that associate circular businesses with the adoption of digital technologies or open innovation approaches, this research seeks to shed light on the role of openness in companies' innovation approach and digital technologies in fostering a circular business model development. In this vein, the authors' purpose is to quantitatively evaluate such elements as predictors of circular business model development and thriving. After pointing out some key features of the research, the paper concludes with the presentation of the expected

findings and the discussion of the potential theoretical and practical implications of the study.

**Keywords** – Circular Economy, Open Innovation, Digital Technologies, Dynamic Capabilities, Resource Orchestration

**Paper type** – Academic Research Paper

## 1 Introduction

In recent years, circular economy (CE) has prompted considerable debate among researchers and practitioners about the fundamental role of economic organizations in driving environmental preservation and social well-being. More and more companies are indeed gradually translating their sustainable purposes into business practices by giving rise to circular business models (CBMs), yet the harsh reality proves that it is not enough (Aranda-Usón et al., 2020; Bocken et al., 2016; Geissdoerfer et al., 2020; Ranta et al., 2018). In spite of the visible effort of policymakers, academics and managers, the world is currently less than 9% circular, while it is supposed to at least double by 2032 to avoid climate breakdown (Circle Economy, 2022; European Commission, 2020a; Pizzi et al., 2020; United Nations, 2021). This testifies how companies around the world are taking their first steps towards a regenerative production system but, most importantly, it demonstrates that there is still a long and impervious road ahead. Countless challenges and opportunities stand in front of academia and businesses, including the chance to boost this sustainable shift by adopting collaborative innovations or surfing the wave of digital transformation.

Drawing on previous studies (e.g. Brown et al., 2019; De Angelis et al., 2023; Hina et al., 2022), two common drivers that can potentially affect the transition toward a circular economy by fostering companies' adoption of circular principles are represented by open innovation strategies and digital technologies adoption. Open strategies, which involve cross-boundary companies' interaction to develop circular innovations, showed to be strictly related to the transition toward a renewable production system (Brown et al., 2021; Jesus & Jugend, 2023; Köhler et al., 2022). On the other hand, digital technologies have the potential to significantly enhance circular business development by leveraging resource optimization, the orchestration of closed-loop systems, circular product design, collaboration, and waste management (Hina et al., 2022; Khan et al., 2021b; Liu et

al., 2022). Open innovation strategies and digital technologies adoption, together, have also the potential to support co-innovation processes of circular businesses (Bresciani et al., 2021; Mubarak et al., 2021; Santoro et al., 2018; Walker et al., 2023). As a result, the purpose of this article is to unveil how an open innovation approach and digital technologies adoption foster circular economy implementation. Besides, the authors also considered how key dynamic and recourse orchestration capabilities can support open innovation processes and companies' digital transformation in approaching a circular transition.

The main gap this research aims to fill is related to testing the predictor effect of those antecedents, by offering new insights based on a quantitative observation. Indeed, from researchers and practitioners' perspectives, a quantitative investigation of this phenomenon in circular businesses is highly demanded.

## **2 Theoretical background**

The burgeoning literature devoted to the circular economy often deals with factors that can improve this kind of sustainable practices in economic organizations. It includes the openness of companies to collaborate with other entities to develop circular products and processes, as well as the adoption of digital technologies to enable and enhance circular businesses.

Drawing from CE literature, academics have put forward that inter-organisational collaboration is a key success factor to develop circular-oriented innovation. In fact, Brown et al. (2019, p3) define circular-oriented innovations "as the coordinated activities that integrate CE goals, principles, and recovery strategies into technical and market-based innovations, such that the circular products and services that are brought to market purposively maintain product integrity and value capture potential across the full life-cycle". While circular-oriented innovation is a novel and little-understood concept, we can identify, in collaborative innovation literature, some antecedents to the adoption of such innovation models. In fact, literature shows that the primary motive for exploring strategic collaborative innovation is the increase of knowledge flows (Appleyard & Chesbrough, 2017). Other reasons that push companies to adopt such models are the increased competitiveness and the market share of innovations, the access to resources or to new markets or the acquisition of new skills (Brown et al., 2019; Bocken & Ritala, 2021). However, circular-oriented innovation exposes the firm to

the opportunistic behaviours of the partners involved in the process (Pouwels & Koster, 2017). Potential partners involved in circular-oriented innovation must be aligned in terms of vision and sustainability policies to overcome the possibility of reputation pitfalls. A practical example of companies' alignment can be found in those that approach circular economy through reverse logistic processes (Cricelli et al., 2021; Mishra et al., 2021). However, despite open innovation strategies adopted by circular businesses have been addressed in previous studies, to the best of the authors' knowledge a measurement of its impact on circular business implementation is still missing.

On the other hand, literature highlighted as digital transformation has a critical role in supporting business sustainability and, more specifically, circularity (Biondi et al., 2002; Hina et al., 2022; Khan et al., 2021b; Kristoffersen et al., 2020; Liu et al., 2022). It has proved to be crucial for transitioning from a linear to a more circular production, with demonstrably positive impacts on both the environment and the economy (European Commission, 2021; Pizzi et al., 2021; Ranta et al., 2021). In practice, digital technologies (e.g., IoT, big data, blockchain, virtual reality, AI and machine learning) can support companies' businesses' circular transition path by transforming CE principles into feasible and practical activities (Chauhan et al., 2022; Ciliberto et al., 2021; Kerin & Pham, 2019; Rajput & Singh, 2022; Rusch et al., 2022). Yet, scant research deals with digital technologies adoption as a predictor element of circular economy implementation from an empirical point of view.

As the conversion, or establishment, of circular practices represent a disruptive change in production and consumption models, as well as in innovation processes, this process is typically addressed in circumscribed agile environments or ambidextrous formations (Bresciani et al., 2018; Chaudhuri et al., 2022; Rialti et al., 2019). From a transitional perspective, the implementation of a circular business may require some dynamic capabilities for companies, in terms of sensing and seizing opportunities, so as to reconfigure the business model according to a renewable production system (Eisenhardt & Martin, 2000; Khan et al., 2021a; Teece, 2014). On the other hand, resource orchestration capabilities concern the optimization of resource management by companies to achieve a competitive advantage (Kristoffersen et al., 2021; Teece, 2014; Gong et al., 2018). Resource orchestration seems to be essential in solving internal conflict and improving resource complementarities in organizations, while supporting the dynamic capabilities needed in facilitating circular innovation (Wang et al., 2020;

Wales et al., 2013; Walker et al., 2023). They can thus represent an incentive that improves open innovation and digital technologies adoption as circular economy implementation antecedents.

### **3 Research design**

As a quantitative deductive study, it is established on the empirical observation of European for-profit organizations that implemented, or are integrating, circular economy principles in their businesses. The authors adopt a non-probability sampling to gather data from a subset of the population of circular companies in Europe to investigate the role of an open approach and the adoption of digital technologies alongside the circular product or process development. The independent and dependent variables of our cross-sectional study (i.e. open innovation, digital technologies adoption, and circular economy implementation) are measured employing items assessed in previous studies (e.g. Khan et al., 2021; Mina et al., 2014; Mubarak et al., 2021), by means of a five-point Likert scales that range from "Totally disagree" to "Totally agree". This empirical study will be based on at least 300 valid responses collected by online surveys delivered through the Prolific online platform (e.g. Talwar et al., 2021). Data validity and reliability will be assessed through confirmatory factor analysis (CFA), to then test our assertion by means of a covariance-based structural equation modelling (CB-SEM) technique.

### **4 Expected findings and research implications**

As such, this study aims to observe if intra-organizational collaboration, in the form of resource exchange in an open innovation setting, and companies' digital technologies implementation can effectively affect circular business establishment. Authors expect to outline a significant positive relationship between our independent (i.e., open innovation and digital technologies implementation) and dependent (i.e., circular economy implementation) variables, alongside a significant positive moderating effect of dynamic and resource orchestration capabilities (see Figure 1). Thus, this study will contribute to circular economy literature as the first empirical-based quantitative study to prove the advanced relationships on a representative sample of European circular businesses.

Both open innovation and digital transformation need to be further studied in circular businesses due to their important implications on processes such as

reverse logistics. Indeed, business digitalisation has been noted to be a backing element in configuring reverse logistics processes for collecting waste and raw materials, so secondary resources can be transformed into new products or service supplies through the implementation of a circular ecosystem for granting a renewable production and consumption system (Ciliberto et al., 2021; Rajput & Singh, 2022). In this vein, also intra-organizational collaborations and open innovation strategies concur to shape business transition toward a circular model enabling circular product and process development (Cricelli et al., 2021; Mishra et al., 2021).

From that perspective, the authors will be able to offer some insightful contributions to the circular economy literature (), as well as respect to open innovation studies (Appleyard & Chesbrough, 2017; Bocken & Ritala, 2021) and the literature stream that deals with digital transformation in business realities (). This study will also offer some practical implications to circular businesses in the form of recommended practices which can support circular transition in sustainable-sensitive businesses.

### **Abstract**

The food sector has been one of the industry fields most severely affected by the Covid-19 pandemics. The food industry, indeed, manufactures essential items, and as such, it is expected to continue supplying goods, despite the (even exceptional) external disruptions. This is why at the beginning of the pandemic period, there has been a great deal of worry regarding food production, processing, distribution, as well as significant changes in the demand for finished products, with various observed phenomena. The Covid-19 pandemic also had a negative impact on the food supply chain from a financial point of view, because of restrictions in labour, unavailability of suppliers and difficulties in quickly finding alternative vendors.

This paper aims at summarizing the key issues experienced by the food supply chains during the Covid-19 pandemic and then at delineating appropriate strategies for building more resilient chains in the post-pandemic period. To achieve this stated aim, the chosen

research methodology is the systematic review of the literature, as the food industry was one of the most investigated systems in the pandemic and post-pandemic era. Results are expected to categorize the available knowledge about the role of Covid-19 on food supply chains, as well as to provide some useful guidelines for managing food supply chain in the future.

**Keywords** – Covid-19, food supply chain, resilience, literature review, post-pandemic strategies.

**Paper type** – Academic Research Paper

## 1 Introduction

The Covid-19 pandemic has disrupted social and economic life worldwide (Kwon, 2020). Still in 2023, it leaves its shortcoming and even if we are entering a post-Covid era, cannot be described as completely over. Hence, how to look at the way of life has changed in many contexts, and new solutions and approaches have been defined either as immediate countermeasures to the Covid-19 pandemics or as permanent measures to better cope with (not only) exceptional disturbances in the future (Bottani et al., 2022; Telukdarie et al., 2020).

The food sector has been one of the industry fields most severely affected by the Covid-19 pandemics. Food supply chains (FSCs) are networks of companies often spread worldwide, that collaborate for procuring raw materials (from the agricultural field), manufacturing a food product, delivering it to the customer and sometimes managing returned goods. As such, a FCS typically consists of five stages, such as agricultural production, postharvest handling, processing, distribution/retailing, and consumption.

During the pandemic period, there has been a great deal of worry regarding food production, processing, distribution, as well as significant changes in the demand for finished products, with various trends. Looking at the *processing* stage, the food industry manufactures essential items, and as such, it is expected to continue supplying goods, despite the (even exceptional) external disruptions, which could cause the unavailability of raw materials or intermediate goods (*agricultural production* and *post-harvest* stages). Restrictions in labour, unavailability of suppliers and difficulties in quickly finding alternative vendors (Montenegro & Young, 2020) are among the reasons why the procurement chain could have been interrupted by the Covid-19 pandemics. Researchers have therefore analyzed the quality of the service level during the pandemic in

*distribution/retailing* activities, by evaluating the rate of cancelled orders (Zhang et al., 2020), unfilled orders (Altig et al., 2020), shipping delays (Gereffi, 2020), and out of stocks (Pantano et al., 2020). At the same time, looking at the *consumption* stage, it is also reasonable to expect that in crisis situations, people tend to buy essential goods (such as food or medical products), while avoiding purchasing non-essential ones (Nader et al., 2022). Accordingly, some authors (e.g., Borsellino, 2020; Loske et al., 2020) have observed that the early lockdown measures have changed the people's purchasing behavior, involving the so-called "panic buying" and causing unexpected peaks of demand for food products; at the same time, however, an opposite trend (i.e., a decrease in demand) was caused by consumers' less frequent store visits and restrictions to movements (Ramakumar, 2020). By the way, Rinaldi et al. (2021) have also found that the impact of Covid-19 on food consumption depends on the type of food category and distribution channel. Overall, early analyses carried out during the first stage of the pandemic have highlighted various aspects, somehow contrasting, related to demand-side shocks and the sudden changes in consumption patterns in FSCs (Hobbs, 2020a). Shafiee et al. (2022) have also noted that a further challenge for food or pharmaceutical products is the perishability of the items handled, which involves additional risks, exacerbated in a pandemic period.

On the basis of the above evidence, some authors (e.g., Aday & Aday, 2020) have delineated a strategic preparedness and response plan including all the measures to guide all the nations to respond to the virus consequences. Also, other authors have investigated the immediate and medium-term strategies for counteracting the pandemic emergency in various contexts, including the FSC (Rinaldi & Bottani, 2022). Because of the progress of the pandemic emergency and the beginning of the "post-Covid-19 era", the time is ripe to conduct an analysis on the immediate and (most importantly) medium-term strategies of food businesses to come out stronger and outstanding for the future (Jagt et al., 2020; Alabi & Ngwenyama, 2023). This is the aim of the present paper, and to achieve that goal, the chosen research methodology is the systematic literature review (SLR), as the FSC was one of the most investigated systems in the pandemic and post-pandemic era.

The remainder of the paper is organized as follows. Section 2 provides an overview of the selected research methodology. Section 3 shows the key results from the SLR and discusses them. Section 4 comments on the implications from this study, the need for future research directions and finally concludes.

## **2 Methodology**

To evaluate the state-of-the-art of pandemic and post-pandemic strategies implemented in the FSC, an SLR was carried out. SLRs aim to search, appraise, synthesize, and analyse all the studies relevant for a specific field of research (Hamja et al., 2019; Palmarini et al., 2018). Moreover, a contextualized analysis of the literature typically helps create or improve our knowledge of 'why, 'in what circumstances' and 'when' certain phenomena can be observed (Durach et al., 2021). This kind of review was selected because it allows to construct and understand specific theoretical concepts, obtain the information needed to construct a set of relevant bibliographical references, analyse the results at a quantitative and qualitative level, as well as suggest future research directions on the subject (Seuring et al., 2005). A typical SLR consists of three steps, i.e., (1) the creation of the sample of papers; (2) the collection of the relevant data; and (3) the analysis of these data (Liao et al., 2017); these steps are illustrated in the subsection that follow.

### ***2.1 Creation of the sample of paper***

The sample of papers relevant to this study was obtained by querying the Scopus database (<http://www.scopus.com/>) in March 2023. The search terms used were quite general in nature, so as to be sufficiently exhaustive in the list of papers retrieved. In particular, the following two queries were combined:

1. "food supply chain" AND "Covid-19";
2. "food supply chain" AND "post-Covid"

The search for the above terms was made in the paper abstract, title and keywords. Results were limited to papers published on journals (with document type "article" or "review") and written in English; no constraints were instead set for the publication timespan. As the terms used are not ambiguous, all the papers resulting from the query were considered as valid and were taken into consideration for inclusion in the sample of documents.

### ***2.2 Data collection***

For each of the queries described above, the "export" function of Scopus was used to download the relevant information about the papers. In particular, besides the paper main data (title, authors, publication year, journal title, etc.), the

list of keywords (“author keywords”) was also exported in .csv file. The two files were then imported into a Microsoft Excel™ spreadsheet for further processing.

### 2.3 Data analysis

Some preliminary elaborations were made on the two groups of papers for checking (and removing) the duplicated studies. Statistical analyses were then made on the papers to highlight the trend in time of the publications. Some keyword analyses were also made taking inspiration from the procedure by Fadlalla and Amani (2015). Such procedure suggests analysing the frequency of any keyword (i.e., the number of occurrences in the publication timespan) coupled with its persistence in time (i.e., the number of years since a keyword was used for the first time), for an effective classification of the resulting research topics.

## 3 Results and discussion

The two queries made on Scopus returned 369 and 29 paper respectively. A preliminary analysis revealed that 28 papers were common across the two queries, while one paper only was specific of the query referring to “post-Covid”. This implicitly means that almost all the papers dealing with “post-Covid” strategies also refer to the “Covid-19” period. The sample of unique papers, therefore, consists of 370 studies (Figure 1). The full list of the documents cannot be reproduced in the paper nor in the reference list, because of the page limits, but interested readers are welcome to ask the authors for a copy of the database.

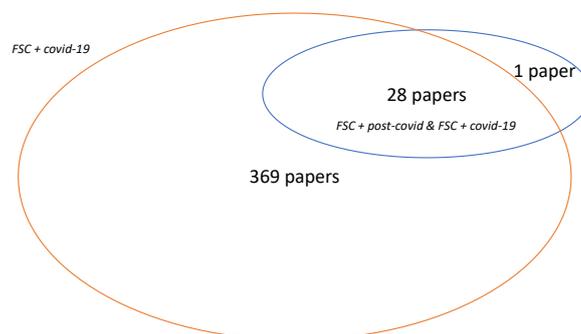

Figure 1: sample of papers.

In terms of the trend in time, the papers retrieved were all published between 2020 and 2023, as it was expected, given the fact that Covid-19 appeared in 2020. Implicitly, this also makes the analysis of the persistence of keywords less important compared to the analysis of their frequency. Looking at Table 1 and Figure 2, it can also be seen that, in general, the number of publications about food supply chains and Covid-related issues has increased in time, growing from 54 in 2020 to >140 in 2021 and 2022 (obviously, results for 2023 are partial). Most of the studies (341 out of 370, >92%) refer to FSC and Covid-19 only, and their trend in time follows the same trend of the whole sample of papers, namely it highlights a significant increase from 2020 to 2022. Similar considerations can be made for the group of papers which are common across the two queries, while the paper dealing with post-Covid aspects only was published in 2022.

Table 1: publication year vs. query.

Publication year	FSC + Covid-19	FSC + post-Covid & FSC + Covid-19	FSC + post-Covid-19	Total
2020	48	6		54
2021	131	11		142
2022	131	10	1	142
2023	31	1		32
<b>Total</b>	<b>341</b>	<b>28</b>	<b>1</b>	<b>370</b>

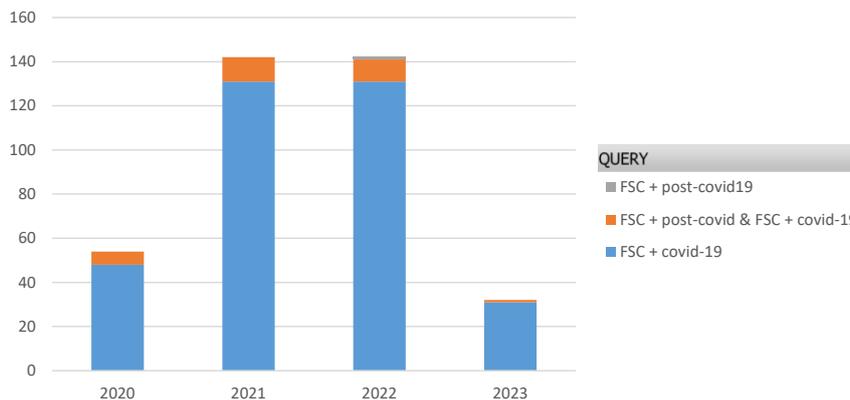

Figure 2: trend of the publications in time.

For these papers, the keywords were then elaborated. In this respect, 25 papers which lack the authors' keywords were omitted in the analysis. A further

preliminary consideration is that the keywords used for the query, and in particular those referring (or related) to Covid-19 and FSC, are obviously expected to have a frequency significantly higher than that of other keywords; hence, they were maintained in the analysis but their reference to the search terms was highlighted, for a correct interpretation of the results. Finally, a manual check of the keywords revealed that authors often use slightly different keywords to express a similar (or the same) concept. This is the case for "Covid"/"Covid-19" or "supply chain"/" supply chains"; hence, keywords were screened and grouped into the same semantic area. This led to a list of 968 unique terms. To be more effective, the analyses of these terms were focused on:

- keywords whose frequency is at least 3, i.e.,  $\cong 100$  terms. This is expected to provide a general overview of the research topics (and related macro-themes) most debated in the literature about FSC, Covid-19 and post-Covid;
- keywords appearing in papers retrieved using the query related to "post-Covid" only. This choice is expected to expressly highlight the strategies suggested in the post-pandemic period;
- keywords appearing in papers published in 2023 (although this set of papers is partial at the time of writing), with the aim to highlight the were recent research topics.

Table 2 displays the list of keywords with frequency  $\geq 3$ , their relationship with the query made and their classification into macro-themes. Most of the terms, as expected, are somehow related to the queries made, but focusing on terms that are not directly related to the keywords used for the queries, some interesting considerations can be made. A numerous groups of papers deal with the area of *agriculture*, which represent the procurement stage of FSCs, as previously mentioned. This confirms the primary role of this phase in the FSC and at the same time suggests that the attention should be directed towards this stage. A second relevant theme is that of the *consumer*, whose behaviour and purchasing patterns had a relevant role in determining the demand for food products (Chowdhury et al., 2021; Nandi et al., 2020). The impact of the pandemic has in fact led to a different consumption habit of consumers, with fish, chicken, egg, mutton, beef and pork becoming less available or available at a higher price on the market (Aday & Aday, 2020).

Some studies have been conducted in specific *countries*, which is a further interesting aspect, as it suggests that Covid-19 has attracted the attention of

researchers in various countries. Developing countries, in particular, suffered most because of the lack of resources and lack of food for all people.

*Decision methods* are another branch of research which has become popular in literature; it is to be assumed that specific decision support systems have been developed for dealing with Covid-related issues. *Sustainability* has been addressed in numerous studies as well, in its various facets, from circular economy to sustainable development goals. About *food safety*, in the FSC there is the need for implementing measures for safeguarding food quality, such as primarily, regulations and laws (mandatory) and use of standards (voluntary). Besides the well-known practice of social distances, which is common across various industry fields, in the FSC control measures encompass food staff health, personal hygiene, protective equipment (gloves and helmets), sanitization of work areas and surfaces, as well as safe handling, preparation, and delivery of food.

Finally, *technologies* are related themes (e.g., digitalization, Industry 4.0, etc.) start being investigated in Covid-related studies. The rise of the e-commerce and other electronic channels, which were the only way of reaching the customers in the Covid-19 period, are good examples of digitalization practices; Rinaldi & Bottani (2022) have found that digitalization within the food SC is an ongoing process, which is expected to be accelerated by the pandemic. By the way, technologies could also facilitate social distancing, reduce business travels, and possibly increase food security (e.g., by providing reliable traceability data), and as such, they are welcome in the FSC (Hobbs, 2021a, b).

Table 2: list of keywords with frequency  $\geq 2$  and classification.

<b>Keyword</b>	<b>Frequency</b>	<b>Year of appearance</b>	<b>Related to the query</b>	<b>Macro-theme</b>

The papers retrieved using the query related to the “post-Covid” period have returned the keywords listed in Table 3. These keywords all refer to 2022 as the publication year of the paper, and the frequency is in general low. Nonetheless, some of these terms suggest countermeasures to Covid-19; this is for instance the case for “labour mobility” or “regularization”, which, coupled with the context of agriculture, could suggest remedies against absenteeism of workers.

Table 3: list of keywords in papers relating to “post-Covid”.

<b>Keyword</b>	<b>Frequency</b>	<b>Year of appearance</b>
Covid-19	2	2022
seasonal migration	1	2022
regularization	1	2022
industrial agriculture	1	2022
social conditionality	1	2022
Labour mobility	1	2022
migrant farmworkers	1	2022

The papers published in 2023 have instead returned the keywords listed in Table 4. All these keywords are single search terms, as can be seen from the frequency; hence, for making the analysis more effective, again a classification

into macro-areas has been carried out. From that classification, it can be seen that *sustainability* is confirmed in its importance even in recent studies, together with other themes related to *risk management* (e.g., *safety/risk management* or *resilience*). It is interesting to note that *sourcing* is a debated topic among recent studies, confirming the relevance of the procurement phase (agriculture) in the FSC. The general role of sourcing decisions in building a resilient supply chain is well-known (see, e.g., Christopher & Peck, 2004), but it is interesting to observe that this strategy is popular in food systems. The role of *decision methods* has also gained importance among recent studies.

Table 4: list of keywords in papers published in 2023 classified into macro-themes.

Macro-theme	Keyword
Agriculture	fresh agricultural product; Crop classification; crop-type mapping
Covid-19	long-term pandemic disruptions; Novel pandemic; Emergency; Covid-19 resurgence
Countermeasures	Organizational flexibility
Country	Bangladesh; South America
Decision methods	two-stage sparse distributionally robust risk mixed integer optimization model; random yield; Greenfield analysis; Network optimization; location allocation; Distributionally robust optimization; Chance-constrained programming; Contingency planning; DS-HPSO algorithm; Absorptive capacity theory; deep learning
Food products / FSC	milk consumption; Vegetable supply chain; global food supply chain; food protection; milk sales; Food supply chain performance measures; Food Hubs; milk vendors; nutrition intake; Farmer producer organization; fish consumption; agri-food waste; contaminated cold-chain food and packaging
Resilience	Supply chain reliability; vulnerability assessment
Risk management / safety	Supply chain risk management; safety climate
Sourcing	Supplier relationship; supplier selection; multi-sourcing
Strategy	supply chain integration; Knowledge management;
Sustainability	Sustainable transition; sustainable distribution; sustainable production; social and environmental sustainability; food supply chain sustainability
Other	Vegetable marketing; urban markets; temperature; potential applications; power structure; Sentinel-2; value chain disruption; vehicle routing; presenteeism; pharmaceutical supply chains; worker; Theory of organizational creativity; valorisation; production and operations management; Geopolitical tension; government subsidy; online services; Nexus; Horizon scanning; minerals; informal sector; consumer preference; Direct marketing

#### 4 Implications and conclusions

The Covid-19 pandemic has severely affected the FSC, but, as per any unexpected disturbance, it is paramount to take advantage of the recent emergency for exploiting the acquired experience to convert the Covid-related disruptions into opportunities for improvement.

In this respect, the set of analyses presented above highlight some key strategies implemented in FSCs for counteracting the pandemic emergency or expected to be implemented in the future for building more robust FSCs. First of all, the role of the procurement phase is of certain importance, as it has been highlighted either in the general analysis of keywords (in the macro-theme of *agriculture*) and in the recent studies relating to *sourcing*. This is the obvious consequence of the fact that availability and supply of a wide range of raw materials, intermediate goods, and finished products have been seriously disrupted by the Covid-19 pandemics. It is therefore to be expected that the future of FSCs will see a reinforcement of the procurement stage, for making the systems more reliable.

The role of technologies, in their various forms (e.g., digitalization or Industry 4.0), is also relevant, and is expected to gain further attention in the future, in line with the progressive digitalization of the FSC.

Similar considerations can be made for the food safety area, which has always played an important role in Covid-related literature. Because the need for ensuring food safety and quality will not cease with the Covid-19 end, it is to be expected that the attention paid to these aspects will increase in the future.

The above considerations, in the meanwhile, suggest as many lines of research that could be undertaken in future studies. In particular, research activities for making the FSC more robust should possibly target the sourcing phase, the digitalization of the system and the food safety issues. Evaluating these aspects on a later date could provide evidence of the progress achieved in this respect.

### **Abstract**

In the following article, we apply a set of machine learning algorithms to analyse a set of 445 Californian Hospitals. We investigate a variable that can be considered as a synthesis of the economic, financial and organizational performance of the hospital i.e. Net Income. First of all, we have applied a regression analysis with OLS-Ordinary Least Squares to verify the presence of significant relationships among the variables in respect to Net Income. Furthermore, we have applied the k-Means algorithm optimized with the Elbow Method to verify the presence of groups of hospitals in the dataset based on more than 200 variables and centred on Net Income. Finally, we propose a comparison among eight different machine-learning algorithms to estimate the future value of Net Income based on an historical series in the period 2014-2018.

Our idea is that the area of inefficiency that are showed thanks to the regression analysis can be optimized with the application of AI and Lean Management. Specifically, the efficiency of hospitals to manage human resources and specifically physicians can be

improved with the application of telemedicine and organizational tools, that can increase either the performance of the hospital and the level of care offered to patients. The mix of Artificial Intelligence and Lean Management can promote better models in healthcare, reducing costs, improving the quality of services, increasing the level of human resources especially physicians, to create a more sustainable and reliable healthcare system.

**Keywords** –Telemedicine, Lean Management, Knowledge Management, A Healthcare, Data Management

## 1 Introduction

The following abstract shows the application of digitization technique in the context of Lean Management applied in healthcare organizations. Specifically the article provides an innovative methodological approach oriented to describe healthcare complex systems improving organizations in terms of Lean Management by means Artificial Intelligence (AI) algorithms and digital platforms monitoring patients in real time. The efficiency of healthcare organizations is expressed in terms of reduction of costs, optimization of human capital, and ability to design the organizational structure to provide healthcare services to patients.

AI-Data Management processes are enabled by the use of medical devices and sensors (Magaletti, et al., 2021) offering the possibility to acquire a large amount of healthcare data. These data converge in software platforms for remote real time monitoring (Massaro, et al., 2018) thus creating a communication among patients, healthcare professionals, and healthcare organizations. Data are used also for the prediction of the health condition of patients. Healthcare platforms and medical devices are furthermore applied for tele-rehabilitation of patients (Massaro, et al., 2022). Data analysed through the application of AI algorithms generate additional information about comorbidities, and the determinants of diseases (Massaro, et al., 2022), (Massaro, et al., 2022), (Massaro, et al., 2022) allowing to optimize healthcare policies. In Fig. 1 is sketched a simplified model of healthcare organizational model improved by digital monitoring platform and AI algorithms. Covid-19 has increased the level of digitization in medical procedures promoting the application of knowledge management in healthcare organizations through process-based information coordination systems (Elia, et al., 2022). The digital and the AI technology can be used to improve the Lean Management

model typically adopted to increase the efficiency in healthcare organizations (La Forgia, et al., 2022). Healthcare organizations oriented to Lean Management have more probabilities to apply a Value Based Model improving their ability to respond to changes in demand of healthcare services (Rosa, et al., 2020). Digitization is a tool to promote Lean Management even in its connections with value Based Model in healthcare (Marsilio & Rosa, 2020). The combination of Lean Management model and Six Sigma method has positive effect on the ability of healthcare organizations to promote more qualitative services (Marolla, et al., 2021). Furthermore, telemedicine and Lean Management can increase the efficiency of hospital consultation processes as in the case of cardiovascular disease (Bossone, et al., 2022). The application of telemedicine and Lean Management change the relationship between doctors and patients: doctors can visit more patients based not only on geographical proximity, and patients can access more easily to doctors consults overcoming the limits of the distance. Hospitals and healthcare organizations are in a certain sense de-territorialized, and can operate also in distance, through telemedicine. AI-Data Management can also have positive effects on the healthcare system at local level: thanks to the predictive ability, AI-Data Management can forecast the patients' health and the future demand of healthcare services and can help healthcare organizations to change their offer based on the updated socio-economic and demographic conditions of the population. Healthcare organizations can acquire efficiency in the application of a more agile, flat, flexible and data-driven organizations. The combination of AI-Data Management and Lean Management can shape the functioning of healthcare organizations towards the creation of more value added either for healthcare workers either for patients. Finally, the model structured in Fig. 1 allows to optimise different processes about homecare assistance, human resource management, clinical/assistance protocols, and other financial resources management.

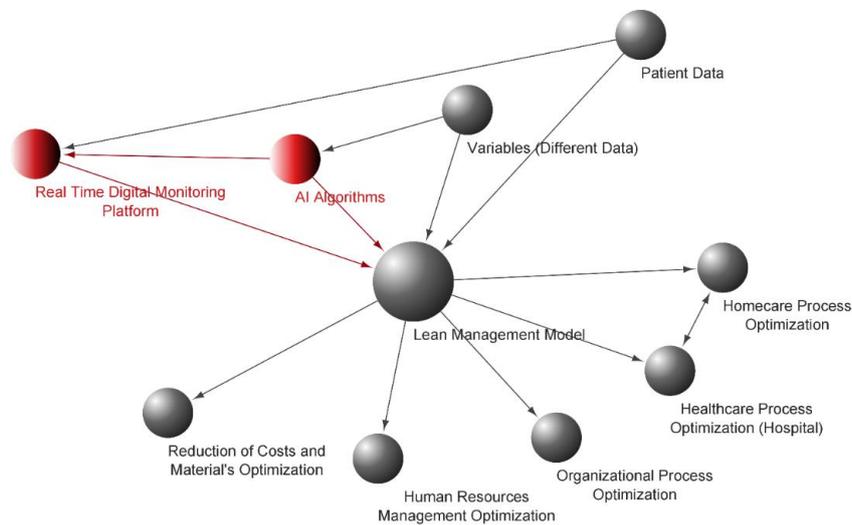

Figure 10. Improvement of the Lean Management model in healthcare processes by AI and telemedicine platforms enabling remote real time monitoring.

The abstract shows the relevance of an interdisciplinary approach in the design of the offer of healthcare services and products improving efficiency through the application of AI-Data Management and through optimised Lean Management procedures. Furthermore, the conjunct application of AI-Data & Lean Management can promote a more efficient orientation towards quality and equity in healthcare organizations (Rosa, 2017).

*Linkages between AI and Lean Management.* Possible links between AI and Lean Management-LM are mainly due to the prediction of risks and inefficiencies. In particular the main areas of connection are:

- Human Resource Management-HRM optimization;
- whole organization re-engineering;
- movement and allocations of resources according to the new organization model;
- re-arrangement of organization according to a new optimized hierarchical structure;
- change of assignments of human resources according to the predicted risks for patients;
- evaluation of results, and automatic generation of Key Performance Indicators-KPI based on qualitative and quantitative metrics.

These linkages create a common framework for the jointly application of AI and LM.

*Data.* We will use open data-possibly Kaggle- processed with machine and deep learning algorithms to investigate the efficiency of the implementation of artificial intelligence models in conjunction with data driven lean management models. The extended version of the work will contain statistical tables and the numerical representation of the results with graphs and visualizations including AI probabilistic errors and evaluations.

*The Main Contributions of the Work.* The main contribution of the work consists in the description of connections among multiple variables either endogenous either exogenous, that are able to design essential characteristics of healthcare management. Specifically, we will focus not only on the logical and methodological applications of the AI-LM in healthcare, but also on the definition and evaluation of the associated metrics. The original contribution consists in the joint application of AI-LM in healthcare organizations. The literature presents various cases of application of AI in connection with LM in the manufacturing sector (Helmold, 2020), (Chen & Wang, 2022), (Perico & Mattioli, 2020), (Ahmed, et al., 2022), (Helmold, et al., 2022). Nonetheless, the conjunct application of AI and LM in the healthcare misses significant investigations in the scientific literature.

## **2 Data Analysis with the Application of OLS Models**

We have used data from 445 Californian hospital in the period 2017-2018 (CHHS, s.d.). The dataset is composite since it contains either financial data from balance sheet either operational data able to represent the economic organization of the hospital. We choose to estimate the level of Net Income i.e. the difference between revenues and costs as a proxy for hospital efficiency. The estimation of the value of Net Income has been performed with the application of the OLS-Ordinary Least Square. We have estimated the following equation:

$$\begin{aligned}
& \text{NetIncome}_t \\
& = a_1 + b_1(\text{OtherSelectedUtilizationInformation})_t \\
& + b_2(\text{GrossPatientRevenuebyRevenueCenterGroup})_t \\
& + b_3(\text{ExpensesbyNaturalClassification})_t \\
& + b_4(\text{SummaryIncomeStatement})_t \\
& + b_5(\text{GrossInpatientRevenuebyPayer})_t \\
& + b_6(\text{OutpatientVisitsbyPayer})_t \\
& + b_7(\text{ProductiveHoursbyEmployeeClassification})_t \\
& + b_8(\text{HospitalPersonnelInformation})_t \\
& + b_9(\text{DeductionsFromRevenue})_t + b_{10}(\text{Beds})_t \\
& + b_{11}(\text{OtherBalanceSheetItems})_t \\
& + b_{12}(\text{TotalPaidHourseByCostCenterGroup})_t \\
& + b_{13}(\text{GrossOutpatientRevenueByPayer})_t \\
& + b_{14}(\text{GrossInpatientRevenueByPayer})_t \\
& + b_{15}(\text{SelectedFinancialItems})_t \\
& + b_{16}(\text{DeductionsFromRevenueCont})_t \\
& + b_{17}(\text{LicensedBedsAndUtilizationByTypeofCareCont})_t \\
& + b_{18}(\text{ExpensesByNaturalClassification})_t \\
& + b_{19}(\text{InpatientUtilizationByPayer})_t \\
& + b_{20}(\text{TotalProductiveHoursByCostCenterGroup})_t \\
& + b_{21}(\text{SummaryIncomeStatement})_t \\
& + b_{22}(\text{NetPatientRevenueByPayer})_t \\
& + b_{23}(\text{LicensedBedsAndUtilizationByTypeofCare})_t \\
& + b_{24}(\text{HospitalPersonnelInformationCont})_t
\end{aligned}$$

$t = 2017$

Each of the variable in the previous equation is a macro-variable. Each macro-variable has been as average of the single micro-variable that are indicated in the appendix. Specifically, the numerical values of the macro-variables have been calculated as the average of the single micro-variable pertaining the same macro-class. But, while the level of p-value is known for each micro-variables, the same value is not relevant in the case of the discussion of macro-variables. The passage from micro-variables to macro-variables has been realized to solve the question of the synthetic representation of the results in the context of AI-LM. In the following table we have the representation of the macro-class of variables, while the complete regression results for the micro-variables is presented in the appendix.

<b>Estimation of Net Income in 445 Californian Hospital by Macro-Class of Variables</b>		
$b_1$	Other Selected Utilization Information	8,85598
$b_2$	Gross Patient Revenue by Revenue Center Group	0,903513
$b_3$	Expenses by Natural Classification (Con't)	0,903081

$b_4$	Summary Income Statement	0,503691
$b_5$	Gross Inpatient Revenue by Payer	0,463342
$b_6$	Outpatient Visits by Payer	0,321771
$b_7$	Productive Hours by Employee Classification	0,171544
$b_8$	Hospital Personnel Information	0,127416
$b_9$	Deductions from Revenue	0,125717
$b_{10}$	Beds	0,124578
$b_{11}$	Other Balance Sheet Items	0,079718
$b_{12}$	Total Paid Hours by Cost Center Group	0,064797
$b_{13}$	Gross Outpatient Revenue by Payer	0,000525
$b_{14}$	Gross Inpatient Revenue by Payer	-0,00177
$b_{15}$	Selected Financial Items	-0,03231
$b_{16}$	Deductions from Revenue (Con't)	-0,10894
$b_{17}$	Licensed Beds and Utilization by Type of Care (Con't)	-0,14698
$b_{18}$	Expenses by Natural Classification	-0,2273
$b_{19}$	Inpatient Utilization by Payer	-0,32652
$b_{20}$	Total Productive Hours by Cost Center Group	-0,86809
$b_{21}$	Summary Income Statement (Con't)	-1,01506
$b_{22}$	Net Patient Revenue by Payer	-3,35907
$b_{23}$	Licensed Beds and Utilization by Type of Care	-128149
$b_{24}$	Hospital Personnel Information (Con't)	-5,74E+07

In synthesis the two macro-variables that have the higher level of positive relationship in determining the value of Net Income area:

- *Other Selected Utilization Information*: i.e. a variable that consider the level of caesarean sections. There is a positive relationship between the level of Cesarean Section and the level of Net Income.
- *Gross Patient Revenue by Revenues Center group*: this is a macro-variable that is constituted by three different variables i.e.: Gross Patient Revenue Daily Hospital Services, Gross Patient Revenue Ambulatory Services and Gross Patient Revenue Ancillary Services. Specifically the calculation of the value of Gross Patient Revenue by Revenue Center Group has been calculated as the average of the three components. There is a positive relationship between Gross Patient Revenue by Revenue Center Groups and the level of Net Income.

The two macro-variables that have the most negative effect on Net Income are:

- *Licensed Beds and Utilization by Type of Care*: the value of this macro-variable has been built as an average of the following micro-variables i.e. Licensed Beds Acute, Licensed Beds Psychiatric, Licensed Beds Chemical Dep, Licensed Rehabilitation, Licensed Beds Residential & Other Daily Services, Patient Days Psychiatric, Patient Days Chemical Dep, Patient Days Long-Term Care, Patient Days Residential & Other Daily Services. All these micro-variables have negative and statistically significant coefficient as showed in the Appendix. Licensed beds are beds that the hospital can offer based on the authorization of the authority. The number of licensed beds can differ from the number of staffed beds that are the beds effectively feasible in the hospital. There is a negative relationship between the number of licensed beds and the level of net income. Hospitals that have a greater number of licensed beds have fewer probabilities to increase their net income.
- *Hospital Personnel Information (Con't)*: is the number of physicians. It comprehends either hospital-based physicians either non-hospital based physicians. Physician in this category are distinguished in Attending, Associate and House Staff. There is a negative relationship between Hospital Personnel Information and Net Income. This means that hospitals that have a greater number of medical staff have lower probabilities to have a positive level in terms of Net Income.

In any case it is necessary to underline that our analysis has some limitations due to the fact the OLS is a not-profound kind of regression. It will be necessary, in further development of the article, to analyse and compare OLS with deeper regression models i.e. Panel Data with Random Effects, Panel Data with Fixed Effects, and Dynamic Panel.

### **3 Clusterization with k-Means Algorithm Optimized with the Elbow Method**

In the following part, we propose a clustering analysis based on k-Means algorithm optimized with the Elbow Method. Results show the presence of five clusters. Calculating the median of each cluster, it is possible to derive an order of clusters based on Net Income. We found the following order of clusters: C1>C3>C2>C4>C5. The cluster 3 has the greatest number of hospital with a value equal to 229 units. The clusterization offers an indication of the level of

financial and economic efficiency of the Californian Hospitals. Specifically we found that 51% of the hospitals have a medium-high level of financial and economic performance. On the other side there are 52 hospitals that have a median value of zero in terms of Net Income.

The presence of a series of hospitals that have a level of Net Income equal to zero is due to missing data. In effect there are hospital for which many of the variables of the balance sheet are empty. Furthermore, we have to consider that, independently from the proposed cluster analysis there are a set of hospitals that are part of the same corporations. The most relevant conglomerate of hospitals are indicated as follows:

- 13 hospitals are part of the conglomerate Adventist Group;
- 32 hospitals are part of the conglomerate Kaiser Foundation;
- 10 hospitals are part of the conglomerate Kindred Hospitals;
- 15 hospitals are part of the conglomerate Sutter.

These conglomerates show that the market of hospitals in California is oriented to a compositions the is far for a pure competition and that is more oriented to the creation of organizations that have a monopolistic tension.

#### **4 Prediction with Machine Learning Algorithms for the Estimation of the Value of Net Income in a set of 445 Californian Hospital in the Period 2014-2018**

In the following section, we present a prediction with eight machine-learning algorithms. Algorithms are compared based on their ability to minimize statistical errors and maximize R-squared. Specifically we have used three kind of statistical errors that are: Mean Squared Error, Mean Absolute Error, Root Means Squared Error. The ranking that each algorithms has in each ranking for each statistical measures has been summed in a global ranking. The lower the total payoff that an algorithm receive the highest the predictive ability. Algorithms has been trained with 70% of the dataset, while the remaining 70% of the data have been used to the prediction. Specifically, we have used data of 445 Californian Hospital using data for the period 2014-2018. We have then predicted the level of Net Income of the 30% of the hospital for the next financial exercise i.e. 2019. The order of algorithms based on their predictive ability is as follows:

- ANN-Artificial Neural Network with a payoff equal to 4;
- Gradient Boosted Trees with a payoff equal to 8;

- Polynomial Regression with a payoff equal to 12;
- Linear Regression with a payoff equal to 17;
- Simple Regression and Random Forest Regression with a payoff equal to 22;
- Tree Ensemble Regression with a payoff equal to 27;
- PNN-Probabilistic Neural Network with a payoff equal to 32.

<b>Statistical Errors of the Machine Learning Algorithms Used for the Prediction of the level of Net Income in a Set of Californian Hospital</b>				
<b>Statistics</b>	<b>ANN</b>	<b>PNN</b>	<b>Simple Regression</b>	<b>Gradient Boosted Trees</b>
<i>R<sup>2</sup></i>	0,825049656	0,224600532	0,657045860	0,796033238
<i>Mean absolute error</i>	0,014669577	0,019674844	0,018658046	0,014900856
<i>Mean squared error</i>	0,001000000	0,003409605	0,001508046	0,001000000
<i>Root mean squared error</i>	0,027736181	0,058391821	0,038833568	0,029948079
<b>Statistics</b>	<b>Random Forest Regression</b>	<b>Tree Ensemble Regression</b>	<b>Linear Regression</b>	<b>Polynomial Regression</b>
<i>R<sup>2</sup></i>	0,628001542	0,60642641	0,710486929	0,755067032
<i>Mean absolute error</i>	0,016991015	0,0175289	0,017042984	0,016266271
<i>Mean squared error</i>	0,001635760	0,00173063	0,001273054	0,001077025
<i>Root mean squared error</i>	0,040444534	0,04160085	0,035679877	0,032818059

The output of the prediction is applied to 133 hospitals. We found that on average the level of NET Income for the 133 hospitals is expected to growth at 4,01%. Specifically there are 86 hospitals for which the level of Net Income is expected the growth and 47 hospitals for which the level of Net Income is expected to diminish. If we consider only the subset of the 86 hospitals for which it is expected a growth in Net Income we have an average level of growth equal to 15,83%. Otherwise, if we consider the subset of the 47 hospitals for which there is a negative level of Net Income, we found an average level of Net Income that is expected to diminish to -17,64%.

The hospitals for which it is expected a greater level of growth in Net Income are:

- Valley Presbyterian Hospital with a level of Net Income that is expected to growth of 129,11%;

- Lac/Rancho Los Amigos National Rehabilitation Center with a Net Income that is expected to growth of 73,22%;
- Sequoia Hospital with a Net Income that is expected to growth of 66,3%;
- Chino Valley Medical Center with a Net Income that is expected to growth of 60,25%;
- Redwood Memorial Hospital with a Net Income that is expected to growth of 57,75%.

If we consider the 47 hospitals for which the level of Net Income is expected to diminish we found that the following hospitals have the worst levels:

- Los Alamitos Medical Center with a Net Income that is expected to diminish of the -34,18%;
- Doctors Hospital of Manteca with a Net Income that is expected to diminish of -36,22%;
- Lac/Harbor-Ucla Medical Center with a Net Income that is expected to diminish of -38,25%;
- La Palma Intercommunity Hospital with a Net Income that is expected to diminish of -57,39%.

<b>Ranking of Algorithms based on their Predictive Ability</b>					
<b>Algorithms</b>	<b>R<sup>2</sup></b>	<b>MAE</b>	<b>MSE</b>	<b>RMSE</b>	<b>SUM</b>
<b>ANN-Artificial Neural Network</b>	1	1	1	1	4
<b>Gradient Boosted Trees</b>	2	2	2	2	8
<b>Polynomial Regression</b>	3	3	3	3	12
<b>Linear Regression</b>	4	5	4	4	17
<b>Simple Regression</b>	5	7	5	5	22
<b>Random Forest Regression</b>	6	4	6	6	22
<b>Tree Ensemble Regression</b>	7	6	7	7	27
<b>PNN-Probabilistic Neural Network</b>	8	8	8	8	32

## 5 Conclusions

In this article we have analysed data from 445 Californian hospitals in the period 2014-2018. We have performed a regression analysis with OLS-Ordinary

Least Squares and we found a set of connections among various macro-variables showing that Net Income increases, among others, with Caesarean Sections and Ambulatory Services. But, we also find that Net Income reduces, among others, with the increase of the number of physicians and the number of beds.

These results are interesting since they found the presence of areas in which it is possible to intervene to reduce the inefficiency i.e. the cost of beds and the costs of physicians. In this sense, it is possible to act with lean management tools and AI to monitor the performance of physicians and to promote a better financial sustainability of the costs of bed. For example, a better organization of the work of physicians assisted with telemedicine tools can reduce significantly the costs of the hospitals and promote a better result in terms of Net Income. On the other side the most efficient activities for the set of Californian hospitals analysed are caesarean sections and a set of services i.e. daily hospitals, ancillary services ambulatory services.

Furthermore we have applied a cluster analysis with the k-Means algorithms optimized with the Elbow Method. Results show the presence of five clusters. The vast majority of the hospitals are in the clusters with the highest level of Net Income i.e. Californian hospital show, as aggregates, a medium-high level of economic, financial and operational performance.

Finally, we propose a confrontation among eight different machine learning algorithms for the predictions of the future level of Net Income based on data on the period 2014-2018. We found that on 133 hospitals for which the future level of Net Income is predicted there is an expected average growth of Net Income of 4%. In any case the number of hospital for which the level of Net Income is expected to growth is equal to 86 while the number of hospital for which the Net Income is expected to diminish is equal to 47.

### Abstract

The paper introduces an innovative approach to model risks in healthcare finding possible solutions in organization models and about Human Resources (HR) managing. Specifically, the method is based on the application of the Business Processing Modelling and Notation (BPMN) workflows in healthcare environments merging Lean management methods and Artificial Intelligence (AI) decision making approaches. The discussion begins with a case study about risk management integrating AI to enable a Decision Support System (DSS) thus defining the innovative BPMN Process Mining (PM) models. The BPMN-PM models are based on AI risk prediction and AI risk classification suitable to optimise the whole HR organizational model. In the specific case study, the AI algorithms allows the optimization of risk assessment. Finally, the work discusses some theoretical BPMN-PM models to integrate in more complex healthcare processes managing efficiently HR. The proposed work provides information about the process design and the key-reading to interpret BPMN-PM workflows

**Keywords** – Business Process Modelling and Notation –BPMN-, Process Mining, Artificial Intelligence, Healthcare DSS

**Paper type** – Academic Research Paper

## 1 Introduction

The Business Process Modelling and Notation (BPMN) is a standard graphical notation (ISO/IEC 19510:2013) suitable to map processes (Massaro, 2021). In healthcare environments, BPMN is applied to design emergency care processes involving Human Resources (HR) (Pufahl, 2022) and is suitable for workflow simulations (Ongoo et al., 2018). BPMN is also an important tool to design Integrated Home Care (IHC) processes (Russo et al., 2015). On the other side, Process Mining (PM) is an innovative approach to optimize processes in industries, including organizational aspects, by means the integration of Artificial Intelligence (AI) algorithms in BPMN (Massaro, 2022 a; Massaro 2022 b): it is possible to integrate PM model into a BPMN workflow constructing an intelligent BPMN-PM decision making engine. The innovative aspect of the PM is the implementation of AI in the management processes enabling the automation of tasks and actions to perform in real time. The process automation is suitable to increase the efficiency in healthcare processes supporting the estimation of important Key Performance Indicators (KPIs). KPIs are defined in different application fields of healthcare processes including the basic ones such as costs, time delays, HR efficiency, and in general processes management. BPMN is also adopted to map Lean production processes in industries (Naciri et al., 2022). In healthcare, the Lean method is applied to solve organizational aspects (Bossone et al., 2022; Rosa, 2017). For the first time the proposed work shows the possibility to match BPMN-PM models with the Lean management approach by analysing a case study involving organization improvements of HR. This matching is possible because public institutions are moving quickly towards digital processes using software platforms allowing interoperability and data processing (digital transformation of public institutions and major availability of digital data to process). In this direction, the Covid19 scenario introduced a new approach tailoring processes by means of digital data and data analytics to decrease the pandemic risk (Elia, 2022). The need to merge organizational clinical procedures with the risk management processes using digital data, 'launched' the adoption of "digitised processes" enabling risk monitoring procedures and patient management processes. This aspect enhances the need to design and map processes integrating data processing methods. An important aspect to consider to map processes is the definition of procedure to perform. The procedure

adopted for the case study is based on the following standard steps typical of engineered school:

- **Step 1:** preliminary analysis institution's organigram to establish the actors to interview (first the sector managers, and then the individual workers);
- **Step 2:** mapping of the 'AS IS' process by means of interviews with responsible of a specific process to analyse (the questions are prepared before according to the case study to map representing a specific application field);
- **Step 3:** definition of the critical points emerging from the 'AS IS' analysis (critical aspects deducted from the interviews);
- **Step 4:** mapping (design) of the 'TO BE' workflow process enhancing solutions found for the critical points, and adding possible KPIs useful for the monitoring of the new designed workflow;
- **Step 5:** simulation of the 'TO BE' process to perform before the execution of the designed process;
- **Step 6:** execution of the 'TO BE' workflow by estimating KPIs (to be considered for a re-engineering of the whole process).

All the steps are included into a Plan Do Check Act (PDCA) model, where the Plan phase is the 'TO BE' process following the 'AS IS' one, the Do action concerns the execution of the 'TO BE' process, the Check is the process monitoring, and the ACT represents the final tailored process.

Specifically, the example discussed in the paper is related to the 'TO BE' process of an Italian public healthcare institution concerning patient fall risk assessment improved by a lean management approach supported by data analytics and PM. Starting to the case study the paper develops correlated BPMN-PM theoretical models based on a Lean management approach. The work is structured as follows:

- description of the symbols used for the BPMN workflows facilitating the process reading;
- presentation of the BPMN-PM model of a case study related a risk management model in healthcare (case study implementing the BPMN-PM model);
- developments of further theoretical BPMN-PM models improving the 'TO BE' healthcare organization deducted from the analysed case study (structuration of the organizational model);

- conclusions discussing advantages and perspectives about implementations of BPMN-PM approaches.

## 2 Main BPMN Symbols Mapping workflows

The symbols adopted for the BPMN models are the following:

- '*Pool*' containing the symbols of a process or of a sub-process;
- Event '*Start*' defining the begin of a process or of a sub-process;
- Event '*Start with a notification*' defining the begin of a process or of a sub-process following a request;
- '*Task box*' representing the actions to perform into the workflow;
- '*Timer*' event indicating a periodicity of an action to perform;
- '*Database*' symbol (local data repository or big data system);
- '*End*' event (end of a process/sub-process);
- '*Message End*' (end of a process/sub-process with a message/notification);
- '*Exclusive Event based*' gateway expressing decision making logics;
- '*Arrow line*' indicating the fluxes of the processes;
- '*Dashed line*' indicating the interconnections between two or many different '*Pools*'.

In order to facilitate the reading of the workflows are adopted for the '*Task boxes*' different colours having the following meaning:

- orange colour indicating the digital data;
- green colour indicating a matching with lean management procedures;
- red colour enhancing the DSS engine integrating the PM model or the AI algorithms improving the decision making actions.

As further symbols adopted to model task are used the dashed line '*Task box*' for an assessment of a particular condition, and the bold edges of box to enhance an important task. The '*Task box*' superimposed between two pools indicates an action to be executed by two processes or sub-processes (two different '*Pools*' executing the same task).

## 3 BPMN-PM Model Applied to an Italian Case Study

The first step adopted to design a '*TO BE*' process for the case study, is to map the actual '*AS IS*' process providing important information about critical points. In the specific analysis, a critical point is found in the risk management process

about the falls in the hospital rooms. In Fig. 1 is illustrated the 'TO BE' BPMN workflow optimizing risk assessment procedures and sketching the PM model. As previously discussed, the BPMN is typically adopted to model processes by allowing the possibility to simulate all the sub-processes. This is an important aspect to comprehend the whole studied scenario by considering all the cases involved in the sub-processes. We observe that the proposed BPMN diagram is a simplification of a more complex workflow which takes into account other system actors (in the proposed example there are only three 'Pools' indicating the three main actors of *Risk management Unit*, *Operative Unit*, and *Medical Direction*). The model considers the following important tasks improving the fall risk management procedure:

- introduction of a tablet or of a mobile app for the digital traceability (digital transformation of the 'AS IS' process) of all events about patient fall conditions and cases (recording of digital data useful for data analytics);
- a new procedure about the reorganization of resources and nurses to improve the organization about the monitoring (lean management of the risk monitoring);
- a HR learning plan able to optimize the checks of the events and the risk assessment (lean management approach about learning organization);
- a new approach for the monitoring of corrective actions by the introduction of effective corrective elements as outputs of the optimization of the organizational management;
- the check of the electronic health records to update the Conley tab (Guzzo et al., 2015) initially filled when the patient enters the hospital room (important aspect to update information useful for the monitoring procedure);
- an advanced data analytics performed by the Decision Support System (DSS) engine implementing AI algorithms (supervised self-learning algorithms used for prediction and for classifications, and unsupervised ones adopted for data clustering).

The main innovative aspect of the model is represented by the DSS highlighted in red in the figure, enabling advanced data analytics (correlation results and data clustering), risk prediction, and risk classification. The workflow of Fig. 1 indicates also the tasks involving directly the lean management approach (green colour)

and the digital data sources (orange colour). The decision making could be therefore optimized by finding by AI algorithms 'hidden' correlations between risk's variables, by classifying new classes of risks, and by predicting the risks. The further advantage of the DSS is the possibility to compute different variables by optimizing the predictive results by training the model through the processing historical dataset contained in the backend of the management platform (database of the software platform).

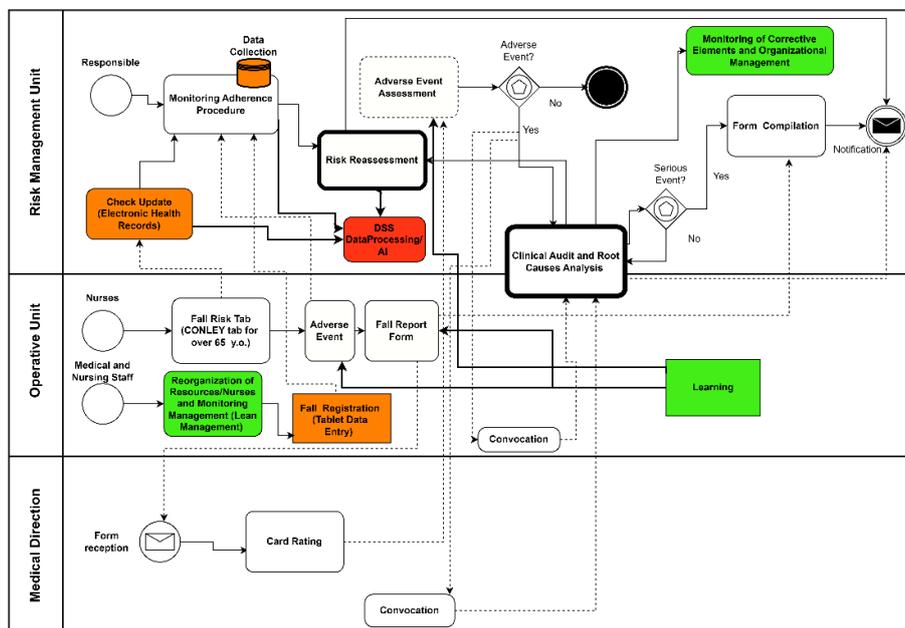

Figure 11. BPMN 'TO BE' model of the fall risk assessment (orange colour indicates digital data, green colour represents tasks involving lean management solution, and red colour highlights the DSS engine implementing Process Mining).

#### 4 BPMN-PM Models and Healthcare Organization Improvements

The case study discussed in the previous section allows to develop new BPMN-PM models supporting HR organization in healthcare environments. Possible 'TO BE' improvements in organizations is described by the BPMN-PM workflow of Fig. 2 defining the AI risk assessment linked to the analysed case study. Specifically, the designed workflow is explained as follows (workflow simulation performed by analysing the use cases):

- if the risk assessment provides a high risk score, will be required urgent interventions about a reengineering plan of HR allocation, consecutively updating the organizational plan;
- if are not checked risk conditions, it is enabled the AI engine providing risk predictions (condition enabling AI data processing);
- if are predicted risks, will be applied interventions (non-urgent interventions) about the HR allocation, consecutively updating the organizational plan;
- if are not predicted risks no actions will be performed;
- the risk assessment is performed periodically according to the indications contained into the updated organizational model.

We observe that the workflow of Fig. 2 is a self-adaptive model: the feedbacks allow to update periodically the organizational model according to the risk assessment and to AI risk prediction results supporting the reengineering of the HR organization in the medium-long period.

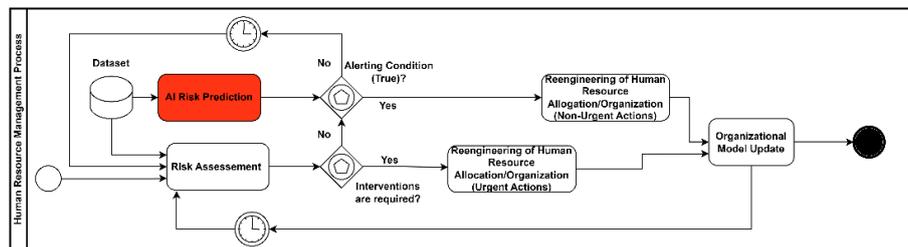

Figure 2. BPMN 'TO BE' model of the HR organisational model construction by means of risk assessment and AI risk prediction.

Figure 3 'explodes' an example of the organizational model indicated in Fig. 2. The workflow is characterised by the following three levels of actions:

- **Action 1:** enabling a learning plan and actuating it;
- **Action 2:** enabling a re-allocation of HR;
- **Action 3:** adding action of HR.

Action 1 is executed when it is evaluated that is enough a formative plan to solve a problem associated to a risk. If after the execution of the formation plan the problem is not solved, it is checked the possibility to activate Action 2 and Action 3 in sequence. For the particular case that also the Action 3 is not required, it is performed the re-analysis about the AI risk classification. Starting to the update of the risk classification (merging

information about risk assessment), it is again followed the iterative cycle.

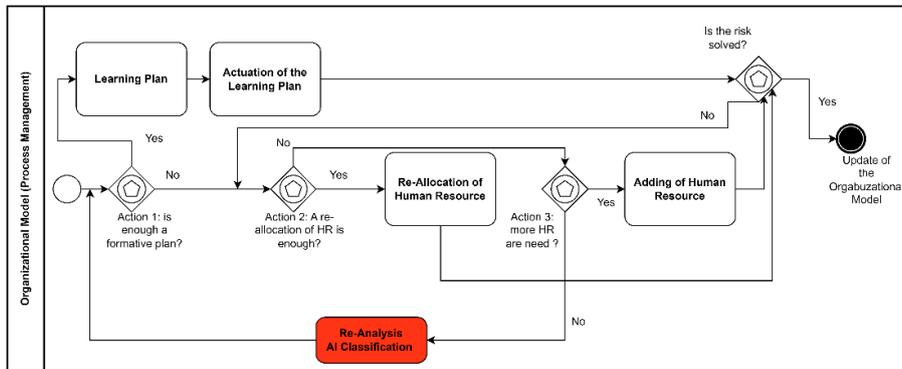

Figure 3. BPMN 'TO BE' model of the human resource organisational model construction by means of a sequential combination of different processes (Learning, Re-allocation, and Adding HR).

The learning plan must be designed after a check of the HR availability and of all competences. This allows to intervene with precision in each single process. The plan is addressed mainly to the upskill of HR. The allocation of HR should be managed according to feasible solutions and real needs.

## 5 Conclusions

The goal of the proposed process is to optimize the risk assessment procedure by decreasing the falls in the hospital rooms by adopting a dynamic process able to update efficiently the risk evaluation criteria and the corrective elements. The used approach merges different concepts and methods such as the lean management approach, BPMN mapping, and PM models. Starting to the analysis of a case study, the proposed work defines intelligent organizational models enhancing the AI role in risk decision making. The advantages of the BPMN-PM models can be summarized in the following main points:

- i) a clear definition of the responsibilities and roles in the process to be executed,
- ii) the formulation of new procedures to follow avoiding possible risks and process failures;
- iii) possibility to simulate the process before to be executed (testing of the process analysing all the workflow cases);

- iv) possibility to check dynamically the correct execution of the process (as for synoptic dashboards able to monitor in real time the performed tasks for each phase of the process);
- v) possibility to translate listed procedures by means of a graphical workflow;
- vi) improvement of procedure quality;
- vii) improvement of process efficiency (monitoring KPI in different stages of the process);
- viii) automated updating of the plan managing HR;
- ix) a significant decrease of risks;
- x) a clear indication of the AI role in the whole decision making process;
- xi) the assessment of risk levels updating the risk classification;
- xii) a possible decrease of costs (related the specific mapped process);
- xiii) a simple way to update quickly the process visualizing their characteristics (process re-engineering).

The perspectives of the BPMN-PM model about lean management in healthcare applications are mainly in a new 'concept' to manage HR and related processes. A possible implementation of AI in decision making could reduce drastically the patient's risks and optimize the whole management of HR. AI algorithms are able to find possible correlations between risk variables thus updating the risk assessment criteria and the risk classification. The international standard notation BPMN is a good way to fix the correct execution of advanced processes characterized by AI analytics. Future works will be addressed on specific data processing and KPI estimation.

### **Abstract**

This paper investigates the role of women who hold top-level positions in the management of firms in managing and overcoming the corporate crisis. The research's main goal relies on discovering the extent to which gender differences affect perceived crisis proneness/preparedness in organisational settings in sport-based entrepreneurship. In particular, we aim to study actions, decision-making, abilities, and opportunities women can exploit to strategically run the business during a crisis.

The research question is answered through a single case study approach based on the basketball club "Virtus Cassino", which participates in the Italian national Serie B basketball championship. We conducted semi-structured interviews with the woman entrepreneur. We analysed strategic business documents, the website, and articles published in the press on Virtus Cassino. Therefore, the female entrepreneur figure represents a vital aspect of the analysis conducted and the strategic management model of crisis management. The

Ratten (2011) and Ahonen (2019) frameworks were used to test our results in achieving the research aims. Finally, a triangulation of the research results was conducted to attest to the integrity and reliability of the data. The paper enriches the literature on gender and crisis by providing a strategic management model for crisis management in sports entrepreneurship, guided by a female entrepreneur. The results of this research contribute to the literature also on sport-based entrepreneurship and entrepreneurship theory, identifying the strategic levers of crisis management guided by a female entrepreneur, including intangible elements such as the manager's entrepreneurial skills, the cultural background of the factors, the relationships established by the sports club with fans and specialized figures in the sector. This model helps to understand how the role of women, even in sports enterprises, can be considered valuable for overcoming corporate managerial crises.

**Keywords** – Gender, crisis management, sport, entrepreneurship, innovation

**Paper type** – Academic Research Paper

## 1 Introduction

This study aims to address three topics of growing interest both at a practical and academic level: i) female entrepreneurship; ii) the organizational management of companies with high cognitive intensity, such as sports clubs; iii) the challenges of running a business during turbulent times, such as lack of satisfactory sporting results.

Our primary focus is to investigate the role of women who hold top-level positions in the management of firms in managing and overcoming the corporate crisis. The research's main goal relies on discovering how gender differences affect perceived crisis proneness/preparedness in organizational settings in sport-based entrepreneurship. The paper of Kanter (1977) on gender differences in management styles heralded a growing academic interest in gender sameness/difference concerning organizational issues. Scholars are increasingly focusing on the results at the corporate level determined by the effects of gender-based differences (Druskat, 1994; Gherardi, 1996; Tomlinson et al., 1997; Rosener, 1990).

“Crisis preparedness is defined as a state of corporate readiness to foresee and address endogenous or exogenous threats liable to inflict a multidimensional crisis by consciously recognising and proactively preparing for their inevitable occurrence” (Sheaffer and Mano-Negrin, 2003). This paper aims to discover the emerging strategic management model able to contrast the enterprises' crisis in

sport-based female entrepreneurship. We study the management activities, actions, decision-making, abilities and opportunities to overcome the corporate crisis.

The research question is answered through a single case study approach (Berg, 2007; Yin, 2014) based on the basketball club "Virtus Cassino", which participating club at the Italian national Serie B championship. We conducted semi-structured interviews with the female entrepreneur assuming the club's board role. Therefore, the female entrepreneur figure represents a vital aspect of the analysis undertaken and the strategic management model of crisis management. We adopted the Ratten (2011) framework and the Ahonen (2019) framework as interpretative lenses to test our results in achieving the research aims. Finally, a triangulation of the research results was conducted to attest to the integrity and reliability of the data.

The paper is novel because it provides a renewed strategic management model for crisis management in sport-based female entrepreneurship. This model is mainly based on intangible factors deriving from innovation, proactiveness, abilities, risk-taking, and orientation owned by the entrepreneur.

We show how the results outline a renewed strategic management model of crisis management based on multiple intangible levers supporting sport-based entrepreneurship. Leadership, risk-taking, capabilities, choices, and ideas are essential in the company recovery process. The results of this research contribute to the literature on sport-based female entrepreneurship, identifying the strategic levers of crisis management, including: i) intangible elements such as platforms for choosing the best athletes on the market, ii) interactions with the right stakeholders to increase the club's possible results, iii) innovative strategies to increase fan-based on social networks and box office revenues, and iv) engagement strategies to increase brand awareness. This model is extensible and applicable to all enterprises, not just the sports ones, developing a new crisis management model.

The remainder of the paper is organised as follows: Section 2 examines relevant literature. Section 3 presents the research methodology. Section 4 presents the findings. Lastly, Section 5 presents the discussion and conclusions of the paper.

## **2 Literature review and research question**

### ***2.1 Female entrepreneurship in the sports industry***

Inequality and discrimination against the female gender have been the subject of global debate, and in particular, in recent decades, research has focused on finding strategic means in business and organizational contexts to encourage greater involvement of women (Baughn et al., 2006; Henry et al., 2016; Yadav and Unni, 2016; Poggesi et al., 2016). Various institutional bodies, such as the United Nations and the European Institute for Gender Equality (EIGE), have tried to find solutions to this problem. Still, at present, the involvement of women in entrepreneurial initiatives could be much higher. A study by the EIGE (EIGE, 2019), gender inequality in the total entrepreneurial activity rate (TEA) remains high, with women's TEA reaching just 5% in many European countries. Consequently, there has been a growing interest on the part of scholars towards the phenomenon of gender inequality from the point of view of entrepreneurial initiatives (Cabrera and Mauricio, 2017) given the subject's nature which transversely affects various fields of knowledge. In this issue, scholars identify universities as institutions capable of exerting a considerable influence in stimulating an entrepreneurial attitude (Kogut and Mejeri, 2022). Universities have an essential educational role in addressing the issue of gender equity to promote women's self-confidence and encourage them to develop entrepreneurial initiatives (Bianchi et al., 2016; Carter et al., 2006); therefore, the higher the education level, the higher the rate of entrepreneurship (Corrêa et al., 2022). The scholarly debate on gender inequality from the point of view of entrepreneurial initiatives crosses several sectors, including sports (Meier, 2000). As supported in studies developed in other productive sectors (Senne, 2016), sports entrepreneurship continues to be culturally associated with the male gender (Sotiriadou and De Haan, 2019). Thus, the problems in the social environment stem from the reality that women entrepreneurs live in a patriarchal society. Turkmen (2015) also argues that further problems identified on the subject are essentially two: i) the absence of female entrepreneurs in the sports sector who can lead and be a model for other women who intend to develop entrepreneurial initiatives; ii) the lack of family support, especially from the husband. Several authors have determined a relationship between the practice of physical/sports activity and the development of entrepreneurial intention levels. From an in-

depth analysis of various contributions on the issue, it is possible to state that women still encounter many obstacles when developing entrepreneurial initiatives. Still, they must keep trying to overcome the cultural barriers and the social contexts they operate presently.

## ***2.2 Crisis Management and sport-based entrepreneurship***

Corporate crises are often unexpected and unpredictable events influencing organizations, among which enterprises (Apostol et al., 2015; Coombs, 1999; David, 2003; Loewendrick, 1993; Paraskevas, 2006). Mainly, corporate crises determine several effects inside and outside the enterprises on the financial and non-financial performance, relationship with employees, reputation, stakeholders and so on (Barton, 1993). Thus, crisis management is necessary for the survival of enterprises trying to delete adverse effects in the organization and in its environment (Pearson and Mitroff, 1993).

Corporate crises are often investigated as the moment or period in which an enterprise faces difficulties, influencing its objectives, strategic decision-making and performance (Fink, 2002; Hart, 1993; Maynard, 1993; Mitroff, 2004; Shrivastava, 1987). Addressing corporate crisis, seven groups of events are recognized (Mitroff, 2004): i) economic problems; ii) information problems; iii) problems with company plants; iv) problems affecting human resources; v) reputational problems; vi) problems deriving from psychopathic acts; vii) problems deriving from natural disasters.

Only some enterprises have comprehensive crisis management plans sometimes included in their strategic process (Pollard and Hotho, 2006; Shrivastava and Mitroff, 1987).

Crisis management is developed through the strategic direction of enterprises assuming strategic and emergency planning to overcome the crisis (Bugge, 1993; Counts and Prowant, 1994; Lagadec, 1996; Mitroff, 2004; Preble, 1997; Perry and Nigg, 1985; Quarantelli, 1996; Sylves and Pavalak, 1990). Enterprises must develop a safety culture within the organizations and their environment (Gherardi, 2009; Pidgeon, 1991).

Entrepreneurship is a complex phenomenon crossing economic sectors (Low and McMillan, 1988) and investing in knowledge-intensive industries, new initiatives and technology-based sectors (Burgel and Murrat, 2000). Even if many entrepreneurship definitions exist (Ahmad and Seymour, 2008; Anderson et al.,

2008; Bygrave et al., 1992; Gartner, 1990; Malerba and Mckelvey, 2016; Venkataraman, 1997), its investigation allows to recognize several elements, among which the profitable business opportunities, ability and skills, performance by entrepreneurs (Covin and Slevin, 1991; Mitchelmore and Rowley, 2010; Muzychenko, 1992; Sambasivan et al., 2009; Shane and Venkataraman, 2000). Entrepreneurship is a process in which entrepreneurs seek opportunities without losing attention to financial resources (Stevenson and Jarillo, 1990).

Enterprise growth is related to the enterprise's success (Davidsson et al., 2006) depending on multiple external and internal factors (controllable and not uncontrollable). Entrepreneurial growth is recognized through the following elements (Ahonen, 2019; Hyrsky and Lipponen, 2004): i) growth orientation, ii) growth capacity, iii) ability to gain competitive advantages and iv) ability to seek market opportunities. The following indicators can be traced back to specific actions implemented by the enterprise.

The enterprises growth also depends on the manager's skills, competencies, knowledge, and ability to obtain and coordinate resources (Shane and Venkataraman, 2000).

Enterprises with a strong entrepreneurial orientation are willing to take risks, be innovative, proactive and oriented towards opportunities (Wiklund et al., 2009; Covin and Slevin, 1991), especially in sports entrepreneurship (Ratten, 2011; Ciletti, 2012). Both sport and entrepreneurship have many common characteristics demanding i) innovation, ii) proactivity and iii) risk-taking, and attention in a turbulent environment (Holt et al., 2007; Ratten, 2011). Sports entrepreneurship develops through activities responding to market opportunities and creating long-term value (Ratten, 2019).

Various entrepreneurial opportunities exist, and entrepreneurial activities are necessary for their development (Ciletti, 2012; Ratten, 2011; Santomier, 2002).

In light of the previous literature review, the research question is as follows:

*RQ1. How does the female entrepreneur face crisis management in sport-based entrepreneurship?*

### **3 Methodology**

We adopted the case study methodology (Yin, 2014) to answer our research question "RQ1. How does the female entrepreneur face crisis management in sport-based entrepreneurship?". The case study allows us to understand "a how

or why the question is being asked about a contemporary set of events over which the investigator has little or no control" (Yin, 2014, p. 14). Additionally, we intend to "... capture various nuances, patterns, more latent elements that other research approaches might overlook" (Berg, 2007). In this perspective, a qualitative method is adopted to understanding the relationships between variables in complex processes (Shah and Corley, 2006).

We have proposed a single case study of sports entrepreneurship of one of the best and few sports clubs operating in the basketball sector, which finds a woman in the top position of president and sole director: the basketball club "Virtus Cassino". Donatella Formisano, the club's president and majority shareholder, is an appropriate subject for this study because she represents an excellent example of a female entrepreneur with personal values and characteristics that influence the decision-making process and the club's results. Between the 2018-19 and 2019-20 basketball seasons, the club faced a critical managerial crisis due to the poor sporting results achieved on the pitch. For this reason, the approach of the single case study allows an analysis of Virtus Cassino and of the characteristics and personal values of its woman entrepreneur Formisano, who was then able to raise the sporting fortunes of the club through important strategic and corporate decisions.

Therefore, the research conducted, considering the important role assumed by its female entrepreneur, aims to determine the entrepreneur's influences on strategic decisions and on the results achieved by Virtus Cassino in turbulent contexts and times. In light of what has been described, understanding is retained from the case study as a relevant and complex process.

The following subsections describe the research context, data collection, and analysis methods.

### ***3.1 Research context, case study design, reliability and validity.***

The research context of this study derives from the analysis of the Virtus Cassino sports club, directed by the female entrepreneur Donatella Formisano, and how through her knowledge and skills, the company has come out of a crisis of managerial and sports results.

Case study research is popular amongst sports organizations or sport policy studies (Skille, 2013) since it can be used to more deeply understand some aspects that have yet to be studied to a great extent.

The basketball club of the study, SSD a RL Virtus Cassino, is one of the emerging sports clubs in the Italian national basketball scene. After the first successful years characterized by victories in the Italian championships of Serie D, Serie C and Serie B, the first managerial and sporting crisis was recorded in the 2018-19 season due to the relegation from Serie A2 back to Serie B.

In Serie B, the new 2019-20 season opens with just one win in 15 games. A trend that forces administrators to change coaches and many players to reverse the bad sporting results achieved. Thanks to the choices made by the club, from the last position in the standings, the club rose to 13th place.

After the period of managerial crisis experienced by the club, the club still plays in the Serie B championship with excellent sporting results achieved on the field.

Therefore, our research focus will focus on the last period subject to context analysis and how the female entrepreneur's entrepreneurial skills at the company's head were fundamental in overcoming the managerial and sporting crisis that Virtus Cassino experienced.

We have analyzed various aspects of the life of a sports club and how Virtus Cassino develops each of them: from topics such as the development of technology and its influence on sports results (Castonguay, 2008; Kurtzman, 2005; Mullin et al., 2007; Olivier, 2006), up to issues such as the social commitment of society in the city area (Miragaia et al., 2017) and the ability to seize market opportunities (Shane and Eckhardt, 2003; Shane and Venkataraman, 2000).

The analysis was developed using a research protocol based on Yin's prescriptions (Yin, 2014) to validate our construction, internal, and external validity results. Following our research protocol, we defined interviews and their questions and length. Thus, our case studies analysis was developed through semi-structured interviews with the female entrepreneur of the team. Our data were principally gathered in three months. The interviews averaged were of 200 minutes in length. They were tape-recorded and then transcribed.

The questions supporting the analysis have been extensively explored. Therefore, the research focused on interviews on the following topics: i) personal values and characteristics of female entrepreneurs; ii) entrepreneurial mindset (EM), entrepreneurial culture (EC) and decision-making processes (DMP); iii) tools that encourage innovation, proactiveness, risk-taking, growth opportunities, growth ability and growth orientation, used by a female entrepreneur in times of crisis to overcome them.

### 3.2 Data analysis

To analyse the data, we used the Ratten (2011) theory and Ahonen (2019) theory to understand the phenomenon of Virtus Cassino sport organization entrepreneurial growth, the characteristics, within the same basketball club, of sports-based entrepreneurship in terms of innovation, proactiveness and risk-taking and, finally, how these tools have been helpful for top management in overcoming the phases of crisis experienced.

The first framework identifies sport-based entrepreneurship as helpful in understanding sport management. The contribution of Ratten (2011) is to illustrate the different aspects of entrepreneurship that imply proactive, innovative and risk-taking behaviours in the business context.

In the second framework, however, the goal is to understand the entrepreneurial growth of sports clubs through the analysis and identification of four managerial attitudes: i) growth orientation, ii) growth capacity, iii) ability to gain competitive advantages and iv) ability to seek market opportunities.

However, it is possible to state that the second framework (Ahonen, 2019) is an evolution linked to the first framework (Ratten, 2011), since the managerial practices aimed at innovation, proactiveness and risk-taking, theorized by Ratten (2011), fall within growth-oriented management practices proposed by Ahonen (2019) (Table I). Nevertheless, Ahonen (2019) considers the company's growth orientation as the last stage of the activities offered by company management, as they are preceded by growth opportunities for companies and by the growth ability in knowing how to exploit them by the administration.

Table I: Topics characterizing the research framework

		Growth Orientation		
		Innovation	Proactiveness	Risk-Taking
Growth Opportunities	Growth Ability	Social Network	Fan's Loyalty	Decision flexibility
		Scouting	Sponsor's Loyalty	Hearing of the right interlocutors
		Interview	Sponsor Day Service's	Sports Results Stakeholder
		Fan engagement	Popular prices Exploiting	Satisfaction
		App mobile	popularity of	Sustainability

		players
	Brand awareness	Media Presence
	Virtual sports experiences	Fun Experience during matches
	Sports equipment innovation	Youth Sector
	Technologies at referee's service	Good relations with insiders
	Sport Bets	Merchandising
		TV rights

These frameworks were chosen because they focused specifically on sports clubs and allowed for an in-depth analysis of the case study. We have tried to understand how the factors studied by Ratten (2011) and Ahonen (2019) were developed in the reality of Virtus Cassino. To this, we added the analysis of the crisis period, trying to understand which attitudes and choices were decisive in overcoming the particular moment of difficulty.

The primary findings of the interviews were discussed with the female entrepreneur to validate the research findings (Yin, 2014). Finally, a chain of evidence matrix was used to ensure reliability (Yin, 2014), providing a consistent interview structure and establishing an archival record. The following section presents the results of the analysis and the discussion.

## 4 Results

The following section presents the case study analyses using Ahonen (2019) and Ratten theory (2011), answering our research question:

*"RQ: How does the female entrepreneur face crisis management in sport-based entrepreneurship?"*

### 4.1 Growth Ability

Growth ability comprises the company's resources, the working environment and the specific features characterizing the industry in which the company under study operates. In this regard, the female entrepreneur of Virtus Cassino underlined:

*In the sports world, two components are fundamental for success: the financial resources, the right managers able to handle the club and the right athletes to achieve a sporting result set by the managers. These factors are attributable to human capital and financial capital.*

The literature on entrepreneurship underlines the roles of human and financial capital (Gilbert et al., 2006) as key to success. The financial resources for this team sport are sponsorships and game event income. Presenting itself as a niche sport, the nature of this business presents an additional financial challenge: operating costs are set, but revenues differ throughout the season based on team success:

*I have always made the management decisions of the club. In a context such as the sporting one, the difficulties to be faced are various but always attributable to the lack of satisfactory sporting results or below those expected compared to the investment made by the club.*

The activities carried out by the clubs to bring sports results above the expected levels of satisfaction are:

*The main actions were purchasing and selling athletes, perhaps by hiring athletes of experience and apparent fame rather than young promises that could have delivered better. Focusing on a coach with more experience and a cultural background made up of many years among professionals has meant more significant serenity and confidence in the players, who were put in a position to perform better on the field from the point of view of individual performances.*

An industry-specific issue concerning human capital is the uncertainty of the outcome concerning the recruitment of athletes and managers into the labor market. Donatella Formisano, on the topic, says that:

*Coaches and athletes are critical parts of the success of sports clubs. They positively and negatively influence creativity, such as the managers' ideas.*

Expensive players, such as coaches who do not reflect the club's right game ideas, could be unsuitable investments in the medium-long term. Despite the risks and uncertainties, numerous studies have underlined the paramount importance of team building: a successful team requires the best players and expert coaches.

Human capital issues that impact club performance and growth on and off the pitch include the right people in all positions, players, technical staff and administration. Successful recruitment and a competent board of directors comprised of executives dedicated to the cause for which they are employed are

the main functions of corporate (Poufelt, 2007) and entrepreneurial growth, resulting in management with positive effects oriented towards the development of the club.

Since broadcast rights do not generate significant revenues, sponsors, customers, and stakeholders are essential for creating value in the clubs' corporate networks and their generated revenue structure. Social entrepreneurship issues, such as corporate social responsibility, are essential for attracting sports sponsorship (Miragaia et al., 2017):

*The social commitment and the activities carried out by the company to involve entrepreneurs rooted in the territory determine a greater probability for the company to achieve the expected results. However, almost all the investments made in the club's structure come from my family's money. Relying on sponsors is unfortunately unsafe, as it inappropriately links the economic destiny of the individual companies' business to that of the sports club. The goal would be to grow our box office sales and revenue from paying customers and season ticket holders. However, this is inextricably linked to the sporting results achieved by the club.*

The last aspects considered relevant in managing a club, especially in times of crisis, are technological innovations (Potts and Ratten, 2016), such as social networks, local media and the press, the local community and the involvement of fans (Ratten, 2018; Woratschek et al. 2014):

*Creating value for stakeholders becomes an activity of primary importance for the company. They start with the fans, which must be able to enjoy the results achieved, passing through the entrepreneurs, who must be satisfied with the visibility obtained by being close to our brand and ending with the spectators at the races, who must be able to appreciate the splendid competitive spectacle that the match offers.*

#### **4.2 Growth Opportunities**

The interviewee stated that the development of her club started from the recognition of the business opportunities in the sports industry in which she operates:

*In the world of sports, knowing how to seize the opportunities that the "sporting reality" offers you is of fundamental importance. This component*

*becomes fundamental, especially if combined with high culture and capacity to detect advantageous situations, such as the purchase of athletes, partnerships with new entrepreneurs, and the use of new technologies capable of exporting the corporate sports product, without forgetting the satisfaction of the various stakeholder's interests.*

Opportunities are essential for business development (Shane and Venkataraman, 2000; Shane and Eckhardt, 2003). Opportunities such as using the sports arena for events other than those characterizing the company's core business can be valuable business strategies for approaching new entrepreneurs and new sponsorships.

However, systematic errors in the selection of technical and sports personnel can significantly limit the development of these activities, especially in times of crisis (Barringer et al., 2012; Carter and Jones-Evans, 2012; Greiner, 1989; Smith and Westerbeck, 2007):

*The purchase and choice of coaches and athletes in a sports club, especially basketball, are fundamental. A possible mistake involves a considerable loss for society, considering that a roster is not composed like soccer by 20/30 elements but by 10/12 athletes. The club, subsequently, to remedy it, must draw on new resources, which might be helpful in infrastructure or otherwise, to replace the athlete not deemed able to meet the objectives that the team needs to achieve. However, they are not the only factors to consider. An opportunity is to undertake new collaborations with entrepreneurs not known before, take advantage of the corporate brand in recent advertising campaigns not launched early, and provide a unique service to fans able to entice them more to come to see the matches. An additional advantage would be making the club's infrastructure available to external companies to generate a chance for money it would never have collected.*

#### **4.3 Growth Orientation: Innovation, Proactiveness, Risk-taking**

Very often, entrepreneurial growth is strongly connected to the entrepreneurial orientation of owners and managers (Ahonen, 2019). Entrepreneurial behavior at the firm level is closely related to the club's economic success and growth orientation (Covin et al., 2006; Covin and Slevin, 1991). What was previously stated in the literature, however, is not always verified:

*Expectations do not always match results. The manager's responsibilities for decisions that do not satisfy a specific future objective are many, but sporting results do not depend only on his work. The manager tries to achieve a goal with the resources he has at his disposal, sometimes taking risks, sometimes making choices that turn out to be successful, and sometimes making mistakes, as is customary. Responsibilities must be distributed among the stakeholders. The economic support of the territory and local entrepreneurs are highly determining factors in sporting results.*

Companies with entrepreneurs willing to take high risks to pursue success are leaders of innovation, proactiveness and risk-taking about the opportunities they are eager to seize (Ciletti, 2012; Ratten, 2011; 2012):

*I consider myself the centrepiece of club decisions. My figure, for better or worse, has always been the one that determined the club's fortune or bad luck. From the promotion from the D series to the A2 series, passing through the missed wins leagues of the 2015-16 and 2016-17 biennium and ending with the relegation from the A2 series, every action and behavior have been determinant.*

*As a sports club, we have grown exponentially over the years, and, I repeat, much of the credit has undoubtedly been mine and my family, which I have involved in this adventure.*

However, in most cases of investments in niche sports, the primary source of income of sports entrepreneurs is not represented by the company itself but by the personal business assets owned. The only motivation that drives them to invest in sports is to provide a social contribution to the community (Gallagher et al., 2012):

*Sport is pure and only passion. I have only invested in my company and never enjoyed any economic benefits.*

However, it has been highlighted in the literature that the interest of communities in the activity of the sports club is a decisive parameter in terms of investment and planning for clubs (Ahonen, 2019):

*The greater the interest of the territory in your activity, the more proportional the passion you put into what you propose. Creating involvement is one of the most important stimuli that lead you to invest more than to achieve a more ambitious goal as a sports club.*

In times of crisis, therefore, innovation, proactiveness, and risk-taking represent the only activities that the entrepreneur can implement to pursue new successful

strategies (Ratten, 2011): the exploitation of 4.0 technologies (Castonguay, 2008; Olivier, 2006), policies aimed at the development of sports tourism (Kurtzman, 2005), partnerships with fashion brands and technical-sports production (Mullin et al., 2007), social participation on virtual realities (Mullin et al., 2007):

*In today's reality, the tools provided to sports clubs are essential for achieving satisfactory sports results and overcoming intense moments of crisis. Technology has allowed us, through partnerships with suppliers of automatic and intelligent cameras on the training pitch, to improve the sports performance of our athletes and to predict their chances of getting injured, but also not to lose potential audiences and investors in times of crisis that we had to face due to the disappointing sporting results achieved. Social networks and good marketing campaigns have allowed us to retain our customers and fan base. Today they have allowed us to get up again, always able to count on solid partnerships in the area.*

## **5 Discussion and conclusions**

This paper presents a single case study approach (Berg, 2007; Yin, 2014), analyzing the theories of Ratten (2011) and Ahonen (2019) to understand the impact of female entrepreneurs' characteristics and values on the strategic entrepreneurial decision-making and the results of a sports club in times of crisis. The intention was to answer the research question: "How does the female entrepreneur face crisis management in sport-based entrepreneurship?" using the analysis of a charismatic and thriving female entrepreneur, Donatella Formisano, president of the Virtus Cassino club, a basketball club playing in the third Italian national championship of Serie B. In the men's national basketball championships, out of 108 teams, Virtus Cassino is the second club, in addition to Germani Brescia, an A1 team, to have of president a woman.

Our results provide both theoretical and practical contributions to the literature on female entrepreneurship and decision-making, in times of crisis, by women entrepreneurs (Kogut and Mejri, 2022). The present study focuses on examining the relationship between the values and personal characteristics of the female entrepreneur and her ability to make strategic decisions in times of crisis with the prospect of obtaining satisfactory results from a sporting and business results point of view through growth ability, growth opportunities, growth orientation, innovation, proactiveness and risk-taking (Ahonen, 2019; Ratten, 2011). These

interconnected concepts play a crucial role in achieving growth and success. From the results collected, we assume that the values and personal characteristics of the female entrepreneur positively influence the company's decision-making process.

Crisis management is crucial for achieving growth and success. A crisis management plan should focus on growth ability, growth opportunities, growth orientation, innovation, proactiveness, risk-taking, and crisis management can help organizations achieve long-term success and reach their full potential.

The set of personal values and essential characteristics of the organization created by Donatella Formisano confirm how these managerial and strategic activities are vitally important for the company's success and have been fundamental for the sports club to overcome the crisis object of analysis. Leaders should be able to remain calm, communicate clearly and effectively, make quick decisions, and take responsibility for the situation. They should also be able to support and guide their team members and ensure that everyone is working towards the same goals. The leadership of the female entrepreneur in the society under study was fundamental for overcoming the crisis and, therefore, could serve as a model for replicable stereotypes in other similar organizations.

Therefore, the research results are relevant for sports clubs, managers, entrepreneurs and researchers. For sports clubs, managers and entrepreneurs, the results suggest that even organizations led by women are ready to overcome situations of managerial crisis brilliantly and, thanks to their excellent leadership, can actively contribute to outstanding company value even in a context such as sports. The findings, for the researchers, broaden the research scope of women's strategic decision-making and their approach to the underperforming business crisis.

The study's limitations derive from the analysis of a single case study. Future research could be directed towards comparing values, characteristics and approaches to the crisis of other women entrepreneurs in Italy and other countries in sporting contexts but not only to extend the existing literature further.

### **Abstract**

This paper empirically demonstrates that an organisation’s ability to exercise phronesis shapes its learning strategy and promotes socially responsible practices. It highlights the implications of organisational phronesis for enhancing an organisation’s performance and contributing to the larger societal good.

This study employs a quantitative approach to investigate the relationship between organisational phronesis, learning strategy, and corporate social responsibility. The empirical analysis was conducted using multiple regression model, by the software STATA, which allows for robust and reliable regression modelling.

The empirical findings of this study demonstrate a significant and positive association between organisational phronesis and both the learning strategy and corporate social responsibility. The multiple regression analysis reveals that higher levels of phronesis within an organisation are associated with a more effective and adaptive learning strategy. Additionally, the results indicate that organisational phronesis is positively linked to corporate social responsibility, reflecting greater commitment to ethical and sustainable

practises that benefit society and the environment. These findings provide novel insights into the role of phronesis in fostering organisational learning and responsible behaviour, highlighting its potential to contribute to long-term organisational success and societal well-being.

**Keywords** – Practical wisdom, Phronesis, Learning strategy, Corporate Social Responsibility

**Paper type** – Academic Research Paper

## 1 Introduction

Current societal challenges such as social injustice, political instability, and climate change require organizations to balance social, ecological, and economic objectives (Rocha & Pinheiro, 2021, p. 69). In response to this need, an increasing number of knowledge management scholars are turning to the ancient *phronesis*, which dates back to Aristotle and emphasizes the practical wisdom necessary for ethical decision-making (Bierly et al., 2000; Nonaka & Toyama, 2007; Rowley & Gibbs, 2008; Rocha & Pinheiro, 2021). By incorporating it, organizations can better navigate the complex and dynamic challenges of today's world.

According to Aristotle (2009/350 B.C.E. - III, 7 1115b19), phronesis is "doing the right thing from the right motive, in the right way and at the right time". Phronesis, also known as prudence, is excellence of character and intellectual excellence; it is "a reasoned and true state of capacity to act with regard to human goods" (Aristotle, 2009: 106 – VI.5, 1140b, 20-21). So, one can see that phronesis serves practical purposes (Nonaka & Takeuchi, 2019, p. 6). Phronesis is action-oriented knowledge that strives for the common good (Nonaka & Takeuchi, 2019, p. 59). Rowley (2006, p.1250) stated that it is "the capacity to put into action the most appropriate behaviour, taking into account what is known (knowledge) and what does the most good (ethical and societal considerations)". As a distinct type of knowledge, it can help individuals, organisations, and societies to understand and respond to the moral expectations placed on them by various stakeholders (Rowley & Gibbs, 2008, p. 357), thereby serving the sustainability agenda.

Considering this increasing need for organisations to balance social, ecological, and economic objectives while navigating complex societal challenges, this study aims to examine the relationship between organisational phronesis, learning strategy, and social responsibility performance. + By investigating this relationship, this research contributes to the theoretical understanding of how phronesis can enhance an organization's ability to navigate complex societal challenges while

still achieving economic goals. The findings provide practical insights into how organizations can cultivate phronesis as a key driver of sustainable business practices, benefiting not only the organizations themselves but also the wider society.

## **2 Theoretical Background**

In this section, we briefly introduce the core concepts of this research, i.e., organisational phronesis, learning strategy, and corporate responsibility, in order to hypothesize about their interrelationships.

### **2.1 Organisational Phronesis**

At the individual level, phronesis is a construct brought about by Aristotle that concerns the correct application of the right means to achieve good outcome (Rocha & Pinheiro, 2021, p.2). It motivates individuals to think deeply about the "good" and what is necessary in order to lead a good life (Bierly et al., 2000, p.603). Since the perceived "good" should be realized through means appropriate to the situation, phronesis emphasizes practices in specific contexts (Nonaka & Toyama, 2007, p.378). In this context, phronesis does not only help individuals to reach the "good" for themselves, but to judge what goodness is for the whole in general (Nonaka & Toyama, 2007, p.380).

In addition, according to Nonaka and Takeuchi phronesis can be interpreted as "experiential knowledge that enables us to make prudent judgements in timely fashion and to take actions guided by values, principles and morals" (Nonaka & Takeuchi, 2021, p.2). Phronesis is based on knowledge, reasoning, and action (Rocha & Pinheiro, 2021, p.3). Especially a person's knowledge and reasoning depend on their life experience (Rocha & Pinheiro, 2021, p.76). So, phronesis has a strong focus on ethical and social considerations guided by a person's experience.

At the organisational level, "a practically wise organization is both a virtuous and a learning organization" (Rowley & Gibbs, 2008, p.367), deeply shaped by experiential development. Phronesis enables organisations to survive successfully and do good for society (Rocha & Pinheiro, 2021, p.68). Thereby, the organisation understands and acts on the complexity within an organisation (Rowley & Gibbs, 2008, p.365). Planet earth is colourful and multi-faced, it exposes the imperfections of humanity (Nonaka & Takeuchi, 2021, p.6). Hence, a wise

organisation should include an understanding of the interdependence and complexity of the relationships between all stakeholders of an organisation. Collaboration across boundaries and borders is necessary to cope with the upcoming bigger problems in society (Rowley & Gibbs, 2008, p.365).

## **2.2 Learning strategy**

Organisational learning is vital for strategic management (Bierly et al., 2000, p.595). To make knowledge transfer effective, key organisational factors such as a learning strategy are essential (Baker & Sinkula, 1999, p.84). A learning strategy can be characterized as behaviours and thoughts that a learner engages in. The goal of a particular learning strategy may be to influence the learner's motivation, but it can also affect the way in which the learner selects, acquires, organises, or integrates new knowledge (Ye et al., 2020, p.3). The capability to learn and adapt leads to new knowledge and increases an organisation's performance and long-term success. This is reflected in an organisational learning strategy that can promote organisational change (Kragulj, 2016, p.225).

## **2.3 Corporate Social Responsibility**

Sustainability and responsibility are an essential part of global business operations (Durst, 2021, p.1). Corporate social responsibility (CSR) is a framework that structures responsible handling of corporate power and social commitment. It combines economic, social, and environmental goals (De Witte & Jonker, 2006, p.2).

Carroll presents an overview that shows the evolution of CSR since the 1950s and illustrates that it is difficult to find a general framework of CSR (Turker, 2009, p.413). His studies show four avenues of CSR. Economic responsibility, which sees profit as the main factor in the creation of the company. Legal responsibility which sees complying with law as a prerequisite. Ethical responsibility which focuses on the expectation society has of the company focusing on ethics. Philanthropic responsibility which is desired by the society and is in comparison with other forms of responsibilities not expected and presents organisations' voluntary attitudes to increasing the communities' well-being (Rocha, d'Angelo, 2021, p.2). Over the past few decades, CSR has evolved from a philanthropic to a mandatory attribute (Carroll, 2008). It can be seen as a successful business model

that offers comparative advantage (Kramer & Porter, 2011) and promotes sustainable development (Ye et al., 2020).

Due to rapid changes in the market and in society, companies are increasingly asking themselves questions that directly affect the sustainability of the company regarding the economic, social, and ecological dimension such as whether the company's business model is sustainable or whether new product, service and management innovations are necessary (Kramer & Porter, 2011, p.6). Regarding this, sustainable entrepreneurs are gaining in importance. According to Parrish and Foxon (2009, p.47) sustainable entrepreneurs design their companies with the main intention of making contribution to the quality of the environment and to the social common good, but they can also act as catalysts for a larger transformation. They implement sustainable development into their core business framework and create new products, services, techniques, and organisational modes that immensely reduce environmental effects and consequently increase the quality of people's life (Schaltegger & Wagner, 2011, p.223).

So, CSR is intended to create a new space in which business and society do not represent a contradiction, but in which companies are embedded in their social environment and can only act successfully in this way. This requires entrepreneurial value creation that benefits both the company and society (Porter & Kramer, 2015, p.153). How organisations respond to the challenge of sustainability profoundly ensures their competitiveness and their survival. CSR can be seen as a strategic opportunity that can be seized (Lubin & Esty, 2010, p.43). In this context, it can lead to innovate business practices that have a positive impact on people, planet and profit (Zwetsloot, 2003, p.201).

### **3 Conceptual Framework and Hypotheses Development**

To find out to what extent organisational phronesis has an effect on the learning strategy of an organisation and CSR, we developed the following framework (Figure 1) and hypotheses.

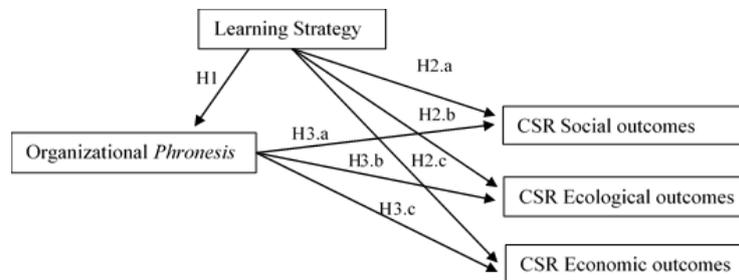

Figure 1: Conceptual Framework.

### 3.1 The effect of organisational learning strategy on organisational phronesis

Experience and actions are the essence of organisational learning. Phronesis can be seen as new high-quality tacit knowledge that gives organisational members the opportunity to make mindful decisions and take appropriate actions inspired by group values, group culture and shared goals (Erden et al., 2008, p.12). Thereby, organisational culture, values and beliefs of organisational members define the outcome of organisational learning (Rocha & Pinheiro, 2021, p.76). With the integration of phronesis in companies, the practical, subjective, and future-creating aspects of the dynamic process of strategy development and implementation in knowledge-creating companies can be explained (Nonaka & Toyama, 2007, p.378).

In order to guarantee a connection and learning between individuals, a *ba*, that is a shared context, ought to be created where phronesis is integrated and the knowledge of each individual is shared, utilized and learned (Rocha & Pinheiro, 2021, p.76). These learning-oriented interactions in a shared context are necessary to spread individual phronesis among members of a team and to develop collective phronesis (Klein, 2015, p.155). A shared context gives organisational members the opportunity to be understood and to see beyond their own limited perspectives (Nonaka & Takeuchi, 2011, p. 64). Based on the above discussion, we hypothesize the following:

*Hypothesis 1. An organisation's learning strategy positively affects organisational phronesis.*

### **3.2 The effect of the learning strategy on corporate social responsibility**

Studies illustrate the relationship between organisational learning and CSR (Valdez-Juárez et al., p.2f; Balasubramanian & Balaji, 2021, p.247). In recent years, academics and practitioners from all fields have found that knowledge can increasingly be considered as one of the key resources for organisations to thrive in the current socio-economic environment (Martínez-Martínez et al., 2022, p.1). Thereby, organisational learning is an instrumental tool in adopting and executing CSR (Ghasemzadeh et al., 2021, p.5).

More and more organisations try to adopt and implement new learning strategies to improve their social responsibility processes (Valdez-Juárez et al., 2019, p.2f). Organisational learning can be seen as a prerequisite for changing the mindsets and motivations of employees, leading to an increase in their commitment to the effectiveness of CSR initiatives (Ghasemzadeh et al., 2021, p.5). A learning organisation is able to build up, develop and pass on knowledge. The behaviour of individual members can be changed to show a new knowledge and understanding (Martínez-Martínez et al., 2022, p.2). Based on that, we can predict the following:

*Hypothesis 2.a. An organisation's learning strategy positively affects the social outcomes of CSR.*

A learning orientation promotes sustainable innovations, which leads to responsible behaviour in organisations (Valdez-Juárez et al., 2019, p.4). For instance, sustainable innovations such as using electric cars, building zero-emissions buildings, and constructing more trains are being promoted (Banerjee & Duflo, 2020, p.209). In addition, organisational learning strategies lead to environmental knowledge. Environmental knowledge is referred to as the knowledge persons have about themselves and the environment around them (Martínez-Martínez et al., 2022, p.5). An ecological perspective enables people to see how a destructive-creative process works. Destruction in any kind of forms - through disease, flood, wind, or fire - gives spaces in an ecosystem, where small innovation can proceed without disruption from lack of resources (Hurst, 2012, p.762). Furthermore, environmental learning consists of processes that acquire, disseminate, and use knowledge about the natural environment. The processes involve the socialization, externalization, combination, and internalization of knowledge, with the goal of increasing sustainable performance (Martínez-Martínez et al., 2022, p.5). Accordingly, we propose the following:

*Hypothesis 2.b. An organisation's learning strategy positively affects the ecological outcomes of CSR.*

Furthermore, companies from various industries have found that organisational learning creates new ideas, products, processes, and technologies performance (Martínez-Martínez et al., 2022, p.1). Moreover, in order to obtain a competitive advantage a good organisational learning strategy is essential (Ghasemzadeh et al., 2021, p.1). The better individuals and organisations are at learning, the greater are their opportunities to understand and seize trends in the business environment (Ghasemzadeh et al., 2021, p.5). Especially in a rapidly changing business environment, learning should become an integral part of the daily operations of a company, as they have a positive effect on an organisations' financial performance (Ghasemzadeh et al., 2021, p.1; Torkelli & Durst, 2022, p.4). Based on the above discussion, we can predict the following:

*Hypothesis 2.c. An organisation's learning strategy positively affects the financial outcomes of CSR.*

### **3.3 The effect of organisational phronesis on corporate social responsibility**

Phronesis is expected to have an impact on CSR. Values and the idea of "doing the right things" are extremely important for CSR (Zwetsloot, 2003, p.201). Phronesis gives organisations the ability to form the business environment and thereby strives for a future combining social, ecological, and economic goals (Rocha et al., 2022, p. 11). As Goede (2010) claims, "the wise organization is a green organization that manages a triple bottom-line: people, planet and profit" (Goede, 2011, p.37).

Phronesis enables organisations to take wise actions which has social well-being as its outcome (Rocha et al., 2022, p.7). It encourages individuals, organisations, and societies to understand and respond to the moral expectations placed on them by various stakeholders (Rowley & Gibbs, 2008, p.357). It can be viewed as a construct that may be one of the pathways to start reconnecting businesses with society (Rocha & Pinheiro, 2021 p.133). Phronesis as knowledge practice extends the social science's agenda as it puts its focus on improving the human condition and making the world a better place to live in (Nonaka & Takeuchi, 2019, p.31).

Organisational scandals, inequality, and climate change scream for improving social well-being (Rocha & Pinheiro, p.2). One great necessity to meet society's

needs is to enhance educational programs, especially business education. Phronesis implemented into business education encourages people to develop a new way of thinking, as they begin to understand that their mental models should go beyond economic importance (Rowley & Gibbs, 2008, p.366; Rocha & Pinheiro, p.74). Especially phronesis encourages people to become part of an open knowledge community driven by a higher purpose (Nonaka & Takeuchi, 2019, p.8). Having a shared purpose that puts commitment to the common good first, helps members of organisations to get united and thus encourages them to accept the common goal or plan, also giving them a reason for action (Rocha & Pinheiro, 2021, p.156). For that, it is important to always bear in mind that phronesis is a necessity as it is "a reasoned and true state of capacity to act with regard to human goods" (Rowley & Gibbs, 2008, p.357). Therefore, we set up the following hypothesis:

*Hypothesis 3.a. Organisational phronesis positively affects the social outcomes of CSR.*

Furthermore, phronesis strives for an interaction between colleagues, customers, business rivals and the environment and therefore helps to move companies, community, and society into a sustainable direction (Nonaka & Takeuchi, 2019, p.31). The loss of natural resources and the consequences of environmental degradation have become critical issues. Climate change threatens the survival and stability of modern societies (Rosário et al., 2022, p.1). As phronesis is an action-oriented construct, it can be integrated in all dimensions of the Sustainable Development Goals (SDGs) goals, which draw attention to the fact that sustainability should become an imperative for organisations all around the world (Rocha et al., p.5).

An early study by Minna Gillberg already showed how a process of change requires a phronetic search for knowledge in which the ethical dimension manifests itself in the form of sustainability through changed practice and rationality (Gillberg, 1999, p.1). This altered rationality can be described as ecological rationality, in which people's minds have evolved to extract cues for action from the contexts in which they find themselves. This allows fast decisions under pressure of time and conditions of uncertainty. Advocators of ecological rationality are convinced that phronesis ought to be seen as the "gold standard" for rationality. Ecological rationality makes people realize that destruction is very rapid, and that innovation and the creation of growth and wealth take a much longer time (Hurst, 2013, p.762). In particular, exceeding certain temperatures

could trigger abrupt, unpredictable and potentially irreversible changes that have massively disruptive effects on the environment (Klein, 2015, p.1).

In relation to this, the common good can be linked to the natural environmental good, since a healthy environment is a prerequisite for living well: In recent decades, environmental psychologists and other social scientists have discovered links between the natural environment and human well-being (Biedenweg et al., 2017, p.112). Specifically, living in a healthy natural environment has positive effects on an individual's stress level (Ulrich et al., & Zelson, 1991; Irvine et al., 2013), emotional well-being (Bratman et al., 2015) and cognitive performance (Keniger et al., 2013). For reaching the natural environmental good, phronesis is required, as it helps to make organisations realize that thoughtful actions towards sustainability and the environment should happen "here and now" with a clear vision in mind (Lee et al., 2020, p.2; Nonaka & Takeuchi, 2019, p.81). Accordingly, the hypothesis reads as:

*Hypothesis 3.b. Organisational phronesis positively affects the ecological outcomes of CSR.*

In order to maintain competitive advantage focusing on organisational performance is necessary for any organisation (Rhodes et al., 2008, p.86). According to Porter and Kramer in order to achieve long-term success, shared value is essential as it creates economic value for society by addressing its needs and challenges. Thus, shared value can be viewed as a new path that leads to economic success. It offers an opportunity for a major transformation of entrepreneurial thinking. To recognize this, leaders and managers need to evolve new knowledge (Kramer & Porter, 2011, p.4). Phronesis can be seen as high tacit new knowledge that strives for the common good, but also economic growth (Rocha et al., 2022, p.2). As a practically wise organisation achieves longevity due to a greatly sustainable performance, its outcomes have social, but also economic value, which can be referred to as shared value (Rocha & Pinheiro, 2021, p.10).

In addition, economic value arises from continuous innovation and the best use of resources (Rocha & Pinheiro, 2021, p.10). Phronesis as knowledge practice can also be seen as an approach that fosters continuous open innovation and performance. (Nonaka & Takeuchi, 2019, p. 50). As Bierly et al. claim, it enables organisations to solve problems and to execute tasks that affect the efficiency and effectiveness of an organisation. In particular, organisations are able to choose the most efficient knowledge for a given situation and put it into action

while doing the least harm possible (Rocha & Pinheiro, 2021, p.141). These statements predict the following:

*Hypothesis 3.c. Organisational phronesis positively affects the economic outcomes of CSR.*

## **4 Research method**

### **4.1 Data collection**

We collected data through an online survey. The sample includes 276 employees in Austria who work in for-profit companies. The role and perception of employees in relation to CSR is crucial, as they can be seen as legitimate stakeholders at the heart of an organisation. They need to be integrated into business activities and practices that lead to organisational change. Therefore, it is necessary to understand how employees perceive their organisation.

### **4.2 Survey design**

The questionnaire of the survey used a five-point Likert scale from Strongly agree (1) to Strongly disagree (5). The survey items were selected based on scales previously validated on organisational phronesis (Rocha et al., 2021), learning strategy (Baker & Sinkula, 1999), and CSR (Balasubramanian & Balaji, 2021). For the latter, we used the following three factors: Employee-Related Sustainability – ERS (i.e., social outcomes), Environmental Management Sustainability – EMS (i.e., ecological outcomes) and Financial Sustainability – FS (i.e., economic outcomes).

### **4.3 Data analysis**

To test the framework, we applied multiple linear regression modelling using STATA software version 17. Regression analysis is a statistical method for studying and modelling the relationship between variables (Montgomery et al., 2021, p.1). It is the most widely used technique for dependency testing and applicable to research questions that involve either prediction or explanation.

Multiple regression analysis is a statistical method within the general linear regression model, analysing the relationship between one dependent and multiple independent variables (Hair et al., p.259f). As our research goal is to

understand the relationship between complex theoretical models, multiple linear regression is suitable.

## 5 Analysis of the Results

### 5.1. Sample profile

The sample is largely composed by females between 20 and 39 years old working in the private sector in micro or small organizations. The characteristics of the sample are displayed below (Table 1).

Table 1: Sample profile\*

<b>Characteristics</b>	<b>Freq.</b>	<b>%</b>
<b>Gender</b>		
Female	149	59.60
Male	100	40.00
Diverse	1	0.400
Total	250	100.00
<b>Age</b>		
20-29	117	46.80
30-39	65	26.00
40-49	28	11.20
50-59	38	15.20
60-69	2	0.80
Total	250	100.00
<b>Time in the company</b>		
Up to 1 year	74	29.60
1-5 years	92	36.80
5-10 years	40	16.00
10-15 years	20	8.00
15-20 years	14	5.60
More than 20 years	10	4.00
Total	250	100.00
<b>Sector</b>		
Private Sector	174	69.60

## 5.2. Descriptive statistics

The Environmental Management Sustainability ( $\mu = 3.372$ ) and the Financial Sustainability ( $\mu = 3.707$ ) have the lower averages, while Learning Strategy ( $\mu = 3.888$ ) and Organisational Practical Wisdom ( $\mu = 3.827$ ) have the highest averages. Table 2 shows the descriptive of all items.

**Table 2. Descriptive statistics of the items**

	Variables	Mean ( $\mu$ )	Minimum	Maximum
Organisational Practical Wisdom	OPW1	3.808	1.000	5.000
	OPW2	3.681	1.000	5.000
	OPW3	3.728	1.000	5.000

	EMS13	3.688	1.000	5.000
	EMS	3.372	1.000	5.000
Financial Sustainability	FS1	3.605	1.000	5.000
	FS2	3.754	1.000	5.000
	FS3	3.667	1.000	5.000
	FS4	3.804	1.000	5.000
	FS	3.707	1.000	5.000

Regarding the correlation coefficients are greater than zero, indicating a positive relationship between the variables (Table 3). The correlation coefficient can assume values between -1 and +1. With a value of 0, the two variables are not linearly related at all; with a value of +1, there is a completely positive linear relationship between the variables considered. A value of 0.8 or above indicates a strongly positive linear correlation, which is the case with our present variables under study (Spearman, 1904).

Table 3: Correlation of the variables.

	<b>OPW</b>	<b>L</b>	<b>ERS</b>	<b>EMS</b>	<b>FS</b>
<b>OPW</b>	1.000				
<b>L</b>	0.903	1.000			
<b>ERS</b>	0.936	0.885	1.000		
<b>EMS</b>	0.919	0.853	0.904	1.000	
<b>FS</b>	0.921	0.844	0.853	0.881	1.000

### 5.3. Regression analysis

Overall, the analysis of the regression indicates that the p-value of the regression model is suitable and significant ( $p < 0.001$ ). It can be read at the top left of Table 4 at Prob > F = 0.0000. The adjusted R-square can take values between 0 and 1. The higher the value is to 1, the better the explanation of the regression equation and thus the better the prediction of the dependent variable (Hair, Black, Babin & Anderson, p.260).

Table 4 reports the results for H1, the value of the adjusted R-squared ( $\text{Adj-r}^2 = 0.9222$ ) achieved here can be regarded as very good and means that the regression can explain 92.22% of the variability of OPW. The coefficient of the variable L is 0.2274. This value states that for every one unit increase in the L, OPW increases by an average of 0.2274. The p-value of the variable OPW is  $< 0.001$ . Thus, H1 is supported, meaning the Learning Strategy has a significant impact on OPW.

Table 4: Testing for Organisational Practical Wisdom (H1)

Number of observations	276				
F (2, 273)	1631.14				
Prob > F	0.0000				
Adj R-squared	0.9222				
Root MSE	502.97				
	OPW	Coefficient	t-value	p-value	95% conf. interval
(H1) L	0.2274	6.96	0.000	0.1631	0.2917
_Cons	20.8947	0.66	0.508	-41.1757	82.9652

Table 5 reports the results of H2.a and H3.a. Since the p-value is  $< 0.001$ , L and OPW have a significant impact on ERS. OPW and L can explain 88.37% ( $\text{Adj-r}^2 = 0.8837$ ) of ERS variability. Also, for every unit increase in OPW, ERS increases by an average of 0.7484. Likewise, for every unit increase in L, ERS increases by an average of 0.187. Thus, both H2.a and H3.a are supported and OPW has more effect than L in ERS.

Table 5: Testing for Employee-Related Sustainability (H2.a and H3.a)

Number of observations	276					
F (2, 273)	1046.24					
Prob > F	0.0000					
Adj R-squared	0.8837					
Root MSE	618					
	ERS	Coefficient	t-value	p-value	95% conf. interval	
(H3.a) OPW		0.7484	15.54	0.000	0.6536	0.8432
(H.2.a) L		0.1871	4.42	0.000	0.1039	0.2705
_Cons		12.9675	0.33	0.738	-63.3174	89.2522

Table 6 reports H.2.b and H3.b. Since the p-value is  $< 0.001$ , L and OPW have a significant impact on EMS. OPW and L can explain 84.60% ( $\text{Adj-r}^2 = 0.8460$ ) of ERS variability. Also, for every unit increase in OPW, EMS increases by an average of 0.8556. Likewise, for every unit increase in L, EMS increases by an average of 0.1174. Thus, both H2.a and H3.a are supported and OPW has more effect than L in EMS.

Table 6: Testing for Environmental Management Sustainability (H2.b and H3.b)

Number of observations	276					
F (2, 273)	756.58					
Prob > F	0.0000					
Adj R-squared	0.8460					
Root MSE	751.89					
	EMS	Coefficient	t-value	p-value	95% conf. interval	
(H3.b) OPW		0.8556	14.60	0.000	0.7403	0.9710
(H.2.b) L		0.1174	2.28	0.023	0.0160	0.2188
_Cons		32.3421	0.69	0.493	-60.4695	125.1538

Table 7 reports H.2.c and H3.c. Since the p-value is  $< 0.001$  for OPW, it have a significant impact on FS. OPW can explain 84.85% ( $\text{Adj-r}^2 = 0.8485$ ) of FS variability. Also, for every unit increase in OPW, FS increases by an average of

0.9236. Conversely, L has no significant impact on FS ( $p = 0.243$ ). Thus, only H3.c is supported.

Table 7: Testing for Financial Sustainability (H2.c and H3.c)

Number of observations	276					
F (2, 273)	770.79					
Prob > F	0.0000					
Adj R-squared	0.8485					
Root MSE	750.92					
FS	Coefficient	t-value	p-value	95% conf. interval		
(H3.c) OPW	0.9236	15.78	0.000	0.8084	1.0388	
(H.2.c) L	0.0601	1.17	0.243	-0.0411	0.1613	
_Cons	10.2208	0.22	0.828	-82.4713	102.9129	

Table 8 displays the results of the hypotheses test. In sum, the study found that an organization's learning strategy has a positive impact on OPW. This, in turn, has a positive influence on CSR, including its social, ecological, and economic outcomes. Moreover, an organization's learning strategy has a positive impact on social and ecological outcomes. These findings emphasize the importance of developing a learning-oriented and phronetic culture within organizations to enhance their overall performance and promote responsible and sustainable practices.

Table 8: Results of the Hypotheses test.

Hypotheses	Results
H1. An organisation's learning strategy positively affects OPW.	Supported
H2.a. An organisation's learning strategy positively affects the social outcomes of CSR.	Supported
H2.b. An organisation's learning strategy positively affects the ecological outcomes of CSR.	Supported
H2.c. An organisation's learning strategy positively affects the financial outcomes of CSR.	Not Supported
H3.a. OPW positively affects the social outcomes of CSR.	Supported
H3.b. OPW positively affects the ecological outcomes of CSR.	Supported
H3.c. OPW positively affects the financial outcomes of CSR.	Supported

## **6 Discussion**

The literature has established a theoretical link between organisational phronesis and the learning strategy of an organisation, respectively between organisational phronesis and CSR (Nonaka & Toyama, 2007; Erden et al., 2008; Rocha & Pinheiro, 2021; Zwetsloot, 2003; Goede, 2011; Rocha et al., 2022). The empirical findings of our study complement the existing literature (Nonaka & Toyama, 2007; Erden et al., 2008; Rocha & Pinheiro, 2021; Zwetsloot, 2003; Goede, 2011; Nonaka & Takeuchi, 2019; Rocha et al., 2022) by quantitatively confirming the qualitatively related constructs in literature.

The findings strengthen the literature on organisational phronesis, as they illustrate that organisational phronesis has an actual effect on key CSR outcomes. First, the correlation analysis confirmed that organizational phronesis, organisation's learning strategy and CSR are highly correlated. Moreover, the outcomes also confirm that higher levels of organisational learning strategy positively influence organisational phronesis, and it positively impacts the social, ecological and economic dimension of CSR. Therefore, phronesis serves as an ethical resource to help organisations to act responsibly and sustainably, benefitting society and the environment (Rocha et al., 2022, p.7). Conversely, the learning strategy impacts only the social and ecological CSR dimensions.

The results of our study demonstrate that companies should develop future-oriented strategies to achieve the common good for organisations, society, and the environment (Nonaka & Takeuchi, 2021). It can be seen as an important facilitating mechanism for an organisation's learning strategy and social responsibility performance.

### **6.1. Research Implications**

The present research provides valuable implications for both academics and practitioners. Firstly, our findings complement and strengthen the existing literature by providing empirical evidence for the theoretical link between organisational phronesis, organisational learning strategy, and CSR. It confirms that organisational phronesis has a significant impact on key CSR outcomes, and it can be considered as an ethical resource for organisations to act responsibly and sustainably.

Secondly, our study highlights the value of developing future-oriented learning strategies that focus on the common good for organisations, society and the

environment. The outcomes suggest that companies ought to adopt an organisational phronesis culture, which can be fostered by an organisation's learning strategy and can serve as a facilitating mechanism for social responsibility performance.

Thirdly, the research provides insights for practitioners on how to improve their organisations' performance in terms of CSR. The findings suggest that companies should focus on developing their organisational phronesis and learning strategy to achieve better CSR outcomes. By adopting an ethical approach, companies can benefit not only their bottom line but also society and the environment.

## **7 Conclusions**

This paper offers first empirical insights on how organisational phronesis supports the social, ecological, and economic dimensions of CSR. The implementation of phronesis into practice fits into the current debate about the common good, as it focuses on the well-being of people and the planet that is essential for long-term sustainability.

This research paper offers initial clarity about the connection between organisational phronesis, the learning strategy of an organisation and CSR. However, regarding limitations, the sample only includes people who work in for-profit companies in Austria. So, culturally specific effects were not considered. Hence, we propose that the relationship between these constructs should be analysed in several countries around the globe and compared. Moreover, it would be valuable to apply mixed quantitative research methods in the future that confirm the relationship of the three constructs. Additionally, future research can investigate the moderating effects of contextual factors such as industry type, company size, and national culture on the relationship between organisational phronesis, organisational learning strategy and CSR.

Since this research empirically established the relationship between organisational phronesis, an organisation's learning strategy and CSR, further research may explore the characteristics and dimensions of a practically wise workplace. In addition, future research should be conducted on how a phronetic-based culture within an organisation can be established and maintained through CSR practices. Regarding entrepreneurship, it would be interesting to find out how phronesis can help to influence the development of sustainable entrepreneurs whose main intention is to contribute to the quality of the

environment and social well-being. Furthermore, the connection between these constructs and organisational spirituality should also be addressed in future research.

### **Abstract**

This paper is a work-in-progress study that focus on the role of KM strategies in the context of sustainable smart cities. Drawing on the previous literature on smart cities and KM strategy concepts, the aim of this paper is to propose a conceptual model to examine the enablers and barriers of KM strategies of codification and personalisation for enhancing sustainable development in smart cities context. The proposed research model will be empirically applied in future study with four qualitative smart city case studies from Finland. The current study's theoretical contribution is to advance the smart city discussion by bringing in KM strategy perspectives to enhance sustainable development among cities.

**Keywords** – Knowledge Management, Sustainability, Smart Cities, Conceptual framework, KM strategies

## 1 Introduction

In the modern knowledge economy, the role of cities involves various centrally important economic and societal service missions, like provision of educational, social and healthcare services; development of urban infrastructure; support for industries and ecosystem of innovation and job creation; and enhancement of local and regional business networks. Besides these central service missions, there are increasing responsibilities of cities to address the impact of uncertain weather patterns, climate change and solve contemporary economic and environmental challenges. In general, the critical purpose and function of cities is to achieve Sustainable Development Goals (SDGs) that have gained importance and relevance in the mindset of individual nations' citizens, policy makers and communities. (Blasi et al., 2022; Trindade et al., 2017)

The strong demand for accountability has increased the impact of cities as central decision-makers and responsible actors in enhancing sustainability. Both in academic and practice-oriented literature, the concept of designing and building smart cities are argued as one way to offer solutions for contemporary sustainability challenges (Neirotti et al., 2014). De Jong et al. (2015) have proposed that smart cities should develop strategic initiatives that aims to create better environmental, social and economic conditions. According to the European Commission (2014, p. 6) smart city is a "place where traditional networks and services are made efficient using digital and telecommunication technologies, for the benefit of inhabitants and businesses". This kind of definition highlights the emphasis on technology and digitalisation in smart cities. However, smart cities are not only technology-oriented places but also need to be understood as strategically distinctive knowledge hubs serving unique mix of value and delivering better future for its citizens and organizations.

According to Israilidis et al. (2021), most studies on smart cities are focused more on the technical and hard aspects (Baccarne et al., 2014; Bakici et al., 2013; Caragliu et al., 2011; Chourabi et al., 2012), leaving room for research that focuses more on the softer side of smart cities. Focusing on the softer side of human and digital elements of strategically managing knowledge, related concepts of creation, transfer, use and application can be considered as integral knowledge processes for the development of sustainable smart cities.

Chong et al (2011) argued that the implementation of KM can be a more demanding undertaking for public sector organizations, such as smart cities,

because of their bureaucratic and political attributes when compared to private sector organisations. They also highlight that effective implementation of KM may help provide stability to organisations and found that an integrated KM strategy enablers of codification and sharing of knowledge as antecedents of organizational performance.

Riege and Lindsay (2006) have suggested the importance to identify stakeholders from multiple perspectives and to create more strategically driven stakeholder policy with more efficient use of resources and increased transfer of knowledge. For instance, efficient ways of creation and use of organisational knowledge resources can be tied to the codification KM strategy, whereas its effectiveness of transfer and application can be linked to the personalisation KM strategy (Venkitachalam and Willmott, 2016) for sustainable development of smart cities. Riege and Lindsay (2006) also suggest the need for empirical based qualitative research to examine policy issues based on KM in public sector organisations.

Drawing on the previous literature on smart cities, sustainability and KM strategy themes, we propose a conceptual model to examine the enablers and barriers of KM strategies of codification and personalisation (or socialisation) for enhancing sustainable development in smart cities context. The proposed research model will be empirically applied in future study with four qualitative smart city case studies from Finland. The current study's theoretical contribution is to advance the smart city discussion by bringing in KM strategy perspective to enhance sustainable development among cities.

To build this kind of research model for further empirical studies, we firstly present the typical knowledge barriers based on the seminal work of Riege (2005) and then discuss the premises of KM strategies. As Riege (2005) has stated, the different knowledge barriers need different kinds of strategies to solve them. Building on these discussions from the viewpoint of the special characteristics of smart cities as the context of our study, we propose the research model as the main result of this paper.

## **2 Knowledge barriers in sustainability**

A factor that disturbs the transmission of knowledge from source to recipient could be argued as a knowledge sharing barrier (Szulanski, 2003). With a view to improve the existing practices regarding knowledge sharing and the identifying

the possible bottle-necks, Riege (2005) presents a categorization of knowledge sharing barriers based on substantial literature review. Riege's (2005) categorization divides knowledge barriers into three categories, which all are interrelated. These categories are namely individual, organisational and technological. In overall these categories include over 30 specific barriers, for example individual category includes barriers such as personal attributes, experience and competence, organisational category includes barriers such as cultural issues, lack of leadership and time as resource, and finally, technological category includes the barriers like unrealistic expectations and lack of technical support. Riege (2005) points out that strategies and practices to overcome the knowledge barriers vary greatly depending on the organisation's attributes. The situation can be even more complex in the smart city context, as they can be regarded as a network of multiple organizational and individual actors, which further challenges the effective knowledge sharing.

When we consider smart city as a nexus of different kinds of actors, i.e. as a complex network organization, the work of Capaldo (2014) offers fruitful viewpoints for knowledge sharing between network organizations. The first viewpoint is knowledge sharing in terms of context specific knowledge, such as environmental knowledge. This kind of knowledge sharing is mostly done between network's key actors and in a very informal way. This kind of personalised codified knowledge deals e.g. sustainability measures in a smart city context. Second viewpoint deals specifically with knowledge transfer. This is mostly related to expert-specific know-how that aims to solve a certain problem at hand. Thus, this viewpoint relates to most acute issues in the smart city context. COVID-19 pandemics and the knowledge transfer needs are a good example of this kind of important issue that requires effective knowledge sharing among the city actors.

Third viewpoint of Capaldo's (2014) study is the in-house knowledge production, that namely focuses more on intra-organizational aspects. Lastly, the fourth viewpoint is knowledge co-production. This fourth viewpoint relates especially to personalization strategy of KM. Capaldo (2014) also states that effective knowledge sharing in the network needs personal relationships, functional macro culture, trust and reciprocity. In other words, these act as knowledge enablers in a networked context of multiple actors. Even though Capaldo (2014) has carried out the study in the context of private sector, these viewpoints are applicable also in the context of smart cities. Being a city can be

regarded as a network entity that includes not only the public actors but more and more also the private actors and even the individuals as citizens.

### **3 KM strategies and sustainable smart cities**

Based on Capaldo (2014) conceptualisation of smart city as a web of actors, it is important to recognise the dynamics of technological, environmental and social spheres of life that are changing today. To navigate in this unknown and emergent nature of circumstances, the need for developing a sustainable-based (Martins et al., 2019) KM strategies perspective on smart cities is necessary. In the development of such a perspective on increasingly complex environmental contexts, the relevance of KM strategies of codification and personalisation and associated process and practices can offer a role to build a sustainable (Abbas and Sağsan, 2019) value-chain in smart city development. For the understanding of the management of smart cities as network organisations, pertinent stakeholder groups such as private organisations, local communities/citizens and government institutions need to develop a better grasp of how to strategically manage knowledge (Dragicevic et al., 2019; Grant, 1996) in a sustainable way (Abbas and Sağsan, 2019; Martins et al. 2019).

Despite the changing nature of cities and its environments, talent mobility, remote working and automation have all contributed to various impact and mix in the management of codification and personalisation KM strategies. Consequently, there are benefits in knowledge codification and sharing but also costs in reinvention and wastage of knowledge assets and resources in modern city developments. Similarly, the expansion and growth of AI-driven technologies, big data etc. can impact smart cities with a huge challenge of overwhelming amount of documented and unstructured knowledge in their digital infrastructures (Trevino et al., 2021) going forward.

To tackle this important knowledge overload challenges (or barriers) in the management of smart cities as network entities, the need for sustainable KM strategies becomes essential. Focusing on KM strategies, smart cities need to effectively and efficiently manage the structured and unstructured knowledge through codification and personalization strategies respectively. Extant literature has argued both codification and personalization KM strategies are pursued (Venkitachalam and Willmott, 2016) at the same time to reduce the process risks of reinvention and ineffective use of network-level organisational knowledge.

Additionally, some studies (Venkitachalam and Willmott, 2015) have confirmed that due to constant change in environmental dynamics, executives need to recognize the importance of a balanced and sustained focus on both KM strategies toward realisation of better management of network-based knowledge in the context of smart cities. Otherwise, this kind of network organisation can be faced with enormous wastage of financial, technological and human capital resulting in unproductive and inept knowledge processes such as creation, transfer, use and application.

#### 4 The proposed research model

Based on the above theoretical discussion we propose a research model that takes into account the KM strategies that enhance the achievement of sustainable development goals in smart cities and provides instruments to analyse the key knowledge sharing barriers and enablers (see Figure 1).

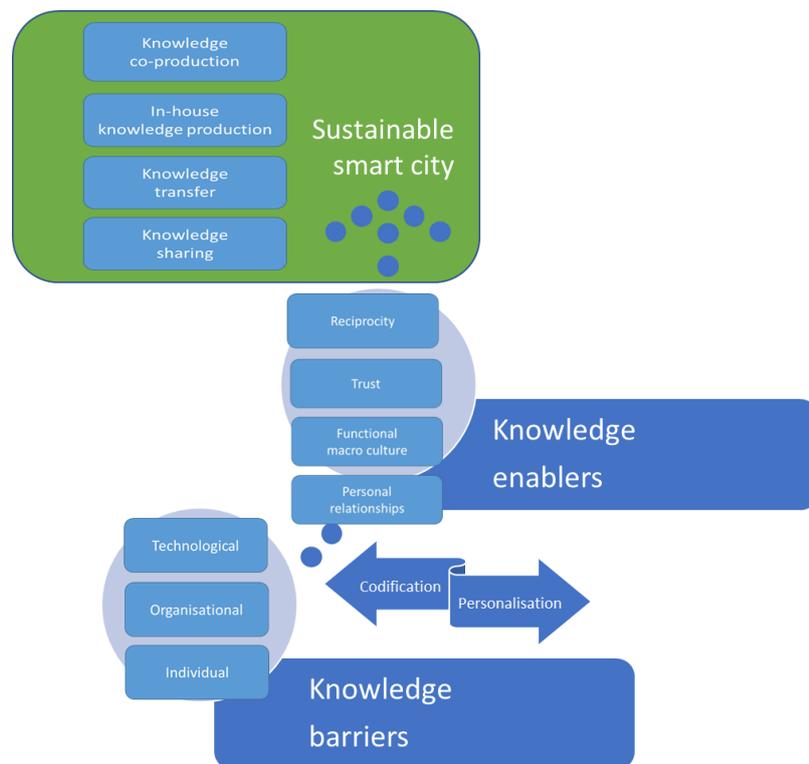

Figure 1. The proposed conceptual research model.

This conceptual model provides the measures to identify the key knowledge barriers based on Riege (2005) main categories of individual, organisational and technological barriers that hinder the efficient knowledge sharing. Each of these three main categories include several specific barriers that can deepen the contextual analysis of the empirical case data related to smart cities. Knowledge enablers based on the work of Capaldo (2014) in which KM has been studied in network setting. Smart cities are indeed a web of varying kinds of actors, thus the proposed (see figure 1) enabling elements of relationships, macro culture, trust and reciprocity offer a functional measure to identify knowledge enablers in smart city context. It is noteworthy that in Riege's (2005) model e.g. lack of trust is mentioned as one of the barriers and in Capaldo's model the existence of trust is logically highlighted as an enabler. Besides of the barriers and enablers the conceptual model includes the KM strategy (Venkitachalam and Willmott, 2016) identification as one of the important phases in the analysis. The model should enhance the analysis of the relationship between the main KM strategy and the key barriers and enablers. This is, however, to be tested in the next phases of this research, the empirical case study of four smart cities aiming towards sustainability.

## **5 Discussion and conclusions**

This paper has proposed a conceptual model to examine the enablers and barriers of KM strategies of codification and personalisation for enhancing sustainable development in smart cities context. The proposed model builds on the seminal works of Riege (2005) on knowledge sharing barriers, Capaldo (2014) on knowledge management in networked context such as smart cities and Venkitachalam and Willmott (2016) on KM strategies.

The main limitation of this paper is the rather straightforward development of the conceptual model, as it has been built only on three selected studies. However, the three studies are all comprehensive in their specific field and they offer multiple and relevant implications to future empirical studies in sustainable smart city context. Nevertheless, the theoretical bases of the proposed conceptual model could be strengthened by leveraging the amount of background studies.

On the other hand, this conceptual research model can be regarded as an initial conceptual level model, and it can be further developed and tested through future empirical studies that we are going to carry out.

### **Abstract**

The aim of this study, which is grounded in decision-making theory, is to explore whether the occurrence of meaningful coincidences can positively influence executive confidence, allowing hospitality industry organizations to cope, if only for short periods, in chaotic and uncertain contexts and settings, such as the COVID-19 pandemic.

Through a qualitative study with 24 interviews, conducted both in person and via Microsoft Teams, this study focuses on Italian hospitality facilities in the Campania Region of southern Italy to explore how executive confidence led by meaningful coincidences can influence managerial decisions.

The results highlight the process through which meaningful coincidences lead to the three different characteristics of executive confidence during a decision-making process – overestimation, overprecision, and overplacement. The insights that emerge suggest a number of positive and beneficial aspects for decision-making in a crisis such as the COVID-19 pandemic.

To the best of the authors' knowledge, this is the first study in the literature aimed at investigating, by means of qualitative methodologies, the positive outcomes of executive confidence in decision-making led by meaningful coincidences during crisis periods in the specific context of the Italian hospitality industry.

**Keywords** – Executive confidence, Meaningful coincidences, Decision-making, Qualitative study, COVID-19.

**Paper type** – Academic Research Paper

## 1 Introduction

Since early 2020, the coronavirus outbreak (COVID-19) has forced many businesses to close, leading to unprecedented disruptions and changes in most industry sectors. Companies have experienced and are still experiencing profound transformations that include the need to redesign of business models, and to rethink governance processes, workforce (see Piscopo *et al.*, 2022, on new working practices adopted in the COVID-19 era), and people skills (Xie *et al.*, 2022). New challenges due to the uncertainty of the context have put managerial decision-making capacity, which is increasingly related to dimensions such as speed and effectiveness, at the center of the debate (Foss, 2020). Thus, the COVID-19 pandemic has placed extraordinary demands on executives. Within this context, managers are called upon to make complex decisions characterized by high levels of ambiguity, in a context where the variables are numerous and, above all, often unknown (Craven *et al.*, 2020). Therefore, there is an urgent need to increasingly implement resilient and dynamic leadership in the business context (Meyer *et al.*, 2022).

Drawing on Heavey and colleagues (2022), this study focuses on executive confidence – that is, an executive's generalized or domain-specific belief in his or her capability to complete tasks, influence events, and/or achieve outcomes; the focus on executive confidence helps us to understand how this variable can be effective in managing decision-making in periods of crisis. We also focus on self-confidence because it represents a widespread trait among managers and is often considered a necessity for holding top positions (Banerjee *et al.*, 2014). Studies on confidence have mainly explored its multifaceted nature (e.g., Moore and Healy, 2008; Moore and Schatz, 2017; Stajkovic, 2006), focusing on overconfidence rather than executive confidence in general and not distinguishing confidence from related constructs. Moreover, other studies on executive confidence have mainly explored its negative effects on organizational performance (Audia *et al.*, 2000; Bloomfield *et al.*, 1999), stating that overconfident managers deviate from the rational model of decision-making by adopting a narrow framing (Bailey *et al.*,

2011). Nevertheless, recently, some studies have defined a good side of executive confidence in contrast to negative ones (Aktas *et al.*, 2019; Banerjee *et al.*, 2014, Chen *et al.*, 2018).

Moreover, in recent years, the influence of emotions on cognition (Lazarus, 2006; Lerner and Keltner, 2000; Lerner *et al.*, 2013) and luck (Liu and De Rond, 2016; Denrell *et al.*, 2019; Stenholm and Jiang, 2019), considered as irrational variables (Sripada and Stich, 2004), has received much attention from researchers and practitioners. Among the recent advancements made for understanding irrational behavior in management research and practice, meaningful coincidences represent a phenomenon that has gained academic and practical relevance in the past 60 years (Durant, 2002; Hocoy, 2012) and that has never been investigated in decision-making theories in management. This concept was introduced by analytical psychologist and psychiatrist Carl Jung (1952) to describe circumstances that appear meaningfully related yet lack a causal connection. Specifically, in contemporary research, meaningful coincidence refers to one's subjective experience that coincidences between events in one's mind and the outside world may be causally unrelated to each other yet have some other unknown connection (Combs and Holland, 1990). These are events that are not intentionally looked for, to which people assign a symbolic meaning and which differ from luck and chance (Cristofaro, 2020).

Responding to calls in the literature (e.g., Heavey *et al.*, 2022), this study aims at investigating if executive confidence led by meaningful coincidences can enable organizations to cope, if only for short periods, with chaotic situations and contexts. Indeed, the literature on executive confidence and meaningful coincidences needs further contributions with reference to non-rational decision making to highlight its impact on business organizations (Heavey *et al.*, 2022). The occurrence of meaningful coincidences can influence executive confidence and the context in which the manager operates; thus the literature needs further contributions on this topic (Cristofaro, 2020; Heavey *et al.*, 2022).

Therefore, the research question guiding this study is as follow: *How does executive confidence led by meaningful coincidences influences management decision-making during turbulent times?* To answer this question, this study aims to investigate whether the occurrence of meaningful coincidences can positively influence executive confidence, allowing hospitality industry organizations to cope, if only for short periods, in chaotic and uncertain contexts and settings, such as the COVID-19 pandemic. Furthermore, this study contributes to the body

of knowledge on decision-making by responding to the demands for qualitative approaches, such as interviews, required to fully understand the impact of irrational forces on management decisions (Cristofaro, 2017). In particular, manager's subordinates of Italian hospitality facilities were interviewed to try to fully investigate the phenomenon and explore perceptions of executives' decision-making in the real work context (Cristofaro and Giardino, 2020). Implications for theory and practice are discussed.

## 2 Theoretical Framework

Within the decision-making theory (see also Loia, 2022, on the organization of the decision-making system), while some studies on irrational behavior have mainly explored its negative effect on organizational performance (Audia *et al.*, 2000; Bloomfield *et al.*, 1999), others have investigated affective states that determine the success of management decisions (Cristofaro, 2020). Further studies have instead focused on criteria and processes in decision-making that are not based solely on rationality (Cristofaro, 2019), and the personality traits that affect managers' actions (Abatecola and Cristofaro, 2019; Loia *et al.*, 2022). Specifically, the concept of executive confidence has recently gained attention (Heavey *et al.*, 2022).

In the business context, executive confidence has been defined as an executive's generalized or domain-specific conviction in his or her capability to complete tasks, influence events, and/or achieve outcomes (Heavey *et al.*, 2022). This definition recognizes that executive confidence beliefs may have different forms (estimation, precision, placement) and purposes (generalized versus domain-specific). Executive confidence is based on individual dispositions and external cues, and it directly affects decision-making processes (Schumacher *et al.*, 2020). Indeed, a confident manager is genuinely interested in improving the organization's well-being while simultaneously enhancing its status (Hribar and Yang, 2016). This attitude reveals why a confident leader has a natural propensity and desire to embark on ambitious, massive, and even risky strategic projects, regardless of the risk of failure (Witkower *et al.*, 2021).

Notably, three forms of executive confidence were identified by Moore and Healy (2008): overestimation, overprecision, and overplacement. Overestimation is observed when chief executive officers (CEOs) "*generally think they are better than they are in terms of skill and judgment or in gauging the prospects of a successful*

*outcome*" (Hribar and Yang, 2016, p. 195). Overprecision occurs when managers/leaders exhibit excessive certainty regarding the accuracy of beliefs (Moore and Healy, 2008), and provide probability distributions of future events with narrow confidence intervals (Hackbarth, 2009; Hayward and Fitza, 2017; Hilary *et al.*, 2016; Levi, *et al.*, 2014). Finally, overplacement is a belief that erroneously rates someone as better than others; it occurs when people believe themselves to be better than others or "*better than the average*" (Thaler and Sunstein, 2008).

Executive confidence differs conceptually from other notions like narcissism, core self-evaluations, optimism (Heavey *et al.*, 2022) and self-immanent pride (Bachkirov, 2022). Although narcissism is a powerful personality feature, there is no evidence for believing that narcissists are more confident than others. In contrast, the narcissist's need to constantly reaffirm him- or herself may in fact indicate the absence of an innate confidence (Chatterjee and Pollock, 2017). Likewise, high core self-evaluations appear similar to executive confidence in capturing positive evaluations of competence, but Heavey *et al.* (2022) add that confidence has more varied origins, may be less enduring, and does not necessarily imply high self-worth or emotional stability. Meanwhile, optimism does not focus on the fact that an individual can influence a positive outcome by applying his or her abilities and influence. Instead, it is a more generalized expectation of positive outcomes (Zuckerman, 2001). Lastly, executive confidence differs from the concept of self-immanent pride, which is conceived as a source of destructive managerial anger (Bachkirov, 2022).

Connected to the theme of executive confidence, the influence of irrational forces on managerial decisions has received increasing attention in recent years. Focusing on irrational behavioral, Ariely (2008) states that people are far less rational than standard economic theory assumes and refutes the common assumption that people behave in fundamentally rational ways.

Kahneman (2011) illustrates the two ways in which the human mind works: the primitive and emotional system (System 1) characterized by "fast thinking" and representing the real protagonist of people's decisions, and the rational system (System 2) characterized by "slow thinking" and judgments made with caution and careful analysis. According to this study, System 1 is the most used during people's daily activities; even when people believe they are coldly pursuing their economic interests, they are actually governed by emotions and blinded by cognitive biases (i.e., the systematic errors of judgement people incur when

applying heuristics). Another study on irrational forces asserts that the use of the right levers on a psychological level can positively influence people's choices without their being aware of it. These levers are called "nudges", and their aim is to try to improve people's well-being by guiding their decisions while maintaining freedom of choice. By leveraging cognitive biases, nudges are designed to induce and persuade individuals to change their behavior in a predictable and non-coercive manner (Thaler and Sunstein, 2008).

Among the recent advancements made in understanding the impact of irrational forces in decision-making in management, in recent years some authors (Durant 2002; Hocoy, 2012) have begun investigating the concept of "synchronicity", which was developed by psychologist Carl Jung to describe a perceived meaningful coincidence – that is, the *"surprising concurrence of events, perceived as meaningfully related, with no apparent causal connection"* (Diaconis and Mosteller, 1989, p. 853). These events have the following characteristics: they must provoke an intense emotion in the subject, they must not be linked by a cause-effect relationship, and they must have a symbolic meaning (Hand, 2014). Meaningful coincidences can alter the course of lives (Brown, 1980) and are the basis of many scientific discoveries (Griffiths and Tenenbaum, 2007) and business foundations (Görling and Rehn, 2008), especially since individuals sometimes rely on them to make important decisions (including business ones) (Beitman, 2016; Govier, 2003).

This topic remains underexplored in relation to decision-making in management theories. Thus, the present study focuses on the bright side of executive confidence led by meaningful coincidences for decision-making (Heavey *et al.*, 2022) in the case of the particular historical period that is, COVID-19 pandemic.

In other ways, this work contributes to the literature by increasing our understanding of the positive decision-making theories of executive confidence led by meaningful coincidences in turbulent and uncertain scenarios (Figure 1).

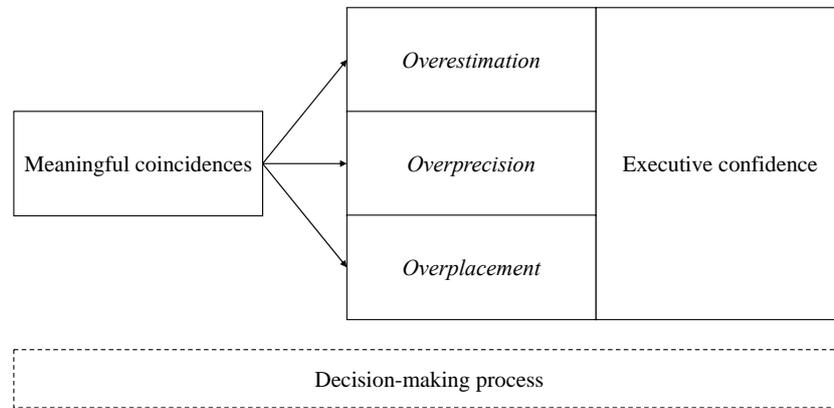

Figure 1

### 3 Method

#### 3.1 Study context

This study was conducted in Italian hospitality businesses in the Campania Region of southern Italy, notably in the Sorrento Peninsula and the Amalfi Coast. These locations were chosen because they are among the most popular tourist destinations in the world.

One of the most immediate economic effects of the crisis associated with COVID-19 pandemic was the blocking of tourist flows. Indeed, the health emergency had a strongly negative impact on the hospitality industry, resulting in unprecedented consequences (Baum *et al.*, 2020, Kang *et al.*, 2021). Italy was the first European epicenter of the virus and therefore the most vulnerable, most likely due to a geographical, logistical, and meteorological situation that was particularly favorable to the spread of the virus. Therefore, the country had little time to prepare for the pandemic's consequences, increasing subsequent organizational and managerial problems. The Italian tourism industry was profoundly affected by the restrictive measures due to the interpretation of tourism as a volatile and non-essential activity. According to ISTAT data, during the first ten months of 2020, overnight stays decreased by 51.4% compared to the same period of the previous year, with the loss of 207 million tourist visits. Indeed, following the COVID-19 shock, the hospitality sector required a redesign

of its business models, including the need to rethink governance processes and operating modes.

Thus, the COVID-19 pandemic and the lockdown in Italy represent a natural experiment that can help us to analyze how executive confidence led by meaningful coincidences can positively influence managerial decision-making in the specific context of the Italian tourism industry. Indeed, the top management of hospitality facilities has been faced with the need to make decisions during a most unusual and complex period in order to ensure proper performance and survival of their organization.

### **3.2 Data Collection**

To answer our research question, we used a qualitative approach consisting of interviews in hospitality facilities, conducted both in person and via Microsoft Teams. The study was conducted in early 2021, at the end of the first period of reorganization and consolidation of new working practices for the hospitality sector due to the COVID-19. In particular, based on a ranking compiled by a hotel trade association in 2021, 10 hotels with the highest tourist flow and revenue during the pandemic crisis were selected. In order to understand executive confidence, we chose to interview manager's subordinates as the main observers of all organizational choices and dynamics implemented during the pandemic period, avoiding interviewing managers themselves and thus avoiding biased judgments about their own choices. After completing each interview, the research team asked the subordinate to suggest another one involved in the decision-making dynamics of the organization, thereby using the snowball sampling technique to ask questions about how decisions were made during the pandemic period. Data saturation (i.e., repetition of the same themes) was used to calculate the size of the final sample. As a result, 24 manager's subordinates of the 10 hotels were interviewed. All interviews were recorded and then transcribed for further examination within 24 hours of conducting the interview.

To answer our research question, we followed an inductive approach, basing our data analysis on a variety of sources to get a more comprehensive understanding of the phenomena under analysis. In fact, using several sources of information is necessary for qualitative research in order to minimize the effects of any potential biases that could arise when using only one source (Bowen, 2009). Accordingly, we asked interviewees and informed actors to provide us with

archival and written data of any kind (e.g., websites of the hospitality facilities, open-source materials, company brochures, etc.) to give us a thorough grasp of how the organization works and the labor conditions that characterized the company under study.

The study's approach was based on the critical incident technique (Flanagan, 1954) to collect episodes, narratives, and sense-making linked to executive confidence during a turbulent time. This method refers to a set of procedures for collecting direct observations of human behavior in such a way as to facilitate their potential usefulness in solving practical problems and developing broad psychological principles (Flanagan, 1954). Through this method, a sequence of procedures is followed to collect firsthand observations of human behavior to generate new hypotheses. Accordingly, during the interviews, we talked in general to the interviewees to direct the flow of the discussion in the desired direction – that is identifying confidence behaviors of managers led by meaningful coincidences – but we did so without mentioning either of these concepts to avoid influencing the sample. Interviews were conducted by two interviewers as informal conversations and lasted an average of 40 minutes.

### **3.3 Coding and Analyzing**

Following the deductive coding for qualitative analysis (Fereday and Muir-Cochrane, 2006), the study's approach depended on a generic research statement: "We aim at investigating how executive confidence led by meaningful coincidences can positively influence managerial decisions during turbulent and crisis periods." The analysis process involved three phases.

In the first phase, we tried to identify recurrent themes in the interviews based on the respondents' answers. Subsequently, the transcripts from the interviews were uploaded into Dedoose, an online software program for qualitative data analysis. Next, two of the researchers independently reviewed the data, allowing for exploratory data analysis (Saldaña, 2021). Later, Cohen's coefficient  $\kappa$  – a statistic for qualitative categorical analysis that represents the degree of accuracy and reliability – was used to estimate the level of agreement between the coders, following an iterative approach (Locke, 2001). By comparing codes and discussing themes when disagreements emerged, the final consensus reached a value of  $\kappa = 0.81$ , reflecting high agreement between the raters.

In the second phase, we translated the previously identified concepts and themes into theoretically relevant terms, fitting them into already existing categories. Finally, in the third phase, we integrated the first-order codes and second-order concepts into a data structure, as shown in Figure 2.

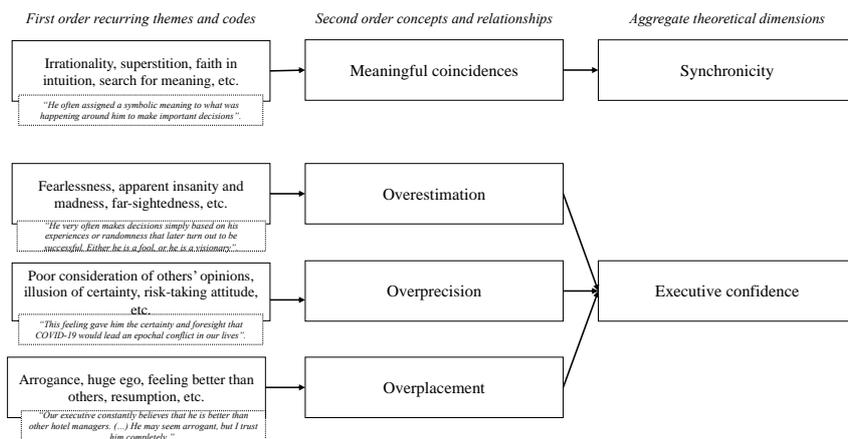

Figure 2

#### 4 Findings

Interestingly, in all of the hospitality facilities in the sample, which were selected on the basis of their excellent tourist flow and revenue during the COVID-19 crisis, certain subordinates' perceptions emerged related to executive confidence and meaningful coincidences.

After collecting and analyzing data, we identified several trends related to the characteristics of executive confidence suggested by Moore and Healy's (2008) classification. In particular, the findings highlight the process through which meaningful coincidences lead to the three different characteristics of executive confidence during a decision-making process – that is, overestimation, overprecision, and overplacement. While these characteristics are typically considered negative (see Moores and Chang, 2009), subordinates' perceptions suggest a number of positive and beneficial aspects for decision-making in a crisis such as the COVID-19 pandemic.

The first recurring aspect in interviews with subordinates concerning managers' decisions in dealing with a turbulent environment is overestimation. This concept

refers to the tendency to overestimate one's own abilities, level of control, or chances of success in seeking to achieve certain outcomes (Drobetz *et al.*, 2020). An interviewee reported: *"the hotel manager is fully aware of his capabilities, and during the COVID-19 emergency, he demonstrated determination and perseverance in his efforts"*. In the next passage, one can observe another example of this manager's tendency:

*Our hotel manager was convinced that it was essential to adopt a high-tech solution that blended sanitation with customer contentment. Would we have the resources to do it? We were a little worried about the outcome of this change, but he believed a lot in this improvement. I am pleased to report that customers really appreciated the implementation of this change.*

Thus, through overestimation in his abilities, this hotel manager has promoted a turnaround that has generated positive outcomes during a turbulent period.

Interviews with manager's subordinates suggest that executives' inclination to overestimate their skills and capacities allowed them to face chaotic and turbulent contexts and that very often this attitude stems from a series of meaningful coincidences experienced by the executive. The following excerpt is an example:

*The manager of this hotel is very confident. (...) In February 2020, he was supposed to go to a meeting but missed the train by seconds. That train derailed, generating difficulties and problems. This experience caused him to propose to all subordinates not to attend a tourism conference that was scheduled a week after that event. Well, we learned later that there was a COVID-19 contagion at that event, which we avoided by staying home. Some hotels had to close for a few days due to lack of sick staff, while we were all healthy. (...) Either he is a fool, or he is a visionary!*

Consequently, due to his experience, this hotel manager made a decision that produced good results in a very unpredictable environment.

A second theme emerging from the interviews is that of overprecision. This is the most ubiquitous form of overconfidence, referring to a situation wherein executives provide specific point estimates with narrow confidence intervals in their forecasts or predictions of outcomes (Hackbarth, 2009; Hayward and Fitzg, 2017).

According to Minson and Mueller (2012), overprecision can make people reluctant to consider others' points of view, listen to suggestions or seek compromise to resolve conflicts. As one interviewee stated, *"our hotel manager doesn't look down his nose at anyone. If he has decided that a direction must be*

followed, he will not be satisfied until he has reached it". Another example of a reluctance toward the others' opinions is given in the following excerpt:

*Our hotel manager is not very inclined to listen to us subordinates, but I have to admit that this attitude was successful during the emergency. During that period, we could not waste time, but we were all afraid of making decisions. Fortunately, our manager made decisions as quickly as possible, and this was ideal in the situation we were living.*

This prejudice subsequently impacts the decision-making process, but the responses of the interviewees showed that the tendency to be overconfident in their own beliefs caused executives to behave in the best way possible during the COVID-19 pandemic and that this attitude is frequently driven by the occurrence of meaningful coincidences. For example, the following excerpt from interviews illustrates this perspective in detail:

*During the pandemic, our hotel manager very often made decisions simply based on his experiences or randomness, and this attitude led him to choose well and achieve excellent results. (...) We all trusted him; he was so confident. I believe that he did his best to deal with the emergency, and the results proved him right.*

The last recurring aspect in interviews with subordinates concerning managers' decisions in dealing with a crisis is overplacement. This refers to a belief that one's knowledge, predictions, or abilities are superior to those of one's peers (Navis and Ozbek, 2016). This explains why many people expose themselves to risk, even when doing so puts their health and lives at risk (Thaler and Sunstein, 2008). "Our manager always puts his heart and soul into his job, and he doesn't believe he has a rival in what he does. In February 2020, he was the first to propose the use of personal protective equipment (PPE) before the State mandated it", an interviewee reported. Subordinates' perceptions suggest that executive overplacement allowed them to cope with uncertain and turbulent contexts and that very often this attitude stems from a series of meaningful coincidences experienced by the executive. Another example is given in the following excerpt:

*Our executive constantly believes that he is better than other hotel managers. In the darkest moments of the virus emergency, this trait has provided a glimmer of hope. He may seem arrogant, but I trust him completely. (...) When the pandemic broke out, our manager told us that he dreamt of a bloody and violent war. (...) This feeling gave him the certainty and foresight that COVID-19 would lead an epochal conflict in our lives,*

*and in early March he made major financial investments to bring the hotel up to safety standards to contain the spread of the virus, allowing guests to have a relaxing and safe stay. (...)*

As mentioned above, the executive's feeling made him sure that he had sufficient information to make the best choices, making risky decisions with unpredictable outcomes, such as disbursing substantial financial resources during a turbulent and uncertain period.

## **5 Discussion**

This work aimed at answering the following research question: "How does executive confidence led by meaningful coincidences influences management decision-making during turbulent times?" The occurrence of meaningful coincidences associated with executive confidence have been underestimated in the literature, but these elements provide insight into how managers make decisions that are not based on rationality (Cristofaro, 2020).

Our work offers several contributions to theory and research. First, we address the call from Heavey *et al.* (2022) to provide new insights into the bright side of executive confidence – which has previously been studied mainly from a negative perspective – and identify some managerial attitudes that represent critical variables in relation to positive executive confidence in uncertain times. Moreover, we respond to Hussain and Khan's (2020) request for studies on the experiences of hospitality facilities in uncertain and turbulent situations, by offering valuable information into how an hotel manager should act during crisis periods. By answering the call for studies on business situations in which rationality must give way to affective states (Cristofaro, 2019), this contribution suggests that the occurrence of meaningful coincidences can positively influence executive confidence, allowing hotel managers to respond to the needs of chaotic and turbulent settings. Finally, in response to calls from the literature on the effects of meaningful coincidences on decision making (Cristofaro, 2020), this research highlights the process through which meaningful coincidences lead to the three different characteristics of executive confidence during the decision-making process – that is, overestimation, overprecision, and overplacement.

According to subordinates' perceptions, executive confidence led by meaningful coincidences can positively influence managerial decision-making by implementing efficient tactics to promote change while establishing an overall

vision, setting ambitious priorities, and motivating people to work. The illusion of certainty and the occurrence of meaningful coincidences made the hotel manager believe that he or she had enough information to make risky decisions which brought unpredictable and favorable outcomes, such as investing huge financial resources without knowing exactly what scenarios would arise. Subordinates' perceptions revealed that confident managers whose choices are led by meaningful coincidences are not very satisfied with what they have, so it is possible for them to implement ambitious strategies to respond quickly to the surrounding environment. According to our findings, these aspects constitute an essential attitude for management because they direct executives and keep them moving forward to achieve goals in the face of uncertainty. Guided by these traits, a manager may be able to lead staff and deal with specific situations, such as the uncertain environment of the hospitality industry during the COVID-19 pandemic. Through meaningful coincidences, the manager may be also able to make decisions by going beyond the traditional boundaries of rationality, providing a solution to crisis situations. Thus, the results, which are consistent with several studies on the decision-making process of confident managers (e.g., Banerjee *et al.*, 2014), and on the occurrence of meaningful coincidences (Cristofaro, 2020), indicate that they positively influence decision-making process.

The results also have important practical implications. Our findings indicate that managers should consider the occurrence of meaningful coincidences, as these increase their confidence and allow them to perform well, even when faced with a turbulent context. In addition, another practical implication of this study concerns the new idea of skills required for management. After the COVID-19 pandemic, new skills must be considered, such as capacities for rapid adaptation to changes and unpredictable conditions, and to deal with abrupt changes without taking into account the viewpoints of all staff members. Moreover, thinking beyond the traditional boundaries of rationality can be critical to surviving the post-COVID-19 pandemic business environment, since confident managers whose decision-making is guided by meaningful coincidences can find themselves one step ahead of the competition during uncertain periods.

This study is not without limitations, including the choice to focus on a particular historical period such as COVID-19. Since this was a very uncertain and chaotic period, further research is needed on different historical periods to bring more rigor and value to these exploratory insights. Furthermore, although this study followed qualitative research methods conducted with rigor, the data are

limited by the inherent subjectivity of the participants' opinions. Similar research questions could be tested in the future on a larger sample through surveys or other methods of quantitative research. Further research may also help to better distinguish between positive and negative executive confidence led by meaningful coincidences.

## 6 Conclusion

This study found that manager's subordinates showed overall positive evaluations of managers' behavior guided by meaningful coincidences in high-performing Italian hospitality facilities during the COVID-19 pandemic. Through interviews with 24 participants, the subordinates' perceptions demonstrated that when an organization faces uncertain and turbulent times such as the COVID-19 pandemic, the occurrence of meaningful coincidences increases executive confidence, enabling managers to deal effectively with the obstacles and ambiguities of the context in which they operate.

### Abstract

SMEs are the economic backbone of Europe. In pharma companies, SMEs are the engines of innovation, playing a critical role in the creation of novel medications for patients. However, in reality, the scenario is not so favourable, and the objective of this research is to identify potential factors of negative growth in the pharmaceutical industry. The study used secondary data from the EU Industrial R&D Investment Scoreboard in 2015 and 2020 to apply a multiple linear regression model, with the dependent variable being operating profit. The results are very interesting, for example, the net sale has positive and operating profit has negative coefficients throughout the years, implying that operating expenses, costs of goods sold, and day-to-day costs are higher than sales revenue in most cases. In the model, we get that R&D expenditure is having a positive relationship in 2015 but an insignificant probability value; however, it is negative and highly significant in 2020. Likewise, R&D expenditures, the capital expenditure also does not go through identical

patterns in these two periods. Therefore, further studies are required to go through several years to generalize an exact relationship among the variables.

## 1 Introduction

The COVID-19 pandemic creates inefficiencies in the healthcare system by having devastating consequences. It has demonstrated how inefficiencies in the health system can significantly impact social cohesion, economic growth, and public confidence in government (OECD, 2022; Blumenthal, Fowler, Abrams, & Collins, 2020). In that instance, Europe was not an exception, while the pharmaceutical sector is a highly capital and knowledge-intensive industry in the world, the amount of investments necessary to meet the rising problems in the demand for health care is what characterizes the pharmaceutical industry, (Mennini, et al., 2016), which spends around 15 % of the total revenue on research and development (R&D), (Downs & Velamuri, 2018). Besides, European Union (EU) has the second largest market by sales account in the world and the increment of total investment becomes more than doubled during the pre-pandemic period (Azierta, 2019).

Our research focuses on the factors of negative growth of the pharmaceutical small and medium enterprises using a sample of pharmaceutical firms in the European Union in 2015 and 2020. To accomplish the research, we conduct several chapters in this paper, such as initially discussing the literature review with the titles of the role of SMEs in the pharmaceutical sector, and factors influencing the growth of SMEs end of the literature, we focused three hypotheses based on it and the emergence of the problem statement. In the next chapter we designed, materials and methods, where the methodology and data collection procedures have been discussed. The result section is divided into two parts, such as descriptive statistics and estimation of the coefficient of the models. Then, finally, it concludes the remarks.

## **2 Literature Review**

### ***2.1 The Role of SMEs in the pharmaceutical sector***

SMEs are the economic backbone of Europe. They account for 99% of all enterprises in the European Union and engage two-thirds of all private-sector workers (Lahkar et al., 2021). In pharma companies, SMEs are the engines of innovation, playing a critical role in the creation of novel medications for patients. SMEs are self-contained businesses with diverse workforce counts from one territory to the next. SMEs have been credited for driving pharmaceutical innovation in the United States and Europe, such as the development of new products, methods, and services (D'Amato et al., 2020). There is evidence that SMEs haven't yet performed a substantial role in pharmaceutical sector innovation in history. It has been stated that SMEs have helped the process of innovation by transforming the traditional "industry and academic" research paradigm into a triangle model. Meanwhile, several other studies have disputed this. Strategic partnerships in the United States among small pharmaceutical enterprises and large pharmaceutical enterprises reveal that the latter is more interested in partnerships for financial utilization rather than discovery (Sieckmann et al., 2018). This exposes the little drug enterprises to suffer the consequences of time. A careful examination of the pattern in the US pharmaceutical industry showed that SMEs have generated outstanding sales growth while maintaining poor profits compared to the pharma industry as a whole (Khoury et al., 2021). SMEs' performance in pharma depends on several essential variables, including innovation, research and development, marketing, contract production, and job placement. The power of partnership, a contemporary trend in the pharma industry, provides opportunities for SMEs in the pharma sector in terms of innovation (Sharma, 2016).

With developed nations' attempts to stimulate innovation, there is a chance that SMEs will gain from such endeavors, which will contribute to economic development. The pharma sector will aid SMEs by sharing knowledge in producing and promoting new goods or procedures. With the cooperation, SMEs will have access to freshly developing manufacturing technology. Furthermore, SMEs collaborations help enhance SMEs' innovation and performance in the worldwide pharmaceutical sector (Bagchi, 2010). Marketing is an important aspect of the pharma business. Insufficient funds might impede the successful entry of

pharma commodities into the marketplace or pharma products into the worldwide market. Partnerships for pharmaceutical drug promotion from SMEs can assist enhance revenues and offer an effective outlet for pharma brand selling both regionally and globally (Renko et al., 2005). Industrial production can be both financial and labour-demanding, necessitating a highly skilled and professional staff. Several businesses may confront issues with enough capital and labour expertise. Pharma SMEs might gain an edge by outsourcing the manufacture of their medications to worldwide production businesses. The ability of SMEs to leverage the knowledge of contracted manufacturing businesses will allow them to concentrate on primary competencies (Wikhamn et al., 2016). This method can reduce operational expenses while also increasing manufacturing process performance. Considering the introduction of novel industrial innovations, there is a greater necessity to train workers in modern technology. Worldwide pharma companies will help emerging nations educate the staff required to keep up with the company's technical changes (Ahmed-Ishmel et al., 2018).

## ***2.2 Factors Influencing the Growth of SMEs***

Numerous pieces of research on SMEs have been conducted on numerous topics about this industry. Among the subjects discussed in the literature are safety, technological utilization, personnel, performance, knowledge, strategy, and financing. Two out of every three employees in the private business are held by SMEs, according to (Ansu-Mensah et al., 2021). The importance of operational support for the industry was also emphasized by the scholars. According to the survey, SMEs confront difficulties such as inadequate information technology utilization, restricted financial availability, poor research and development spending, a scarcity of databases, low levels of monetary involvement, and inefficient distribution channels. These were held responsible for the SME sector's poor growth. Nikolić et al., 2019 concentrated on the impact of loan availability on SMEs' growth and operations. According to Nikolić et al., 2019., SMEs' ability to access loans is crucial to their sustainability and expansion. It is further claimed that regulators ought to support financial industry regulations that encourage financial facilitators to provide services and products that are suitable for SMEs. The expansion of small enterprises is severely constrained by the majority of SMEs' inadequate access to funding. The reasoning is predicated on the idea that

money is necessary for investments in reformation and innovations, among several other things (Wahab et al., 2016).

The impact of competition and globalization on SMEs was examined by (Thompson Agyapong et al., 2018) According to the report, globalization brought about technological advancements and increased levels of competitiveness. Park et al., 2019 evaluated the issues SMEs face. They also examined how easily SMEs could obtain credit from conventional financial institutions and how government policies affected their development and day-to-day operations. According to the survey, financial institutions were providing SMEs with insufficient financial support. It was discovered that the sector's expansion was also being constrained by an unpredictable overall economy. Lomatey et al., 2020 studied the difficulties SMEs face while trying to raise money. The study employed the social capital theory to demonstrate how difficult it is for SMEs to raise money. Other issues that have been looked into include insufficient security, unclear information, low technical proficiency levels, poor management capabilities, competitiveness, a lack of competence, and the absence of appropriate credit agreements. Njanike, 2020 researched the obstacles SMEs encountered that affected their productivity, expansion, and company operations. The results demonstrated a lack of govt assistance, unfavourable local authorities treatment, competitive pressures, a lack of marketplaces, a lack of financing, unfair local authorities treatment, increased competition, an insufficient amount of training, and low rates of technological use. Inadequate infrastructures and supplier distrust were also mentioned as barriers to SMEs formalizing their operations (Bouazza et al., 2015).

### **2.3 Hypothesis of the Study**

*H1: The relationship between net sales and operating profit is expected to be positive.*

*H2: The relationship between R&D expenditure and operating profit is expected to be positive.*

*H3: The relationship between capital expenditure and operating profit is expected to be positive.*

### **3 Materials and Methods**

#### **3.1 Data**

The conceptual framework of the study is designed through secondary data. The data includes the growth of pharmaceutical company-level variables, such as operating profits, net sales, market capitalization, R&D spending, employee count, and capital expenditures for pharma SMEs. In addition, the firm-level data of the above-mentioned variables are also obtained. The information can also be found in reputable sources like the European Commission, European Medicines Agency, and the EU Industrial R&D Investment Scoreboard. The financial statement, annual report, and other disclosure documents of the company are used to gather firm-level data for the in-depth analysis of negative operating profit.

#### **3.2 Method and Data Analysis Process**

The analysis will be done through descriptive statistics and a multi-variable regression model from the panel data. By fitting a line to the observed data, regression models are used to describe relationships between variables. Regression estimates the change in a dependent variable as the independent variable(s) change. To estimate the relationship between two or more independent variables and one dependent variable, multiple linear regression is used. Econometric software, such as Microsoft Excel, and STATA-14 will be used to analyze the results.

The process first recognizes the SME pharmaceutical companies and then estimates the multiple linear regression model. In the case of, recognition of the particular SME companies, we applied the turnover ratio of the company by net sales, if net sales are less than \$50 million, we consider the company in this group.

### **4. Results**

#### **4.1 Descriptive Statistics**

According to European Commission (2021), "Small and medium-sized enterprises (SMEs) are defined in the EU recommendation 2003/361". There are

two main factors determining whether an enterprise is an SME or not, staff headcount either turnover or balance sheet total.

Table 1: The European Commission criteria for SMEs

<b>Company Category</b>	<b>Staff headcount</b>	<b>Turnover</b>	<b>Balance sheet total</b>
Medium-sized	< 250	≤ € 50 m	≤ € 43 m
Small	< 50	≤ € 10 m	≤ € 10 m
Micro	< 10	≤ € 2 m	≤ € 2 m

Source: European Commission (2021).

Small and medium-sized businesses (SMEs) in the biopharmaceutical industry are major forces behind innovation in Europe. They have a significant impact on the creation of novel medications, especially in fields like biology, future pandemics, infectious diseases, and uncommon diseases and these fields are neglected due to technological obstacles or lower expected market potential (EFPIA,2020). Diverse financing sources are crucial for fostering innovation in the pharmaceutical sector. National programs R&D, including for small and medium-sized firms (SMEs) and academia, will be a fundamental component of the Strategy's assistance (European Commission, 2020).

But reality always has a few ugly edges. Numerous businesses in the European Union experience incredibly low profitability year after year. For instance, one medium-sized company, MEDIGENE AG in Germany, had 142 employees overall in 2019 and 121 in 2020. Although there is still a persistently negative net profit, such as -19,962 in 2019 and -28,875 in 2020. Not only Germany, but other leading economies also has several pharma companies with negative operating profit over the years. Table 2 just represents a sample of the data set in 2015 negative operating profit, while the data since 2020 shows strong evidence of it.

Table 2: Operating profit loss (€ million) in EU pharma Industry

<b>Country</b>	<b>year</b>	<b>Total companies facing negative OP</b>	<b>OP loss in total</b>
United Kingdom	2015	21	-546.3
Germany	2015	5	-149.6
France	2015	11	-213.3
Denmark	2015	6	-1089.4
Netherlands	2015	5	-146.5
Ireland	2015	4	-2973.1

Source: European Commission (2023)

The majority of businesses, including EU pharmaceutical companies, have negative or zero operational profits, as shown in Table 1, while net sales, capital outlays, and R&D investment have increased over time.

Table 3: Pharmaceutical Companies in the EU with negative or zero operating profit

Year	Total number of firms	Firms with negative or zero operating profit
2015	133	82
2016	150	89
2018	166	99
2019	159	102
2020	143	90

Source: EU Industrial R&D Investment Scoreboard (2023).

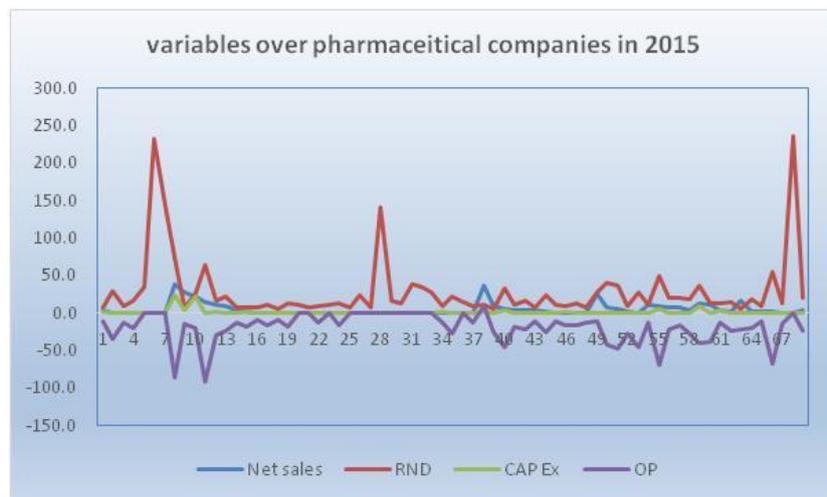

Figure 1: The variables over EU pharmaceutical companies in 2015.

The figures show that operating profit is having zero and negative values throughout the companies. While R&D expenditures are containing greater values in both years to the pharmaceutical companies in the EU.

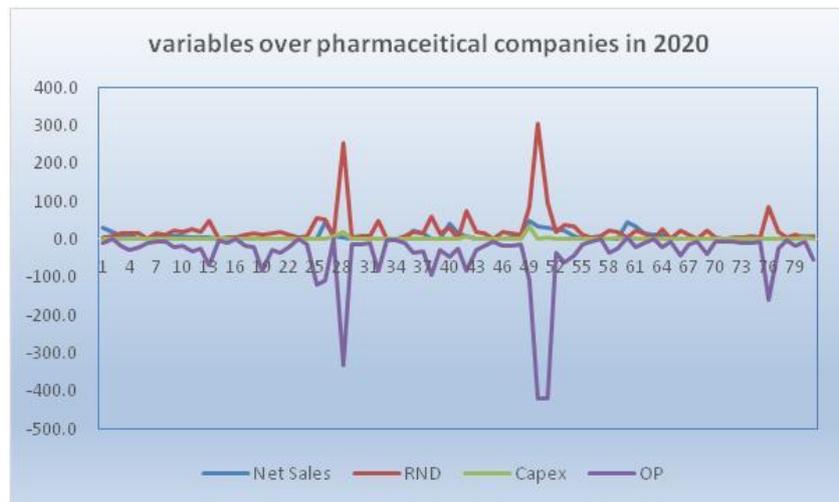

Figure 2: The variables over EU pharmaceutical companies in 2020.

#### 4.2 Empirical Models and Estimations

We estimate the following multiple linear regression model by using the econometric software STATA-14.

$$Op = \alpha + \beta \text{ netsales} + \gamma R\&D + \delta CapExp + \mu$$

Where, OP= Operating profit of the company in a particular year

$\alpha$  = constant or intercept term

$\beta$  = the interaction coefficient for net sales

netsales = Net sales of the company in a particular year

$\gamma$  = the interaction coefficient for Research and Development expenditure

R&D = Research and Development expenditure in a particular year

$\delta$  = interaction coefficient for capital expenditure

CapExp = Capital expenditure for a particular year

$\mu$  = error term

Table 4 displays the projected results of the multiple linear regression model, which has two parts: one for the cross-sectional data for the year 2020 and another for the cross-sectional data for 2015. It includes panel data when combined. The procedure first identifies SMEs and small pharmaceutical companies before estimating multiple linear regression models. In the case of identifying a specific SME company, we used the company's turnover ratio of the company by net sales; if net sales are less than \$50 million, we consider the company to be in this group.

To avoid the impact of non-constant variance, we use a robust regression model rather than a simple multiple regression on the data for the years 2015 and

2020. The robust multiple linear regression model is useful in this regard because it implies different standard error values, which control the model's heteroscedasticity problem. Stata-14 software was used to perform the Breusch-Pagan / Cook-Weisberg test for heteroskedasticity.

Table 4 (a): Estimated Results of the Multiple Linear Regression Model

Dependent Variable: OP  
 Method: Least Square  
 Observation: 69  
 Year Value estimated: 2015

Variable	Coefficient	Robust Standard Error	t-statistics	Probability
_cons	-14.84196	2.256381	-6.58	0.000*
net sales	-0.4533791	0.60478	-0.75	0.456
R&D	0.0014992	0.048464	0.03	0.975
capex	-1.360881	1.207344	-1.13	0.264
R-squared	0.1826			
Adj R-squared	0.1449			
Prob > F	0.0978			

Note: \* indicates a 1 % significance level. (Source: Authors' estimation)

Table 4 (b): Estimated Results of the Multiple Linear Regression Model

Dependent Variable: OP  
 Method: Least Square  
 Observation: 81  
 Year Value estimated: 2020

Variable	Coefficient	Robust Standard Error	t-statistics	Probability
_cons	0.9885575	3.180403	0.31	0.757
net sales	-0.4005767	0.4681217	-0.86	0.395
R&D	-1.486248	0.1438423	-10.33	0.000*
capex	0.650943	0.6969763	0.93	0.353
R-squared	0.8001			
Adj R-squared	0.7923			
Prob > F	0.0000			

Note: \* indicates a 1 % significance level. (Source: Authors' estimation.)

When we compare the results from Table 4(a) and Table 4(b), we can see that the estimated coefficients have useful interpretations, such as "only the relationship between operating profit and net sales is similar in these two periods as negative", while the other variables, R&D expenditure and capital expenditure, vary depending on the years. The relationship between net sales and operating profit is indeed negative in these SMEs of pharmaceutical companies in the European Union, implying that net sales do not provide the strength for these companies to have a positive operating profit, which will suffer in the future for sustainability if there is insufficient profit generation. Operating profit is calculated as follows: Operating Profit = Revenue - Operational Expenses - Cost of Goods Sold - Day-to-Day Costs (like depreciation and amortization). Operating profit is significant because it allows businesses to evaluate their financial performance. In most cases, the operating profit of firms is negative, while net sales are positive from the data set, therefore, the operating expenses, costs of goods sold, and day-by-day costs are higher than the sales revenue. Negative profit margins can temporarily halt those activities, affecting both investors and your company's access to credit. It is not desirable for businesses' sustainability.

R&D spending does not guarantee profitability or strong stock performance on its own. When projects are deemed successful, some companies see a payoff from investing heavily in R&D. Companies, on the other hand, can suffer from poor performance losses despite investing heavily in R&D each year (Morbey, 1989). In the model, we get R&D expenditure having a positive relationship in 2015 but an insignificant probability value; however, it is negative and highly significant in 2020 as a p-value of less than 0.05 implies significance and that of less than 0.01 implies high significance. Therefore  $p=0.0000$  implies high significance. Similar to R&D expenditure, capital expenditure does not signify the same direction for both periods. In 2015, it is negative and insignificant but in 2020 it is positive and insignificant. The actual cost of capital expenditure has no immediate impact on the income statement, but depreciation gradually reduces profit on the income statement over the asset's life. However, depending on the type of asset, capital expenditure may have an immediate impact on the income statement in other ways.

## **5 Conclusion**

SMEs are the economic backbone of Europe. In pharma companies, SMEs are the engines of innovation, playing a critical role in the creation of novel medications for patients. SMEs have been credited for driving pharmaceutical innovation in the United States and Europe, such as the development of new products, methods, and services. However, numerous businesses in the European Union experience incredibly low profitability year after year. The study will focus on an empirical analysis of the factors influencing the growth of pharmaceutical SMEs in the EU.

But in reality, the scenario is not the EU Industrial R&D Investment Scoreboard so favourable, the study aims to find out the potential factors of negative growth in the pharmaceutical industry. The study collected secondary data from the EU Industrial R&D Investment Scoreboard in 2015 and 2020 to apply a multiple linear regression model, where the dependent variable is the operating profit, which has very interesting results, for instance, the net sales and operating profit have negative coefficients throughout the years, which implied that the operating expenses, costs of goods sold, and day by day costs are higher than the sales revenue as most cases operating profit is negative; however net sales are positive throughout companies. In the model, we get that R&D expenditure is having a positive relationship in 2015 but an insignificant probability value; however, it is negative and highly significant in 2020. Likewise, R&D expenditures, the capital expenditure also does not go through identical patterns in these two periods. Therefore, further studies are required to go through several years to generalize an exact relationship among the variables.

### **Abstract**

Although telemedicine practices may be traced back to decades ago, their real potential has only been recognized during Covid-19 outbreak. As the pandemic has abated, the implementation of telemedicine has revealed many managerial considerations that are crucial for its optimal deployment. The technical and social connotation of telemedicine is central for both understanding and promoting its implementation. This dual nature has been shown to peculiarly affect the organization of work, in particular coordination among health professionals. This study investigates which coordination mechanisms are enacted within telemedicine services among health professionals and how these mechanisms unfold to achieve collective performance within these services. To do that, three case studies, concerning telemedicine services provided by public healthcare organizations in the Italian context, were analysed. Results shed novel light on coordination mechanisms enacted within telemedicine services and their integrated conditions, meant as the

instruments through which coordination mechanisms unfold to achieve collective performance. Practical implications are discussed to support managers in interpreting how coordination mechanisms work within telemedicine services and consequently how to effectively design them.

**Keywords** – Coordination, Organization, Telemedicine, Healthcare

**Paper type** – Academic Research Paper

## 1 Introduction

Although telemedicine practices may be traced back to decades ago (Hjelm & Julius, 2005), their real potential has only been recognized in recent years. Covid-19 pandemic acted as catalyst for the awareness and diffusion of telemedicine, which – during lockdown – had essentially become the only possible manner to provide non-urgent medical services (Lukas et al., 2020).

This unprecedented awareness on telemedicine has led to the introduction of related policies and investments, addressing issues such as public reimbursement, data privacy, infrastructures, etc. (Bokolo, 2021). The Italian context is representative in this sense, as telemedicine has been central in the process of reform of the Italian National Health System (NHS), mainly through the National Recovery and Resilience Plan<sup>1</sup>.

As the pandemic has abated, the implementation of telemedicine has revealed many managerial considerations, which are crucial for its optimal deployment. The complexity of integrating telemedicine within current practice is linked to the extension of the concept itself. In fact, telemedicine has been defined as the *provision of health services at distance*<sup>2</sup> and it is substantially characterized by a technological connotation (mainly related to digital technologies), as well as social implications (Bashshur et al., 2011).

The dual technical and social-related connotation of telemedicine is central for understanding and promoting its implementation (Khodadad-Saryazdi, 2021). In particular, this dual nature has been shown to peculiarly affect the organization of work (Barlow, 2015; Khodadad-Saryazdi, 2021; Nicolini, 2006, 2007). Nicolini (2006) argues how telemedicine affects coordination, through task shifting in the form of delegation of medical work towards non-medical roles (e.g. nurses) and

<sup>2</sup> Available at: <https://apps.who.int/iris/handle/10665/357828>

affecting the “geography of care delivery”. Thus, coordination emerges as a central concept for understanding how medical work changes with the introduction of telemedicine, both from a theoretical and practical standpoint.

From a theoretical viewpoint, the significance of telemedicine lies in its capacity to embody the sociomaterial entanglement of technology and service, thus serving as peculiar and example case for our understanding of coordination (Orlikowski, 2007). However, this potential has not been fully explored, with respect to studies related to other technological domains in healthcare settings (see, for example, Sergeeva et al., 2020).

From a practical perspective, understanding how coordination mechanisms unfold within telemedicine services is of paramount importance for their effective design. This is particularly significant given the growing prevalence of telemedicine services in various national healthcare systems. The Italian NHS, for instance, calls for further coordination among healthcare professionals – including specialist doctors, general practitioners (GPs), and nurses – both within and across organizations. In this regard, the responsibility of ensuring coordination falls on the new roles and organizations established through healthcare system reforms<sup>1</sup>. To that end, it is essential for healthcare providers offering telemedicine services to work toward process and organizational convergence.

Finally, over the years, the scientific literature in the medical field has extensively discussed the matter of coordinating care with a pragmatic approach, often aimed at gathering evidence of the efficacy and effectiveness of integrated and coordinated care. Several articles have addressed this concern in diverse specializations, including – among others – diabetes (Northwood et al., 2022), cardiology (Doughty et al., 2002), gastroenterology (Chey et al., 2021), oncology (Kaasa et al., 2018). There is also evidence linked to the introduction of telemedicine within coordinated or integrated care (see, for example, Hays & Skootsky, 2022; Palmer et al., 2021; Pluymaekers et al., 2021; Silva-Cardoso et al., 2021; Sinsky et al., 2021; Tourkmani et al., 2021). This underscores the presence of an empirical problem, which offers the opportunity to analyse the issue from a theoretical viewpoint and derive practical conclusions with a more distinctly managerial approach.

Given these premises, this study investigates which coordination mechanisms are enacted within telemedicine services among health professionals and how these mechanisms unfold to achieve collective performance within these services.

An overview on the main relevant issues concerning the empirical setting is hereby provided and the theoretical framework adopted within the study is then discussed. As our understanding related to the objective of the study is limited, a multiple case study methodology was adopted to gather data from the actors involved in the phenomenon under investigation (Gioia et al., 2013) “within its real-life context” (Yin, 2013). Results are presented and discussed, along with conclusions and limitations of the study.

## **2 Background**

### **2.1 Telemedicine**

One of the currently most acknowledged definitions of Telemedicine is provided by the World Health Organization, which delineates it as the *provision of health services at a distance*<sup>1</sup>. The key feature of telemedicine consists in the physical distance between the actors involved within the telemedicine service, which is typically enabled by digital technologies.

Although the very definition of telemedicine is debated, the taxonomy proposed by Bashshur et al. (2011) clarifies a set of issues that are relevant for this research. Their taxonomy is based on three intersectional dimensions: technology (synchronicity, network and connectivity), functionality (diagnosis, consulting, monitoring and mentoring) and applications (treatment, specialty, disease and site).

The authors wished for the recurrence to a coherent and unified taxonomy not only for scholars, but also for policymakers. This taxonomy is in fact still far from being achieved (Harst et al., 2022), as it can also be noticed by different definitions given to specific telemedicine services among international policies (Edmunds et al., 2017). However, the proposed taxonomy conceptually shows the multi-faced structure of telemedicine, which can be intrinsically considered as a set of technologies, functionalities and applications integrating traditional healthcare service delivery (Bashshur et al., 2011). In other terms, telemedicine can be meant

---

<sup>1</sup> Available at: <https://apps.who.int/iris/handle/10665/357828>

as an “integrated system of healthcare delivery” , both in presence and at distance, through the deployment of digital technologies (Bashshur, 1995).

Therefore, telemedicine comprises a plethora of different specific typologies of services, such as teleconsultation and telemonitoring. Practical definitions of different common types of telemedicine services are provided in Annex 2 (Glossary).

## **2.2 Coordination mechanisms: the adopted framework**

To investigate how telemedicine changes coordination mechanisms within healthcare services provision, the framework proposed by Okhuysen & Bechky (2009) was exploited. The authors define coordination mechanisms as *the organizational arrangements that allow individuals to realize a collective performance*. Five coordination mechanisms were identified as recurrent in the literature and conceptualized as plans and rules, objects and representations, roles, routines, and proximity.

However, it is argued that coordination mechanisms alone fail to provide a comprehensive view of “how” these mechanisms work. The need for a further level of conceptualization stems from: i) the emergence of different approaches depending on the object of analysis (Crowston, 1997; Gittell, 2000); ii) the “embeddedness of findings in particular contexts”, i.e. the fact that past research has investigated coordination mechanisms on a variety of empirical context, resulting not only in a fragmented terminology, but in a difficult comparability among findings; iii) a lack of focus on the means through which coordination mechanisms are enacted, i.e. “how” they happen.

Therefore, Okhuysen & Bechky (2009) went further and identified the three *integrating conditions* depicted in Table 1, through which agents achieve collective performance.

Table 5. Integrating Conditions for Coordination: definitions

<b>Integrating condition</b>	<b>Definition</b>
Accountability	It answers to the question “who” is responsible for specific elements of the task
Predictability	It enables interdependent parties to anticipate subsequent task-related activities, by knowing what the elements of the task are and when they happen
Common understanding	It provides a shared perspective on the whole task and how individuals’ work fits within the whole

Source: adapted from Okhuysen & Bechky (2009)

Each of these conditions can be achieved through a combination of coordination mechanisms, which are reported in Table 6.

The specific approach taken in the present research is coherent with the perspective of Crowston's work (Crowston, 1997; Malone & Crowston, 1990, 1994), which focuses on task interdependence in situations in which resources are shared among agents, or tasks need to be divided into sub-tasks in order for goals to be accomplished. Therefore, the empirical focus is medical and health professionals' work.

Table 6. Integrating Conditions for Coordination and their Relationship to Coordination Mechanisms

	<b>Accountability</b>	<b>Predictability</b>	<b>Common understanding</b>
<b>Plans and rules</b>	Defining responsibilities for tasks	Defining responsibilities for tasks Resource allocation	Developing agreement
<b>Objects and representations</b>	Scaffoldings Acknowledging and aligning work	Scaffolding	Direct information sharing Creating a common perspective
<b>Roles</b>	Monitoring and updating		Substitution Creating a common perspective
<b>Routines</b>	Hand-off work	Task completion/stability	Bringing groups together Developing agreement
<b>Proximity</b>	Visibility: monitoring and updating Familiarity: developing trust	Familiarity: anticipating and responding	Familiarity: store of knowledge

### 3 Methods

To address the research question, a multiple case study methodology was employed, focusing on coordination mechanisms in telemedicine services as units of analysis.

Following the recommendations for multiple case study theory building (Eisenhardt 1989; Eisenhardt and Graebner 2007), within- and cross-case analyses were performed (Yin, 2013). Cases were selected through empirical sampling, considering the geographical area and legal nature of the organizations where services are provided.

In Italy, Regions have considerable autonomy in defining the organizations of health services delivery, and healthcare provision takes place at various institutional levels, such as Local Health Authorities (LHAs) and hospitals, which follow partially different institutional criteria. All cases were selected in the Italian context to control for policy, political, and regulatory factors that might affect the provision of telemedicine services. Three cases, namely North-East, North-West, and Centre (NE, NW, and CE), were chosen to limit potential biases (Eisenhardt and Graebner 2007) and gather stronger insights (Eisenhardt 1989). Each service includes teleconsultation, telemonitoring and tele-expertise.

Their main features are shown in Table 1. More information is available in Annex 1.

Table 1: Features of the three case studies

<b>Feature/Case</b>	<b>NE</b>	<b>NW</b>	<b>CE</b>
Geographic Area	Northern Eastern Italy	Northern Western Italy	Central Italy
Juridical nature of the organization	LHA	Hospital within LHA	LHA
Dimension	300 patients involved	300 patients involved	4,000 patients involved
Type of patients	Patients with (low risk) heart failure	Diabetics	Various (cardiology, endocrinology, psychology, etc.)
Interviewees	Project Manager (interviewed twice), Doctor (interviewed once) and Nurse (interviewed once)	Doctor (interviewed once)	Doctor (Head of Digital Transformation) (interviewed twice)

To ensure robust data collection, multiple sources of evidence were relied upon, including primary data, such as semi-structured interviews, and secondary data, such as reports, online news articles, and websites.

The interviewees for this study included individuals who were both healthcare professionals and managers. For the region of NE, the three professionals interviewed were a Project Manager, a doctor, and a nurse. In NW and CE, the interviewed doctors held prominent managerial positions, which are commonly referred to as "hybrid" roles in previous studies (see, for example, Mcgivern et al. (2015).

The information from the interviews has been complemented by several other sources of evidence, including institutional websites, academic papers, newspaper

articles, and practitioners' reports. The convergence of evidence, which emerged from data triangulation, has strengthened construct validity (Jick, 1979).

After transcribing the interviews verbatim, they were analysed following the Gioia Methodology (Gioia et al., 2013), identifying theory-driven codes, categories, and themes.

## **4 Findings**

Findings are described based on the integrating conditions for coordination mechanism identified by Okhuysen & Bechky (2009).

### **4.1 Accountability**

By defining who is responsible for specific tasks or sub-tasks, accountability enables clarity for organization members with respect to their shared responsibilities in reaching a common goal (Okhuysen & Bechky, 2009).

Plans and rules contribute to accountability by defining task responsibilities. In Project-NE, effort was put in defining formal procedures concerning the management of patients through telemedicine tools and to make professionals aware of them:

*"We are defining detailed internal procedures and we are pushing to make them public, so that each professional will be aware of what are their responsibilities." – Project Manager, NE*

Moreover, the roles of pre-existing actors within the organization were "updated". This is particularly true for nurses, who have experienced job enlargement more than other professionals. New professional figures were established as well: within Project-NE, dedicated project managers were assigned to specific parts of the project:

*"While there is an ongoing negotiation on tasks and activities, which is redistributing tasks and activities among nurses, specialized doctors and GPs, [...] the coordinating role for technical deployment were assigned to dedicated Project Managers." – Doctor, NE*

Within Project-NW, telemedicine has been integrated within integrated pathways for chronic patients. These pathways describe the journey of the patient and the responsibilities for each actor who deals with the patient:

*"We have defined two integrated care pathways: the first one for patients with hyper-glycemia that are firstly treated with urgency; the other one*

*concerns patients with insulin infusers, who are followed also through telemedicine services.” – Doctor, NW*

Therefore, the evidence suggests that:

*Proposition 1: Within telemedicine services, accountability is accomplished through the design of new procedures, the definition of new roles and the revision of existing ones.*

#### **4.2 Predictability**

Predictability enables organizational agents to anticipate the sequence of tasks related to activities, knowing which tasks will be performed and when (Okhuysen & Bechky, 2009).

In Project-NE, the telemedicine platform has a specific functionality that allows health professionals to view which tasks have been carried out and to “activate” new ones, i.e. to request other professionals to perform another task:

*“Through our platform it is possible for health professionals to [...] view and activate tasks, through a task planner.” - Nurse, NE*

The interviewed doctor for Project-NW has highlighted that the availability of data gathered through telemonitoring allows for professionals to understand more easily which tasks are needed to be performed:

*“Being able to regularly view the data concerning patients managed within the project, it is easy for nurses and doctors to define when it is appropriate to intervene.” - Doctor, NW*

Finally, Project-CE has developed informative materials and tutorials for both health professionals and patients, consisting in presentations and short videos. Although their purpose is mainly informative, these materials are substantially protocols and they contribute to create a sequence of interdependent actions that should be clear to all the agents:

*“These videos and materials are available through a QR code. They are useful to understand the overall process, with a step-by-step approach and they are very easy to follow. [...] We also have extended versions, e.g. the one for tele-expertise is 29 pages long.” - Doctor, CE*

Thus, evidence points out that:

*Proposition 2: Within telemedicine services, predictability is achieved through representations of task advancement and patients’ status, enabled*

*by the telemedicine platforms themselves, and through protocols establishing sequences of actions.*

#### **4.3 Common understanding**

Common understanding is meant as a shared perspective on overall activities and shared goals (Okhuysen & Bechky, 2009).

In Project-CE, common understanding was meant as the understanding of the overall required sub-tasks that make up the overall health service, through both the formalization of procedures and the possibility to visualize the overall process within the platform.

*“Managing the process through the platform allows to see the unpacking of the different activities (e.g. booking, paying, doing a visit). Now everyone can understand the overall process, with respect to traditional services. Now you can be mad at the patient or to your colleagues knowing that you were right.” - Doctor, CE*

Moreover, different professional figures typically intervene in managing care for chronic patients, in both acute situations of follow-ups. The interviewed doctor of NW pointed out that different perspectives are intrinsic of different professional backgrounds. However, the possibility to monitor, visit and manage patients remotely contributes to set appropriate priorities for intervention, both physically and remotely.

*“Without telemedicine it was difficult for surgeons and clinical doctors to have a common view on the patients, as they prioritize their part of the pathway. It is still difficult, but we are developing agreement.”- Doctor, NW*

In the Italian context, much effort is being put on aligning goals between the hospital setting and the territorial setting. In this sense, within Project-NE telemedicine is viewed as a tool to share information as it was not previously done, creating a bridge among actors in different settings.

*“Usually there has been a lack of direct communication with hospital doctors. This project was born with the aim of not working in silos.” - Project Manager, NE*

In conclusion, findings indicate that:

*Proposition 3: Within telemedicine services, common understanding is enabled by new channels for communication and information provision, as well as the possibility for each actor to "visualize" and understand the overall process.*

## **5 Discussion**

The three cases allowed to gather evidence to improve our understanding on coordination mechanisms enacted within telemedicine services in public healthcare organizations.

From a theoretical perspective, the sociomaterial connotation of telemedicine, which defines its technological and service nature (Bashshur et al., 2011), are fundamental for comprehending the impact of telemedicine on enacted coordination mechanisms. Telemedicine platforms function as coordinating objects and representations, while coordination is enacted also as rules, procedures, and roles defined within telemedicine services.

The purpose of the present study was not only to identify the coordination mechanisms used, but also to further our understanding on how these mechanisms fulfil the three integrated conditions conceptualized by Okhuysen & Bechky (2009).

Accountability, which refers to the awareness of organizational agents regarding their responsibilities for each task and sub-task, depended on the presence of formal procedures associated with telemedicine services. Management took the initiative to promote the diffusion and awareness of these procedures among health professionals. The introduction of telemedicine services in Italy necessitated the revision of pre-existing roles, which are now being distributed among professionals, such as GPs and nurses. Additionally, new roles have been introduced to manage technological deployment and coordination among settings. Finally, integrated pathways, which include telemedicine services, functioned as procedures that define tasks and responsibilities for each agent involved in patient care.

Predictability, which refers to the ability of agents to anticipate tasks or sub-tasks in space and time, was achieved through detailed protocols, which should be easily accessible by professionals, which contribute to clarifying the sequence of actions needed to provide the overall service. The availability of data through

telemedicine platforms enables health professionals to anticipate when it is appropriate to intervene, thus providing predictability. Finally, task planners specifically provide professionals a tool to activate tasks and foresee them to some extent.

Finally, a shared understanding of tasks and objectives relies on the possibility of visualizing and comprehending the overall process of service provision through technology. Furthermore, the availability of data provides a common view on priority setting for professionals who typically have a siloed view of their piece of the process. Lastly, the possibility of communicating and exchanging data among hospital and territory actors activates a virtuous channel that aims to build bridges between these two domains (although these bridges are still a “work in progress”).

The examination of the coordination mechanisms that are enacted and “how” they satisfy these conditions offers relevant practical implications. The three integrating conditions are derived from a formal and emergent view of coordination mechanisms. Thus, when designing formal coordination mechanisms for telemedicine services, managers must be aware of how these mechanisms operate among professionals to be effective. It is not sufficient to merely clarify the tools, procedures, and overall formal arrangements; rather, it is necessary to link coordination mechanisms to the integrating conditions to enable their optimal implementation. Understanding how accountability, predictability, and common understanding arise from the organization is a key component of the design of coordination mechanisms.

Within the empirical setting under examination, the evidence is associated with relatively small projects that are currently being implemented. While it already emerged how coordination mechanisms are linked to the integrating conditions, it is also clear that more must be done to enhance their effectiveness. Given the nature of healthcare organizations, accountability is challenging as the structure of belief of professionals affects their perception of accountability “sticking” it to their traditional view. With regard to predictability, the consolidation of these services should contribute to creating “new routines” for health professionals. Finally, common understanding is likely the most overlooked integrating condition, but it is also arguably the most relevant at present time. The awareness of how each actor's contribution is linked to the overall process and objectives is one of the primary missing links between the enactment of coordination mechanisms and their effectiveness.

## 6 Limitations and future directions

The present study is currently at an initial phase and requires further evidence to support its conclusions. The three case studies will be deepened with more evidence, and additional case studies will be added with a replication logic. To support the reliability of the findings, it would be beneficial to examine case studies related to healthcare providers in various geographical locations and with different legal structures, such as private healthcare providers. By doing so, the evidence linked to the results will be strengthened.

In the future, it is desirable to collect sufficient evidence to discuss not only the coordination mechanisms in use and how they function, but also how they develop over time or with maturity (attributing them the meaning of “organizing structures” as defined by Okhuysen & Bechky (2009)). It would also be useful to examine the dynamics between formal arrangements and emergent practices, deepening the interpretation based on the existing debate.

## **Annex 1: The three selected case study**

### ***Case study 1: North-East (NE)***

"North-East" (NE) is a publicly funded Local Health Authority (LHA) that serves as the sole healthcare provider within its designated regional territory, which renders it an essential entity of the region itself. Its mandate is to manage and coordinate healthcare and social welfare activities throughout the Region. Notably, the Region holds unique regulatory autonomy within the constraints of the Italian constitution. The regional territory is predominantly mountainous, and there are numerous scattered settlements throughout the area. The LHA and the region have a longstanding focus on digital transformation in healthcare, as evidenced by their creation of dedicated strategic support entities.

Project-NE is a service provided by NE, a healthcare organization operating in collaboration with the region and other supporting bodies. This service is specifically designed to address the growing number of chronic heart failure patients, which poses a significant challenge to the healthcare system for the coming years.

The project enables healthcare professionals, such as cardiologists and cardiology unit nurses, to conduct teleconsultations and telemonitoring of chronic heart failure patients. A web-based clinical dashboard provides healthcare professionals with comprehensive data while patients are provided with a smartphone app that includes specific functionalities prescribed by the cardiologist. The platform integrates digitally connected devices, such as implantable devices and smartwatches, to provide healthcare personnel with real-time patient data for a complete clinical overview. The dashboard allows healthcare professionals to monitor patient data and registered parameters, schedule and initiate video calls, and share multimedia files.

Currently, three local healthcare hospitals and clinics manage over 300 chronic heart failure patients within this telemedicine service.

### ***Case study 2: North-West (NW)***

"North-West" is a publicly funded LHA situated in the most densely populated Italian Region. It encompasses one of Italy's largest hospitals, in terms of hospital beds, and provides comprehensive clinical and surgical specialties organized

across more than 50 departments. As an LHA, NW also encompasses territorial clinics that provide both health and social care services, with the mission of integrating specialty and social care.

Project-NW is a service designed for patients with diabetes, both type I and II, and it is delivered via a telemedicine platform, allowing teleconsultation and telemonitoring. Teleconsultations are meant for follow-up consultations to monitor therapy and receive specialist prescription. Telemonitoring enables continuous gathering of data related to diabetes-related parameters from sensors. The service was initially developed in NW hospital in collaboration with the Region and has the potential to expand to other healthcare providers. Over 300 patients are currently involved in this project.

The platform used for these services is integrated with the regional Electronic Health Record (EHR), providing access to the patient's entire clinical history. The platform also allows for real-time uploading and viewing of attachments, including documents, images, and videos exchanged between the doctor and the patient.

### ***Case study 3: Centre (CE)***

"Centre" is a publicly funded LHA located in one of the most populated Regions of Centre Italy, which provides medical care to over 500,000 citizens. The region encompasses a vast territory of over 3,000 square kilometres, with less than 100 towns and a population density of less than 150 individuals per square kilometre.

The Project-CE has been implemented in the primary hospital of "Centre" as well as in smaller public clinics specialized in specific medical practices within the territory. Telemedicine services have been integrated into various clinical specialties, including cardiology, psychology, dermatology, and endocrinology.

Teleconsultations are commonly used for follow-up appointments and recurrent meetings with chronic patients across various specialties, while telemonitoring is spread for detecting specific parameters, such as glycaemia. To increase accessibility to specialized physicians in remote and isolated areas, such as small towns, a tele-expertise project has been initiated. This project enables GPs to discuss their patients with specialized physicians located in the primary hospital, receiving feedback and suggestions without the need to travel long distances.

Finally, an ECG telerefertation service is provided, which involves a nurse visiting a patient's home and using specialized equipment to transmit the results of the electrocardiogram to a cardiologist at the hospital in real-time. The cardiologist can then request further tests from the nurse as needed.

## Annex 2: Glossary

Telemedicine service	Definition
Teleconsultation	Medical consultation to a patient taking place remotely through the employment of digital technologies. In the Italian context is referred to as "televisit" and it may be provided under specific circumstances, e.g. periodical consultations for chronic patients
Tele-expertise	Consultation between doctors who are not in the same physical location concerning the status of a patient, via digital technologies. In the Italian context it is referred to as "teleconsultation"
Telemonitoring	Patient monitoring service involving the use of devices (sensors, wearables, etc.) to gather data from patients concerning clinical parameters
Telerefertation	Provision of a clinical medical report, involving a healthcare professional supporting the patient in performing a specific clinical exam in presence and a doctor providing a medical report based on gathered data

### Abstract

Demographic changes together with scarce resources means that a transformation is needed in healthcare. A national work is on-going in Sweden to change the healthcare system to get it closer to the patients and users. In this transition work mobile local care is an important area. The aim of this paper is to learn and find out important flows of action that drive the healthcare transformation in mobile local care to evolve in a timely movement. A main challenge is the larger number of involved partners with different autonomous political governance, different in size and with different cultures. The study is based on a qualitative study and the collected data is analysed in accordance with the three modalities timing, attentionally, and undergoing as defined Baygi, et al (2021). The used approach opened the horizon of possibilities in a novel way, to understand the phenomenon of transformation in healthcare. The work also reveals that the used modalities have different possibilities for learning related to organizational, digital, and medical conditions. In the further work it would be crucial to study how the learning is interweaved by coinciding flows of action in this context.

**Keywords** – Transformation, Flow, Healthcare, Digitalization, Learning.

**Paper type** – Academic Research Paper

## 1 Introduction

Transformation in healthcare is required due to the demographic changes in the western world, where the population grows older, with more complex diseases (Lindberg, et al., 2017). Healthcare is marked by challenges of scarce resources, lack of digital knowledge and experiences, as well as increased demand for specialized knowledge (Gjellebæk, et al., 2020). Especially, the challenges are prevalent in the rural areas. In Sweden there is a national on-going work performed on national, regional, and local levels called transition to close care, to change the healthcare system to get it closer to the patients and users (translated from SKR, 2022). In this transition work mobile local care is an important area. Mobile local care is about local mobile teams in for example community care, home care and rehabilitation, home monitoring and digital care visits. In mobile local care close cooperation between regions and municipalities, digital transformation and skills supply are pointed out as success factors (translated from SKR, 2022). In this paper the geographical area Fyrbodal, in the western part of Sweden, is studied, where the joint organization "Care Cooperation Fyrbodal" is leading the transformation work. Challenges and knowledge critical to digitalization in healthcare have been identified and outlined (Svensson, et al., 2022) and successful digital transformation requires a healthcare system-wide reorganization as well as changes in ways of working (Vallo Hult, et al., 2019). The opportunities with the digital transformation of health services are far from fully utilized (Svensson, et al., 2021) and there are demands on learning in health service organizations to create more innovative practices (Gjellebæk, et al., 2020). The aim of this paper is to learn and find out important flows of action that drive the healthcare transformation in mobile local care to evolve in a timely movement.

Healthcare systems are complex, emerging from the many interconnected and interdependent elements and their feedback structures, but also the relations with multiple independent elements in the surrounding environment (Linnéusson, et al., 2022). This means that having a holistic approach and being sensitive for the context is critical in the digital transformation (Aggestam and Van Laere, 2012). Therefore, our research is based on a holistic approach and a flow approach as described by Baygi, et al (2021). This gives a possibility to focus on flows of action from a holistic approach, without concentrating on actors or specific stakeholders.

The paper is organized as follows: In the next section we outline the research method and describe the case. The findings concerning important flows of action that drive the healthcare transformation in mobile local care are then presented. In the last section we end up with some conclusion and thoughts concerning future work.

## **2 Research method and case introduction**

The study is based on a qualitative study in a Swedish rural area, which is a part of the national on-going transition work to change the healthcare system to get it closer to the patients and users is (translated from SKR, 2022). The number of inhabitants varies between maximum around 60,000 in urban municipalities to less than 5,000 in rural municipalities in this area. The study produces context-dependent knowledge and experiences with an attempt to understand complex issues in real life (Flyvbjerg, 2006). Participating partners in this rural area are regional public and private healthcare as well as the 15 municipalities in the area responsible for health and social care, social services, and schools (translated from Vårdsamverkan Fyrbodalen - Public\_Vardsamverkan VG). Descriptions here inform that there are 15 local cooperation groups, one group for each municipality, and the work is performed on strategic and operative levels. Thus, in each municipal areas, there is one primary healthcare center, where most of the primary healthcare centers are governed by the region. But there are also a few healthcare centers governed by private companies. Each healthcare center has its own operative level. Notably, the region and the municipalities have different autonomous political governance, differ in size, and have different cultures.

The large number of autonomous partners and its accompanying size and complexity is a challenge the work must manage. This requires a need to understand the whole picture, use systems thinking and having a holistic approach, i.e. consider each part from its role and condition in the whole. Close cooperation between regions and municipalities is pointed out as one success factors (translated from SKR, 2022). The transition work is based on a collaboration agreement between the 15 participating municipalities and the region. In this study the specific transformation work is based on the collaboration between each municipality and the primary healthcare center located in each municipal area. The transformation work is in this way based on

the specific local conditions, in collaboration between the municipal healthcare professionals and the primary healthcare centers' professionals in each local area.

The aim with this study is to learn and find out important flows of action that drive the healthcare transformation in mobile local. This means that the process is in focus, not the actors, and a flow-oriented approach was used. The flow-oriented approach has potentials to reveal novel insights for researchers to understand and theorize the temporal dynamics of action possibilities along our overflowing digital world (Baygi, et al., 2021). Furthermore, a flow-oriented approach contributes to learning and includes dynamic aspects, attentional orientation, and an experience for undergoing, as conditions for flows of action (Baygi, et al., 2021). According to Baygi, et al (2021), the three modalities timing, attentionally, and undergoing together explain the dynamics of creation, sensing, and actualization of transformative possibilities for practical actions.

The study started with a workshop identifying teamwork, competence as well as digital work methods as the major challenges that should be focused on to achieve a plan for the transformation. Twelve focus group interviews were then held in each of the rural municipalities in the region. The interviews were aimed to identify ways forward to transform healthcare, of the pace that would be enabled in practice. Each focus group interview lasted for about one hour. Two head nurses from municipality healthcare, together with two heads of the healthcare center located in each of the municipalities, participated in each focus group interview. The focus group interviews were led by the process director from the regional healthcare organization, and one of the researchers participated, observing, and asking a few questions. The data collected at the focus group interviews were analysed deductively, based on the flow approach and the three modalities timing, attentionally, and undergoing as described by Baygi, et al (2021), by thematic analysis (Braun and Clark, 2006).

### **3 Findings**

The transformation work was grounded in local conditions and people because different solutions may need different priorities in different municipal areas. There is a common agreement in this region to work together for the transformation of the rural areas, compared to urban areas, as the healthcare in rural areas has very small resources in relation to the demand of healthcare. Small municipalities may not either have the capacity to act on its own, thus they need to collaborate. In

accordance with the analysis, the findings are presented in the three modalities, as defined Baygi, et al (2021).

### **3.1 Timing – creating possibilities**

The planned actions were focused on the work to remove boundaries between care organizations, trying to cross organizational boundaries. The common work, led by the process director from the regional healthcare organization, gives the opportunity for a neutral party to lead the work forward, in different ways in different municipalities, where there are different conditions for digital solutions. Strategies for digital technologies need to be identified as early as possible, to achieve availability for special needs and for mobile decision support. The boundary-crossing collaboration between different municipal areas and from different organizations offers timing where shared actions are suggested towards transformation of healthcare.

Managers, business developers and other professionals with certain responsibilities were gathered for a workshop to identify common interests and priorities. The aim was also to find common point of departures to support each other in the transformation process. The common base was the local prerequisites and professionals, where different solutions could need different priorities in different local areas. The workshop was a kind of a starting point for discussing these things together. The plan was to investigate the needs in the different local areas, whereas knowing that the coastal and forest municipalities as well as smaller towns could have different needs.

The steering group of the region has decided that the transformation work should be based on local characteristics, be conducted locally, and involve professionals at the local healthcare organizations. The transformation work should also be based on which patients there are in each local area, what competences are available, what equipment will be needed and what competence development that will be needed in each of those areas. Therefore, the professionals have to be asked to identify who will be involved so they could be included in the transformation work. It is emphasized that it is important to ask the professionals about their needs, and to identify the professionals who will be affected to involve them in the transformation work.

The ongoing collaboration between healthcare organizations for the transition of elderly people with complex care needs is a challenging activity. The local

professionals at each municipality and primary healthcare center have to plan and act together to have a seamless healthcare for the patients. However, each local organization has its own prerequisites and conditions to conduct this work. The need for streamlining the work processes to make the work at the hospitals smooth and uniform is identified. Therefore, it is valuable to recognize at each local healthcare organization what they need from the hospital. The region is intended to keep the work together as the small municipalities do not have capacity to analyse their own needs. There is also a suggestion that model municipalities should be selected, with the aim to disseminate knowledge. The joint organization "Care Cooperation Fyrbodal" in this geographical area should act as a facilitator between the healthcare organizations. A coordinator in the "Care Cooperation Fyrbodal" has arranged unconditional meetings between the municipality healthcare and the primary healthcare center in the local contexts.

The transformation process is intended to remove barriers and borders between the healthcare organizations. However, there exist different views on how the collaboration would look like, so this implies challenges. Therefore, a neutral part as "Care Cooperation Fyrbodal" is dedicated to lead the work.

### ***3.2 Attentionality – sensing possibilities***

In this work there are intentional planning executed by the process director, led by a group with participants from different healthcare organizations in the region. This gives attentionality to the transformation work where the sensing of possibilities is considered.

There are examples of smaller collaboration initiatives, as projects that have been successful. For example, collaboration with dental hygienists have been implemented in a few municipalities' healthcare. This kind of collaboration has had very good effects in the local healthcare that can be continued on a local basis. There is also an opportunity to arrange workshops with professionals from the rehabilitation unit at the primary healthcare center and the home healthcare in the municipality. To have mobile x-ray equipment with own professionals and to use different digital tools for mobile solutions have also been identified as possibilities, together with the opportunity to have more advanced technical equipment to collect vital parameters and EKG values of the patients to carry out qualified assessment, also before if a physician needs to be contacted. Digital technology could be implemented for the doctor to be able to connect to a

digital appointment, so the patient can stay at home. It is also efficient for nurses to have internet access when they are visiting patients in their homes, to have the ability to contact colleagues at the primary healthcare center. Especially, at the small island in the Bohuslän archipelago, it would be suitable with opportunities for home monitoring, as the patients have a long distance, including trips with ferries, to both the primary healthcare center and the hospital. There could also be arranged for a room at each island, where the social care personnel could assist the patients in the monitoring and contacts with the primary healthcare center or the hospital. Therefore, different considerations need to be taken if it concerns patients who live in inland, coastal, or urban municipalities. However, different examples can give different healthcare teams certain possibilities for development of more efficient work processes based on different conditions.

Possibilities have been sensed for the municipality and the healthcare center to trust each other to prescribe medicines for each other. Other possibilities could be to create assessment teams with different professions for home visits where, for example, both a nurse and a physiotherapist from the municipality can be included. Elderly teams can also be created at the healthcare center, with, for example, elderly nurses and doctors, with different skills and roles. Relationships between assessment teams and elderly teams are identified as valuable to conduct the work in an effective way, and to achieve benefits for the patients, including patients' feeling of security. Moreover, if there were dieticians attached to the hospital the dietary advice to patients could be of better quality.

The healthcare professionals have found out that if they could plan the activities of care for the patients to be conducted at daytime, there will be less activities to conduct at evenings and nights. Some extra work could be avoided if the work is planned preventively for the patients, then there will not be so many questions during the day either. Sending out and disseminating good examples is another thing that the healthcare professionals have found that they can do. If something has been done successfully, it is good to disseminate this for a good exchange of knowledge, experience, and learning.

### ***3.3 Undergoing – actualizing possibilities***

The creative transformation work is thereafter undergoing, where the transformative possibilities are actualized, and intentional actions are formulated. With the possibility for a common gathering among the local professionals the

transformation is taken a step forward. The ongoing discussions also imply collaboration between other healthcare departments where for example municipality nurses have dialogues with rehabilitation managers at the primary healthcare center. During the pandemic monthly meetings have also been held between the municipality and the primary healthcare center in most of the municipalities, and this has also been applied with private primary healthcare centers. Reconciliations are also held between primary healthcare centers and the hospital, but the rehabilitation department at the primary healthcare center would also be a partner in this collaboration. The collaboration between the primary healthcare center and the municipality home care, with both physicians and nurses is well functioning in the most areas and is prioritized by the primary healthcare centers.

The transformation work is in its full activity, where the steering group is having meetings to prioritize different activities in different areas in the region. A document is set up, describing all the activities and their priority. A one-day workshop should be held in the near future, where the priorities should be presented for the representatives for the primary healthcare centers and the municipalities.

## **4 Discussion**

Learning is of vital importance in all these three modalities, to provide approaches and conditions for successful transformation. Still, there are demands in learning in this complex healthcare context. New dynamic streams of experiences in the studied context are certainly resulting in learning moments for the professionals (Baygi, et al., 2021). The organizational conditions are interacting with enabling conditions that come from both the digital and the medical areas, that situate the transformation and learning along the flowing lines of action.

### ***4.1 Organizational conditions of possibility***

The holistic approach taken from the organizational level are intended to cross organizational boundaries. The intention is also to work together among the municipal areas as small municipalities has not capacity to act on its own, but to consider local varieties of conditions. The timing to have a neutral process director leading the strategic transformation work enable all the included

professionals to learn about the boundary-crossing organizational conditions in each municipal area. There are potentials for learning at boundaries, as emphasized by Lave and Wenger (1991) as well as Engeström and Sannino (2010). From this situational learning, the healthcare organizations together take actions forward in the transformation work.

A coordinating organization in the geographical area acting as a facilitator in the collaboration between the healthcare organizations. The coordinating organization has arranged meetings between the municipality healthcare and the primary healthcare center in the local contexts. Such a structure can build inclusiveness and can meet the network members' expectations regarding participation (Vermeiren, et al., 2021).

#### ***4.2 Digital conditions of possibility***

Possible use of existent digital technologies is identified in this timing collaboration going on. To sense how digital technologies can be used for different needs is crucial to really exploit digital tools for effective utilization of healthcare, for example for digital care meetings and remote patient monitoring, as well as digital contacts between healthcare professionals. The timing to create such a learning eco-system is made possible through the boundary-crossing collaboration. According to Alrahbi, et al. (2020), this is not possible to achieve this in a dispersed knowledge environment.

To arrange workshops with professionals from different professional areas at the primary healthcare center and the healthcare in the municipality have been enabled by digital video-conferencing tools. This has in turn enabled the healthcare organizations to create teams including various professionals. To sense and learn approaches that can support the digital transformation of healthcare, it is crucial to focus on the healthcare professionals' competencies and experiences, and to integrate their knowledge (Patricio, et al., 2020).

#### ***4.3 Medical conditions of possibility***

Advanced mobile medical equipment has been developed to support to carry out diverse qualified assessments. Patients' vital parameters, as EKG and other values, could be collected before deciding to send a patient from home to the emergency department at the hospital. Such conditions have been identified as

possibilities in the context of this study. Thus, the professionals from the different care organizations are learning together about medical conditions to move the transformation forward. Schot, et al. (2020) also emphasize the creation of spaces for interprofessional collaboration to bridge knowledge gaps and to overlap in roles and tasks. Moreover, arenas for professional knowledge integration are crucial for their learning processes (Svensson, 2012).

## **5 Conclusions**

Learning is vital in socio-technical transformation in healthcare. The flow approach has been used to identify the flows of action that are crucial elements in the transformation work. The shift from an actor-centric to a flow-oriented approach opened the horizon of possibilities in a novel way, to understand the phenomenon of transformation in healthcare. The transformation work offers timing where shared actions are suggested towards transformation of healthcare. This gives attentionality to the transformation work where the sensing of possibilities is considered. The creative transformation work is thereafter undergoing, where the transformative possibilities are actualized.

The study has also revealed a contingent and conditioned storyline in this healthcare practice. These flow-oriented modalities of timing, attentionally and undergoing have showed different possibilities for learning related to organizational, digital, and medical conditions. Learning is of vital importance in all these three modalities to provide approaches and conditions for successful transformation. The possibilities are also related to boundary-crossing collaboration between health service providers in different geographical areas, organizations, and professions, which give favour to the learning. The possibilities have emerged from the conditions on the move for transformation, that are revealed in this study. The flows are about the continuity in this studied context, and how the possibilities will be followed by further actions. In the further work it would be crucial to study how the learning is interweaved by coinciding flows of action in this context.

### **Abstract**

Recent years have seen a rise in popularity of the vegan or plant-based consumption/production, which is deemed to reduce the environmental burden (Fresán & Sabaté, 2019) since the impacts of animal products can markedly exceed those of vegetable substitutes (Poore & Nemecek, 2018).

Our research focuses on sustainable business models applied to vegan production with the aim to scrutinize how companies may achieve positive impacts on people, the planet, and sustainable economic performance. Surprisingly, academic studies by management scholars on this matter are very rare and we discovered that most contributions come from researchers with knowledge and expertise in other disciplines such as environmental science or agricultural and biological sciences.

In light of the above-mentioned literature gap, our explanatory research, based on secondary data (i.e. academic and grey literature), offers an understanding of how sustainable business models can be applied to vegan production.

Namely, we elucidate the concept of Circular Bioeconomy and its applications through biocyclic vegan production and cultured meat production.

Our research highlights that the production of alternative proteins (AP), such as plant-based ones, mostly produced from legumes, may provide benefits not only for the environment but also for human health. However, there is still an ongoing debate on the controversial effects of APs and their nature of being "ultra-processed" food. To deepen this debate, future research should develop an interdisciplinary approach with input from scholars in biotechnology, human nutrition, medicine and management.

Our research has not only theoretical implications but also managerial implications for vegan food production which is undergoing a phase of evolution both in terms of technologies and markets.

**Paper type** – Academic Research Paper

## 1 Background

The concept of vegan was “invented” in 1944 by Donald Watson, a founder of The Vegan Society and which refers to a vegetarian diet that excludes eggs, dairy products, and all other animal-derived ingredients. Watson wanted to underline the importance of using not only alternative non-animal products in general but also encouraging a vegan lifestyle in relation to the use of any kind of product with the rejection of any animal ingredients or components (Judge & Wilson, 2015). The “veganism style” is not new but it has raised awareness and attention from people in the last few years (Statista, 2018). It is not applied only to food but also to general products, like cosmetics or hygiene products, and it is engaged as a real lifestyle that produces less harm for animals and the planet (Beardsworth, 1991; Loh et al. 2021; Gendel-Guterman& Derqui, 2021).

Due to the growing attention from customers to health and climate change, the global vegan food market is expected to grow in the following years, passing from \$23.31 billion in 2020 to \$61.35 billion in 2028 (Fortune Business Insights, 2020).

In Europe, the biggest and most important companies in this market are: Danone SA, Hain Celestial Group, Inc, Conagra Brands, Inc., Beyond Meat, Inc., and Nestle SA; companies like these sell their products to retailers which are mainly supermarkets/hypermarkets, online websites, convenience stores, etc. Mostly of consumers make their purchases in supermarkets or big retail stores but, since the pandemic started in 2020, it has also grown the usage of e-commerce for vegan products based on data provided by Google AdWords which showed a growth of 47% of vegan products searches from 2020 (Saari et al., 2021). In brief, the market for vegan food is continuously expanding, being influenced by customers’ choices driven by both health and environmental concerns (Apostolidis, & McLeay, 2016; Dedehayir, 2017; Carfi et al., 2018; Cooper et al. 2022).

Beyond these statistics and market trends, the starting point of our research interest is food sustainability (Vermeulen, 2012; Arslan et al., 2021). On the one side, it has been already noticed that some phenomena such as urbanisation,

industrialisation, development, and an increase in the global population, especially in underdeveloped countries, have highlighted important problems related to the food industry. It has been already assessed that meat and dairy industries cause a big amount of negative impacts on the ecosystem in terms of GHGs (Deckers, 2009; Judge & Wilson, 2015; Poore & Nemecek, 2018). Food's environmental impacts are created by millions of diverse producers. With current diets and production practices, feeding almost 8 billion people is degrading terrestrial and aquatic ecosystems, depleting water resources, and driving climate change. Namely, it has been demonstrated that *"impacts of the lowest-impact animal products typically exceed those of vegetable substitutes"* (Poore & Nemecek, 2018, p.987). Hence, a dietary change oriented toward vegetable substitutes of animal products might be an option to consider to meet the requirements derived from the SDS12, driving a more sustainable and eco-friendly food production and supply system (Revell, 2015; Fresán & Sabaté, 2019).

Our study will not discuss the scarcity of food, actual and potential, or the burden on the environment of food production systems, which is already a piece of evidence but it will scrutinise how sustainable business models may be applied to vegan food production systems. Generally, it is well known that the application of circular economy principles to the food production system can help to reduce the negative impacts on the environment (Lu et al., 2022). Namely, this paper will focus on the application of new business models with the aim to scrutinize how vegan companies may achieve positive impacts on the environment, flora, fauna, health, and people's life (Sadhukhan et al., 2020).

A preliminary literature review was conducted by using the following keywords: "vegan production" and "circular economy" or "vegan company" and "business model" or "sustainable production". These keywords were selected to find as much as possible information, research, and case studies both on SCOPUS database and google scholar platform.

Surprisingly, academic studies by management scholars are very rare on this topic and we discovered that most contributions come from researchers in other disciplines such as environmental science or agricultural and biological sciences.

In light of this literature gap, our research, based on secondary data (i.e. academic and grey literature), offers an understanding of how new business models may be applied by vegan companies. The circular economy, in fact, has different and various variants and applications (Brown et al., 2021; Alcade et al.,

2022; Hofmann et al., 2022) which lead to the possibility of developing new models applied to vegan companies.

Our contribution as management scholars is to delve into a hot topic issue, such as the production of vegetal substitutes and alternative proteins.

In this still gray field, the application of technological and process innovations to business activity must follow principles of responsibility and impact assessment that consider individual and collective, private and public interests. Food production is a key issue for humankind's survival and represents what we call a wicked problem. Producing alternative proteins may be an option to reduce environmental impact and respond to the problem of food scarcity, but the phenomenon must be studied in depth and from a multidisciplinary and interdisciplinary perspective. Without a thorough understanding of the short-, medium- and long-term impacts, the risk is that the interests of a few will prevail over those of the community.

The remainder of the paper is structured as follows: section two presents the research design and the methodological issues we faced; section three illustrates how companies that produce plant-based food or companies that decide to shift their strategy towards a vegan and sustainable one can reduce the harmful effects of their processes and generate positive impacts on the environment and human health; conclusions are drawn in section 4.

## **2 Research Design and Methodology**

As well known, studies can be divided into: exploratory studies, which are useful when researchers want to understand a particular problem; descriptive studies, which describe a profile or a situation; and explanatory studies, which explain the relationship between different facets/variables of a phenomenon. (Ghauri et al., 2020). In our case, based on the hypothesis that vegan production is less harmful to the environment, as argued by scholars from other disciplines (Fresán & Sabaté, 2019), we deemed it necessary to start from an understanding of the business models (BM) that can be applied by companies producing vegan products. We therefore chose an explanatory research approach. The latter is a research method that explores why something occurs when limited information is available, as in our inquiry, since vegan food production on an industrial scale is a phenomenon that has spread very recently. Explanatory research can help to increase the understanding of a topic, and ascertain "how" and "why" a particular

phenomenon is occurring. Namely, the aim of this paper is to analyse how sustainable business models are applied to vegan production.

Hence, we formulate the following Research Question:

*How new sustainable business models applied to vegan production can reduce its burden on the environment and promote responsible food production/consumption goals?*

To answer the above-mentioned RQ we gathered secondary data (i.e. academic and grey literature). Grey literature is materials and research produced by organizations outside of the traditional academic publishing and distribution channels. Common grey literature publication types include reports (annual, research, technical, project, etc.), working papers, government documents, white papers and evaluations.

The outcome of our study is an “explanatory journey”, which starting from the Circular Economy applications combined with the Green Economy principles, leads to the design of new business models applied to vegan companies.

### **3 Sustainable Business Models for Vegan production**

Since in the last decade new production systems which are based on the application of the Circular Economy principles have been implemented in the vegan sector, in the following the main features of new business models for sustainable development will be briefly depicted before analyzing the deployment of specific technology to the vegan food production.

#### **3.1. New Business Models for Sustainable Development**

One of the most powerful tools and keys to changing the way of producing and doing business has been the passage from the old business models and the old producing mechanisms and processes to the new concept of “Circular Economy” (CE), which has been defined as “*an economic system that emerges to oppose the linear open-ended system (produce, consume, dispose), with the aim to accomplish sustainable development, simultaneously creating environmental quality, economic prosperity and social equity to the benefit of current and future generations.*” (Homrich et al., 2018; Reike et al., 2018). Accordingly, The circular business model is a business model that is based on the principles of the circular economy, such as the reuse, repair, recycling and reconditioning of materials and products in order to minimise waste (Zucchella & Previtali, 2019). Circular

business models can be defined as *"business models that are cycling, extending, intensifying, and/or dematerialising material and energy loops to reduce the resource inputs into and the waste and emission leakage out of an organisational system. This comprises recycling measures (cycling), use phase extensions (extending), a more intense use phase (intensifying), and the substitution of products by service and software solutions (dematerialising)"* (Geissdoerfer et al. 2020). Circular business models imply another important feature that is innovation. In fact, the passage from old business models to new ones, circular business models are the result of innovative strategies and methodologies which contributed to its creation. Still, innovation can be generated not only through the design of a new business model, but also through the transformation, the acquisition, or the diversification of an existing one. a company can innovate its business model by only changing some elements or introducing new ones instead of totally recreating a new one.

One last noteworthy theme, is the importance of circular oriented innovation, which represents the combination of product design, business model, and value creation, and helps to the development and the advancement of circular economy strategies (Brown et al., 2021). As this goal sometimes can be difficult to realise by companies themselves, it implies the collaboration among actors and agents, which can be both individuals or firms, with the purpose of exchanging information, expertise, data, and resources to achieve a common goal. Hence, collaborative innovation is needed as it lies in the process of agents' contribution to creating and developing new ideas, products, services, or business models. Creating a network of relationships with different agents and actors is essential for the companies to implement their circular strategies by sharing information and resources in order to be able to accomplish sustainable goals (Brown et al., 2021).

### *3.1.1 Bioeconomy and Circular Bioeconomy*

The Circular Economy is based on reusing and recycling materials minimizing the external negative effects and maximising the utility of each input. In a "carbon-constrained" future where greenhouse gas emissions are limited through policy or technology, a circular economy approach can minimize the impact of the population on the planet (Geng et al., 2009).

Connected to this concept we can consider "bioeconomy" which essentially relies on biological inputs that are used in production instead of fossil fuels and

non-renewable resources. "Bio-based economy" or "knowledge-based bio-economy" (BE) underlines the importance and power of biological resources from land and sea for the manufacturing of products, by substituting fossil fuels with the biomass integrated with biotechnology innovations.

Bioeconomy products consist of biomass and low-value products (i.e., biofuels) and high-value products, such as bio-based chemicals or compounds. (McCormick and Kautto, 2013).

If we think about the application of BE in management production, for example to food production, there has to be proper management of the resources, which is often characterized by a high level of uncertainty, in order to be really sustainable.

Indeed, the use of biomass for unsustainable food production can lead to negative effects on the environment, such as deforestation, and on the society; for this reason, institutions have to release proper regulations and policies not only globally but also in particular in Europe, as BE policies tend to prioritize economic value rather than environmental and social ones (European Commission, 2018).

BE, as it was captured from its definition, can be linked to the CE and transformed in "circular bioeconomy" (CBE), which refers to the concept of bioeconomy integrated with elements of CE. (Institute for European Environmental Policy, 2018; Kershaw et al., 2021; Muscat et al, 2021).

Since we are discussing about vegan production, the Plant Based Products Council, which is the leading organization promoting sustainable products derived from nature, firmly promotes the circular bioeconomy through the creation of renewable products at the market scale and supporting policies that ensure vegan products to become part of the circular bioeconomy. Taken together, these actions reduce carbon emissions, improve water quality, enrich our soil health, and curtail solid waste destined for landfills. (Plant Based Products Council, 2022)

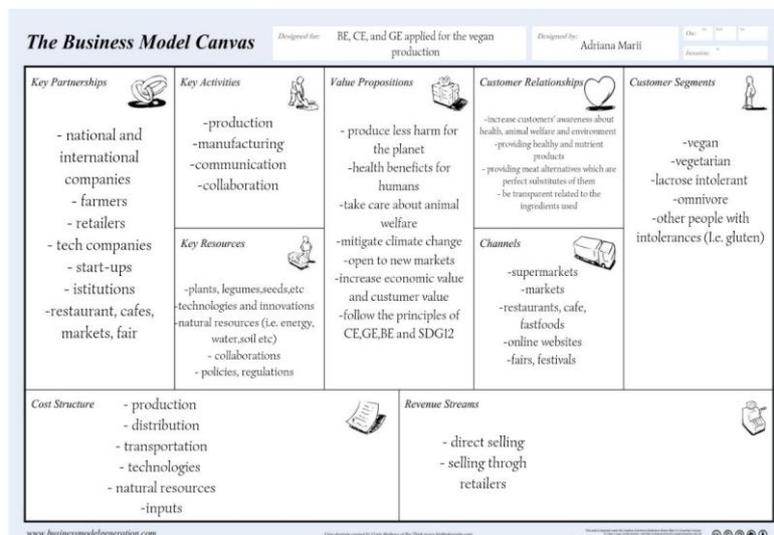

### *3.1.2 The inclusion of Circular Economy, Green Economy and BioEconomy in the Business Model Canvas*

Some initiatives, such as "The Economics of Ecosystems and Biodiversity", state that all three concepts (Circular Economy, Green Economy and BioEconomy) are linked between them by the interest and the effort to preserve nature and, in

general, they are applied based on the same concepts (D'Amato, 2021)(see Annex 1).

Through this excursus of the different applications of a Circular Business Model to the vegan food production, it can be said that these models are necessary to be adopted by companies and substitute the old ones, in order to be able to face environmental issues, and meet the new requirements established by policy makers and institutions.

To our purpose, the inclusion of these principles in a company business model applied to vegan production can ensure positive impacts on planet and society (see Fig. 1).

### 3.2 Biocyclic-vegan production

In the following, we discuss about a new trend introduced in Germany in 2017, that is named the "biocyclic-vegan" label, which basically refers to the exclusion of any animal by-product during production.

The concept is based on a vegan approach and indeed, in 2016, the producer association "Biocyclic-vegan cultivation" was founded, whose task is to support the biocyclic vegan agriculture by following the guidelines provided by The International Federation of Organic Agriculture Movements - Organics International (IFOAM Organics International).

This new production methodology is based on the combination of organic agriculture and stock-free agriculture, which emphasises the importance of using natural resources and, meanwhile, enabling them to ensure their availability in the future, meaning that they do not have to be depleted.

Essentially, it is primarily based on excluding materials such as horn meal, blood meal and composted manure from farming in the land cultivation, and, as it aims to re-establish a healthy life cycle, coherent with the concept of a closed-loop approach, it is followed by a compensation for the resources that are used in order to guarantee their availability in the future.

Biocyclic-vegan production, in particular in the agriculture sector, is strictly based on the total exclusion of animal products and farm animals, a strategy which strives to increase in the following years, in particular in Germany.

The first countries in which it was introduced and applied vegan biocyclic are Germany, Austria and Switzerland, and are also the ones which follow the labelling guidelines since 2016, in order to be transparent about their production methods (Jürkenbeck et al., 2019)

### **3.3 Alternative Meat (plant-based and cultured meat) Production**

Since animal products are expected to be more requested by consumers, there is an urgency of increasing the production and distribution of alternative products especially alternative meat products made by using innovative food technologies able to reproduce the taste and texture of real meat and meat-based products.

The University of Nottingham (2018) has defined alternative proteins as it follows: "*Alternative protein, such as plant-based meat substitute, or edible insects, provides a substantial amount of protein, but requires less natural inputs (e.g. water) to produce, compared to the most common and conventional protein sources (i.e. meat and fish). They are also called 'novel food proteins' and are composed of different sequences of amino acids, which are responsible for building lean body tissues and human health.*"

Alternative protein of plant-based meat basically refers to alternatives to meat-based protein which replace and replicate it not only in the taste and texture, but also in nutritional characteristics, by trying to be even more economically convenient than meat and to contribute to the environment and to decrease the health negative impacts derived from meat production (BCG, 2021).

One of the most important reasons to produce alternative protein and adopt a different diet consists of the awareness of human health.

Actually, meat causes diseases such as cancer and obesity in relation to its high level of saturated fat, cholesterol, while AP propose to funnel its same nutritional benefits related to the level of protein and essential nutrients with relatively low levels of cholesterol, saturated fats and nitrates. (Chen & Eriksson, 2019)

Cultured meat, instead, is produced by culturing animal cells in vitro using tissue engineering techniques and is presented by its advocates as a good alternative for consumers who want to be more responsible in front of the increasing demand for food by the growing human population but do not wish to change their diet (Chriki & Hocquette, 2020; Reis et al. 2020).

Alternative meat (i.e., plant-based and cultured meat) produces smaller environmental negative impacts with smaller GHG emissions, land use, and water, but at the same time, since it involves activities which are highly processed and request a huge amount of energy, it can also be a threat for the environment. (Tuomisto & Teixeira de Mattos, 2011).

This new production system is expected to acquire more attention from companies due to the growth of the demand for protein and the expected failure of traditional meat production, which would allow to create new opportunities (Mancini & Antonioli, 2022).

Shifting to new sectors, plant-based meat can offer opportunities for farmers to diversify or completely change into the production of plants, algae, mycoprotein, seaweed, etc., and, at the same time, to companies by enlarging their offering and their markets (Luiz Morais-da-Silva et al. 2022).

As an example, we can take into consideration the NotCo company, which is a US start-up whose aim is to reinvent the food industry by using artificial intelligence and replicating animal products starting from plants and vegetables. The company offers a few substitutes for animal products, such as NotMilk, NotMayo, NotIcecream and NotMeat, which are the perfect replication and replacement of real meat and animal milk products, produced with less energy, less water and less CO<sub>2</sub> emissions. (e.g., NotCo 2022).

However, not all scholars agree on the positive impacts on people and planet of the production of alternative meat. Despite the promising purposes of these products, at the same time, there are doubts about the processing activities of AP, which can be considered as "ultra-processed food" (Monteiro et al., 2019). Indeed, health care institutes recognize that processed food can be linked to some health

issues and diseases such as obesity, diabetes, etc, related to the presence of additives or flavour enhancers.

Moreover, by analysing a study conducted on the effects of the production of cultured meat, (Tuomisto & Teixeira de Mattos 2011) it has been seen that, by calculating the energy input of cultured meat, this could be relatively high due to the additional processes involved; however, this high energy consumption could be decreased by adding and improving various technologies.

Table 1 summarises positive and negative aspects of the production of alternative meat.

Table 1. Positive and negative sides of the production of alternative meat.

	<b>Health</b>	<b>Economic</b>	<b>Environmental</b>
<i>Positive</i>	Benefits that come from the reduction of consumption of meat.	Possibilities for companies to expand their market; possibilities for farmers to enlarge their offering by diversifying or completely changing	Reduction of GHGs
<i>Negative</i>	Ultra-processed food which is doubted to be healthier	Increase in land use in order to grow the inputs necessary	A huge amount of energy used

### **3.4. A summary of different vegan production systems**

In order to answer our RQs, the table below (2) summarises the characteristics of the main three vegan and plant-based productions, which incorporates principles of Circular Economy, Green Economy and BioEconomy in their business models. Other than proper vegan products, it has been important to take into our analysis also the newest production system for cultured meat, which is done by using the same principles of AP products (i.e., bicyclic-vegan products), with the involvement of technologies to recreate protein products and alternatives to the real meat.

Table 2. A picture of different vegan productions

<b>Type</b>	<b>Description</b>	<b>Benefits</b>	<b>Categories</b>
<i>Biocyclic-vegan</i>	excluding materials such as horn meal, blood meal and composted manure from farming in the land cultivation	using natural resources and enabling them to ensure their availability in the future, which means that they do not have to be depleted. it aims to re-establish a healthy life cycle	Algae protein; yeast; mycoprotein
<i>Plant-based</i>	Protein products made from natural resources, alternative to real meat in texture, flavours and aspect.	Eco-friendly, more sustainable, nutritious and healthy and more affordability	Pulses/legumes; Seeds; cereals; Seaweed. e.g. Pea, soy, chia seed etc.
<i>Cultured meat</i>	cellular agriculture and is molecularly identical to conventional meat but produced through bioprocesses from animal cells extracted through biopsies	environmental and health benefits, reduced risk of contamination and foodborne illness, as well as being more ethically acceptable	In vitro cultured meat cells

#### 4 Conclusions

The outcome of our study is an “explanatory journey”, which starting from the Circular Economy applications combined with the Green Economy principles, leads to the possibility of thinking new business models applied to vegan companies.

Namely, in this paper we elucidated the concept of circular Bioeconomy, and its applications in order to produce vegan products through biocyclic-vegan production and alternative meat production. Indeed, both processes and technologies are used to produce alternative protein (AP) through sustainable and ecological activities. Furthermore, vegan production impacts on society are directly linked to the goals of SDG12, which consists of responsible consumption and production.

Based on academic and grey literature analyses, our research highlights that:

- The production of vegan alternatives, mostly produced from legumes provide benefits both for the environment and for human health.

- New production technologies and processes may create opportunities for companies to expand their market and increase their economic values.
- The production of alternative meat, based on technological innovations has been demonstrated that is a replacement for real meat products, since it is able to replicate the texture, the taste and nutritional values of meat products, such as beef, pork, etc..
- However, there is still an ongoing discussion about alternative meat and its real effects on the environment and human health, being “ultra-processed” food. To deepen this debate, we deem future research should embed an interdisciplinary approach with inputs from scholars in biotechnology, human nutrition, medicine and management.

In this still gray area, the application of technological and process innovations to business activity must follow principles of responsibility and impact assessment that consider individual and collective, private and public interests. Food production is a key issue for humankind’s survival and represents what we call a wicked problem. Our research has not only theoretical implications but also managerial implications for vegan food production which is undergoing a phase of evolution both in terms of technologies and markets.

### **Abstract**

The change from a linear to a circular business model requires the development of new services integrating information exchange and product usage to prolong product life through maintenance and repair. Information exchange has been identified as important for promoting circular economy, and this study draws on empirical data from a two case studies to demonstrate which kind of information supports maintenance and repair, and how the information exchange can be facilitated. Case company A offered maintenance of white goods (e.g., washing machine) as a subscription service where reminders and maintenance guides were emailed monthly to customers. Company B offered virtually guided repairs of white goods. The study finds that sharing information on what and when to do something facilitates end-users to participate in maintenance and learn about maintenance; more than half of the company A questioned customers reported that they learnt from guides and were involved in maintenance due to guides and reminders. For repair the problem description and possible solutions is information that must be exchanged, and a simple voice and video call can facilitate repairs that prolong product life with a minimum cost for the end-user. Both types of information exchange are facilitated by simple-tech solutions relying on known and cheap technology (e.g., email service, video call, and text-messaging). The findings of the study suggest that the development of circular business models does not always require expensive high-tech solutions to integrate information flow with product flow and usage, and companies are recommended to experiment with designing solutions based on known technology.

**Paper type** – Academic Research Paper

## 1 Introduction

Circular economy aims at reducing energy and material leakage from systems to disconnect goods manufacturing from raw material usage (Bocken et al., 2016; The Ellen MacArthur Foundation, 2013). To promote circular economy within businesses legislators are developing new policies e.g. European Circular Economy Action Plan, with the intent of increasing business focus on product life-time. Focus on product life-time is also promoted by changes in customer awareness and behaviours towards after-sales services to ensure better economic and environmental performance of products (Shokohyar et al., 2014). A circular business model contrasts with a linear business model by prolonging the useful life of product, part, and material through continuous cycles of maintenance, repair, reuse, refurbishing, remanufacturing, and recycling (Geissdoerfer et al., 2020). From a resource perspective maintenance is generally prioritized over recycling because the functional value of the product is retained through maintenance instead of the product being shredded down to its constitutive material through recycling (The Ellen MacArthur Foundation, 2013). Thus, policy and customer requirements change market conditions making the product life-prolonging activities *maintenance* and *repair* impending for companies to develop in the transition from linear to a circular business model.

The efficiency and effectiveness of circular economy is dependent on information exchange spanning intra- and extra-organizationally (Bhatia et al., 2020; Bressanelli et al., 2022; Guldmann & Huulgaard, 2020; Škapa, 2019). However, there is scarce empirical evidence of integration between information management and circular business models (Atiku, 2020; Klapalová, 2019), and the link between information management and the principles of circular economy (Jäger-Roschko & Petersen, 2022). In particular there is limited research on after sales services and product life extension (Islam & Huda, 2018).

This paper addresses the lack of empirical evidence through a multiple case study of two companies; company A sold a service that assisted consumers in maintaining their white goods (e.g., washing machine and dishwasher), and the

case is analysed to inform how information exchange supports maintenance. Company B refurbished and sold pre-owned white goods and it is analysed to inform how information exchange supports repair. Collectively, the cases inform an analysis of how information exchange prolongs product life-time and how information exchange is integrated with a circular business model. The aim of the paper is to develop recommendations for operationalization of information exchange supporting circular economy principles. At this aim, the following two research questions are directive:

1. What information exchanged between a company and end-user can facilitate maintenance and repair?
2. How can the information exchange be facilitated?

## **2 Theoretical background**

Circular business models are an important enabler for companies adopting circular economy practices. A circular business model prolongs product and part life-time through successive cycles of maintenance, reuse, repair, remanufacturing, and closing material loops (Geissdoerfer et al., 2020). To capitalise on circular economy a business must facilitate prolonged usage and capture of product embedded value, and facilitate information management in relation to products (Nußholz, 2018).

Since it is a recent issue, there are limited studies highlighting the interplay between information management and circular economy (Atiku, 2020). Extant studies underline the positive implications for integrating information flows and knowledge management with the circular economy (De Marchi & Di Maria, 2020). However, current information flow practices focus on supporting production and sales of new goods, whereas the information flow in the circular processes dealing with used products is often overlooked (Jäger-Roschko & Petersen, 2022). To increase circularity by addressing barriers of information flow three initiatives are necessary (Jäger-Roschko & Petersen, 2022): i) interorganizational information sharing between business areas like manufacturing and recycling must be improved (often smaller companies lack technology and knowledge to engage in information sharing (Burger et al., 2018)); ii) access to information for all circular economy actors must be facilitated (manufacturers often restrict third party recyclers or maintenance companies access to information (Burger et al., 2018)); iii) incentives for circular economy information sharing must be created. Reducing

barriers for integration of information flow enables end-users to become more proactive actors within the life-cycle of a product and engage in life-prolonging maintenance and repair (Emmanouilidis et al., 2018). User engagement towards acting on the data provided by products is essential for the information flow to have an impact (Mulcahy et al., 2019). The lack of engagement has several sources e.g. engagement of end-users in monitoring power consumption of their refrigerator is inhibited by several barriers; smart plug cannot be installed, instruction guide is missing, and monitoring tools introduce more complexity (Fensel et al., 2017). To increase user engagement, companies must address both the perceived impact in terms of privacy and the ease of use (Kim et al., 2017). Therefore, in the design of after-sales services, like repair and maintenance, user interaction needs and methods for inducing behavioural change must be considered in order to increase engagement (Geelen et al., 2013).

Maintenance and repair keep a product in good working condition and capable of delivering functional value to the end-user, thus increasing the functional value realized over time (Morseletto, 2020). Maintenance of equipment is, in general, a crucial element of keeping a process relying on technical equipment running stable and without unwanted stops. The functional value is maintained by keeping the function available for an end user, e.g. keeping a car running by changing oil, but maintenance can also retain the visual value of a product and thus retain the functional value. Extending the life-time of product is not always a straightforward decision (Boldoczki et al., 2020) and requires assessment of *“environmental benefits/drawbacks of extending the operating time of products that can be achieved due to specific design and maintenance actions, in comparison to their replacement with newer ones”* (Ardente et al., 2018).

### **3 Research design and methodology**

Given the study's exploratory aim a case study approach is adopted (Yin, 2009), analysing information exchange practices of two Danish companies operating in the white goods sector. The case companies were established as circular business models that incorporate information exchange, and were selected by purposeful sampling (Suri, 2011); Company A informed the study of information exchange for maintenance and company B informed the study of information exchange for repair. Access to data were facilitated by the lead author that co-founded both companies.

Case company A was a start-up born circular offering life-prolonging preventive maintenance for white goods and was called FIXRS. The company operated for 3 years (from 2020 to 2022) and assisted the end-user through a virtual DIY (Do-It-Yourself) solution comprising emails, monthly reminders (Figure 12) and video-guides (Figure 13). The reminders and guides were sent monthly and divided in a wheel lay-out, and the guides were accessible via the website and paying customers were emailed the reminders. The reminders were developed as short stories with video, pictures, and text, and the picture in Figure 13 show step 3 in the guide on how to clean the filter of a washing machine. The customers were sent emails and text messages as reminders and containing links to maintenance video guides e.g. on how to remove calcium or clean filters. The company had approximately 70 paying customers at the time it was closed, and the customers were both private and public (e.g. offices with small kitchens). The company closed because the business model was not financially viable.

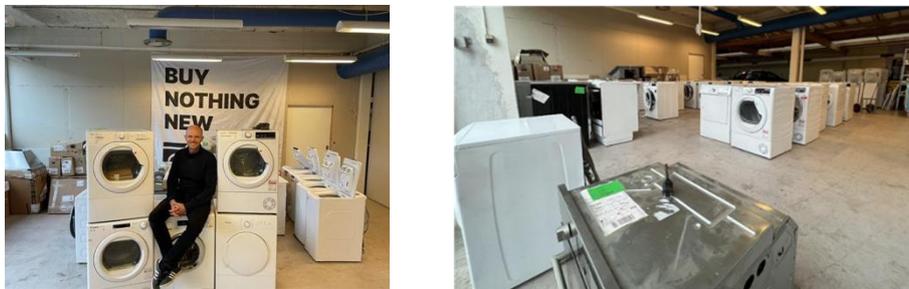

Figure 12: Overview of maintenance tasks for a year

Figure 13: A still from a video guide in story format

Case company B existed from 2019-2022 and was called SimpleVerySimple (SVS). SVS was a privately owned company established with the purpose of creating a profit by reusing and refurbishing whitegoods and selling them to B2C and B2B. The company had a combined workshop and store near greater Copenhagen, where units were refurbished and sold as pre-owned (see Figure 14). SVS incorporated information exchange between technicians and customers to remotely diagnose problems and complete repairs through virtual guidance of

the customer by the technician. Information exchange on repairs was an effort to reduce the cost of repairs by avoiding transport and to reduce the downtime of the unit. During the 3 years, approximately 3300 machines were processed of which 1100 machines were either reused or refurbished and sold, and the remaining 2200 were recycled at a professional recycling facility. SVS main supplier of raw material (used whitegoods) was the largest Danish retailer of whitegoods, which was supplemented with used whitegoods from various sources. The company was closed as it was not possible to find investors.

*Figure 14 – Pictures from the workshop and sales room*

### **3.1 Data collection and analysis**

Data was collected and analysed with different methods for company A and B, respectively. Company A had a large uniform customer base that received a comparable service from the company thus a questionnaire approach was chosen to infer general conclusions about the impact of information exchange for maintenance. Company B had limited cases (Situations with information exchange to repair a unit) and each case was considered unique in terms of the situation (Problem and repair) and the customer. The characteristics suited a case approach studying the particularities, contextual factors, and common traits to inform general insight on information exchange for repair.

Data for Company A was collected and analysed as follows:

1. A questionnaire was developed by the lead author. The questions were validated with three independent informants to improve and qualify questions and answers.
2. After the company was closed, the questionnaire was emailed to previous customers asking 3 questions regarding usage and impact of reminders and guide and included an open ended text field with room

for comments. The data informed an analysis of how information exchange impacted end-users to perform maintenance, and analysis of how the guides on conveyed knowledge to the customers. The text field had no stated purpose, and the data was expected to inform a qualitative analysis of the responses.

3. The questionnaire was emailed with an explanatory text and no reminders were sent.
4. Additional supporting data was extracted from the newsletter service used to send and track email reminders to further analyse the impact of reminders and guides using data on how many customers opened the email and clicked a link to a guide. Data from the text message service could not be extracted.
5. The questionnaire data was analysed and corroborated with quotes from the text field.

Data from Company B was collected and analysed as follows:

1. Two paradigmatic examples where a technician solved a problem and completed a repair over the phone were identified.
2. Semi-structured interviews with the technician were performed by the lead author to inform a qualitative based analysis of the successful.
3. Examples to derive findings of general validity were analysed.

## **4 Results**

In the following pages, the results of study are briefly illustrated.

### ***4.1 Company A: maintenance***

The questionnaire was sent to 70 previous customers and 31 responded, yielding a response rate of 43% (see Figure 15), and 14 respondents left comments and one respondent choose not to answer question 2. In the text field 9 respondents left positive comments regarding the service in general and two comments that raised the issue about maintenance being difficult to judge the impact of thus reducing the motivation.

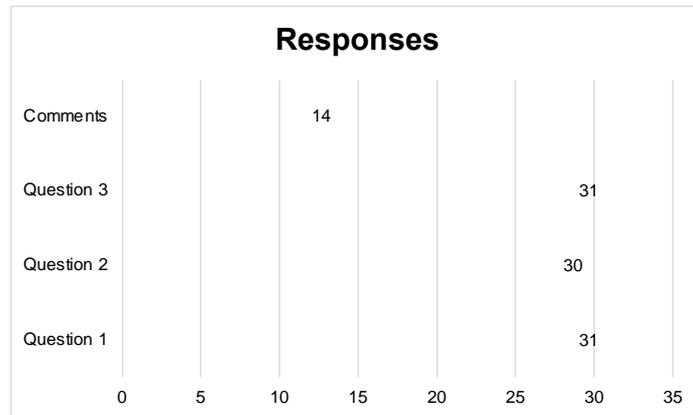

Figure 15 – Response rate

The majority of the respondents (60.3%) affirmed that they to a large extent or complete extent learned something new about maintenance through the guides (See Figure 16). One comment was positive towards the content of the guides e.g. *"For a non-handyman the guides were great"*. However, two other comments raised an issue: The character of maintenance and how it fits the end-user's capabilities appear to have an impact, as two respondents left comments on maintenance tasks they were unable to perform, such as moving a washing machine or refrigerator. Exemplified by this quote from a respondent: *"It was demotivating to be reminded of tasks that I could not do for example pulling out the washing machine"*.

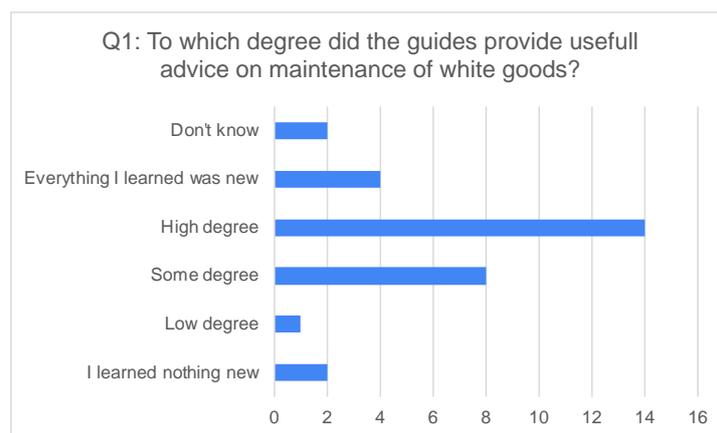

Figure 16 – Responses to question 1

More than half (56.7%) of the respondents considered the reminders to have a high or decisive degree on their behaviour for getting the maintenance done (see Figure 17). This finding is supported by the open text field where 10 of the respondents indicated that reminders were important to get maintenance done, as exemplified by this quote: *"I think the product was great, particularly because I was reminded of maintenance"*. One respondent stated that they already did some maintenance, and no negative comments were stated regarding the reminders.

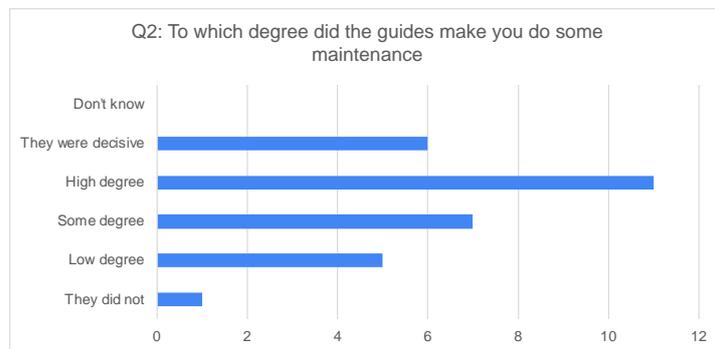

Figure 17 – Responses to question 2

The data from the email service shows a downward trend in terms of reminders being opened and clicked (See Figure 18). When an email was opened it was registered as "open" and a subsequent click on a link to a guide is registered as "click". Data for text messages is not included. Data were tracked for an 8-month period during which few customers were added, and few cancelled their subscription.

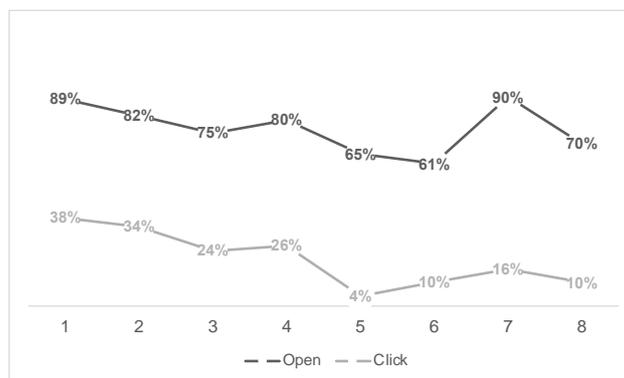

Figure 18 – Data from email service pr. month

## **4.2 Company B: Repair**

Two cases of repair assisted by information exchange were identified with company B. These are examples of small problems that could be handled over the phone and potentially avoid a technician driving out to the customer or the customer scrapping the machine.

### *4.2.1 Case A: A piece of glass in dishwasher pump*

An end-user (customer of the company) contacted the company with a complain regarding a noise coming from the dishwasher when it was running. A call was scheduled between the end-user and the technician. During the first call the technician asked the customer to notice if there was a specific time during the wash cycle that the machine made the noise. A second call was scheduled where the customer informed the technician that the noise came when the machine was pumping water out, and the technician explained the end-user that there probably was something stuck in the pump (e.g. a small piece of glass or porcelain) and instructed the customer to vacuum the pump to remove the foreign object. The customer did as instructed and confirmed over mail that solution worked and solve the problem.

### *4.2.2 Case B: Lack of cleaning*

An end-user complained that the washing machine did not pump water out or was very slow to pump water out. A call was scheduled between the end-user and the technician, and the technician gave instructions on how to clean the pump-filter inside the machine. The filter catches large objects (e.g. coins and hairpins) that enter the machine with the clothes, and if the filter is clogged, that pump takes longer to remove water from inside the machine. The end-user completed the instruction and confirmed that the solution had solved the problem.

In both cases A and B the problem was identified and solved using a simple technical solution that facilitated the conversation between technician and end-user.

## **5 Discussion**

In the following pages, what emerges from the investigated cases is discussed.

The study confirms that information exchange supports circular economy (De Marchi & Di Maria, 2020), and hence that the information flows between actors

must be facilitated, with the case companies acting as facilitators of information. Neither company studied end-user perceptions of the solutions and still managed to support end-users, which provides a different perspective on the necessity of studying user perception before building service (Geelen et al., 2013). One reason could be that the companies relied on proven and known technology.

### **5.1 End-user information need**

The study finds that the information needs of end-users are different for maintenance and repair, respectively. For maintenance, end-users require knowledge about when to do something and what to do, which can be integrated to one information flow where a monthly reminder comprises when and what to do. The information needed can be identified and comprised using existing and available knowledge on maintenance. The findings of the study highlight that end-users have limited knowledge about maintenance indicating the existence of a potential for operationalization of circular economy through reminders of maintenance. For repair the information need is instantaneous, i.e., when a machine stops working, and the needed information exchange cannot be prepared but resides *in situ* with the end-user that must describe the problem, and the technician that must identify and communicate a remedy.

The study finds that the user engagement in maintenance reminders declines over time, demonstrated by the downward trend of emails being opened and clicked. This could indicate that end-users learn and thus are less prone to use the guides which is supported by the 60.3% of the respondents that learned something new through the guides. However, the decline could also indicate a need for feedback on the impact of maintenance to continuously engage end-user (Geelen et al., 2013), something which company A did not provide to their customers. Future studies could explore the user engagement by adopting a longitudinal approach to study barriers and enablers of long-term engagement.

### **5.2 Simple tech solution**

The study finds that simple-tech solutions (i.e., solutions relying on proven and available technology, e.g., email subscription services and text messages) can facilitate information exchange supporting life-prolonging maintenance and repair. Communication from a company to end-users concerning maintenance

can be facilitated by a standard e-mail and text message service, and video guides can be developed using free software. For repair, the solution is more rudimentary; a simple video and voice call service was used. The technologies used by the companies are simple and available at a very low cost, which is in contrast with previous findings, where a low diffusion rate of technology is a barrier for information exchange with high investment costs being a reason for the barrier (Jäger-Roschko & Petersen, 2022). This study places a new perspective on this barrier; there might be a low diffusion rate of technology, but cost is not necessarily a barrier. Instead, a reason for the low diffusion rate could be that companies have yet to develop the services that rely on the technology or perhaps have too grand technological perspectives and thus overlook simple and easily accessible solutions.

The technical solutions identified in this study do not rely on monitoring end-users through sensors; thus, the barrier of privacy is not present (Kim et al., 2017). However, not having sensors makes the advice on maintenance simpler by relying on pre-determined timing on when to do something instead of analyzing data and providing specific advice. This could potentially reduce the impact of maintenance. The findings suggest a potential trade-off between a simple-tech, low-cost, and non-intrusive solution and a high-tech, high-cost, and high-intrusive solution and future studies could address the trade-off and how the different solutions engage end-users.

#### **4 Conclusions: contributions and limitations**

Circular business models are important enablers of the shift towards a circular economy, and integration of information flow with the physical product improves efficiency and effectiveness of the business model. There is, however, a lack of empirical evidence for the link between information flow and the life-prolonging activities maintenance and repair (Jäger-Roschko & Petersen, 2022). This study contributes with empirical evidence through a multiple case study aiming at answering the research questions "What information exchanged between a company and end-user can facilitate maintenance and repair?" and "How can the information exchange be facilitated?".

From the academic point of view, the study contributes to the scarce research about the interplay between information and knowledge management and circular economy. The study indicates that the kind of information that has to be

exchanged to support circular economy depends on to the specific nature of the activity involved. The study provides empirical insight on how sharing information on what and when to do something facilitates that end-users engage in maintenance, however, the long-term engagement remains unclear. For repair the problem description and possible solutions is information that must be exchanged when the problem emerges, and a simple voice and video call can facilitate repairs that prolong product life with a minimum cost for the end-user.

For practitioners, the study provides suggestion about the tools that can facilitate information flow and what kind of information to share with end-user to engage them in extending product life.

The study is not without limitations. In particular it is affected by the usual limitations of a case study methodology, and especially the difficult generalization of the results. This paves the way for future research devoted to confirming what emerged from the present analysis, for example, by means of surveys.

# Street-Scale Logistic Hubs for Enhancing Urban Vitality and Public Space Usage

---

Jesús López-Baeza

Digital City Science  
HafenCity Universität Hamburg  
Henning-Voscherau-Platz 1 20457 Hamburg DE

## Abstract

The article discusses the impact of the trends towards online shopping and personal last-mile micro-mobility on urban mobility and public spaces. These trends reflect changes in consumer behavior and preferences driven by technology and the increasing availability of online services. The article argues that the preference for door-to-door services can potentially lead to a reduction in pedestrian foot traffic and affect the social sustainability of neighborhoods. To address this challenge, the article proposes the use of small-scale transport hubs strategically positioned to cater to evolving consumption and mobility practices, while also preserving the vitality of public spaces and reducing carbon emissions. The article suggests the need for transdisciplinary approaches and digital tools for knowledge management to address the complex challenges of selecting suitable locations for these hubs in cross-cultural settings. The paper proposes a methodology based on digital tools for addressing the clash between general standardized criteria and context-tailored interests in the process of locating small-scale transport hubs, applied for the case study of six European cities to illustrate the methodology.

## 1 Introduction

In recent times, the dynamic and evolving nature of cities and their capability for swift development has become increasingly evident. The global pandemic has further accentuated this phenomenon, as urban environments and societies underwent substantial changes in the way individuals interact with the urban space, as well as in their social conventions and relationships. The changes in consumption patterns and urban mobility offer a telling example of these transformations. Particularly in Western European countries, there are two

phenomena that have radically evolved in the last years: (1) the decrease in physical consumption linked to a rise in demand for online shopping and home deliveries (Beckers et al., 2021; Chava et al., 2022), and (2) the increase in the variety and availability of personal mobility services, including micro-mobility and MaaS solutions that are offered virtually everywhere (Arias-Molinares, García-Palomares & Gutiérrez, 2022).

These two phenomena are related in the sense that they both reflect changes in consumer behavior and preferences that are influenced by technology and the increasing availability of online services. As people increasingly rely on online shopping, they are less likely to visit physical stores and engage in traditional forms of shopping that involve traveling to different locations, when traveling to locations is less cost-effective than receiving goods at home (Kickert et al., 2020). This phenomenon is especially relevant in mid and low-density urban environments where the 15-minute city principles are not applied, and therefore physical consumption requires a considerable amount of effort (Istrate et al., 2020). In parallel, the increase in the variety of available personal mobility services also reflects consumer preferences for more flexible and convenient ways of transportation that enable door-to-door. Again, the newest transportation options (personal last-mile micro-mobility) are sometimes the most cost-effective choices over public transportation (waiting times, walking to stations), car transportation (finding a parking spot), or even walking (slower) (Wang et al., 2023). The positive effects in congestion and emissions reduction are visible as the modal share of private cars is being reduced and bikes and e-scooters are on the rise.

These two trends are characterized by the rationalization of economic choices in consumption behavior (e.g. preference for using a food-delivery app over traveling to a restaurant and waiting for the food, as the most cost-effective option). Nonetheless, the pragmatic implications of such rationalized consumption choices can be witnessed in the realm of urban mobility dynamics, which unfold in public spaces. Therefore, it is of paramount importance to take into account the ramifications of these two trends for public space. In doing so, one must acknowledge that the trend towards door-to-door mobility and logistics may precipitate a reduction in pedestrian foot traffic. For instance, Wang et al., (2023) report that modal displacement of micro-mobility (e-scooters as an alternative to other modes) coming from walking at a rate of 60% in Oslo, and 80% in Munich, and they find a statistically significant and positive correlation

with population density, presence of mixed-use areas and commercial areas, street connectivity, and land-use entropy.

The preference for the convenience and comfort of door-to-door phenomena among individuals presents a significant concern in terms of pedestrian foot traffic, which is directly related to the social sustainability of neighborhoods (Mateo-Babiano & Ieda, 2007; Asif et al., 2022). Should this trend continue, there is a risk of a reduction in pedestrian activity, thereby posing a potential threat to public spaces detrimentally impacting their vitality and liveliness, causing a loss of social cohesion and hampering the development of community identity. The link between pedestrian flow and urban vitality is well-established, as the presence of an active pedestrian environment is indicative of a lively and thriving urban area. Compact urban areas, which provide a greater concentration of destinations within a smaller area, are especially conducive to pedestrian activity, as they offer easy navigation on foot (Berghauser Pont, Stavroulaki & Marcus, 2019). In mid- and low-density areas where the concentration of destinations and general complexity may be lower, any changes in the volume of pedestrian flow would be more significant and could have a more substantial impact on social sustainability in terms of public space vitality, community identity, and social cohesion.

### ***1.1 Micro-hubs for urban vitality***

In light of this, contemporary urbanists are working towards developing and implementing innovative solutions that can cater to the evolving consumption and mobility practices. One such example is the exploration of small-scale transport hubs to facilitate mobility and freight transportation while also preserving the vitality of public spaces, and reducing carbon emissions. The “micro-hubs” are small logistic centers based on a two-stage delivery system, where consolidation of cargo and re-distribution into smaller vehicles or self-pick-up are integrated (Hribernik et al., 2020). The successful implementation of these micro-hubs requires strategic positioning based on the social and geographical features of the urban fabric, along with the integration of supplementary services.

The concept of small-scale logistic hubs has gained increasing attention as a solution to the challenges posed by the growing trends described above. The currently existing methods for selecting a location to host a micro-hub for logistics are reviewed by Novotná et al. (2022) based on the problems considered. While the most common methods BWM, CRITIC and WASPAS have already

assessed distribution, energy, and traffic problems, there is currently no established standard set of variables for selecting a suitable location for such hubs that maximizes its positive social sustainability outcomes. This is a complex challenge, particularly in cross-cultural settings where multiple factors influence policy priorities, understandings, and goals.

To address this challenge, transdisciplinary approaches and digital tools for knowledge management must be explored. This paper proposes a methodology based on digital tools for addressing the clash between general standardized criteria and context-tailored interests in the process of locating small-scale transport hubs. The approach considers the unique social conditions of a local context while also incorporating general goals and replicable processes. This contribution highlights the need for transdisciplinary approaches and digital tools for knowledge management to address the complex challenges of selecting suitable locations for small-scale logistic hubs in cross-cultural settings.

## 2 Methodology

**Case study selection:** The cities of Oslo, Gothenburg, Hamburg, Munich, Bologna, and Rome were chosen for this study. These cities represent different regions in Europe, providing a broad understanding of urban environments across different contexts, which allows for a more comprehensive analysis of the effectiveness of various urban strategies, and their applicability in different settings.

**Data sources:** This study utilizes various open-source data formats. To calculate urban accessibility, walkability, connectivity, and street network parameters, space syntax is employed on the street network of the cities, downloaded from OpenStreetMap (OSM), and processed through OSMnx (Boeing, 2017). To determine morphological characteristics of the areas, such as ground floor built density, OSM building polygons are utilized. Additionally, POI (point of interest) data from OSM, such as restaurants, cafes, and offices, are used to calculate the number amenities in urban spaces.

**Spatial aggregation:** Using this data, virtually available in any city, a methodology was developed to analyze urban areas and identify suitable locations for transport hubs. This method involves merging data from various geospatial formats into a grid of cells of equal size. During the merging process, statistical analyses are performed, including counting the number of items,

calculating item density, and computing average values. This results in a set of metrics for each cell of the grid.

**Metrics calculated:** Once the data is aggregated by the grid cell, a series of metrics are calculated (Table 1). Those metrics make it possible to compare characteristics of the richness of places, their diversity, their degree of connectivity to the rest of the city, their perceived compactness, and the relevance of their spatial clustering.

Table 1. Description of the metrics calculated.

<b>Metric</b>	<b>Variables</b>	<b>Calculation method</b>
<b>Ground-floor coverage</b> Source: OpenStreetMap buildings Shape type: polygons	Ground-floor coverage ratio	Ratio of ground-floor built area divided by cell area, expressed in %.
<b>Street network configuration</b> Source: OSMnx (Boeing, 2017) street network data input for SpaceSyntax (Hillier et al., 1976) Shape type: lines	Urban integration: relation between one space and the rest of the city	Angular integration with infinite radius (Hillier et al., 1976) normalized by street segment length in each cell.
	Local Integration: relation between one space and adjacent spaces	Angular integration with radius 3 (Kim & Penn, 2004) normalized by street segment length in each cell.
	Walkability: relation between one space and adjacent spaces, at a walkable distance	Metric segment analysis with radius 300m (van Nes, 2021) normalized by street segment length in each cell.
<b>Activities, amenities, and services</b> Source: OpenStreetMap points of interest Shape type: points	Number of places (also referred to as density of activity)	Counting the number of points contained in each cell.
	Number of unique categories of places (also referred to as richness)	Aggregating the place types (Cerrone et al. 2018) by general category, and counting the number of unique categories contained in each cell.
	Diversity indices applied to the number of places and categories (also referred to as entropy or complexity)	Gini-Simpson: detecting rare categories Inverse Simpson: measuring the impact of rare categories Renyi-entropy (alpha value =2): detecting rare dominant categories Shannon: detecting changes in categories richness and evenness Shannon-Wiener: comparing diversity among multiple samples Simpson: detecting dominant categories
	Spatial clustering of	Local Moran's I: Clustering type of

	places	clusters and outliers Local Moran's P: Significance of clustering
	Spatial clustering of each specific place category (consumption, workplaces, third places, leisure, etc.)	Getis-Ord-Gi* Z: Critical value Getis-Ord-Gi* P: Significance of clustering

**Standardization:** To facilitate comparison across metrics (e.g. built density vs street integration of an area), the scales of each type of metric are standardized. To achieve this, percentile rankings are computed for each metric, considering the minimum and maximum values of each city.

$$\text{Standardized Value} = \text{Percentile Rank} = (\text{number of values below the given value} / \text{total number of values}) \times 100$$

*Figure 1: Percentile rank where the given value is the value for which the percentile rank is being calculated. This formula is used to determine the percentage of values in a dataset that falls below a given value and express it as a percentage.*

**Scenario definition:** In order to develop a tailored strategy for each case study city and scenario, co-creation workshops were conducted as part of the Horizon2020 project "MOVE21". The outcome of those workshops made it possible to explore scenarios that align with the priorities manifested by local stakeholders. These priorities are subsequently translated into a weight index ranging from -1 to 1 (negative values indicated characteristics that should be avoided and positive values represent characteristics that should be maximized). Acknowledging the significant direct correlation between the factors that Wang et al. (2023) reported in micro-mobility usage rates, one could argue that two scenarios necessary to explore would represent the ends of the spectrum ranging from compact city centers to disperse suburbia. Therefore, this work takes those two scenarios to test the data pipeline methodology. In the future, the method described by Novotná et al. (2022) could be applied to determine the weights that define each scenario.

**Scoring:** Once the weights are applied, a weighted average of all metrics is computed for each cell. This results in a single suitability value for each cell, which represents its suitability for the hypothetical scenario set for that city. Overall, this methodology provides a standardized approach to analyzing cities and

identifying suitable locations for transport hubs, while also allowing for tailoring to the unique needs and scenarios of each city.

$$\text{Scenario Score} = \text{Weighted Average} = (w1 * x1 + w2 * x2 + \dots + wn * xn) / (w1 + w2 + \dots + wn)$$

*Figure 2: Weighted average where  $w1, w2, \dots, wn$  are the weights assigned to each variable, and  $x1, x2, \dots, xn$  are the corresponding values of each variable. The weighted average provides a representation of the data by giving more importance to the variables with higher weights, and less importance to those with lower weights.*

### **3 Results**

The results of this research depict socio-spatial characteristics that are deemed important for future consideration and analysis. The results also provide a broad city-scale narrative that can be used to understand the research findings at a neighborhood scale. Moreover, the methodology itself has the potential to reveal patterns in the data and highlights the importance of considering both urban and local scales in understanding the functionality of small-scale public open urban spaces from both social and spatial perspectives.

#### **3.1 Ground-floor coverage**

The density of built spaces is an important aspect of urban spaces, as it has been shown to be connected to the social fabric of the environment. According to Jacobs (1961), a dense urban environment is more engaging and attractive to people, particularly in terms of building types. Having a high ground floor density might indicate that the areas are built with a more human scale, narrow streets, multiple building fronts, and ground floor activities such as retail.

In most cases, we find these areas in the most central locations of the city, likely to be the historical city center and in close proximity to a central station, to combine residential types with commercial uses. On the other hand, the lower density tends to likely consist of purely industrial fabric or residential single-family suburbs. In the mid-range, we find modern-era fabrics with large building fronts and extensive green spaces in between – in both cases showing a low mix of diverse building types.

Despite the different nature and size of the case study cities selected, one can observe a general trend in which the majority of urban areas contain a low ratio

of coverage, concentrating the highest ratios in specific areas (city centers) or specific points (industrial facilities or shopping malls). In order to compare across cities of different sizes, the aforementioned standardization process is deployed. As a result, we can observe the relative distribution of the ground-floor coverage ratio across cities. The distribution of Gothenburg highlights the presence of a large number of low-density areas, while Bologna and Munich show the highest relative numbers of high-density areas. The cases of Hamburg and Rome show a similar trend in which mid-density areas are more common than in the other cases (e.g. Figure 3). In all of the cases mentioned, a gradient of density can be observed, from the generally most common low density to the less common high density. In the case of Oslo, this gradient is rather an abrupt leap between low and high density, being low-density areas the most common.

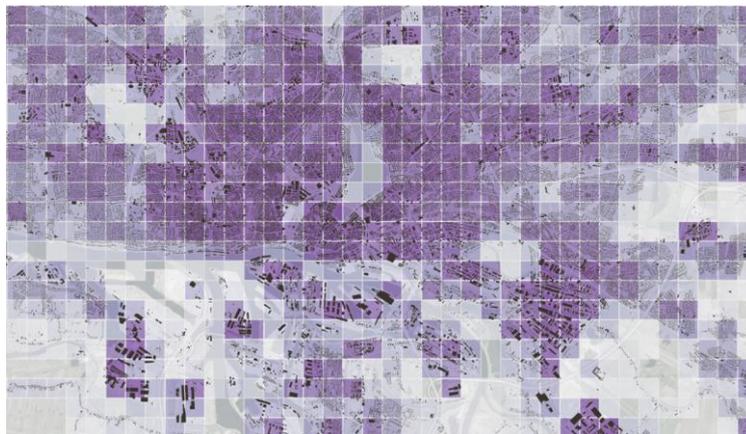

Figure 3. Map of ground floor density in Hamburg, Germany. (Cell size: 600x600m) (Source: authors)

### **3.2 Street network configuration: connection to other spaces**

Assessing potential footfall and traffic flows in a city depends notably on the significance of street segments within the network of streets. The relevance of certain streets over others in terms of connectivity can be determined by using Space Syntax and Segment Analysis, which provide quantifiable metrics to define the spatial role of streets and street segments in the entire urban network. Integration is computed to analyze street networks at both urban and local levels (the number of turns required to reach all other street segments from each segment; a higher Integration is achieved when maximum segments can be

reached with minimum turns). Integration is usually used to "predict" pedestrian and traffic flow, as turns are believed to create cognitive resistance in the network and indicates how well-connected a space is to the rest of the city. Therefore, locations in proximity to highly integrated streets are more accessible, which can be deemed as a favorable aspect for micro-hubs (Barros et al., 2006; Leccese et al., 2020).

In order to transfer the linear metrics of space syntax into the surface covered by a grid cell, the linear metrics are normalized by distance multiplied by the area covered by each cell. Similarly to the ground-floor coverage metrics, the space syntax results are also standardized across cities enabling comparison. In absolute numbers, the city of Rome shows integration values ten times higher than the city of Hamburg. However, when we observe the distribution and location of more integrated streets, we find certain commonalities, such as the higher integration values in the areas closer to the city centers because of the tendency to present a dense and complex urban fabric with narrow and short streets with multiple intersections and corners, compared to suburban fabrics. In this context, Oslo, Gothenburg, and Hamburg present a similar structure in which the majority of walkable areas are found in areas of mid-density, in contrast to Munich, Bologna, and Rome where the most walkable streets are located in the densest areas. In the cases of Oslo and Gothenburg, the metric of integration shows isolated high values that coincide with the presence of isolated areas of high density corresponding to shopping malls, big box strips, and large industrial areas that are located next to highly connected roads (Figure 4).

Figure 4. Map of street integration in Rome, Italy. (Cell size: 600x600m) (Source: authors)

### **3.3 Activities, amenities, and services**

Previous literature has explored the activities that take place within the urban space, with a focus on the primary function of the places, their adherence to normative land-use categories, or their significance in daily routines and necessity levels. Scholars such as Seamon (1979), Buttner and Seamon (1980), Gehl (2011), Ben-akiva and Bowman (1998), and Jiang, Ferreira, and González (2012) have delved into these topics. Cerrone et al. (2018) utilize these references to develop a classification of urban activities based primarily on the need for action, as proposed by Gehl (2011), aiming to encompass all types of activity in the city regardless of the specific space in which they occur. They apply it to Foursquare POI datasets. From an urban-social standpoint, the distribution of activities (or functions) is approached based on its ability to influence pedestrians. If functions are segregated or concentrated in specific areas, this can limit spontaneous choices, serendipity, and randomness. Such segregation can also lead to an increase in motorized traffic modes and subsequent congestion, as multi-purpose trips would require traveling to different parts of the city beyond a walkable distance threshold. This would also reduce temporal entropy, resulting in areas of the city being visited by people at the same times of the day, creating temporal-activeness imbalances and traffic congestion during rush hours (e.g. people leaving downtown at the end of the workday). In contrast, areas with a higher mix of functions, such as residential, commercial, and services, offer more sustainable everyday dynamics, are more walkable, and align with the 15-minute city approach (Balletto et al., 2021). These areas also provide opportunities for serendipitous interactions, making the neighborhood more interesting, as Walking the Walk (2009) suggests. For this reason, this work approaches the distribution of functions as the key factor to define whether an area will potentially be benefited from the presence of a micro-hub.

Using the POI database of OpenStreetMap, it is possible to evaluate the presence of amenities, services, and functions in urban space (hereafter, activities). In this contribution, we focus (1) on the overall presence of activities per unit of area in order to notice their degree of concentration, and (2) on the presence of diverse types of activities in order to evaluate the degree of mix. In order to do so, ecosystem entropy evaluation methodologies can be implemented to assess the degree of complexity of activities in a given urban area. In our case study cities, there is a partial correlation between the ground floor density and both the

density of activities, and the diversity of types; the most complex areas are those with higher ground floor density such as the city centers and isolated shopping malls. However, not all highly-dense areas are also complex, since industrial areas appear as dense but only host one type of function thus a low complexity index (Figure 5).

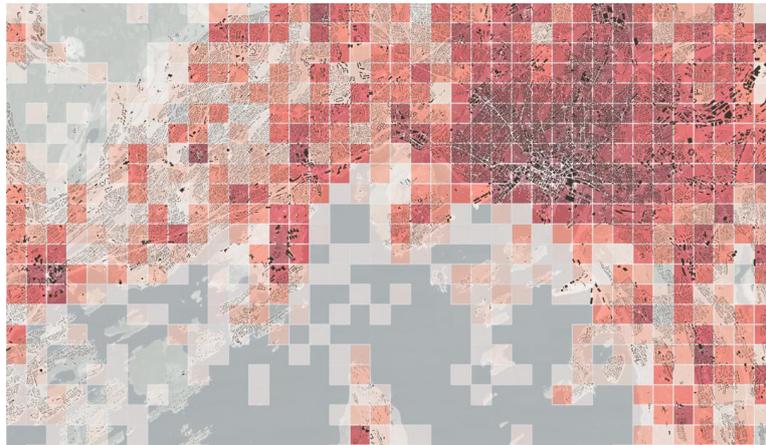

Figure 5. Map of POI diversity (Shannon-Wiener) in Oslo, Norway. (Cell size: 600x600m)  
(Source: authors)

### **3.4 Scenario definition**

In order to define scenarios in which to assess the feasibility of an area to host a small-scale transport hub, co-creation sessions were carried out in the context of the European Horizon 2020 project "MOVE21". In these sessions, stakeholders in a quadruple helix setting (public authorities, research institutions, private companies, and proxies for citizenship) discussed (1) the existing problems that a space might have, that a transport hub could solve, and (2) the ideal spatial conditions that a space should have for hosting the implementation of a such transport hub.

Considering the overall goals of reducing traffic and carbon emissions, as well as increasing the presence of people in public spaces, two main scenarios were considered. This first scenario takes advantage of an existing consistently high level of pedestrian flow and introduces a micro-scale transport hub in an area that is dense, walkable, popular, and has a high density and diversity of activities. By doing so, a convenient location for collecting small parcels would frequently be on the way from one place to another, being subject to multipurpose trips at a

walking distance instead of a targeted trip in a longer distance potentially using a vehicle. In this context, metrics of ground-floor converge ratio, the density of activity, complexity, and walkability have a heavier weight in this scenario.

The second scenario poses a situation in which an area with a low ground-floor coverage ratio, low density of activity, and low complexity is highly accessible to motorized traffic (e.g. single-family residential fabrics). In this case, the presence of a small-scale transport hub would include additional functions with the intention of creating a “neighborhood hub” that attracts people. By doing so, the transport hub in the second scenario is intended to activate the social fabric of these areas. In this context, the metrics described in the previous scenario would have an inverse weight, while integration at infinite radius would be heavier.

By applying the weights to the indicators and computing the weighted average, one score (from 0 to 100) is given to each cell in the urban grid, for each scenario. The score represents the suitability of that individual cell to meet the requirements of the scenario, and is therefore a recommended location to establish a small-scale transport hub (Table 2, Figure 6).

Table 2. Summary of the number of cells matching the scenarios defined by the stakeholders over 99/100.

<b>City</b>	<b>Total number of cells (100%)</b>	<b>Cells scoring over 99/100 in scenario 1</b>		<b>Cells scoring over 99/100 in scenario 2</b>	
<i>Oslo</i>	4047	5	0,12%	4	0,10%
<i>Gothenburg</i>	3654	4	0,11%	4	0,11%
<i>Hamburg</i>	3965	5	0,13%	5	0,13%
<i>Munich</i>	1140	3	0,26%	3	0,26%
<i>Bologna</i>	483	1	0,21%	1	0,21%
<i>Rome</i>	4224	6	0,14%	5	0,11%

#### 4 Discussion

The methodology presented in this paper could be a valuable tool for narrowing down possibilities and evaluating the suitability of different areas for finding the location of a small-scale logistic hub. In addition to its effectiveness in location finding, the methodology has provided insight into the correlation between different factors and their impact on urban environments. The results have confirmed that city centers are generally the most suitable locations when looking for dense, diverse, and vital urban areas. In addition, the methodology has also provided quantitative information on specific areas within those centers at a micro level (specific plot, or building), that may be more suitable for certain purposes.

Interestingly, the methodology has revealed surprising similarities in correlations across different case study cities, despite differences in size, cultural context, age, and form. By quantifying these correlations, the methodology has allowed for a deeper understanding of how different factors impact urban environments. For instance, it has been shown that density and functional clustering works similarly in large and isolated shopping malls than in dense city centers.

In general, it is possible to observe correlation across the metrics that are grouped in the three variables of ground-floor density, street network integration, and presence of amenities and services (Figure 7). In general, one can distinguish dense integrated areas that are rich in services from low-density isolated and

disperse areas. Furthermore, in all six cities, one can observe the same ratio of areas with a statistically significant concentration of amenities and services (between 25% and 28% of the areas in the city show statistically significant concentrations).

However, the correlation across metrics is slightly different in our case study cities and establishes two groups. The northern cities are more spread, and the southern cities are more compact, and compact areas are surrounded by sprawl. This grouping is reflected by characteristics such as:

- The correlation between ground floor density and urban complexity is higher in compact cities than in large mid-density cities: (1) over 75% correlation between density and complexity in Munich, Bologna, and Rome showing high-density city center and low-density suburbs, with amenities clustered in the dense area, and (2) under 68% correlation in Oslo, Gothenburg, and Hamburg showing lower built density in the city centers and higher density in the suburbs than the previous group, with amenities spread relatively equally.
- Integration (both infinite radius and walking distance) and urban complexity are correlated under 60% in Oslo and Gothenburg, between 60% and 70% in Hamburg, and over 70% in Munich, Bologna, and Rome. This factor underlines again the greater divide between dense areas and suburbs in the second group, versus a more homogeneous urban fabric in the first group.

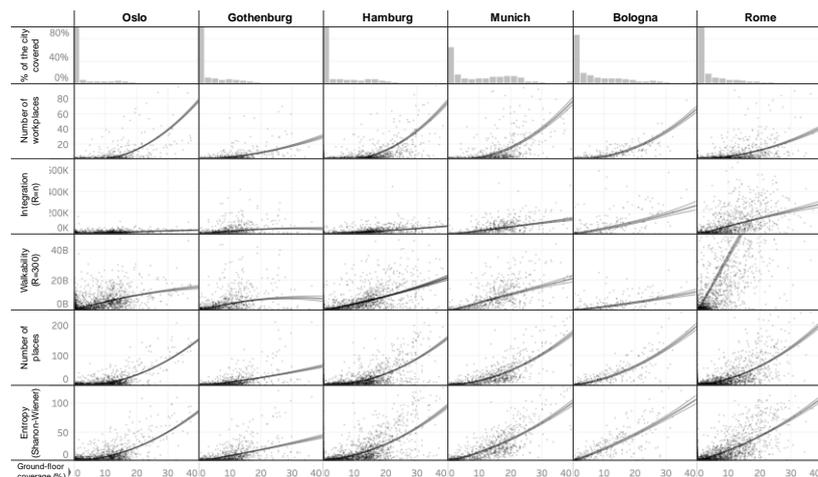

Figure 7. Scatter plot showing the correlation between ground-floor coverage and other variables in the six cities. Source: Authors

With this in mind, the methodology presented in this contribution offers the potential of tailoring specific strategies to a certain context while keeping a standardized thus replicable course of action. In relation to the specific use case of location finding for micro-scale transport hubs, the observations about the divide between urban and suburban in the group of compact cities might offer insights about the values worth maximizing, when designing a location finding strategy based on multi-criteria weighted analytics.

Once each area of the city receives a score that represents its suitability for a given list of priorities, one can: (1) select a location in the city based on the results of the scoring, or (2) evaluate the suitability of a given area in the city, compared to all other locations. For instance, the location of such service in a low-density residential fabric with a general absence of other services could create pedestrian flow around a catchment area of walkable distance. If such space is wanted, one can prioritize low density of buildings, amenities, services, and a low index of integration within a walkable radius to highlight the areas in the city that would benefit the most from such intervention. Similarly, a micro-scale transport hub would maximize its uptake by the end user in an area that is dense, walkable, and has other destinations. The trip to collect a package, for instance, would be most likely included in a scheme of multiple destinations thus avoiding the generation of additional trips (if by car, reducing traffic). From a governance and decision-making perspective, the choice of a location would be depending on the desired impact, which can be given as weights to the multiple factors described in this contribution. Additionally, the pipeline focuses on data standardization and comparison, being adaptable and scalable to include different data.

In general, these findings suggest that the spatial arrangement and characteristics of urban areas can significantly influence the relationship between factors, highlighting the need for a nuanced understanding of how these variables interact. Overall, we believe that the methodology presented in this contribution has the potential to significantly impact urban planning and design by providing a data-driven approach to evaluating and improving urban environments.

#### ***4.1 Limitations and further development***

The data used is often very general, and the results are limited to the scale of 600x600 tiles, which can limit the level of detail that can be achieved. A deeper

understanding can be gained by looking at more specific areas, but this must be balanced with the computational power required to do so. Additionally, the results only provide an overview of a city from a strategic perspective using open data with general information, and may not be useful for more specific discussions that might need the proper level of detail in the data. Further development of this tool may involve incorporating more detailed datasets and exploring the use of other statistical measures to provide a more holistic and detailed understanding of urban spaces.

Regarding the definition of the scenarios, this work assumed two test scenarios (compact urban space and disperse suburban areas) in order to test the data pipeline and the suitability of the application to maximize potential social sustainability outcomes. However, further development should include standardized methodologies for establishing the weights of the multi-criteria assessment. The Hybrid BWM-CRITIC-WASPAS model described by Novotná et al. (2022) could be applied to determine the weights that define each scenario, considering the criteria described in this contribution.

## **5 Conclusion**

In conclusion, the use of data-driven approaches, such as the one presented in this study, can support decision-making processes related to the location selection. By selecting an area that maximizes the outcome that decision-makers decide, the implementation of this approach can provide quantitative proof to justify the location selection, streamlining the process. Moreover, this approach enables knowledge sharing in an inter/trans-disciplinary context, involving several stakeholders with different interests. Additionally, the weights used in this study can be easily adapted for different scenario definitions, further enhancing its applicability. Overall, this study demonstrates the potential of data-driven approaches to provide strategic insights for location selection, and it can be a valuable tool for decision-makers in various fields.

Our research methodology involves the use of three different approaches: (1) a morphological description of ground-floor density distribution (2) a network-analysis-based approach that identifies which streets are more likely to host flow; (3) a functional classification of places and activities with an interpretation of the distribution of places and types of places. This approach outputs a comprehensive pre-selection of places to host a small-scale transport hub. This pre-selection

comes from an understanding of some relevant socio-spatial characteristics of urban areas, allowing for an informed assessment of the potential likeliness to reduce carbon emissions by nudging the modal shift towards walking while keeping urban spaces vital.

### **Abstract**

This paper analyses the different adaptations of TOSCA, an open-source geographical information system (GIS) toolkit to different urban contexts across the world and the learnings through these adaptations; involving the synthesis of extracted knowledge, its translation and final adaptation into a location-customised tool for decision-support in the context of planning. Knowledge management and extraction methodologies developed and adapted in the process of implementation of this toolkit in India, Ecuador and Palestine provide insights into the application of digital tools for urban planning and contribute to the streamline of knowledge extraction mechanisms across different cultural contexts.

TOSCA, or Toolkit for Open and Sustainable City Planning and Analysis, has been developed since 2019, between the HafenCity University Hamburg (HCU) as research partner and the German Agency for International Cooperation (GIZ) GmbH as funding partner, to develop strategies and tools for sustainable urban development in two initial pilot locations \_India and Ecuador\_ and from 2022 in Palestine; for each case involving additional local cooperation partners. The tool was conceptualised as an open-source, easy-to-use and scalable tool for accessing complex urban analyses, as a solution to the

fact that GIS tends to be an expensive, complex and inaccessible software for many rapidly urbanising contexts with low resources.

The three contexts of India, Ecuador and Palestine presented vastly different urban challenges and actors, which required the customization of a tool development process to carry out the implementation of the project in each location. Necessary steps involved the identification of pressing issues, the definition of a relevant use case, the identification of roles and mobilisation of the local stakeholders, tool adaptation, technical revisions and knowledge transfer for its sustainable take-up.

After understanding the outcomes of the three past implementation projects, a model of ideal cooperation for knowledge management emerges as a potential way to systematise the methods for gathering knowledge and rendering it applicable to different scenarios. The identification of four fundamental agents in this model emerge, according to their roles and produced effect in the development process for TOSCA: (the funding agent) dissemination of means for sustainable development, (the R&D agent) incorporation of digital technologies in urban systems, (the local institution agent) consolidating local capacity building and (the local authority agent) public outreach and uptake activities. TOSCA, as a tool intended to contribute to sustainable growth in urban regions, lies at the intersection of these four roles, which are codependent on each other in different ways.

The objective of this paper is a first approximation to the exploration of this model as a potential solution for knowledge management and dissemination of a toolkit such as TOSCA.

**Paper type** – Academic Research Paper

## 1 Introduction

In an Era of rapid urbanisation, especially in the Global South, it is expected that 90% of the rise of the world's urban population will take place in Asia and Africa. (UN, 2018). This estimation highlights the urgent need for revision of processes adopted by policy-makers to address sustainable urbanisation (Moleiro, M. et al., 2023).

In order to mitigate the effects of urban sprawl resulting from rapid urbanisation, effective measures are required. Information and Communications Technology (ICT) is playing a pivotal role to replace traditional methods and services, pushing governance into a new dimension, and is focussed on the use of data and data-driven tools for enhancing exchange and transfer of information (Moleiro Dale,.M. and Mukherjee, A., 2022). In this context, digital planning tools

based on geographic information systems (GIS) can be game-changers for spatial analysis for faster decision-making and participation in urban planning processes.

The Toolkit for Open and Sustainable City Planning and Analysis (TOSCA) was developed in 2019 by the HafenCity University (HCU) in cooperation with the German Agency for International Cooperation (GIZ) to develop a web-based, open-source GIS tool to be used on a multi-touch table or browser technology. It was piloted in the cities of Bhubaneswar (India), Latacunga (Ecuador) and in the Palestinian regions between 2019 to 2023. Conceptualised and designed as a scalable, low-cost and low-tech solution (Moleiro Dale, M. and Mukherjee, A., 2022), TOSCA was built to address identification of land for affordable housing in India, to adopt volcanic-risk governance strategies in Ecuador and to build a citizen participation tool for the Palestinian regions. The implementation of TOSCA in the three contexts led to the emergence of a knowledge management model to address challenges for sustainable urban planning and decision-making for integrated urban development. A key challenge in the process was the creation of explicit knowledge from tacit knowledge, comparable to creating concrete technical solutions from wider, general urban challenges.

The focus of this paper is to understand the role of TOSCA in translating tacit knowledge to explicit knowledge through the development and adaptation of the tool to address different use-cases in the area of urban development. Several methods and tools were adopted for this purpose which is elaborated in section 3.

## **2 Background**

Tacit knowledge refers to knowledge made up of judgements, know-how and other skills. Usually, it refers to knowledge difficult to articulate or codify. Explicit or codified knowledge on the other hand, is knowledge that can be written down in a form which allows others to understand and reproduce (Gamble, J.R., 2020).

The Nonaka and Takeuchi knowledge management model is based on the concept of knowledge creation and refers to a cyclical process involving four different modes of knowledge conversion namely, socialisation, externalisation, combination and internalisation.

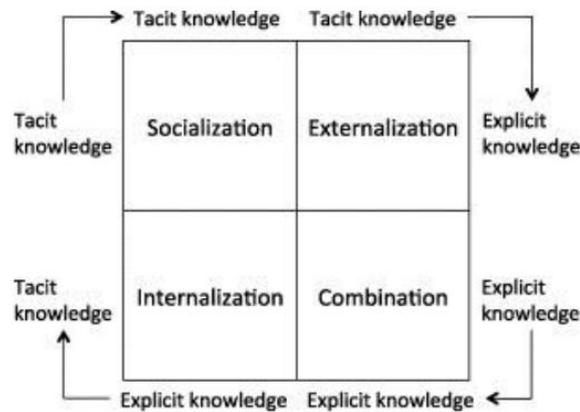

Fig. 1. The Knowledge creation process according to the Nonaka and Takeuchi model (Angraini, A., 2018)

Socialisation refers to the modification of tacit knowledge to other types of tacit knowledge and includes sharing experiences, images, ideas among others. It usually takes place through joint activities, observation, imitation and practices instead of through written instructions. Externalisation is the conversion of tacit knowledge to explicit knowledge, that is, hidden tacit knowledge like concepts and ideas are converted to a comprehensible format. This may include computer-based techniques like visual modelling, machine learning methodologies, etc. that are able to support individuals to express an inherent conceptualisation. Combination refers to explicit knowledge conversion into more complex sets of explicit knowledge. Finally, internalisation refers to the extension of explicit knowledge to tacit knowledge. These processes usually produce experience knowledge through an explicit knowledge source (Dakoulakis, I.E. et al. (2004)).

In urban planning, tacit knowledge plays an important role in collecting and identifying urban challenges, such as identifying key issues within different realms of society and potentially contributing to generate hypotheses about relational factors. Such information is often not apparent or available from explicit data sources such as maps or census data.

It is of crucial significance to be able to communicate and transfer such tacit knowledge in a way that is understood by other stakeholders involved in a planning process. Given the spatial significance of urban planning, usually visualisation, diagrams and models are a good way to represent tacit knowledge to make it easily communicable and actionable.

Often, tacit knowledge in urban planning refers to non-spatial information that may refer to strategies, visions, opinions, observations that may not be easily captured. However, such knowledge is essential to consider for effective decision-making and inclusive urban policies and interventions. Spatial information can be classified as a type of explicit knowledge because it can be visualised, stored and communicated in a formalised and structured manner. Spatial data such as maps, satellite imagery and geographic information system (GIS) data can be represented using different digital formats that can be further shared and analysed.

Translating such non-spatial information to spatial information is a critical aspect of the usefulness of tools like TOSCA to support decision-making in urban planning processes. For the implementation of TOSCA, translating knowledge from city partners onto a technical solution to address identified issues was significant. The biggest challenge in the implementation of such a tool was to collect tacit knowledge from partners in each location and to identify adequate methods for its translation into explicit knowledge that could ultimately be applied through a GIS system, enabling further dissemination through concrete documentation and knowledge transfer.

### **3 Knowledge building and management tools**

The approach for implementing TOSCA was an interactive and non-linear process that allows understanding the user, challenges assumptions, redefines problems and creates innovative solutions that can be prototyped and tested, inspired by design thinking (Dam, R.F. and Siang, T.Y., 2023). In such a process, engagement with several different cognitive processes are required that include preparation, assimilation and strategic control (Razzouk, R. and Shute, V., 2012). The following tools and methods were used in the implementation of the knowledge management of TOSCA to facilitate creative design activities such as use case definition, user requirement analysis, conceptual design, prototyping, testing and implementation by way of the design thinking approach.

For all pilot locations, the applied implementation methodology carried out was similar and was adapted to specific contexts (Moleiro, M. et al., 2023). As seen in Fig. 2, it consisted of a demand and requirement analysis with local partners, workshops with users and administrators, development of the software and performance of usability tests to identify technical challenges for improvement.

The tools and methods described in the next sections have been integrated into the implementation methodology to highlight the phases in which they were used.

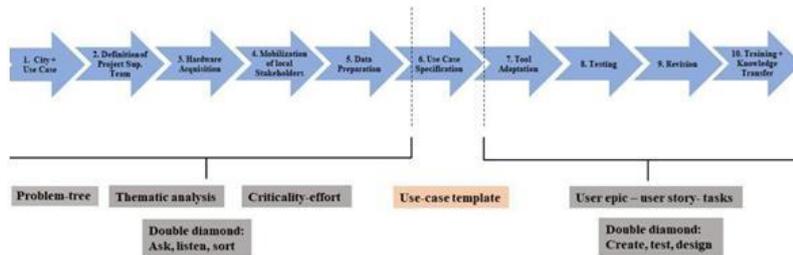

Fig. 2. The integration of the different tools and methods used along the implementation process of TOSCA (Digital City Science, HafenCity University Hamburg)

### 3.1 Use case template

A use-case may be defined as a description of ways in which a user interacts with a system or a tool and accomplishes a goal. By defining a specific situation in which such a system could be used, it is possible to develop and test data-driven solutions for addressing urban development issues. In the development of TOSCA, a use-case template was defined to identify the most crucial aspects in the definition of such a use-case.

TOSCA Use Case Definition Template	
<b>Issue to be addressed</b> <ul style="list-style-type: none"> <li>What issue / problem needs to be addressed? e.g. finding right locations for facilities</li> <li>Why is it critical? e.g. shortage of social infrastructures in the neighbourhood</li> <li>What ideas exist to solve the issue? e.g. running participatory planning workshops</li> </ul>	<b>General Background</b> <ul style="list-style-type: none"> <li>Geographical, cultural e.g. regular torrential rains, floods, and landslides</li> <li>Societal, demographics e.g. risk prone areas populated by low income residents</li> <li>Political, administrative e.g. land classification according to disaster risk</li> </ul>
<b>Users and User Context</b> <ul style="list-style-type: none"> <li>Who are the main users of the OCT? e.g. expert planners, decision makers, children</li> <li>What is their background and context? e.g. education, expertise, technical skills</li> <li>What is the main interest of these users? e.g. solving the issue, learning facts</li> </ul>	<b>Data &amp; Technical Background</b> <ul style="list-style-type: none"> <li>What is the IT maturity level? e.g. Geodata infrastructure implemented and accessible</li> <li>What data and systems are available? e.g. open GIS data, statistical demographic data</li> <li>What partners are available? e.g. local IT startups, technical college</li> </ul>
<b>Application Scenario</b> <ul style="list-style-type: none"> <li>In which setting will the tool be used? e.g. workshops, office work, public places</li> <li>How many users will use the tool, how often? e.g. groups of 20 people, once a week</li> <li>What functions and features are needed? e.g. interactive maps, 3D viewer, voting poll</li> </ul>	<b>Implementation</b> <ul style="list-style-type: none"> <li>When is the implementation expected? e.g. testrun in 1/2 year, full implementation 1 y.</li> <li>What resources are available? Financial support, workforce, technology, knowledge</li> <li>Who will supervise &amp; maintain the tool? e.g. municipality technicians, NGO</li> </ul>
<b>Other relevant information</b> <ul style="list-style-type: none"> <li>Other partners to be involved? e.g. contact to local technical college, international agencies</li> <li>First Step, next steps? e.g. demonstration workshop with decision makers</li> <li>Previous experiences, preliminary work? e.g. test implementation of GIS</li> </ul>	

Fig. 3. The use-case template (Digital City Science, HafenCity University Hamburg)

The use-case template helps to identify user-stories that aid in the further advancement of the use case definition, which ultimately translate into tasks and tool functionalities. In order to fill out a use-case template, other knowledge processing tools were implemented, elaborated below.

### 3.2 The Problem - Tree

A problem tree is an analysis tool that can be used to help stakeholders consider potential solutions that may be implemented to address identified key challenges and provides the opportunity of an overview of all known causes and effects of the identified challenge.

An example of clustering main issues from a general problem statement (Fig. 4) could refer to the beneficiary related issues such as defining accurately the issues citizens, or beneficiaries, face in the approval process for housing development in Palestine. These problems were concluded as- (1) too few broadcasting channels for publication of projects, (2) limitation of news regarding housing projects by only being published in printed newspaper media for two months, (3) unidirectional source of information without an exchange with citizens, and (4) citizens feeling uninformed, unheard and disadvantaged.

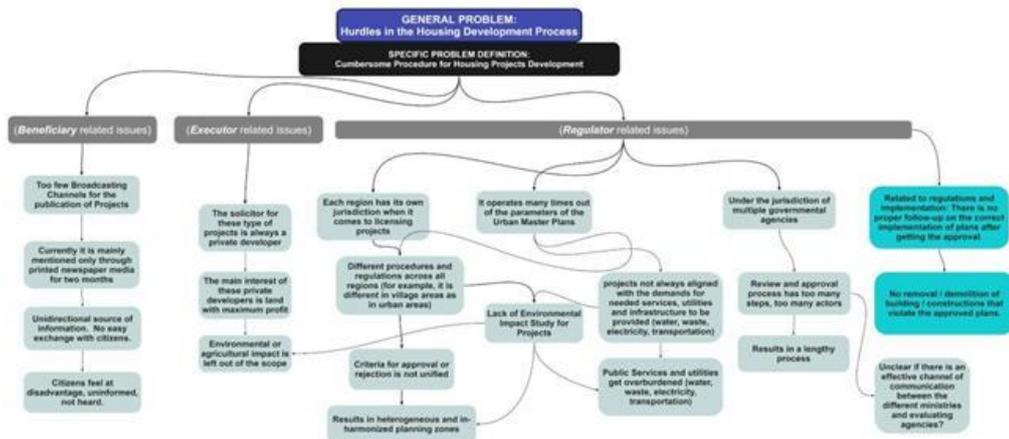

Fig. 4. A Problem Tree Diagram clustering the main issues raised from the case of TOSCA Palestine (Digital City Science, HafenCity University Hamburg)

Understanding these issues in detail made it possible to run a thematic analysis on the identified topics, assess patterns and to reach valuable conclusions.

### 3.3 Thematic Analysis

A thematic analysis is an approach of qualitative research which allows organising and identification of patterns to interpret the possible relations between the sub-topics of the collected data. After the definition of user-stories, a thematic analysis can lead to certain conclusions that may be valuable for the project, such as the example below, where types of users could be identified for the purpose of an evaluation process and for the purpose of consultation. In the case of TOSCA Palestine, the thematic analysis also helped to identify concrete tasks which could then be translated into technological development tasks.

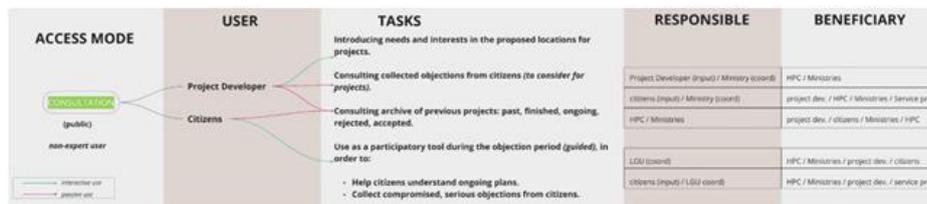

Fig. 5. Streamlining and synthesis of the User Stories into concrete tasks, responsibilities and beneficiaries (Digital City Science, HafenCity University Hamburg)

An example of thematic analysis (Fig. 5) could be seen in the conclusion of specific tasks and responsibilities such as the need to build a citizen participation tool during the objection period to help citizens understand ongoing housing development plans and to collect serious and compromised objections from citizens.

### 3.4 Criticality Effort graph

From the multiple identified user stories, the Criticality Effort graph is used to assess the hierarchy of these user stories according to their level of criticality to be addressed versus effort to be developed. The core idea of this tool is to identify the most pressing needs to be addressed and the effort associated with such needs. The tasks with the highest criticality and least effort of technological development would be selected, while the tasks with least criticality and high

effort of technological development would be considered as low priority to be selected for development within the tool. The Criticality Effort graph was first adapted by the research team to be implemented for the MICADO project where a toolkit was developed for migrant integration in European cities (Zagórski, P. *et al.*, 2021).

Among the different stakeholder brainstorming sessions held during the TOSCA Palestine Use Case, the example below highlights the identification of Task 7 as the task with the highest criticality and least effort of technological development to be fulfilled for the case of Palestine. It was finally selected as the main task to focus on for the definition of the necessary functionalities of TOSCA Palestine. An important criteria considered in the selection of the task was not to re-develop any functionalities covered by the current spatial information system platform, already in use by the local authorities in the region.

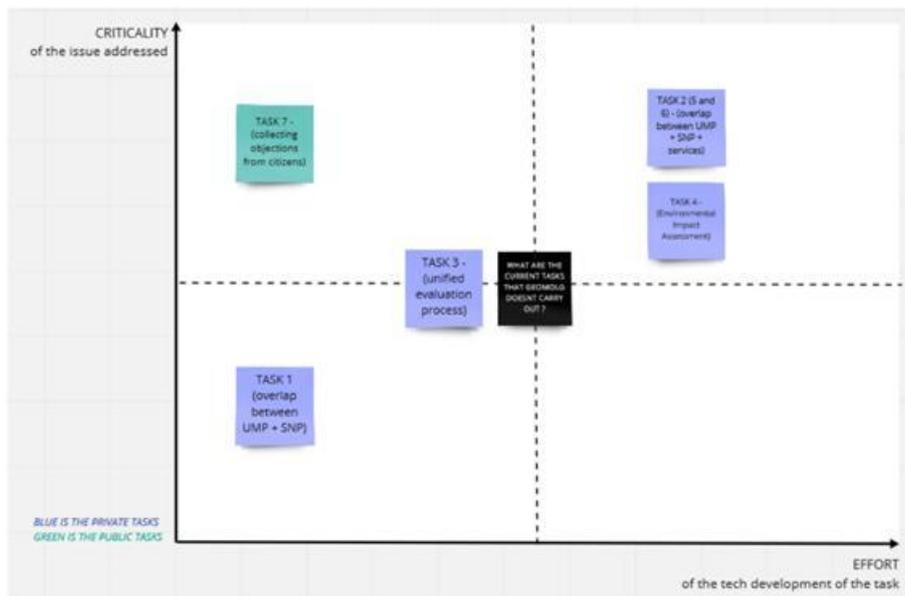

Fig. 6. Collaborative definition on the location of the defined tasks, according to the Criticality-Effort Diagram for the Palestine case (Digital City Science, HafenCity University Hamburg)

### 3.5 Double-diamond

In order to transition from a larger scope of discussion among all involved stakeholders to the synthesis of the most important topics collected throughout

the process, the double diamond process is used for the development of user experience design (Eissa, C., 2020). This tool aids in the transition from the collective discussion of needs to a more specific and technologically oriented second stage of the project.

Activities such as *asking*, *listening* and *sorting* are utilised to reflect upon the need of the user which leads to the problem definition. The middle point of the double-diamond process has been reached when a consensus on the problem definition is achieved. This marks a pivotal point where activities will shift towards the creative process of designing the requirements for the chosen solution. It consists of *creating*, *testing* and *designing* in an interactive mode of development during the second phase of the project.

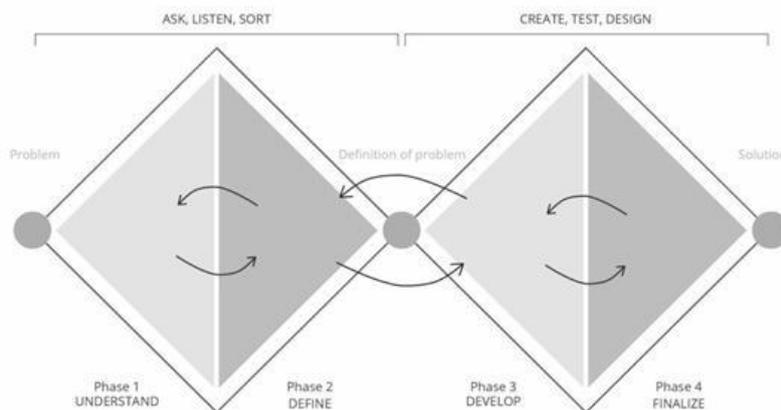

Fig. 7. The Double Diamond Process, implemented for User Experience design methods (Retrieved from Eissa, C., 2020)

### 3.6 From the Use-Case Epic, to User Stories, to Tasks

The following diagram highlights the process of funnelling the scope of the problem (the use case epic) into a defined use-case and user-stories to concrete tasks and tool functionalities. The ideal scenario is to reach consensus on one main user epic statement, define a specific use-case from the user epic, generate a series of user stories and to break these user stories further into technical tasks and functionalities for the technological development of TOSCA. The synthesis process can be better understood in the diagram below.

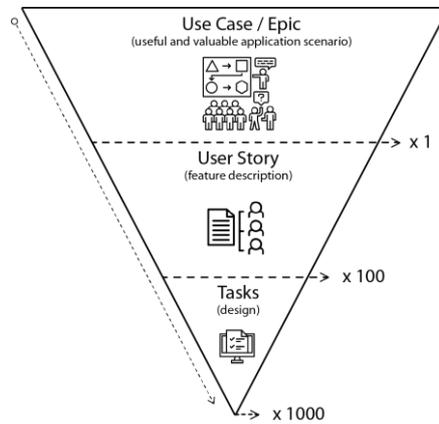

Fig. 8. Diagram depicting the synthesis process from Use Case Epic to user stories and functional tasks (Digital City Science, HafenCity University Hamburg)

An example of this process where content collected through interactive brainstorming sessions carried out at the beginning of a project were clustered and translated into a narrative of multiple user stories is shown in the diagram below. The main Use Case Epic here was 'Streamlining Regulatory Process in land use management for Housing Development in the Palestinian territories' which was broken down by type of user. The example below shows user stories generated for the citizens as end-users.

From the indirect-Beneficiary perspective (Citizens)
<ul style="list-style-type: none"> <li>As a citizen, I would like to have a more direct source of consultation to the ongoing housing development projects.</li> </ul>
<ul style="list-style-type: none"> <li>Citizens would like to have a more interactive, participatory means of submitting their opinions, input and objections to evaluated housing projects.</li> </ul>
<ul style="list-style-type: none"> <li>The general public (and also the developers and authorities) should have a means of consultation archive of the location of historically approved, pending or rejected projects.</li> </ul>
<ul style="list-style-type: none"> <li>Citizens believe the social impact of projects in the region is relevant enough to be considered, or even to be reason to object to a project. (How to link social impact to environmental impact in the case of the Palestinian regions?)</li> </ul>
<ul style="list-style-type: none"> <li>The process of UMP involves citizen participation, but plans for housing projects don't. It could be beneficial for Citizens and also for Public Authorities, that the input collected from participatory processes related to UMP, where visible in the tool (can this input be geo-referenced?...LIG?) so it can be considered for the Housing Development Projects Review?</li> </ul>
<ul style="list-style-type: none"> <li>Citizens would be interested in the use of this Tool in a workshop session during the period for objection (60 days) to (a) help citizens understand the plans and (b) facilitate citizens' right to make objections.</li> </ul>
<ul style="list-style-type: none"> <li>Truly concerned citizens would like to not be overlooked, when there is the disruption of non-serious or invalid objections during the objection period. Through the implementation of an assisted, guided, digital participatory process, the truthful and argued objections can be better identified.</li> </ul>

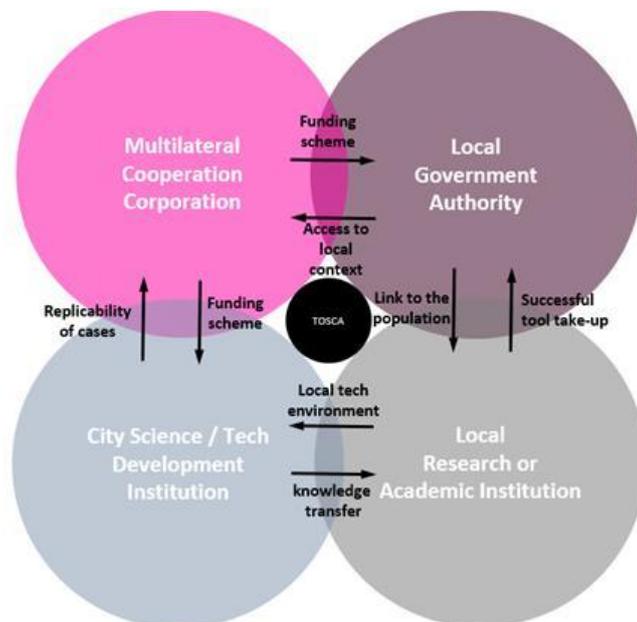

Fig. 9. Clustered list of user stories for the Palestine use-case, according to the citizen as the end-user (Digital City Science, HafenCity University Hamburg)

The use of these tools and methods were instrumental in the collection of tacit knowledge and needs from the user and to translate them into explicit knowledge. The development and adaptation of TOSCA through the use of these methods helped to identify core needs, to engage with different processes and

stakeholders and to adapt the tool for the defined needs of its final user during the implementation of the tool in the three contexts of India, Ecuador and Palestine.

#### 4 Discussion

The implementation of TOSCA across the different cities has helped in identifying four core roles to cover all activities of a successful project. 1) A multilateral corporation as an overarching coordinating and funding agency, 2) a R&D partner capable of adapting and bridging technological knowledge for the specific needs of each location, 3) a local government authority which ensures the provision of data and on-ground connection and 4) a local academic and/or research institution capable of receiving the transferred knowledge and ensuring the sustainable take-up of the tool after the end of the project. The cooperation diagram below depicts the ideal cooperation exchange for knowledge management applicable to TOSCA. This cooperation model emerged after consolidating the learnings from the implementation of TOSCA in the three contexts of India, Ecuador and Palestine.

*Fig. 10. Emerging knowledge management cooperation model from the on-going learnings on the ideal cooperation scenario resulting from the implementation of TOSCA (authors, 2023)*

While the ideal scenario comprises all four roles playing an equal part in the cooperation, empirical work of implementing TOSCA highlighted the varying degrees to which the four roles acquired more or less level of responsibility and active involvement. From this ideal four-helix constellation of actors, the following diagram (Fig. 11) depicts a visual representation of the variation according to the actual involvement of the four identified roles based on the approximate number of people who participated under each of these roles. The radius of each circle was adjusted to the number of people involved in each case. As a result, it can be seen how the Ecuador-case had the largest number of people involved as local partners, distributed across different institutions and technical developers. This was reflected in the wider use of the tool by different end-users after the end of the project. In the case of India, the local institute also played a significant role, however due to the strong technological expertise in this context, the tool was taken up mostly by a concentrated ecosystem. The Palestine case had the most balanced involvement of all its parts, in comparison to the other contexts. However, this model does not account for other qualitative factors such as political willingness, type of local partner, the socio-economic environment or other cultural or social parameters. The adaptation of the knowledge management cooperation model to the different contexts is still in development.

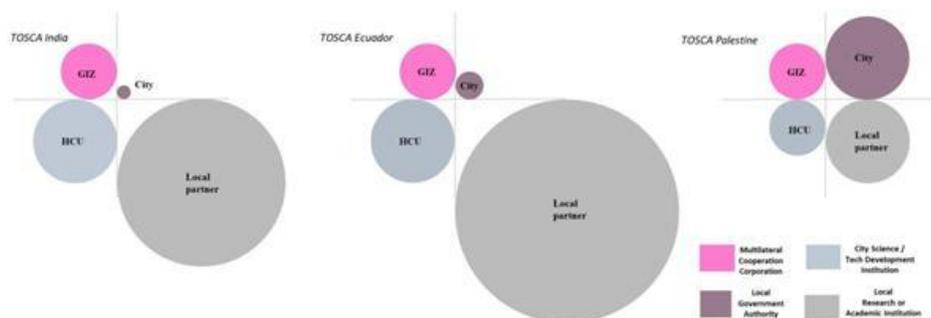

Fig. 11. Adaptation of the knowledge management cooperation model to the three contexts of India, Ecuador and Palestine based on number of participants for each role (authors, 2023)

Some preliminary conclusions which can be drawn from the resulting diagrams can illustrate, for example, that the size of involvement of the city government is similar in the first phase in India and Ecuador that took place from 2019 to 2021. This can be attributed largely to the Corona pandemic that hindered participation

and potentially evidence limited resources or political factors limiting the role of the city for the sustainable application of TOSCA in that phase. There is a need to support capacity building activities for future cases of TOSCA with knowledge transfer to local institutes whose role, locally, can be to ultimately support city governments in the long-term with the acquired knowledge on TOSCA.

## 5 Conclusions

The implementation of tools like TOSCA highlight the need to consider innovative methods to acquire and process local, emerging knowledge, which can contribute to address more effectively pressing urban challenges, especially in the Global South. An early exploration of the emerging knowledge management cooperation model offers a potential way to systemise methods for gathering knowledge and rendering it applicable to different scenarios. TOSCA as a tool intended to contribute to sustainable urban development, lies at the intersection of these four roles that are codependent on each other in different ways. As an interactive, table-oriented tool, TOSCA has the capacity to bring tacit knowledge at the table and to connect it to the explicit knowledge that is represented through maps and visualisations. The future of TOSCA lies in furthering the 'voicing' of tacit knowledge through table discussions into new explicit knowledge by designing new features though new feedback collection mechanisms, actively augmenting presented data and other methods.

Future TOSCA cases will aim at further refinement of the emerging knowledge management cooperation model and to define and document more tools and methods to streamline the knowledge creation process.

### **Abstract**

In today's globalized world, cross-cultural settings, projects, and institutional setups are becoming increasingly common, presenting both opportunities and challenges. Knowledge creation and management plays a critical role in addressing these challenges by facilitating the sharing of information, ideas, and best practices across different cultures and contexts. However, effective knowledge creation and management in cross-cultural settings requires a nuanced understanding of different cultures, as well as a recognition of the potential barriers to communication and collaboration. One specific area where knowledge generation and management is of particular importance is sustainable development in the built environment. As the world's population continues to grow and urbanization accelerates, sustainable development is increasingly recognized as a critical challenge that requires urgent action. To address this challenge, knowledge creation and management approaches that can facilitate the exchange of ideas, best practices, and innovative solutions are essential. However, effective knowledge creation and management in this context requires an understanding of the unique cultural, social, and economic factors that shape different communities' perspectives on sustainability.

Against this backdrop, this paper presents the set-up of the SURE Facilitation and Synthesis Research Project, focusing on the conceptual architecture for its synthesis research. Part of the BMBF funding initiative SURE along with the ten collaborative projects, this project facilitates the synthesis of knowledge about and the development of solutions for sustainable and resilient urban and rural development in Southeast Asia and China. The project focuses on the transdisciplinary synthesis of research outputs from the SURE collaborative projects, the identification of research gaps, and the development of knowledge generation and management approaches to support the implementation of sustainable solutions, while its primary goal is to contribute to transdisciplinary knowledge synthesis, sustainability research, and urban research. The project focuses on utilizing a multi-method approach that combines empirical research with artificial intelligence tools to analyse qualitative and quantitative data. The project team employs digital tools to structure data and turn it into accessible knowledge that can be used in transdisciplinary urban sustainability projects and beyond. The overarching goal of the project is to contribute to a new research approach that synthesizes knowledge in the topic area of urban sustainability.

**Keywords** – qualitative meta-analysis; synthesis research; sustainability science; knowledge creation and management, transdisciplinary knowledge synthesis

**Paper type** – Academic Research Paper

## 1 Introduction

This paper is a detailed introduction one of the two main pillars, or focus areas, of the large-scope meta-research SURE facilitation and Synthesis research project. Thematically, SURE Facilitation and Synthesis research Project (SURE FSR) explores the challenges of synthesis research in cross-cultural settings and institutional set-ups, with a particular focus on sustainable development in the built environment in South-East Asia and China. The activity of this complex project is divided in two main “wings”: facilitation and synthesis research.

While this paper only sketches out what the facilitation tasks of the SURE FSR project ecosystem mean, it dives deeper into the project’s view on the role of synthesizing knowledge in facilitating cross-cultural collaboration and information-sharing, as well as the potential barriers to effective knowledge generation and management in these contexts – in other words, into the project’s synthesis research architecture.

Alongside that, the paper explains the project’s knowledge creation and management approach that can support sustainable development in the built

environment in a globalized setting, taking into account the unique challenges and opportunities presented by cross-cultural collaboration. By addressing these critical issues, the project and this paper aim to contribute to a more nuanced understanding of the role of knowledge generation and management in promoting sustainable development and cross-cultural collaboration.

The approach used in the SURE Facilitation and Synthesis research project is transdisciplinary, problem-driven, and solution-oriented. The project employs a meta-study methodology that synthesizes and consolidates existing conceptual, methodological, and empirical knowledge from literature and the ten collaborative projects within the SURE funding priority.

The project also uses a flexible project architecture and adaptive management methods to address the partly asynchronous runtimes and heterogeneous contexts of the different collaborative projects. The research is guided by a set of guiding questions, which are designed to provide practice-relevant results and insights.

Overall, the approach used in the SURE Facilitation and Synthesis research project is designed to support individual research projects and to systematically leverage the cross-project synergy potentials at the funding priority level. The goal is to create conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address the issue of sustainable urban development.

The SURE funding priority, which stands for Sustainable and Resilient Urban-Rural Development, is an initiative created by the German Federal Ministry of Research and Education (BMBF) focused on the challenges of sustainable development in the face of urbanization, natural resource depletion, and climate change. The SURE funding priority supports collaborative projects that develop locally implementable solution strategies for the sustainable use of resources and an improved quality of life in urban regions in Southeast Asia and China. The focus is on the development and testing of concepts for a sustainable transformation of fast-growing urban regions, which lead to the strengthening of ecological factors and greater resilience in the face of natural disasters and other consequences of climate change.

#### *Facilitation activities within the SURE Facilitation and Synthesis research project*

Apart from the synthesis research – the topic of this paper – SURE's other pillar of activity is facilitation. To briefly outline the project's tasks in that regard, three

main areas of work can be named. The first one is offering support to projects at individual project level. This entails, for example, regular one-on-one meetings, project visits (both in Germany and in Asia), or the establishment of an collaboration and exchange platform called SURExChange. The second one is putting in effort to create or expand impact that the ten projects will have in their target locations, but also beyond the programme, understood geographically, formally, practically and scientifically. The third one is working to identify synergies between the projects, creating awareness of such synergies in the project teams, and helping the sides to capitalise on the synergies. Importantly, the facilitation side of SFSRP's activity and the synthesis research side feed into each other in a dynamic feedback loop.

## **2 Transdisciplinary research and synthesis research: background and theory**

Henrik von Wehrden et al. (2019) define transdisciplinary research as "a collaborative approach that engages researchers from different disciplines, as well as non-academic stakeholders such as practitioners, decision-makers, and civil society representatives, in the co-creation of knowledge, solutions, and policies that address complex real-world problems." They emphasize the importance of integrating different types of knowledge, including academic, lay, and practical knowledge, in order to develop more holistic and effective solutions to societal challenges. They also note that transdisciplinary research requires a process of continuous dialogue and learning between all participants, and that it is often characterized by a focus on real-world impact and the co-production of knowledge with stakeholders.

Complementary to that, Walsh and Downe's 2005 publication "Meta-synthesis method for qualitative research: a literature review" discusses the use of meta-synthesis as a method for synthesizing qualitative research. The authors note that meta-synthesis involves a systematic and rigorous process of analyzing and synthesizing qualitative research findings from multiple studies. They highlight the importance of developing clear research questions, establishing inclusion and exclusion criteria, and using a transparent and reproducible process for data analysis. Walsh and Downe also discuss the challenges of conducting meta-synthesis, including the need for careful consideration of the quality and relevance of the included studies, the potential for bias in the synthesis process,

and the difficulty of combining findings from studies with diverse methodologies and epistemologies. Overall, the authors argue that meta-synthesis can be a valuable approach for synthesizing qualitative research findings and generating new insights, but emphasize the need for methodological rigor and transparency in order to ensure the validity and reliability of the results.

Furthermore, Wyborn et al.'s paper (2018) on "Understanding the impacts of research synthesis" aimed to explore the impacts of research synthesis, particularly in the context of environmental management and sustainability. The paper identified four main types of impacts of research synthesis: instrumental, conceptual, capacity-building, and empowerment. Instrumental impacts refer to the tangible, material changes that result from the application of research synthesis, such as changes in policy or management decisions. Conceptual impacts refer to changes in understanding or perception, such as changes in how researchers view an issue or how stakeholders understand the implications of research. Capacity-building impacts refer to the development of skills or knowledge that can be applied beyond the specific context of the research synthesis. Empowerment impacts refer to changes in power dynamics or relationships, such as increased participation of marginalized groups in decision-making processes. The paper also highlighted some challenges and limitations of research synthesis, such as the potential for oversimplification or the exclusion of important perspectives or sources of knowledge. The authors emphasized the importance of transparency and stakeholder engagement throughout the research synthesis process to mitigate these challenges. Overall, Wyborn concluded that research synthesis can have significant impacts in environmental management and sustainability, but that these impacts are context-dependent and require careful consideration of the specific goals and methods.

Cooper, Hedges, and Valentine discussed (2019) the potentials and limitations of research synthesis. Their findings can be distilled into the following list:

Potentials:

- Research synthesis provides a way to integrate the results of multiple studies and identify patterns and trends that may not be apparent in individual studies.
- It can increase the generalizability of findings by combining data from multiple sources and contexts.
- It can help identify areas where further research is needed or where conflicting findings need to be resolved.

- It can provide a way to summarize and communicate the findings of research to practitioners, policymakers, and the general public.

Limitations:

- Research synthesis is limited by the quality and quantity of the studies included. Poorly designed or executed studies may bias the overall findings.
- Synthesizing results across different contexts or populations can be challenging due to differences in study design, measurement, and other factors.
- Publication bias can occur, where studies with null or negative findings are less likely to be published, leading to an overestimation of effect sizes.
- The process of synthesizing studies involves making decisions about which studies to include or exclude, and these decisions can be subjective and may introduce bias.

In all, we hold that the challenges of knowledge creation and management in cross-cultural settings, projects, and institutional set-ups are being tackled through various approaches. Some ways to achieve that are:

1. Building cross-cultural understanding is an important first step. This can be achieved by creating opportunities for individuals from different cultures to interact and exchange knowledge. Cross-cultural training can also be provided to employees to improve their cultural sensitivity and communication skills.
2. Technology can be a powerful tool for knowledge creation and management in cross-cultural settings. Collaboration tools, such as video conferencing, project management software, and online collaboration platforms, such as SURExChange, can help overcome language and distance barriers. Additionally, machine translation software can be used to facilitate communication between individuals who speak different languages.
3. Encouraging knowledge sharing is critical to effective knowledge generation and management in cross-cultural settings. This can be achieved by creating a culture of knowledge sharing within the organization and providing incentives for individuals to share their

knowledge. Knowledge sharing can also be facilitated through the use of social media platforms and other online tools.

4. Building trust is key to effective knowledge creation and management in cross-cultural settings. Trust can be built by demonstrating a commitment to cultural sensitivity, establishing open lines of communication, and being transparent in decision-making.
5. Partnering with local organizations can help overcome cultural and linguistic barriers. Local organizations can provide valuable insights into the cultural norms and expectations of the local community, and can help facilitate communication and knowledge sharing.
6. Adopting a participatory approach can help overcome cultural barriers and promote collaboration. This requires involving stakeholders from different cultures in the knowledge creation and management process, and actively seeking their input and feedback.
7. Finally, creating a strategy is essential to effective knowledge creation and management in cross-cultural settings. This involves identifying the organization's knowledge needs, developing a plan for meeting those needs, and regularly evaluating the effectiveness of the strategy.

Knowledge creation and management approaches for sustainable development in the built environment in a globalized setting have been developed to address the challenges of promoting sustainability in the face of rapid urbanization and globalization. While these approaches are crucial, they also face several critical challenges and limitations.

One of the significant challenges is the difficulty in effectively sharing knowledge across different organizations, communities, and stakeholders. Sustainable development in the built environment requires the collaboration and cooperation of multiple actors, each with their unique knowledge and perspectives. Knowledge creation and management approaches must be designed to promote collaboration and communication across these actors, but it can be challenging to do so effectively.

Another limitation is the lack of empirical evidence on the effectiveness of knowledge creation and management approaches for sustainable development in the built environment. Many knowledge creation and management strategies are theoretical or conceptual, and there is a lack of empirical research evaluating their effectiveness in real-world settings. Without evidence to support these

approaches, it is challenging to determine their impact on promoting sustainability in the built environment.

Finally, knowledge creation and management approaches must be designed to address the social, economic, and environmental dimensions of sustainability. However, many knowledge creation and management strategies focus primarily on environmental sustainability and fail to address the social and economic aspects of sustainability adequately. Without addressing all three dimensions of sustainability, knowledge creation and management approaches may not be effective in promoting sustainable development in the built environment.

In conclusion, knowledge creation and management approaches are crucial for promoting sustainable development in the built environment in a globalized setting. However, these approaches face several critical challenges and limitations that must be addressed to maximize their effectiveness. To overcome these challenges, knowledge creation and management approaches must be designed to promote collaboration and communication across actors, address different institutional structures and policies, and address all three dimensions of sustainability. Furthermore, empirical research is necessary to evaluate the effectiveness of knowledge creation and management approaches in promoting sustainability in the built environment. Additionally, we need a thorough understanding how (differently) scientific knowledge is created in the different cultural settings and within different contexts, which includes following the questions of how researchers work in different contexts and what are their different rationalities as well as asking ourselves and others: what is supposed to be scientific?

### **3 SURE facilitation and synthesis research architecture**

#### ***3.1. Architecture logic***

The project looks to synthesize and consolidate existing conceptual, methodological, and empirical knowledge from literature and the ten SURE collaborative projects. This qualitative meta-study aims to contribute to the transdisciplinary sustainable research discourse by providing a scientific contribution to the third epistemic way (Lang, Wiek et al. 2012). The third epistemic way refers to a mode of knowledge production that goes beyond traditional disciplinary and interdisciplinary approaches. This epistemic way is

called "transdisciplinary" and is characterized by the integration of diverse knowledge systems, including scientific, local, and experiential knowledge, as well as the involvement of multiple stakeholders in the research process. The research project is designed to support individual research projects on the one hand and to systematically leverage the cross-project synergy potentials at the funding priority level based on the collected and structured knowledge from the projects and beyond. Conducting meta-research across disciplines and across cultural borders requires a management of knowledge that is sensitive towards these challenges (Ioannidis, Fanelli et al. 2015). Within the SURE facilitation and synthesis research approach, we developed a research and knowledge architecture that allows for constant reflection to improve the applied concepts.

The project goals described above necessitate the several research questions that SURE Facilitation and Synthesis research posits for itself. The six most important ones are:

- Which user group requires/uses what results of the funding priority?
- Which of the results are transferrable or scalable to other regions?
- Is it possible to draw general conclusions?
- How can the gained knowledge be consolidated?
- How are the results fed into the ongoing expert discussions?
- How are the results transferred to experts?

Guided by these, and some more detailed and minor, research questions, the SURE FSR project collects, generates, and structures data before it is turned into knowledge (see Rowley 2007 in contrast to Nonaka 1990). The data is composed of three types of sources: scientific, non-scientific, and directly from the ten projects ("project data"). However, these three sources types can, on another dimension, be split into coming from two "directions": the former two kinds from internal efforts of the project team, while the latter kind thanks to the facilitation activities carried out with the ten projects.

Scientific data can easily be categorized to come from two origins: scientific literature and policy documents (regional, national, international). Non-scientific data includes social media, professional network websites, news outlets, websites, and geo-spatial data. Finally, project data consists of:

- project proposal and report texts
- scholarly publications of the researchers working for the ten projects
- the so-called Synergy Workshops (regular workshops of the ten projects along with the SURE facilitation and synthesis research team)

- project profiles
- peer-to-peer observations
- reference picture questionnaires; network structure
- conference participation output

The data is then organised, structured and stored in a database (Directus).

The collected, generated, and structured data then (1) becomes the object of preliminary data analysis and (2) is used to form research hypotheses. In a double-step approach, the preliminary data analysis then also feeds into the research hypotheses formulation effort, with the goal of solidifying the reasoning and legitimizing the creating hypotheses. Moreover, the research hypotheses are revisited in one of the later steps of the research construction logic. The current set of SURE FSR project's research hypotheses is the following:

- There is a need for thorough knowledge synthesis and consolidation, as well as for methods and practices to do so;
- There is an urgency in recalibrating evaluation schemes and funding criteria;
- There is a necessity for deeper understanding of and sensitivity to cultural intricacies, as well as a guideline on how such skills can be evaluated;
- There is a necessity for a better identification of emerging and existing urgencies and topics;
- There is a need to identify and consolidate cross-cutting issues across the SURE funding priority;
- Project architectures influence the local impact of implementation and how sustainable the projects results will continue to be.

In the next, fundamentally important step of the architecture logic, the data is analysed through the lens of the research hypotheses. This, in turn, activates two further tasks: (1) validation of hypotheses and (2) answering of research questions. Naturally, the exercise of validating the hypotheses is the aforementioned revisiting of that item; moreover, the research questions also receive a rededication in this advanced research stage (see Peirce's writings on the three-stage cognitive logic of abduction, deduction and induction, Peirce (1974 [1934]), or Hanson (1958) and Hoffmann (2005)).

### **3.2. Methodology: a multi-method approach**

In awareness that a complex challenge requires a fitting methodology. According to Ashby's Law of Requisite Complexity states that a system must be at least as complex as the problem it is trying to solve. This means that in order to effectively address complex problems, a system must have a certain level of complexity and variety in order to match the complexity and variety of the problem. The law suggests that if a system is not complex enough to handle the demands of the problem, it will be unable to effectively address the problem and will likely fail. Therefore, the Law of Requisite Complexity emphasizes the importance of ensuring that a system is appropriately designed and structured to address the complexity of the problem it is intended to solve (Ashby 2004 [1962]). The SURE Facilitation and Synthesis research project consortium has created a multi-method approach that this section briefly presents. Departing from the vantage point of understanding transdisciplinary knowledge synthesis as integrating knowledge from different disciplines and stakeholders to address complex problems, the SURE FSR team has analysed the state of the art in approaches towards it and has distilled the following five overall, theoretical approaches:

- Participatory research: this approach involves engaging stakeholders, including community members, policymakers, and practitioners, in the research process. That helps to ensure that the research is relevant and useful to those who will ultimately use the findings;
- Systematic reviews: This approach involves identifying, evaluating, and synthesizing existing research to answer a specific research question. Systematic reviews use rigorous methods to minimize bias and ensure that all relevant evidence is included;
- Meta-analysis: This approach involves using statistical methods to combine the results of multiple studies to produce a summary estimate of an effect. Meta-analysis can be used to identify patterns and trends across different studies;
- Mixed-methods research: This approach involves using both qualitative and quantitative research methods to answer a research question. Mixed-methods research can provide a more comprehensive understanding of complex problems by combining the strengths of different research methods;

- Co-creation of knowledge: This approach involves bringing together stakeholders from different disciplines and backgrounds to jointly develop new knowledge. Co-creation of knowledge emphasizes the importance of collaboration and the active involvement of stakeholders in the research process.

Having weighed the strengths and weaknesses of the analysed approaches, the SURE partnership has arrived at the following list of methods applied in daily project work:

- pattern analysis,
- cross-sectional analysis,
- AI-supported data analysis,
  - NLP, MaxQDA,
  - machine learning,
- topic modelling,
- literature review,
- multi-layer analysis,
- knowledge integration,
- knowledge synthesis.

It is necessary to note that one of the items from this list, the AI-supported data analysis within the SURE FSR project framework, is the topic of another paper and presentation during the 2023 IFKAD conference (ID 203), authored by Chintan Patel et al. from the HafenCity University Hamburg with the title *'Unlocking the potential of AI in qualitative data analysis for sustainable urban development'*. It talks about the application of AI to support data and knowledge creation and management in sustainable urban development research by presenting the first results of the ongoing AI-based analysis and discussing how it could contribute to a systemic qualitative analysis of large text-based data sets in urban sustainable knowledge creation and management.

### **3.3. Outputs**

Finally, SURE Facilitation and Synthesis Research Projects's research outputs – another fundamentally important element of a project – can be categorised in two main ones: the so-called Knowledge Synthesizer and the Reference Picture. The former aims to support the generation, integration, and access to sustainability knowledge overall and to include an interactive digital tool for

multiple stakeholders. The latter involves the ten projects' own reference picture and a global reference picture.

Importantly, the current conference will see both of these project outputs items embodied in the form of contributions. The SURE Knowledge Synthesizer is the object of a paper by Agota Barabas et al., titled *'sustainable knowledge synthesizer: a modular tool for urban research'*, from the HafenCity University Hamburg (ID 245) and shows how databases, as well as data services for knowledge creation and management and communication and collaboration, are provided, adapting solutions from business intelligence (e.g. project dashboard, monitors, cockpits), and then aggregated in the functional tool "Synthesizer". The paper discusses the concept of such a synthesizing system and its application in a meta-research environment of transdisciplinary sustainable urban development approaches, sheds light on the opportunities and challenges of the development of such a synthesizing tool, and draws a first picture of the complexity accompanying the development of a "synthesizer". The Reference Picture, in turn, is tackled by the paper authored by Dietrich et al. from the Technische Hochschule Lübeck (ID 209), with the title *'Sustainable development of urban regions. Transformative Research Project as (self-) learning Systems?'* in which, among other angles, the architecture of the SURE Framework and the related Reference Pictures developed by the SURE Facilitation and Synthesis Research project to support the process of observation and reflection are described as a self-learning process of complex systems, and the question how to make the gained knowledge explicit is discussed.

Finally, it is crucial to highlight that both types of outputs in the SURE FSR are systemically tied to the facilitation activity, wherein the Reference Picture is being created directly thanks to the individual project support task, and wherein the Knowledge Synthesizer directly informs all three facilitation tasks.

Figure 1 below *'Overview of SURE Facilitation and Synthesis Research Architecture and linked IFKAD'23 paper presentations'* is a visualisation of the delivered description and the Reader is encouraged to confront the graph with the respective text sections.

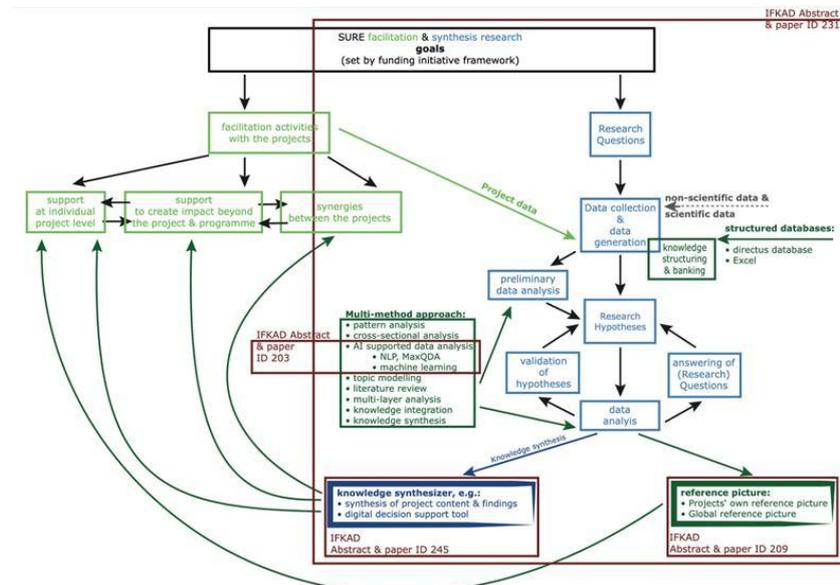

Figure 19: Overview of SURE Facilitation and Synthesis Research Architecture and linked IFKAD'23 paper presentations

#### 4 Summary

The goal of synthesis research is to provide a comprehensive overview of the current state of knowledge on a particular topic, and to identify gaps or limitations in existing research. This information can then be used to guide future research and policy decisions. In the context of the SURE Facilitation and Synthesis research project, the synthesis research involves bringing together the conceptual, methodological, and empirical knowledge from literature and the ten SURE collaborative projects within the SURE funding priority. The aim is to identify patterns, themes, and relationships in the data, and to generate new insights that go beyond what is available in individual studies or disciplines.

The SURE Facilitation and Synthesis research architecture presented in this paper aims to provide a comprehensive overview of the current state of knowledge on sustainable urban development. By identifying gaps or limitations in existing research, information can be used to guide future research and policy decisions. The project aims to create conceptual, theoretical, methodological, and translational innovations that integrate and push beyond discipline-specific approaches to address the issue of sustainable urban development. Overall, the

SURE Facilitation and Synthesis research project aims to contribute to the field of sustainability science and is expected to impact on policy decisions in the future.

### **Abstract**

This paper, normative in nature and scope, addresses the social role of working organizations in addressing inequality, one of the Grand Challenges of our time and the 10th Goal among UN SDGs. More in depth, it focuses on a gap in organizational and business ethics literature, so far lacking a perspective on inequality able to bridge Integral Human Development and Intersectionality. While there has been an increase in studies deploying Intersectionality as analytical framework to understand inequality and studies adopting integral human development and the capability approach to suggest strategies and policies to tackle it, no unifying perspective has been conveyed using the two. We argue for their joint deployment with the aim to increase effectiveness of diversity management and policies, as well as to face the challenges connected to the organizational reproduction of inequality. Ultimately, this study provides an original theoretical stance able to propose further path of research as well as suggestions to practitioners aiming to building organizational strategies and cultures based on the values of fairness and gender, racial and social justice.

**Keywords** – humanistic management, human integral development, intersectionality, gender issue, humanism in business

**Nature of proposed paper:** Academic research paper, normative

## 1 Introduction

Grand Challenges of our time are rarely detached one from the other, nor are their consequences on people and societies: climate crisis, economic crisis, geopolitical crisis, all are bound together (Fontrodona & Melé, 2022; Klein, 2007; Waddock, 2020; Wasieleski, 2021). This entangling leads to widespread social inequality and marginalization, thus combining different sources of inequality together (Dil & Zambrana, 2020; Battilana, Ferreras et al., 2022; Philips, Jun et al., 2022; Zhrao & Wry, 2016). Working organizations are increasingly invested by the need to provide robust answer to complex scenarios (Ferraro, Etzion et al., 2015; Waddock & Kuenkel, 2022), whether because of social expectations towards the private for-profit sector (Scherer and Palazzo, 2011) or because of their social mission and hybrid nature (Battilana, Besharov et al., 2017; Vaccaro and Ramus, 2022; Del Baldo, 2019). Lastly, rising inequality keeps raising ethical concerns intertwined with organizational challenges connected to them (Bapuji, Ertug et al., 2020).

Contemporary challenges, even when different in nature, have shown the same underpinning tendency to enhance already existing inequalities, among which gender inequality holds a recurrent central role (Grosser, Moon et al., 2017; Heisig & Kannan, 2020). Disruptive events, such as Covid 19 Pandemic and its social and economic consequences (Alon, Doepke et al., 2020; Carli, 2020; Richter & Patel, 2021; Del Baldo, 2022), as well as fast pace technological innovations, such as Artificial Intelligence widespread implementing (Kelley, Ovchinnikov et al., 2022; Daugherty, Wilson et al., 2019), have shown to be drivers of enhanced preexisting inequality, social exclusion, and marginalization. As inequality imposes significant ethical concern (Beal & Ashtakova, 2017; Heath, Moriarty et al., 2010) as well as economic downfalls on business and societies (Stiglitz, 2016; Stiglitz, 2012) organizational scholars have been recently stressing organizational role in enhancing or halting it (Amis, Brickson et al., 2021; Bapuji, Hertog et al., 2020; Adam Cobb, 2016; Fioravante & Del Baldo, 2021).

Among different streams of research aiming to tackling inequality by addressing its different dimensions altogether, theories of Integral Human Development and Capabilities (Keleher, 2018; Sen 20021) hold a privileged standpoint. Indeed, this approach, both in its confessional stream (Kraemer, 1998; Melé, 2015) and secular one (Nussbaum & Sen, 1993), has been proven valuable

in placing human intrinsic dignity (Melé, 2015) at the heart of business ethics and organizational studies (Schieffer & Lessem, 2016). IHD has led to an ambitious rethinking of the understanding and addressing of different sources of lack of wellbeing, building on the importance of human flourishing in all human life dimensions (such as: physical, moral, psychological), targeting the meeting of all levels of human needs, which inequality undermines (Melé, 2019). This approach has succeeded in stressing the importance of inclusive and fair organizations (Garriga & Melé, 2020), as well as the integral responsibility of working organization to prevent and halt social shortcomings and promote the Common Good (Fontrodona & Sison, 2012).

Alongside the growing interest for the above-mentioned humanistic perspective (Koon, 2021), tackling inequality as intertwining of different sources is increasingly gaining attention from the perspective of intersectionality and intersectionality theories (Kaufmann, 2021; Woodhams, Fernando et al., 2022). Intersectionality as a theoretical approach and a methodology of social enquiry (Raghuram, 2021; Rogers & Kelly, 2021; de Leon & Rosette, 2022) has rapidly been deployed also as framework for organizational guidance and reform (Smith, Watkins et al., 2017; Hearn & Louvrier, 2015). Stemming from debates on feminist ethics (Wicks, 1996; Grosser & Moon, 2019; McKay, 2019) as well as racial segregation and exclusion (Chowdhury, 2021), the intersectionality approach has established a framework for assessing the interplay of different dimensions of oppression at individual, organizational, social and systemic dimension (Collins, 2020).

While a very limited body of literature has so far tried to enquiry into some specific aspects belonging to the IHD and the intersectionality approach (for instance by bridging diversity and the Common Good, Frémeaux, 2020; virtue ethics and feminist ethics, Dillon & Snow, 2018), we highlight a severe lacking of a perspective bridging Humanism and Intersectionality, only marginally discussed in studies focused on other topics (Liu, 2019; Thompson, 2020; Pinn, 2018; Contu, 2020). Which is the theoretical relation between the intersectionality approach and the Integral Human Development in tackling social inequality? How can they be deployed together to discuss organizations' responsibility to do so? Are there specific implications for knowledge management scholars?

The paper contributes to literature on organizational reproduction of inequality (Amis, Mair et al., 2020) and humanistic based social responsibility (Garriga & Melé, 2004; Pirson & Goodpaster, 2016), with specific focus on diversity

knowledge management scholarship (Zifaro, 2010 and 2020). It does so by adding to business ethics literature concerned with inequality a unified framework between Integral Human Development in working organizations (Mongelli, Versari et al.; Del Baldo, 2018) and intersectionality in working organizational (Grosser & McCharthy, 2019). By arguing that IHD and Intersectionality can be adopted as complementary and, therefore, unified theoretical framework for organizational inequality discussion and tackling purpose, we contribute by providing further path of research through defining a model: intersectionality as inequality starting point analysis, addressing the structural causes; IHD as strategic ends setting; organizational practice reform as bridge.

Although inequality is such a wide issue that needs joint efforts by all institutions, by political and social society spheres, and throughout all levels of policy making (Oestreich, 2018; Doyle & Stiglitz, 2014), we contribute to discussing organizational effort towards UN SDG #10<sup>1</sup>.

The remainder of the paper is organized as follows: in §1 we present a literature review of the debate concerning organizational inequality and why it needed to be implemented by intersectionality and IHD perspectives; §2 we discuss how to bridge the two within organizational studies and their organizational potential implications; in §3 we discuss consequences and further path of research for Knowledge Management scholars focusing on ethical challenges.

## **2 Organizations' responsibility towards inequality**

Being one of the greatest challenges of our time (Oxfam, 2019), inequality is increasingly discussed by different fields and different perspectives. Social inequality has been at the heart of a long-lasting debate concerning its causes, its justifications, its implications, involving philosophers, sociologists, economists, historians and other fields. This work builds on the perspective of those traditions beholding social inequality as undesirable (Sen, 1997) both for instrumental reasons, such as being economically inefficient for growth purposes (Stiglitz, 2015; Alvaredo, Canchel et al., 2017), and because it increases possibilities of leading to illegal and/or unethical behavior (Rosenblatt, 2012); as well as for intrinsic reasons, being unfair (Sunajko, 2016; Singer, 2018) and stemming from

morally unacceptable socio-economic preeminence of profits over people (Sandel, 2000; Sen 1985; Sen, 1995; Sandelands, 2009).

Nonetheless, the debate on organizational impact of social inequality and organizational responsibility towards it (Bapuji, Ertug et al., 2020), is relatively recent and its implications have not been discussed thoroughly yet. Since management scholars have started focusing on the topic (Beal & Astakhova, 2017), recent comprehensive addressing of what social inequality consists of has been defined as: "To gain clarity on the construct of economic inequality, we contend that it needs to be contrasted with three related constructs: income inequality, wealth inequality, and poverty" (Bapuji, Ertug et al., 2020, p.7). This notion expands previous addressing of social inequality as being focused mainly on one or two of these dimensions (Simpson, 2009; Bapuji & Neville, 2015). Nonetheless, as studies in development ethics stress, social inequality can be understood not only in terms of current monetary disposals and macroeconomics index (such as the Gini coefficient; Hicks, 1997), but in terms of capabilities which are endowed and allowed to each person (Sen, 2001). According to this view, development is consistent not only with economic achievements, but a wider set of variables, among which political freedom, economic opportunity, social opportunities, transparency, security (Sen, 2001). This work aims to integrating the scholarly debate on the dynamics underpinning organizations' influence on social inequality by implementing the adopted perspective with considerations that overcome the understanding of inequality as stemming from income, wealth, and poverty; rather, understanding it in terms of Integral Human Development (Keleher, 2018; Mongelli, Versari et al., 2018). Human Integral Development addresses three level of human needs: basic needs, such as food and shelter; commodities, such as comfort and security and a third level of amenities which comprehend rewarding relationships, fulfilling spiritual life, vocational achievements, among others (Goulet, 2006). According to this view, development is reached only when physical, moral and psychological wellbeing are ensured, when human flourishing is possible (Shrivasta & Zsolnai, 2022; Giovanola, 2019) and all the constitutive humanistic levels are reached at higher capabilities: freedom, transcendence and relationality (Sandonà, 2013; Melé, 2015). This change in perspective on inequality has vast organizational implications, as it is clear that organizations' commitment to lessen inequality and work through goals of integral development entail a larger number of variables to focus on when reforming strategies, policies and practices (Ranis, Stewart et al., 2006).

As anticipated, scholars are beginning to assess organizations' crucial responsibility in addressing social inequality. As society expects higher and enhanced level of commitment towards social welfare as corporations' responsibility (Garriga & Melé, 2004; Baden, 2016). Different streams of social responsibility theories, such as Political CSR, have highlighted how even those social shortcomings once bestowed upon the State and public institutions' responsibility, now fall under private entities reach (Scherer, 2018; Scherer, Rasche et al., 2016). These considerations can be further detailed and addressed to the specifics of all working organizations, whether traditional for profit, no profit and hybrids (Di Lorenzo & Scarlata, 2019). Social inequality can be considered among the latter. Indeed, the blurring of the lines between public, private and civil society spheres, leads to consider business actors as endowed with the responsibility to act as intermediate bodies (Fioravante & Del Baldo, 2021) and engage in reducing social inequality both for moral reasons of contributing to the Common Good (Sison & Fontrodona, 2012; Schlag & Melé, 2020), as well as to ensure the quality of democracy (Fioravante & Del Baldo, 2023).

Among the many reasons discussed by scholars to promote organizations' responsibility in tackling social inequality (Enderle, 2018), some focus on inequality undesirable consequences in terms of organizational misbehavior and malpractice (Hudson, Gonzales-Gomez, 2021), some on inequality impact on organizational wellbeing (Pfeffer, 2010; Baron & Pfeffer, 1994), as well as on organizational performance (Bapuji, 2015). Different dimensions of organizational practices and policies are addressed, such as the managerial style (Fujimoto & Uddin, 2021), the institutionalization of organizational myths and the performative effect of inequality framing and discourse (Amis, Munir et al., 2018; Suddaby, Bruton et al., 2018) and organizational values (Bourne, Jenkins et al., 2019). This heterogeneous body of literature, which accurately discusses in particular organizational practices which reinforce inequality (Amis, Mair et al., 2020) has already paved the way for further research on how to address inequality through tackling its different sources (Amis, Munir et al., 2018). Nonetheless, extant literature can count on a relatively small number of publications pursuing this goal, both from a normative and empirical perspective (Kaufmann, 2022; Smith, Watkins et al., 2019; Hall & Hall, 1976; Hekman, Aquino et al., 2010). Indeed, while much of the current literature extensively discusses practices to deal with social inequality, a unifying theoretical framework able to

bridge a comprehensive analysis of causes of inequality and suggest organizational actions to tame them, is still lacking.

### **3 Intersectionality as the starting point**

We argue that the literature gaps above discussed, first a lack of research in organizational reproduction of inequality adopting IHD variables, second a lack of research able to fully identify sources of inequality and how they can be tackled together, can be overcome by adopting an intersectionality approach (Atewologun, 2018; Crenshaw, 1991). Indeed, within business ethics literature, neither literature focusing on the organizational reproduction of inequality, nor literature on IHD in organizations has been proposing a unified theory of inequality drawing on intersectionality.

The latter discusses how different sources of structural inequality are intertwined together and how these entangling yields different impacts on individuals, organizations, and societies. Intersectionality is here recalled in its two main aspects, being both a theory of inequality as well as a method of social research (Atewologun & Mahalingam, 2018). As it has been stressed: "Intersectionality can be conceptualized as an overarching knowledge project whose changing contours grow from and respond to social formations of complex social inequalities" (Collins, 2015). According to this view: "race, class, gender, sexuality, ethnicity, nation, ability, and age operate not as unitary, mutually exclusive entities, but as reciprocally constructing phenomena that in turn shape complex social inequalities" (Collins, 2015). The intersectionality approach is thus useful to discuss sources of inequalities inasmuch it recognizes cornerstone features of their analysis:

- The structural presence of disadvantage (Bowleg, 2013)
- The structural dimension of privilege (Atewologun & Sealy, 2014)
- The structural experience of disadvantage (Smith, Watkins et al., 2019)
- The structural reinforcement of disadvantage (Hall, Hall et al., 2019).

Intersectionality discusses how the above-mentioned different sources of marginalization impact on people's everyday personal and professional life, combining different effects given by structures of power, systems of oppression and discrimination, impediments to certain positions, roles achievements, self-determination, as well as combining psychological and sociological aspects of personal experience of disadvantage, oppression and injustices. This notion has

been summarized by Davis: "the interaction between gender, race, and other categories of difference in individual lives, social practices, institutional arrangements, and cultural ideologies and the outcomes of these interactions in terms of power" (Davis, 2008, p. 68).

These topics have been dealt with only marginally by scholarship on diversity. Diversity has been conceived as "any mixture of items characterised by differences and similarities" (Thomas, 1996, p. 5). It encompasses several dimensions (primary, secondary and tertiary dimension). The primary dimensions of diversity include age, ethnicity, gender, physical abilities/qualities, race and sexual orientation. Secondary dimensions – that are less visible and sensible than the primary and can be changed - include, but are not limited to: educational background, religion, first language, family, marital and parental status, work experience, military experience, income, communication style and geographic location. Tertiary dimensions comprise features such as: beliefs, assumptions, perceptions, attitudes, feelings, values, and group norms (Rijamampianina & Carmichael 2005; Jirincova, 2013). Diversity can bring a variety of perspectives and insights to an organization, which can lead to increased innovation and creativity. It is also important because it gives organizations access to new markets and talent. In addition, having a diverse workforce can also lead to greater job satisfaction, improved employee morale, and better customer service. When knowledge management and diversity are combined, organizations can benefit from the variety of insights, skills, and experiences that their employees bring. This can lead to increased innovation and creativity, as well as improved performance. In addition, diversity can help organizations identify new markets and gain access to different types of talent. During the last decades both globalization and demographic changes has contributed at increasing diversity of population and labour force. Therefore, the issues of inclusion and diversity are considered key aspects of current society and world politics. In a globalized economy companies recognize the opportunities deriving from a multicultural workforce and try to create more inclusive work environments (Cox, 2001). However, many organizations have been disappointed with the results achieved to meet the diversity challenge (Pless & Maak, 2004). Indeed, most of diversity scholarship addresses organizational behavior and reform concerned with particular marginalized groups (Pless & Maak, 2004), and understands people belonging to these groups as being generally disadvantages in present society, therefore needing specific attention. The same can be said about scholarship

concerned with similar variables and research questions, such as minority entrepreneurship (Vorobeva, 2022). As it is underlined by most literature on diversity and intersectionality, the latter differs from the former in the understanding of a multiplicity of categories of disadvantage instead of identifying groups of disadvantaged (Pompper, 2014; Hearn & Louvrier, 2015). This change in perspective holds vast organizational implications: first, because intersectionality challenges directly how power structures are conceived, while diversity management, policies and practices can be group-specific while overlooking the current hierarchical structure (Hearn & Louvrier 2015; Ely & Thomas, 2020). Secondly, it entails a holistic rethinking of organizational governance, including leadership, to include further subjectivities enacting it (Liu, 2019). Third, it implies a finer grain analysis of inequality as everyday personal life experience, which differs from one case to the other, thus safeguarding the uniqueness of the person and addressing all the causes withholding her development (Steinfeld, Stanghvi et al., 2019 ; de Leon & Rosette 2022).

#### **4 From Intersectionality to IHD: organizational role in tackling inequality**

In this vein, we propose to use intersectionality as the fundamental approach to discuss inequality in organizations, in order to provide a comprehensive analysis of which are the relevant variables to be tackled in understanding their interplay. As above discussed, within both scholarship and business practice, diversity mostly tackles one diversity group, disregarding the interplay of different factors enabling or disabling people's achievements. Combining intersectionality and IHD as starting point level analysis (intersectionality) and target setting dimension (IHD), it is possible to envision organizational reform entirely based on a holistic people centered approach aimed to lessen causes and consequences of social inequality in its different drivers and manifestations (Figure1):

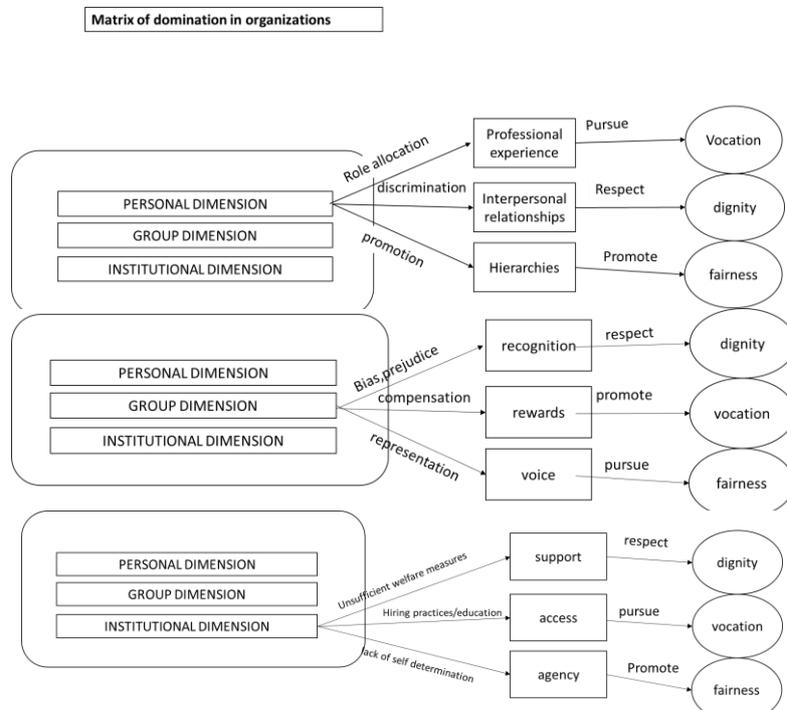

Figure 20 - Process model for combining intersectionality and IHD.

To overcome such limits, in the following figures we discuss how. First, by taking into consideration the three levels of the matrix of domination discussed by Collins (2010), personal level of experiencing oppression due to one or more sources of inequality, group level as in culturally driven dynamics of social reproduction of one or more sources of inequality and institutional level, as in institutional shortcomings determined by inequality. Second, we highlight three variables connected to each dimension which yield higher or lower level of experienced oppression due to inequality and we highlight organizational practices that can directly enhance or halt inequality concerning each variable.

Our analysis is consistent with previous studies on organizational reproduction or halting of inequality (Amis, Brickson et al., 2021), which enlist common practices playing a crucial role in determining increased or decreased inequality outcome: for example, hiring practices, promotion, role allocation (Amis, Mair et al., 2020). We implement them by discussing their relationship with each dimension of the matrix, as well as by adopting for each dimension the interplay in between different sources of inequality (i.e., class, gender, race).

We highlight how each of the three groups of variables have a direct impact in terms of the three constitutive dimensions of IHD: freedom, relationality, and transcendence through three of their main axes: Dignity as foundational of transcendence [Dignity: RESPECTING INTRINSIC VALUE], Fairness as fundamental to relationality [Fairness: SENSE OF BELONGING, PARTICIPATION], Vocation as fundamental to freedom, [Vocation: PURSUE ONE'S TALENT AND HUMAN FLOURISHING].

## 5 Implications for Knowledge Management Scholarship

Knowledge management and diversity are two key concepts in today's business environment. Both are necessary for organizations to succeed in today's ever-changing world. Knowledge management (KM) is the practice of capturing, organizing, and disseminating knowledge within an organization (Prusak, 2001). KM enables organizations to utilize the skills, experience, and expertise of their workforce to maximize the effectiveness of their operations. It also helps organizations to ensure that new knowledge is incorporated into their operations, thus improving their overall performance.

As such, knowledge management, combined with a renewed perspective on diversity through intersectionality and human integral development, can be powerful tools to help organizations remain competitive and successful in today's rapidly changing business environment. In conclusion, knowledge management and diversity are two key concepts that are essential for organizational success. Combining knowledge management and diversity can lead to increased innovation, creativity, and improved performance. Diversity management fosters

relationships and stimulates discursive processes between diverse cultures. The culture of inclusion and the reciprocal understanding are fundamental to create an organizational culture in which people from different backgrounds respect each other and work to reach common goals. This requires the openness to get involved with people with different perspectives and standpoints. Accordingly, pillars of diversity management are: inclusiveness; integrity; challenging assumptions and mindsets.

Inclusiveness requires openness to different standpoints. Getting people from different cultural backgrounds to share their knowledge, experiences and viewpoints presupposes a basis of trust. Second, a culture of inclusion rests on moral reliability and coherence (integrity). Second, the creation of an inclusive organizational environment implies a cultural change process promoted by cooperative teamworks. Moreover, an inclusive working environment which fosters creativity and innovation potentials of a diverse workforce, rests on a "reflection work" aimed to shed light on existing diversity barriers, remove assumptions that hinder an inclusive approach and identify the steps that are necessary to operationalize management practices. Several authors have investigated the process of learning to effectively implement diversity management, starting from manage (Cox & Beale, 1997) and lead change (Kotter, 1996). The steps of the organizational learning to accommodate an inclusive diversity culture include: raising awareness, creating understanding and encouraging reflection; developing a vision of inclusion; rethinking key management concepts and principles and adapting systems and processes. Accordingly, the funding principles of a human relations management system should include: showing respect and recognition for others and appreciation for different voices; encouraging open and frank communication; cultivating participative decision making and problem solving processes; showing integrity and advanced moral reasoning; adopting a cooperative and consultative leadership style. Our model implements such approach by integrating within it a special attention on structural conditions of marginalization, their interplay and targets to be met to enhance each dimension of Integral Human Development.

Knowledge Management can extensively profit from this approach, for several reasons: first, as intersectionality + IHD model fosters a people-centered approach, it can be applied not only to large firms but also to small medium enterprises; the latter have been relatively less discussed within KM literature (Cantù et al., 2009; Serenko, 2013). Indeed, following Desouza and Awazu (2006,

p.36) it is possible to observe how in SMEs, “knowledge becomes part of the organization’s fabric when it is socialized from the manager to the employees, seldom does knowledge move the other way, i.e. from employee to manager” (Massaro et al., 2016, p. 270). Therefore, enhancing higher dimensions of IHD for internal stakeholders can lead to increased bottom-up exchange as well. Second, this model helps to overcome a shortcoming of literature within KM on understanding and discussing variables such as gender, which appears as quasi absent in keywords, and when it does appear mainly as a control variable (Massaro et al., 2016; Cantù et al., 2009; Graham & Nafukho, 2007). Third, since extensive change in organizational culture is needed to implement intersectionality + IHD, this model helps to fill a gap within KM discussing organizational culture in relation with knowledge innovation: results build on Serenko & Dumay (2015, p. 410), who found when analysing citation classics that “Knowledge as a process and managing/competitive advantage dominate earlier rather than later articles”, thus underestimating the dimension of organizational culture. Forth, the intersectionality + IHD approach focuses on personal experiences and personal achievements. We recall studies highlighting how knowledge assets or products result from the experience and expertise of individuals. However, the “physical, social, and resource allocation structure” of organizations are important if such experience and expertise is to be translated into competencies that help generate knowledge products (Teece, 2000; McGregor et al., 2004). Therefore, the model helps in addressing possible organizational failings to unleash the personal ability to contribute to knowledge generation, because of structural causes of marginalization and inequality. Lastly, by adopting this standpoint, it is possible to address KM dynamics and social inequality contrast target by the organization at the same time, thus yielding both economic value and social value at the same time.

## **6 Contributions**

This work contributes to scholarship on business ethics and knowledge management in at least three domains:

First, it draws on emerging debate on intersectionality within working organizations, bridging it with a longstanding and relevant tradition of humanism in business as foundational of business ethics scholarship.

Second, it contributes to literature on addressing social inequality through organizations by proposing a model which targets different sources of inequality together, both in understanding their causes and interplay as well as their consequences, thus proposing to overcome some limits of scholarship on diversity and some practical limits of diversity programs.

Third, it proposes a model suitable to address knowledge management in all organizations, including small and medium, which have been so far overlooked; as well as proposing a model focused on people's dignity, fairness, and vocation enhancement, which contribute to build organizational culture and environment suitable for increased innovation and bottom-up knowledge creation and sharing.

## Developing a Knowledge-Based Framework in Financial Firms for Sustainability Change and Reporting

---

John Holland

University of Glasgow  
Main Building, Glasgow, G12 8QQ, Scotland, UK

### Abstract

This paper aims to enhance understanding and increase visibility and accountability of financial firms through developments in a knowledge-based framework, 'integrated thinking', and reporting for sustainability purposes. This is essential to understand and manage Net Zero and CSR change and associated 'sustainability reporting' and make financial firms accountable in their central role in economy and society.

More specifically, the paper aims to make large international financial firms, and their dynamic change processes, comprehensible, transparent, and accountable.

Three connected knowledge-based problems arise in financial firms– managing change – integrated reporting – and authenticity (Adams 2017; Torre et al 2018, Larsen , 2017, Cho et al 2015). These problems arise when rapid, complex external change such as CSR and Net Zero change pressures, interact with problematic internal predispositions in financial firms. They arise because finance system stakeholders mediate such change and its impact on reporting and 'principles', in their interests (Flower, 2015).

Given these problems the paper argues there is a need to understand how the financial firm is evolving to understand how its sustainability reporting is evolving.

A 'whole firm' or holistic view is required to understand change in financial firm and change in their sustainability oriented integrated reporting (<IR>) by individual firms and standard setting bodies such as IFRS and EFRAG. This takes the form of a 'Behavioural theory of the financial firm' (BTFF), adapted to incorporate CSR, Net Zero, and financial orientations (Holland, 2021, 2022a,b).

This is a knowledge-based framework for guiding financial firm practice and academic research in uncertain times

This sustainability oriented BTFF is used to argue for changes to create a modified <IR> frame for sustainability reporting by individual firms and standard setting bodies such as IFRS and EFRAG. This includes changes in the <IR> 'Octopus' model' of value creation, and development of multi-dimensional view of integrated thinking. The combined BTFF and modified <IR> frames are used to develop a coherent change narrative and metrics as new content in the modified <IR> structure.

The new knowledge in the combined BTFF and <IR> frames and proposed changes in reporting content, are means to change information flows, reporting, and behaviour in the financial firm and in wider systems. They are the basis to enhance management of change and wider stakeholder understanding of change. They are means to develop and exploit new empirical research and theory building on change and reporting.

**Keywords** – Financial firms, Change, Knowledge, Sustainability, Reporting

## **1 A ‘behavioural theory of the financial firm’ (BTFF) and Sustainability Reporting**

**Section 1** argues that given these problems with change and in developing ideas in the world of practice, an *alternative* research-based approach is required to develop <IR> and sustainability reporting at financial firm and finance sector levels. There is a need to understand how the financial firm is evolving to understand how its sustainability reporting is evolving.

### *Research approach*

A ‘finance’ oriented BTFF has been developed in embryonic form in a group of publications including Chen et al (2014, 2019), Holland (2010, 2016, 2017b, 2018, 2019a,b). In this paper the BTFF has been adapted to include climate change and CSR issues (Holland, 2021, 2022a,b).

In this paper the BTFF is used to investigate thinking, reporting and <IR> issues associated with such complex and rapid changes. A grounded theory research process (Strauss and Corbin, 1998) is used to show ‘What is going on’ (Kay and King, 2020), in each BTFF metaphor area and associated ‘integrated’ thinking, and reporting problem areas. The resulting empirical narrative was interpreted through relevant literature to create a theoretical narrative (Golden-Biddle and Locke; 2007; Barnett-Page, 2009). Thus, the BTFF and its grounded theory process (Strauss and Corbin, 1998), was extended by using additional case and archival data. These are used to develop a sustainability oriented BTFF and modify the <IR> frame and its role in sustainability reporting on Net Zero and CSR change (IFRS, 2022a; EFRAG, 2021). This creates a combined conceptual frame to explore how to change <IR> and enhance authenticity. The process of building of a BTFF (Holland, 2016, 2019a, 2021, 2022a,b), and modifying the <IR> frame for sustainability reporting is of significance to this paper because it involves *academic processes of integrated thinking*.

### *Brief statement of the adapted BTFF*

The brief statement of the *adapted* BTFF discussed below provides a “sneak peek into the investigated scene” (Locke, 2001, p. 121). The BTFF is based on insights from an “empirical narrative” interpreted within a “theoretical narrative”. This provides readers with a simplified “map” to navigate the paper (Golden-Biddle and Locke, 2007; Barnett-Page, 2009). This draws on a finance oriented BTFF (Holland, 2019a) and green (Holland, 2021) and CSR (Holland, 2022) oriented versions of the BTFF.

The ‘Behavioural theory of the financial firm’ (BTFF) is based on four case-based themes. These are portrayed as four metaphors (Morgan, 1997) concerning: the ‘Head’ (top teams), the ‘House’ (socio-technical system), the ‘Community’ (‘lived and living’ experience of employees, customers, and others in system), and decision making in a financial ‘Machine’. These non-financial and financial elements form a connected, interacting, changing system.

*The first part of the empirical narrative* involves top teams (‘Head’) ‘looking out’ in peer groups to learn (Pedler et al., 1997) about external climate change and CSR change pressures and ‘looking in’ and learning how to change the firm and avoid harm to individuals, teams, and environment. *The second part* involves Top teams making Net Zero and CSR oriented strategic changes to purpose, ‘socio-technical’ infrastructure in the firm ‘House’.

*The third part* concerns how firm social and knowledge resources are mobilised, how changes are enabled and driven by organisation processes in the ‘community’. The latter involve Net Zero and CSR based purposeful communications and interactions at individual, team, firm, and network levels. These multidimensional interactions in internal employees and external stakeholder relations are the locus and focus of change in information production, behaviour, and decisions. This is where much ‘value’ is created from intangibles and where CSR, Net Zero and financial values are expressed and operationalised. Key internal communications and interactions, occur between top teams, middle management, front, and back-office employees.

*The fourth part* highlights how changes to the non-financial context and working conditions, supports Net Zero and CSR oriented, financial decisions, and products. The latter concern creation of new Net Zero and CSR oriented financial assets and liabilities (and derivatives of) in each firm’s specialist domain such as banking, fund management, and insurance. These satisfy CSR and Net Zero aims and avoid harms.

The above *adapted* BTFF is a form of integrated thinking on how to pursue a complex mix of financial and non-financial aims including financial and real economy aims, and CSR and climate change (CC) outcomes. This forms a new conceptual framework for understanding financial firms and developing <IR> ideas in a world of changing sustainability reporting (IFRS, 2022a; EFRAG, 2021).

## **2 BTFF interpretation of 'Octopus model' of <IR> for financial firms**

**Section 2** uses the BTFF as a novel theoretical and empirical base to modify the <IR> frame by adapting the <IR> based '**Octopus model**' of value creation (figure 1, p20, VRF, 2022) to reflect the unique finance dominated characteristics and functions of financial firms. Figure 1 shows how the <IR> 'octopus' view of the business model of firms (figure 2, p20, VRF, 2022) including financial firms can be modified to reflect the BTFF and its metaphors. This links BTFF metaphors of 'Head, House, Community, and Machine' to the structure of the <IR> 'Octopus model' and idea of a business model. The BTFF clarifies links between 'non-financial' value creation' and 'financial resources value creation' to achieve Net Zero, CSR, and financial outcomes.

The static and two-dimensional view embodied in the 'Octopus model' does not capture the multidimensional nature of intangibles and financial resource and their dynamic interactions over time. However, the BTFF empirical narrative and interdisciplinary theoretical interpretation and their role in modifying the <IR> octopus model provides a 'window' into these resources and their dynamics in the highly significant finance sector. This provides novel content in *the* <IR> 'octopus model' about financial firms. These can aid the reader to understand more about the complex nature of intangibles and financial resources and the way they interact to change information, behaviour, and financial decisions in the business model. Thus the <IR> narrative concerning the modified 'Octopus model' and its connections between 'intangibles value creation' and 'financial resources value creation' in financial firms can be further developed by exploiting the BTFF empirical insights, and associated literature. The latter includes literature on say business models (IIRC, 2013; Rimmel et al, 2019); and on financial intermediation (Scholtens and Wensveen, 2003; Holland, 2019a, Mio et al, 2022).

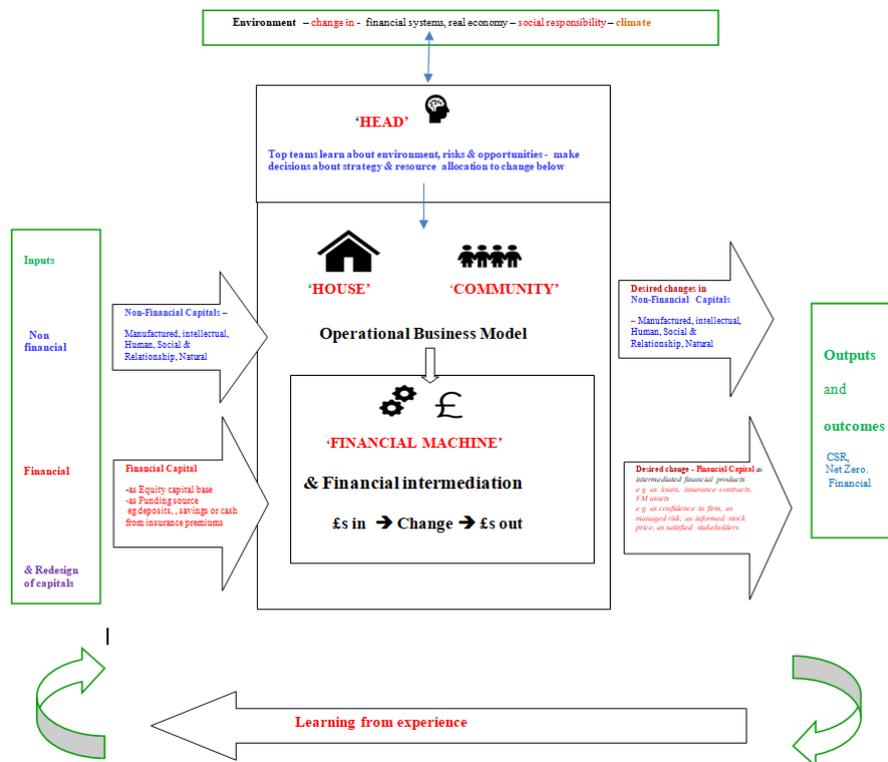

Figure 1 - BTFF interpretation of 'Octopus model' of <IR> for financial firms

From the IIRC (2013) and VRF (2022) perspective, the BTFF version of the 'Octopus model' illustrates how the financial firm's business model is a top team ('Head') driven system for transforming intangible and financial resource inputs to achieve CSR, Net Zero, and financial aims. It does this through social and knowledge structures (in 'House'), and processes and business activities involving team behaviours (in 'Community'), and their impact on financial decision activities (in the financial 'Machine').

The financial 'Machine' as the core of the specialised business model encompasses the formal means for management of risk and return within the firm and external customer networks. These include management of specialist financial portfolios such as loans, deposits, equities, and insurance products. It includes the transformation of financial capital (risk, return, liquidity, maturity etc) through financial intermediation. This shows how many input resources are transformed into outputs.

Thus the 'Head','House' and 'Community', as non- financial resources, have a major impact on the use of financial resources and in supporting their resilience in the financial 'Machine'. Intangibles in these metaphor areas such as knowledge and social structure, *influence* strategic choices about financial risk behaviour, soundness, and orientation. They form additional non-financial buffers against risk. They influence the CSR, Net Zero and financial orientations of such behaviour when using financial resources.

### **3 Developing 'integrated thinking'**

**Section 3** uses the BTFF and its connections to the <IR> 'Octopus' model to articulate academic and practice ideas of 'Integrated thinking'. The BTFF is an academic form of 'Integrated thinking'. In grounded theory academic research (Strauss and Corbin, 1998), integrated thinking occurs when academics identify connected empirical themes. They build a theory such as BTFF that reflects insight and themes from cases (problems, working solutions) and literature interpretation. The BTFF, once developed, is a form of integrated thinking which can contribute to such processes in practice.

The BTFF provides a research and case-based idea and example of 'integrated thinking' by connecting metaphors of 'Head, House, Community, and Machine' in a holistic conceptual framework. This aids the identification of clear aims, core factors, connections, and interactions in financial firms, backed by evidence. In the BTFF terms, 'Integrated thinking' concerns how resources (strategic, intangible, and financial) are co-ordinated, connected, and mobilised.

The BTFF's approach to integrated thinking also provided a means to develop more complete and integrated explanation of the business model (IIRC, 2013) in specialist financial firms pursuing Net Zero, CSR, and financial aims. Hence the BTFF is consistent with the aims of the Integrated Reporting framework (IIRC, 2013; VRF, 2022) to place the business model and its explanation of the entire value creation process in firms at the heart of corporate reports. This aids development of Integrated Reporting or <IR> and its principles in financial firms consistent with changes in sustainability reporting (IFRS, 2022a; EFRAG, 2022).

The case firms indicated that, 'Integrated thinking' reflects the ability of top teams and other employees and external stakeholders to understand *change, intangibles, and tangibles, and their development, and interactions, to change thinking capabilities, behaviour, and produce desired outcomes in the whole firm*

and external networks. The BTFF indicates that these interactions and connections must be directed in a comprehensible, open, and explicit way in the firm.

#### **4 Developing Integrated Reporting content about financial firms**

In **section 4** the BTFF and modified <IR> frame and principles ('Octopus' model and Integrated thinking) are used to analyse 'missing information' and gaps between internal and external accounts by the firm in communications and integrated reporting (Rimmel et al, 2019).

##### ***4.1 Gaps between internal and external accounts and 'missing' information in <IR>***

Chen et al (2014, 2019) and Rimmel et al, (2019) note how differences or gaps arise between internal and external accounts of how financial firm transform inputs and produce outputs and outcomes (Chen et al 2014, 2019). Problems of 'missing' information arise for stakeholders in these accounts when communicated internally and reported externally.

Gaps and variation in internal and external accounts by financial firms persist despite improvements in reporting. For example, significant gaps have been observed between the inside information positions of bank management ('Head'), and observers in external MFI communities such as bank analysts and fund managers, especially in problem cases such as RBS and Well Fargo. Questions have raised about the authenticity of publicly stated sustainability policies and sustainability reporting in fund managers and banks such as Blackrock (Fancy, 2021) and HSBC (Kirk,2022; Liang, (2022), as a result of actions by employees to 'lift the veil' on internal accounts.

The UK FCA (2021, 2022) has identified problems with asset managers ESG oriented products; marketing and use of labels such as ESG', 'green' or 'sustainable'; and disclosures on ESG funds and demanded improvements to build high standards and clamp down on greenwashing.

##### ***4.2 Using BTFF and modified <IR> - to find 'missing' information in <IR>***

The BTFF is used to summarise broad categories of narrative disclosure content possible in <IR>. These **broad** categories and factors in each metaphor

area, have all been identified from the BTFF (Holland, 2016, 2019a, 2021, 2022a,b). For example, 'missing' information could be identified by additional narrative reports on specific intangibles such as human capital of top teams ('Head') and employees ('Community') and financial investment required to develop these. This could involve discussion of expected benefits of creating other intangibles (in the 'Head' or 'House'), and their role in increasing value, or avoiding risk in the financial 'Machine'. For example, NatWest reported how it had recruited climate change expert Nicholas Stern to help shape its sustainability strategy. Stern was recruited to challenge and advise them as they worked in a collaborative way to move forward (NatWest, 2020).

'Missing information' could include explanatory narrative how these decisions and intangibles were connected in processes that encouraged employee cooperation required for innovation and creativity. In case financial firms, innovation concerns, inter alia, adoption of CSR and Net Zero policies in top team and employee behaviour, and in behaviour with customers. Innovation concerns the design and delivery of CSR and Net Zero oriented financial products desired by customers, leading to financial value for shareholders. Information relevant to this could include narrative based insights into staff development, retention, and succession and how this is connected to other key intangibles such as customer relations and new product design. Information on these activities reflects integrated thinking in the firm. Disclosure is likely to enhance <IR> by overcoming problems of connectivity, definitions, and use of terms such as ESG (Liang, 2022) and 'capitals' (Larsen, 2017). Zanin al (2021) demonstrated that innovative firms with connected narrative of firm dynamics are more likely to disclose <IR> policies than non-innovative firms, and innovative firms that demonstrate high outputs of innovation activities are likely to disclose <IR> policies.

External guidance and frames of reference can also be used to identify 'missing information'. Triodos's use of UN SDGs to structure web-based narrative communications to the public (Vaccaro, 2019), demonstrates their integrated thinking on these matters. It indicates how financial firms can use SDGs to further develop <IR> as suggested by Rizzato et al (2021). In this paper, the BTFF and modified 'Octopus' model of <IR> provides an external academic frame for financial firms to think how to develop <IR>.

## 5 Discussion and analysis

The above sections illustrate how the BTFF and modified <IR> frames are a combined basis in the world of practice, both at the level of individual firms and in system wide reporting standard setting processes, to enhance integrated thinking, and <IR> structure and content. The adapted 'Octopus' model in Figure 1 connects the four metaphors of 'Head', 'House', 'Community', and 'Machine' in the BTFF to the core components of the business model in <IR>.

This provides new insights into the social, knowledge and technology context for the business model in financial firms. It provides means to overcome problems of reporting in <IR> on intellectual capital or knowledge-based intangibles (Songini et al, 2021). These insights can be used to support and enhance <IR> narrative and metrics on CSR and Net Zero Change in financial firms.

This provides means to closely connect internal and external accounts of business models and identify 'missing information' in <IR>. They provide means for internal and external observers to assess how wide the gap between internal and external accounts of business models may be, and how they can be closed.

This can be used for internal purposes to improve communications and performance, and for external corporate reporting purposes (such as <IR>) to enhance understanding of the financial firm.

The combined BTFF and <IR> frames provide a common - conceptual basis, narrative, and metrics – to improve transparency across all financial firms in 'Sustainability Reporting' standard setting (IFRS, 2021; EFRAG, 2021; GRI, 2022). The frames are a basis for ISSB, EFRAG, and GRI to exploit <IR> principles and core ideas, when developing sustainability reporting standards (structure and content), to match the complex nature, purpose, function, and dynamics of financial firms identified in the paper. This theory-based approach can complement attempts by practitioners as they continue to use <IR> ideas (IFRS, 2022a; EFRAG, 2021) and apply a principles-based approach to 'sustainability reporting' to individual sectors, and all sectors.

The paper reveals the central role of existing theory in business and management, sociology, and finance to explore insights into empirical findings in integrated thinking and integrated reporting. This indicate that existing paradigms, when used in new ways can help progress thinking about sustainability reporting both in academe and practice.

The paper also argues that enhanced <IR> disclosure and use of new BTFF metaphor-based categories, data, and metrics is a new basis for hypothesis generation and tests of hypotheses. The metaphor-based narratives and metrics form a new basis to develop tests for 'IRwash', 'CSRwash' and 'Greenwash'.

It could be hypothesised that the degree of achievement of CSR, Green and financial aims is a function of connected and combined changes in key variables in all of the empirical themes or metaphors. The positive or negative role of quantifiable factors in each metaphor area – on CSR, green and financial 'success', (and in history, dominant context) is a way to test for '<IR>wash', 'CSRwash' (Pope et al, 2016) and 'Greenwash' (Mattis, 2008) in very different banking firms such as Triodos and NatWest.

This is a means to test for the authentic behaviour, or for false and dysfunctional behaviour - in each metaphor area of top teams (Head), organisational life (House, and Community), and financial decisions (Machine) – and in the firm overall.

## **6 Summary**

The paper has noted problems in understanding and managing financial firms such as banks, insurance firms and fund managers (Chen et al 2014,2019, Holland, 2010, 2018, 2019a,b) during complex and rapid change. These have contributed to problems of integrated thinking and development of integrated reporting (<IR>) in financial firms (IIRC, 2013, Larsen, 2017; De Villiers & Dimes,2022). Questions have arisen about the role of top teams, institutional shareholders, and accounting professionals, in mediating wider understanding and reporting of complex changes such as climate change and CSR change pressures, in their shared interests (Flower, 2015; Holland, 2017a, 2019b). This interpreted as 'organised hypocrisy' and use of facades in action and reporting (Cho et al, 2015; Brunsson,1993) at meso level by elites in 'community of practice' (Lave and Wenger 1991).

The above contribute to problems of 'missing information' in integrated sustainability reporting. These problems are a basis for scepticism that organisations such as financial firms will deliver authentic CSR change and reporting (Schoeneborn et al, 2020; Cho et al, 2015; Brunsson,1993).

Given these problems the paper argued that developing <IR> and sustainability reporting needs an *alternative* research and theory-based approach

at financial firm and finance sector levels. There is a need to understand how the financial firm is evolving to understand how its sustainability reporting is evolving.

Thus, the paper argued that a 'whole firm' view was required to understand change in financial firm and to use this to modify use of <IR> principles in sustainability reporting (IFRS, 2022a; EFRAG, 2021). This whole firm view was expressed as a 'Behavioural theory of the financial firm' or BTFF, with CSR, Net Zero, financial orientations (Holland, 2021, 2022). The 'soft' components of the BTFF (as 'Head, House, and Community' metaphors) are where authenticity is developed for 'hard' financial activities and their sustainability outcomes in the financial 'Machine' metaphor as the core of the business model.

This *sustainability oriented* BTFF is used to argue for changes to create a *modified* <IR> frame for sustainability reporting by individual firms and standard setting bodies such as IFRS and EFRAG. This includes changes in the <IR> 'Octopus' model of value creation, and development of multi-dimensional view of integrated thinking. The combined BTFF and modified <IR> frames are used to develop new content in the *modified* <IR> structure.

Knowledge' in these forms, is the basis for employees and stakeholders to understand what 'non-financial information' and 'Relevant or material information' (EU, 2014; Baumuller, 2018) is in financial firms. This shows the importance of a field research and theory approach to developing corporate reporting.

The joint use of the BTFF and <IR> frames create a dynamic investigative tool to develop theory, research, integrated thinking, <IR>, and authenticity. For example, the combined frames are the basis to develop new academic research on <IR>, including empirical tests and conceptual development of the links between <IR> and the nature of the firm. These can form the basis for tests of '<IR>wash', 'Greenwash' and 'CSRwash'.

### Abstract

During the last two decades, sustainability issues, such as climate change, depletion of natural resources, or bad working conditions, gained considerable attention in the literature. Investors, consumers, suppliers, employees, public powers, and non-governmental organisations are increasingly requiring the development and implementation of sustainable practices, considering that sustainability and environmental, social and governance (ESG) factors became drivers able to affect companies' performance and are considered a source of competitive advantage.

In the current scenario, universities play a pivotal role in the transition to a sustainable society, providing students with knowledge about sustainability, ethical values, and human rights, contributing also to the achievement of the 17 Sustainable Development Goals (SDGs) of the 2030 UN Agenda. The perception of the relevance of sustainability and ESG issues fosters the universities to make investments for organizational restructuring, adjusting planning and controls, transforming their own missions, broadening their curricula, and providing non-financial disclosure. Particularly, non-financial disclosure is a strategic tool at least for the following three main reasons: to i) affect the way they are perceived and regarded externally; ii) legitimize their business activities to stakeholders; and iii) appear as good corporate citizens.

In the light of the previous considerations, this research paper tried to understand if the ESG factors can affect the performance of universities. Our analysis considered only the Italian mega-universities and was based on the ESG Perception Index for the period June-October 2021 as a tool for assessing the value of the relevance given to ESG issues by universities. This indicator was retrieved from the Reputation Science's Report. We carried out a multi-stakeholder analysis to understand if there is a correlation between the ESG Perception Index and economic variables related to the following three categories: i) students; ii) professors; iii) the Ministry of Higher Education. The findings showed a significant positive correlation between the ESG Perception Index and the considered variables. In order to validate these results, we developed a content analysis of universities' sustainability reports, based on the presence of keywords related to environmental, social, governance/transparency, and sustainability issues and then we used the retrieved level of non-financial disclosure as a control variable. Thus, these findings provide insight into how ESG perception can affect universities' performance and can be useful for academic researchers, policy-makers, and practitioners.

**Keywords** – University, ESG, sustainability, disclosure, non-financial report

**Paper type** – Academic Research Paper

## 1 Introduction

During the last two decades, more and more stakeholders are posing non-financial elements as the main theme in their investment choices, especially from an ethical point of view (Amstrong et al., 2020; Huang et al., 2022). Sustainability issues, such as climate change, depletion of natural resources, or bad working conditions, gained considerable attention (Simoni et al., 2020) and environmental, social and governance (ESG) factors became drivers able to affect companies' performance and are considered a source of competitive advantage (Eccles and Serafeim, 2013). In this scenario, the adoption by all United Nations (UN) members of the 2030 Agenda for Sustainable Development Goals (SDGs) represents an important step towards a more sustainable future (ONU, 2015; Huang et al., 2022).

In this process of transformation, universities play a crucial role, because they are called to form the future ruling classes. Universities have rethought their curricula to train managers and leaders who can help make the society to be more sustainable (Schimperna et al., 2022). The social role of universities is not limited to the promotion of principles and values through research and teaching (Sitnikov et al. 2018; Ali et al. 2021), but it also concerns the development of

management and community outreach (Hernández and Saldarriaga, 2009; Schimperna et al., 2022). All the new trends and needs led to a greater perception of the relevance of sustainability and ESG issues, pushing universities to make investments for organizational restructuring, adjusting planning and controls, transforming their own missions, broadening their curricula, and providing non-financial disclosure (del Mar Alonso-Almeida et al., 2015; Hernández García de Velazco et al., 2020).

In the light of the previous considerations, this paper tried to understand if the ESG factors can affect the performance of universities. The analysis considered only the Italian mega-universities and relied on the ESG Perception Index for the period June-October 2021 as a tool for assessing the value of the relevance given to ESG issues by universities. This indicator was retrieved from the Reputation Science's Report. We carried out a multi-stakeholder analysis to understand if there is a correlation between the ESG Perception Index and economic variables related to the following three categories: i) students; ii) professors; iii) the Ministry of Higher Education. Lastly, we validated our results through a content analysis of universities' sustainability reports.

The rest of the paper has the following structure: paragraph 2 shows the literature review; paragraph 3 explains the research methodology; paragraph 4 provides results; and paragraph 5 highlights the conclusions.

## **2 Literature review**

Climate change, pollution, depletion of natural resources, and bad working conditions are problems of our times no longer negligible and need a solution (Russo et al., 2021; Lombardi et al., 2022). The current condition of the planet requires today's generation not to make the same mistakes as in the past: it is necessary to reverse course. All this can only be done through sustainable development (Griggs et al., 2013). The World Commission on Environment and Development (1987) defined sustainable development "*the development that meets the needs of the present without compromising the ability of future generation to meet their own needs*". Sustainable development is also demanded by stakeholders, like investors, employees, consumers, public power, non-governmental organisations, and suppliers (Kolk and van Tulder 2010; Duque-Grisales and Aguilera-Caracuel 2019; Russo et al., 2021; Schimperna et al., 2022)

and the application of corporate social responsibility (CSR) principles can positively affect firm's market value (Lu et al., 2021).

In 2006, when the United Nations launched the Principles for Responsible Investment (PRI), the acronym "ESG" was introduced for the first time (Huang et al., 2022) and now ESG factors are also considered three central elements in measuring sustainability of an investment. On the basis of the most commonly used frameworks, local pollution, GHG emissions, biodiversity, water usage, energy consumption, waste management and production can be valuable examples of environmental factors; social factors can refer to inequality, discrimination, human rights, labour and workforce, and gender rights; while governance factors include issues related to the board and management, such as anti-corruption, codes of conduct, and board diversity (Loizzo and Schimperna, 2022).

Many features can affect ESG performance, among which the size of a company through the availability of more resources (Drempetic *et al.*, 2020). The proper implementation of ESG practices with positive ESG performances is considered a source of competitive advantage (Eccles and Serafeim, 2013), leading to many benefits, among which: i) to be perceived as positively contributing to environmental and social issues, ii) improve one's standing with the stakeholders; iii) avoid accusations of greenwashing; iv) improve the non-financial (e.g. increase in process and energy efficiency, and reduction in usage of materials) and financial performance; v) increase in firm value (Aras and Crowther, 2008; Friede et al., 2015; Fatemi et al., 2018; Chouaibi et al., 2021; Ahmad et al., 2021; Sheehan et al., 2023).

The 2030 UN Agenda, among the 17 SDGs, calls on Member States to "*ensure inclusive and equitable quality education and promote lifelong learning opportunities for all*" (English *et al.*, 2019). During these years, universities have developed education about CSR and sustainability, introducing new types of curricula, considering that the achievement of sustainable development is related also to the innovation that relies on the availability, creation, management, and sharing of knowledge (Schimperna et al., 2022). All universities are called upon to pursue the following fundamental missions: "*provide students with new competences to create a more sustainable society (Adams et al. 2011) and reduce the environmental impact of their operations (Disterheft et al., 2012)*" (del Mar Alonso-Almeida et al., 2015). However, the social role of universities is not limited to knowledge production and dissemination, typical features of research and

teaching (Sitnikov et al. 2018; Ali et al. 2021), but it also concerns the promotion of principles and values through the development of management and community outreach. The latter two elements, together with research and teaching, are the key attributes of the university social responsibility (USR) (Hernández and Saldarriaga, 2009; Schimperna et al., 2022).

In this scenario, the perception of the relevance of sustainability and ESG issues fosters the universities to make investments for organizational restructuring, adjusting planning and controls, transforming their own missions, broadening their curricula, and providing non-financial disclosure (del Mar Alonso-Almeida et al., 2015; Hernández García de Velazco et al., 2020). Particularly, non-financial disclosure represents an opportunity to communicate the commitment to sustainability (Aureli et al., 2020) and it is a strategic tool at least for the following three main reasons to: i) affect the way they are perceived and regarded externally (Deegan, 2002); ii) legitimize their business activities to stakeholders (Joshi and Gao, 2009); and iii) appear as good corporate citizens (Guthrie and Parker, 1989). In this scenario, the implementation of ESG factors in universities fosters the improvement of the organization's quality and the achievement of the SDGs (Huang et al., 2022).

In the light of the previous considerations, we selected the following research question:

*RQ: Can ESG factors affect the performance of universities?*

### **3 Methodology**

This research paper tried to understand if ESG factors can affect the performance of universities, considering the role of their perception in influencing stakeholder decisions. Our analysis considered only the Italian mega-universities (excluding the University of Palermo and the Federico II University because of lack of data) and was based on the ESG Perception Index for the period June-October 2021 as a tool for assessing the value of the relevance given to ESG issues by universities. This indicator was retrieved from the Reputation Science's Report and it was built analysing the proximity of the largest companies in the Italian market (according to Piazza Affari capitalisation, Mediobanca ranking, and Interbrand ranking) to the 17 UN SDGs. Particularly, a ranking of 200 companies was provided, and for each of them an indicator was developed (from 0 to 100), based on qualitative-quantitative and structural parameters: in addition to the volume of

content reporting the association between the brand and sustainability, the reputational impact of this content on the brand, the association of the brand identity with sustainability on search engines and the extent to which the company explains sustainability through its proprietary channels (e.g. website, social media) also weigh on the score. 60% weight was given to web intelligence and ESG reputation index (analysing 4 million web contents), and 40% weight to ESG corporate communication, encyclopaedic presence, and digital identity. The result is an expression of the perception generated in the last six months as well as the historical one, because on the web content persists and the past influences the current perception (<https://www.esgreputation.it/metodologia>).

To answer our research question, we applied a quantitative research method (Black, 1999; Waters and Waters, 2008), carrying out a multi-stakeholder analysis to understand if there is a correlation between the ESG Perception Index and economic variables related to the following three categories: i) students; ii) professors; iii) Ministry of Higher Education (tab. 1).

Tab.1: Selected variables and related category

<b>Variables</b>	<b>Category</b>
Number of enrolled students	Students
Total Ordinary Financing Fund for Universities basic quota	Ministry of Higher Education
Revenues for teaching	Professors
Revenues from commissioned research and technology transfer	Professors
Research and teaching staff costs	Professors

Source: our elaboration

Lastly, in order to validate these results, we developed a content analysis of universities' 2020-2021 sustainability reports, based on the presence of keywords related to environmental, social, governance/transparency, and sustainability issues and then we used the retrieved level of non-financial disclosure as a control variable, making a correlation with the ESG index. The following table (tab.2) shows the selected words for the content analysis.

Tab.2: Selected words for the content analysis

<b>Keyword</b>	<b>Group of keywords</b>
Environment	Environment
Environmental	Environment
Environments	Environment
Social	Social
Sociality	Social
Socialisation	Social
Governance	Governance/Transparency
Transparency	Governance/Transparency
Sustainability	Sustainability
Sustainable	Sustainability

Source: our elaboration

#### 4 Findings and discussion

The first step of our research was the analysis of the correlation between the ESG Perception Index and the selected variables. Initially, we correlated the ESG Perception Index with the number of enrolled students. The results highlight a significant positive correlation, showing a Pearson's correlation index of 0,93 (tab.3).

Tab.3: Correlation between ESG Perception Index and number of enrolled students

<b>University</b>	<b>ESG Perception Index</b>	<b>Number of enrolled students</b>
University of Rome La Sapienza	47,135	18.390
University of Bologna	41,995	14.382
University of Turin	41,335	14.505
University of Milan	38,705	11.967
University of Florence	35,79	10.116
University of Padua	34,88	12.342
University of Pisa	32,41	7.343
University of Bari	26,07	7.694
	Correlation	0,931142994

Source: our elaboration

Later, we made an analysis of the correlation between the ESG Perception Index and the Total Ordinary Financing Fund for Universities basic quota. The results

show a significant positive correlation, indeed, Pearson's correlation index is 0,89 (tab.4).

Tab.4: Correlation between ESG Perception Index and Total Ordinary Financing Fund for Universities basic quota

<b>University</b>	<b>ESG Perception Index</b>	<b>Total Ordinary Financing Fund for Universities basic quota</b>
University of Rome La Sapienza	47,135	291.987.567,00
University of Bologna	41,995	225.321.933,00
University of Turin	41,335	173.236.231,00
University of Milan	38,705	161.926.360,00
University of Florence	35,79	137.314.102,00
University of Padua	34,88	173.615.578,00
University of Pisa	32,41	115.412.030,00
University of Bari	26,07	111.965.663,00
	Correlation	0,885331221

Source: our elaboration

The following analysis concerned the correlation between the ESG Perception Index and revenues for teaching. We found a significant positive correlation with a Pearson's correlation index of 0,84 (tab.5).

Tab.5: Correlation between ESG Perception Index and revenues for teaching

<b>University</b>	<b>ESG Perception Index</b>	<b>Revenues for teaching</b>
University of Rome La Sapienza	47,135	116.474.169,55
University of Bologna	41,995	132.888.794,42
University of Turin	41,335	92.923.236,75
University of Milan	38,705	97.150.000,00
University of Florence	35,79	50.460.877,02
University of Padua	34,88	98.455.895,00
University of Pisa	32,41	48.471.696,00
University of Bari	26,07	35.246.086,00
	Correlation	0,8377935

Source: our elaboration

Then, we correlated the ESG Perception Index with revenues from commissioned research and technology transfer. The results highlight a positive correlation with a Pearson's correlation index of 0,50 (tab.6). Compared to the relationship between the ESG Perception Index and other variables, this correlation is the least significant.

Tab.6: Correlation between ESG Perception Index and revenues from commissioned research and technology transfer

<b>University</b>	<b>ESG Perception Index</b>	<b>Revenues from commissioned research and technology transfer</b>
University of Rome La Sapienza	47,135	14.501.370,11
University of Bologna	41,995	22.309.707,94
University of Turin	41,335	4.705.986,74
University of Milan	38,705	-
University of Florence	35,79	10.517.097,14
University of Padua	34,88	14.578.013,00
University of Pisa	32,41	6.690.580,00
University of Bari	26,07	665.637,00
	Correlation	0,502369820

Source: our elaboration

Finally, we correlated the ESG Perception Index with research and teaching staff costs. Pearson's correlation index emerged is 0,86 (tab.7).

Tab.7: Correlation between ESG Perception Index and research and teaching staff costs

<b>University</b>	<b>ESG Perception Index</b>	<b>Research and teaching staff costs</b>
University of Rome La Sapienza	47,135	310.456.376,40
University of Bologna	41,995	279.105.847,12
University of Turin	41,335	191.027.488,80
University of Milan	38,705	189.531.111,18
University of Florence	35,79	169.272.074,49
University of Padua	34,88	228.765.076,00
University of Pisa	32,41	145.083.892,00

University of Bari	26,07	124.867.840,00
	Correlation	0,854674911

Source: our elaboration

From the previous analysis, it is possible to state that the most significant correlation is between the ESG Perception Index and the number of enrolled students, with Pearson's index closer to 1 than other variables.

Lastly, we carried out a content analysis on the 2020-2021 sustainability reports, to validate the results of previous correlations. The first step was the calculation of the number of times the words indicated in the methodology section were used for each of the following topics: environment (E), social (S), governance/transparency (G/T), and sustainability (Sus.). Then, we aggregated the results to understand the total value that emerged from the analysis and we correlated it with the ESG Perception Index, obtaining a positive correlation with a Pearson's index of 0,78 that confirms our previous findings. The University of Bari was excluded from the sample because the last document available refers to 2017 (tab.8).

Tab.8: Correlation between ESG Perception Index and content analysis on sustainability report

## 5 Conclusions

ESG factors became drivers able to affect companies' performance and are a considered source of competitive advantage (Eccles and Serafeim, 2013) and stakeholders, like investors, consumers, suppliers, employees, public powers, and

non-governmental organization require more sustainable practices from companies (Kolk and van Tulder 2010; Duque-Grisales and Aguilera-Caracuel 2019; Russo et al., 2021; Schimperna et al., 2022). In the current scenario, universities play an essential role in the path towards sustainability, contributing to the achievement of the 17 SDGs of the 2030 UN Agenda. Indeed, universities provide students with knowledge about sustainability, ethical values, and human rights, carry out research about ESG and sustainability, and promote principles and values through the improvement and development of their management and community outreach (Hernández and Saldarriaga, 2009; Schimperna et al., 2022). Thus, the perception of the relevance of sustainability and ESG issues fosters the universities to make investments and innovate their own missions, providing also non-financial disclosure (del Mar Alonso-Almeida et al., 2015; Hernández García de Velazco et al., 2020).

In the light of these considerations, we tried to understand if the ESG factors, considering their perception, can affect the performance of universities. Our analysis was based only on the Italian mega-universities and relied on the ESG Perception Index for the period June-October 2021. We carried out a multi-stakeholder analysis to understand if there is a correlation between the ESG Perception Index and economic variables related to the following three categories: i) students; ii) professors; iii) the Ministry of Higher Education. Our findings show a positive correlation between the ESG Perception Index and the following variables: i) number of enrolled students (0,931142994); ii) Total Ordinary Financing Fund for Universities basic quota (0,885331221); iii) revenues for teaching (0,8377935); iv) revenues from commissioned research and technology transfer (0,502369820); and v) research and teaching staff costs (0,854674911). Lastly, we developed a content analysis of universities' 2020-2021 sustainability reports, obtaining a positive correlation of 0,777785709 that validated our results.

However, this research has the following three main limitations: i) it only considers the ESG Perception Index; ii) it is limited to only Italian mega-universities; iii) it was carried out by considering only one year.

The next steps of future research will be the overcoming of these limitations and the development of a more comprehensive analysis of possible ESG-related impacts on universities, in order to investigate more extensively this research field. Moreover, other efforts will be made to provide cross-country comparisons.

### Abstract

The importance of the impact created by different uncertainties in the policies on the overall economy of a country or a region cannot be denied. The Visegrád Group (V4 countries, including the Czech Republic, Hungary, Poland, and Slovakia) has certain political and cultural alliances and a significant economic influence in both central Europe and the European Union. The researchers conducted a systematic literature review on the background of economic policy uncertainty and financial innovation in Visegrad economies to understand the real fact of economic uncertainty in financial innovation in this region. The PRISMA 2020 framework has been updated to extract more detailed and accurate systematic literature reviews that were previously ignored and 22 papers have been finally selected to have the results. The common characteristics of these economies are in their transition from planned to market economies, particularly in Slovakia and the Czech Republic. In the common background of these economies, fiscal policy uncertainties, stock market volatility, exchange rate fluctuations, and political uncertainty are also responsible for the EPU. However, a significant influence is that the rapid innovation priority and emphasis on R&D development help the economy to rapidly converge with the EU economies stream.

**Nature of proposed paper** - Academic Research Paper

## 1 Introduction

The four Visegrad countries – the Czech Republic, Hungary, Slovakia, and Poland – have many similarities, particularly when compared to other transition economies in Eastern Europe and the former Soviet Union. They are more developed than most other communist countries, have a similar history and traditions, and lead the way in initiating reforms among post-communist countries. They have also consistently performed significantly better than the majority of transition economies, and are currently among the leading contenders for EU membership. However, there were significant differences between the Visegrad countries in terms of initial conditions, transition paths chosen, and resulting economic developments. As a result, the Visegrad group is an ideal candidate for comparative research into the effects of economic policies on financial performance or economic innovation, (Fidrmuc, Fidrmuc, & Horvath, 2002), (Zybała, 2019).

Economic policy uncertainty (EPU) is a risk that occurs when government policies and regulatory frameworks are ambiguous for the foreseeable future. Because of the market's uncertainty, this phenomenon may induce businesses and individuals to postpone spending and investments. Increases in the cost of capital in the economy are exacerbated by increases in economic policy uncertainty. As a result of the irreversibility of investment, increased economic policy uncertainty reduces investment. Economic policy uncertainty raises the value of the decision to wait because investment reversibility affects investment and innovation. Taking this into account, business innovation is essential to capture the potential risks posed by EPU.

This is the research's main goal, using V4 economies as the purposive selection. The justification for this geographical selection is that the world uncertainty index (2021) data still shows the volatility in uncertainty measurement of these economies. The researchers are conducting a systematic literature review on the background of economic policy uncertainty and financial innovation in Visegrad

economies to understand the real fact of economic uncertainty in financial innovation in this region. The study is significant because it will offer pertinent information for the V4 economies' uncertain economic policies and it will enable policymakers to have a comprehensive understanding of such a group of economies.

## 2 Materials and Methods

This study employed a systematic literature review method (Denyer, & Tranfield, 2009). Our study adopted inclusion and exclusion criteria after constructive reviewing articles from Web of Science and Scopus databases with key terms " Economic policy Uncertainty in Visegrad Economies ", " Economic policy Uncertainty in Respective Economies (Czech Republic, Slovakia, Poland and Hungary)", " Uncertainty in Financial Innovation in Visegrad Economies", and " Uncertainty in Financial Innovation in Respective Economies (Czech Republic, Slovakia, Poland and Hungary) during the period from 1992 to 2022.

This study finds 577 papers as records<sup>1</sup> on " Economic policy Uncertainty in Visegrad Economies ", and " Economic policy Uncertainty in Respective Economies (Czech Republic, Slovakia, Poland and Hungary)". In addition, it finds 563 records on " Uncertainty in Financial Innovation in Visegrad Economies", and " Uncertainty in Financial Innovation in Respective Economies (Czech Republic, Slovakia, Poland and Hungary).

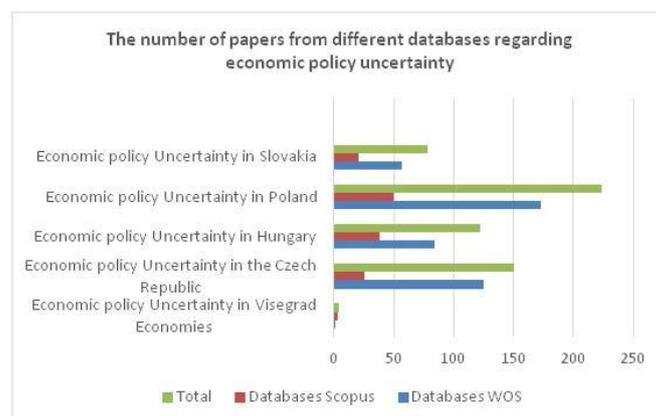

Figure 1: The number of papers from different databases regarding economic policy uncertainty

<sup>1</sup> Records are the title or abstract (may be both) of a report indexed in website or data ba

For this evidence-based research, the researchers would like to use the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework, which uses a small number of items to describe systematic reviews and meta-analyses. In recent years, highly cited literature from the Web of Science, Scopus, and Google Scholar databases has been used for this purpose (2010-2021). The PRISMA 2020 framework has been updated to extract more detailed and accurate systematic literature reviews that were previously ignored.

A total of 1140 records<sup>1</sup> are obtained on the concerned topic with the other sub-topic mentioned. We employed the Excel software for this purpose, which we used as a manual perspective, because of duplication and other reasons. The study will be conducted through three stages of the PRISMA framework, such as identification, screening and eligibility, and inclusion.

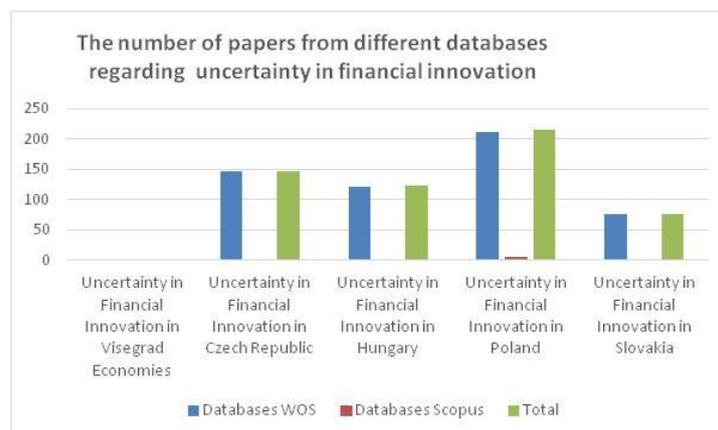

Fig.2 The number of papers from different databases regarding uncertainty in financial innovation.

We employed the Excel software for this purpose, which we used as a manual perspective, because of duplication and other reasons we removed 230 records before the screening. As a result, 910 records are now ready for screening, which can be done in two ways: one by title and abstract, and the other by the full text of the records. First, we eliminate the 568 titles and abstracts that are identical; secondly, after screening the entire text of the remaining 342 reports<sup>2</sup>, we decided to remove 256 papers because the concepts are similar. We have 86

<sup>2</sup> Reports are documents on particular study, such as journal article, conference paper, dissertations and others.

reports for eligibility purposes, and we have decided to exclude some of them due to a lack of clarity, non-compliance with the V4 economies framework, and a lack of business and economic, and financial ideas, as some papers only focused on this particular issue but very old information in nature. Finally, we chose 22 papers for our literature assessment, five of which are studies<sup>1</sup>, and the others are reports.

<sup>1</sup> Studies are investigations, such as clinical trial, primary outcome, statistical analysis plan, and others

### **3 Results and Discussions**

Economic Policy Uncertainty in Visegrad Economies has been discussed in each country separately to establish a common background for the study.

#### **3.1 Slovakia**

Slovakia has a mixed economic system with a mixture of private freedom and centralized economic planning and government regulation. Slovakia is a European Union member (EU). The transition from a supply-constrained centrally planned economy to a demand-constrained market economy represents a search for an acceptable relationship between growth and a balanced economy from a macroeconomic standpoint. Conditions related to insufficient restructuring and a distorted institutional framework have exacerbated this. Slovakia appears to have completed this transition successfully. However, opportunities for economic growth based on stimulating the economy's demand side have been exhausted (Marcincin, & Beblavy, 2000). Slovakia is an intriguing example of a country with high economic growth but low levels of Research, Technological Development, and Innovation (RTDI) development. A slew of economic and social reforms implemented between 1998 and 2005, as well as cheap and educated labour, aided in attracting a large amount of FDI to manufacturing industries. However, by 2006, Slovakia had become more of a processing economy than a knowledge-based one. The Slovak government's priorities are shifting. It developed several innovation policy concepts (for example, the Competitiveness Strategy) and directed more financial resources toward RTDI activities to avoid becoming a low-cost, low-value-added country. FinTech should include any financial innovation, regardless of the technology used; these innovations should result in new business models, applications, processes, or products that significantly impact financial markets, financial institutions, and financial service providers. Payment services, banking, and insurance are the areas with the greatest potential for financial innovation growth, with numerous innovative products and technological solutions already in place (Ministry of Finance of the Slovak Republic, retrieved in 2023). The study of Jasova, (2019) discussed EPU as especially true in 1999 when Central European countries were transitioning from a planned social and economic system to a market economy. This was followed by a period between the turn of the years 2008 and 2009 when Slovakia experienced a more moderate phase of the financial crisis than the United States. The opposite

occurred at the turn of 2009 and 2010, when Slovakia did not see such a significant decrease in business uncertainty as the US economy, with even an annual increase observed in one quarter.

Table 1: The Reasons for Economic policy uncertainty and Impacts in Slovakia

<b>Author/s</b>	<b>Reason of EPU</b>	<b>Impact/s</b>

Vondrová, & Valach, (2014).	Determining economic policy priorities	Ensuring quality economic growth along with quantity growth
Sum, (2012)	Economic policy uncertainty in Europe	Hardly any impact on the Slovak stock market performance

Source: Authors (2023)

According to OECD (2022) report on "Slovak Republic Economic Snapshot: Economic Forecast Summary (November 2022)", Following a deep recession in 2020, economic activity has begun to recover. However, supply disruptions and a low vaccination rate make the recovery's future pace uncertain. An ambitious recovery plan and significant inflows of EU funds present a once-in-a-lifetime opportunity to strengthen the economy, but effective and timely implementation will necessitate ongoing efforts to improve public procurement and public investment management. Rapid population ageing will exacerbate fiscal challenges and weigh on long-term growth in the medium term. Pension, health and long-term care, and labour market reforms are required to extend working lives, improve the health of the ageing population, and increase the efficiency of government spending to prepare for an ageing society. At the same time, population ageing emphasizes the need for increased productivity. Policies to

promote adequate skills, foster domestic innovation capacity, and better price environmentally harmful activities are required to reenergize the economic convergence process and make growth more inclusive and sustainable. Policies to promote adequate skills, foster domestic innovation capacity, and better price environmentally harmful activities are required to reenergize the economic convergence process and make growth more inclusive and sustainable. In addition, Vondrová, & Valach, (2014) emphasized determining economic policy priorities to ensure quality economic growth along with quantity economic growth. The quantitative dimension of economic growth, as measured by GDP, is necessary but not sufficient in the global economy to express the qualitative development of the economy and society. Statisticians and economists recognized the need to provide policymakers and civil society with a dependable, timely, and credible indicator that can quantitatively and qualitatively assess the current situation and forecast future economic growth. The Better Life Index is the most recent international attempt to present the best of a range of a comparable and comprehensive set of indicators of well-being, leading to the attempt and discovery of a better way to measure growth and identify key aspects necessary for prosperity. These aspects must be understood and applied in decision-making processes for determining economic policy priorities and objectives to ensure not only the quantity but also the quality of economic growth, and thus the quality of life. There are some optimistic experiences from the Slovakian economy and one of them is changes in economic policy uncertainty in Europe negatively affect all stock market returns in the European Union, Croatia, Norway, Russia, Switzerland, Turkey and Ukraine, and the effect is statistically significant for all countries except Croatia and seven members (Bulgaria, Estonia, Latvia, Lithuania, Malta, Slovakia and Slovenia) of the European Union.

### **3.2 The Czech Republic**

The Czech Republic's economic freedom score is 71.9, placing it 21st in the 2023 Index. Its score is 2.5 points lower than last year. The Czech Republic is ranked 15th out of 44 countries in Europe, and its overall score is higher than the regional and global averages. The Czech Republic has developed a modern and flexible economy and performs above world averages in many of the four pillars of economic freedom. Open-market policies have allowed the economy to capitalize even more on regulatory efficiencies gained through previous reforms

(Index of Economic Reform, 2023). The Czech National Bank (CNB) recognizes the innovation potential based on the application of digital technologies to streamline the functioning of all sectors of the financial market, improve its financial service provision, and foster a stronger and more resilient Czech Republic real economy. As a result, the CNB has decided to develop a new specialized communication channel to handle FinTech-related inquiries from all financial market participants. The FinTech contact point is the title given to the new channel. Through more active communication with incumbent institutions and potential new entrants, the contact point aims to promote the introduction of innovative technologies in the Czech financial market, (Czech National Bank, retrieved on 2023). When it comes to mean causality, the Czech Republic, Greece, Hungary, Poland, Qatar, and Turkey are more open to EPU. In the Czech Republic, researchers can easily see that EPU predictability is higher in the upper quantiles between 0.60-0.85, implying that EPU is more causal in rising market states (Das, Kannadhasan, & Bhattacharyya, (2019).

Table 2: The reasons for Economic policy uncertainty and its impacts in the Czech Republic

<b>Author/s</b>	<b>Reason of EPU</b>	<b>Impact/s</b>
Das, Kannadhasan, & Bhattacharyya, (2019).	asset prices in the emerging stock markets volatility	EPU is more causal in rising market states.
Index of Economic Reform, (2023)	Open market policies through the economic reform strategy	Capitalize the economy efficiently.
Czech National Bank (2023)	Innovation for economic development	FinTech-related development from all financial market participants.
Nestoroska, (2020).	EPU and firm performance	EPU has an overall negative impact on firm performance, the interest rate has a positive impact on firm performance and inflation is only positive when the net profit margin is used as a proxy for firm performance.
Julio, & Yook, (2012).	Political uncertainty causes EPU	Firms cut investment until the electoral uncertainty is resolved.
Békesová, & Bohdalová, (2022).	EPU due to exchange rate change	USD/EUR has a significant impact on the exchange rate returns

Source: Authors (2023).

Nestoroska, (2020) obtained results from various non-financial firms in the Czech Republic regarding EPU and firm performance in the Czech Republic. These findings indicate that EPU has a significant and negative impact on firm performance, whereas interest rates have a significant and positive impact on firm performance. However, the impact of the inflation rate is significant and positive only when the net profit margin is used as a proxy for firm performance. Based on these findings, it is possible to conclude that non-financial firms in the Czech Republic must develop policies and regulations regarding precautionary measures that can be taken in the event of EPU to maintain the firm's financial performance. In addition, political uncertainty causes firms to cut investment until the electoral uncertainty is resolved. These findings from Julio, & Yook, (2012) imply that political uncertainty is a significant channel through which the political process influences real economic outcomes. Moreover, Békesová, & Bohdalová, (2022) examined the effect of uncertainty on the exchange rate returns of the Czech crown, Hungarian forint, and Polish zloty (3 of Visegrad Group exchange rates). The main findings show that the USD/EUR has a significant impact on the exchange rate returns of all the currencies under consideration.

The OECD report (2023) finds out structural reform priorities in the Czech Republic as follows:

- Make the labour market more flexible and inclusive.
- Innovation and digitization: Improve the business environment by increasing R&D investment.
- Policy on the environment: Greener growth should be pursued.
- Reform the pension system and promote longer working lives in the labour market.
- Efficiency in the public sector: Consolidating local government services will increase public sector efficiency.

### **3.3 Hungary**

In 1968, Hungary, in response to slowing economic growth, the government implemented the New Economic Mechanism (NEM). The NEM implemented market-style reforms to rationalize the behaviour of Hungary's state-owned enterprises, as well as the emergence of privately owned businesses. By the end of the 1980s, private business had generated one-third of the gross domestic product (GDP), accounting for nearly three-fifths of services and more than three-

fourths of construction. However, the Hungarian economy failed to meet the challenge of the 1973 global economic crisis. The dramatic price increases for oil and modern technology resulted in a large external trade deficit, which increased foreign debt. Growth slowed and inflation increased, resulting in a period of stagflation.

Table 3: The reasons for Economic policy uncertainty and its impacts in Hungary

Author/s	Reason of EPU	Impact/s
Das, Kannadhasan, & Bhattacharyya, (2019)	Asset prices in the emerging stock markets volatility	Greater impact on price drops rather than causing volatility.
Mallinguh, & Zoltan, (2020)	Lowest IT budgetary support from the government.	The Hungarian FinTech market tends to lag behind its peers in the central European region.
Bod. (2019).	EPU relates to economic structural reforms	income convergence proved to be uneven and slow, leading to widespread frustration
(Oblath, 2016)	Unnecessary fiscal policy implementation	flat income tax, combined with discriminatory sectoral taxes and dependency on EU funds for fiscal support.
Virág, B. (2018).	Global financial crisis 2008-2009.	high foreign and domestic debt increased the vulnerability

Authors (2023).

The Hungarian FinTech market tends to lag behind its peers in the central European region. The financial sector, which is entirely regulated by the Hungarian government, faces significant challenges in implementing information technology (IT) innovations. More specifically, the banking sector fails to develop game-changing innovations because the country has one of the lowest IT budgetary support levels in the region, with the dominant player (OTP bank) being the only notable active innovator over time. The situation is similar in the insurance industry, the capital market, and asset management. The Hungarian National Bank (MNB) regulation, which only allows banks to lend, discourages FinTech investors from targeting borrowers. On the plus side, there has been a significant increase in online shopping and the use of digital payments because of the increased use of smart handheld devices and digital payments, (Mallinguh, & Zoltan, 2020). In the case of emerging European markets, the causality-invariance is largely insignificant for Hungary and Poland. This phenomenon

essentially means that in these markets, economic policy uncertainty, geopolitical risk, and the Financial Stress Indicator have a greater impact on price drops rather than causing volatility (Das, Kannadhasan, & Bhattacharyya, 2019). The stirring social and political events of the regime change in 1989/1990 and subsequent periods had a huge impact on the transformation of the Hungarian economy. Hungary entered the European market economy with partial monetization, an overburdened industry, and neglected infrastructure. Worries about external debt and the intention of definitively joining the Western political system dominated economic policy thinking, while social expectations focused on closing the income gap between Hungary and the developed West. Although the establishment of the institutional system of market economy and entry into the Western order was eventually successful, income convergence proved to be uneven and slow, leading to widespread frustration (Bod, 2019). Hungary's GDP growth accelerated to 3.7% in 2014 and was close to 3% in 2015. The reasons for the country's economic performance over the last six years are only partially related to the government's economic policies during that time. Between 2010 and 2013, deleveraging (the reduction of excessive debt at both the macroeconomic and microeconomic levels) harmed growth performance (though the introduction of the flat income tax, combined with discriminatory sectoral taxes, also hampered the country's growth). However, the acceleration in economic growth seen in 2014 is primarily due to "exogenous" factors, specifically unusually large transfers from EU funds (Oblath, 2016).

The Hungarian economy's structural and financing problems were evident long before the 2008-2009 financial crisis. Low labour market activity slowed the economy's growth potential, while high foreign and domestic debt increased vulnerability. The global crisis had severe negative real economic consequences, and the escalating political crisis has hampered effective crisis management. Recognizing the unique nature of the crisis, Hungarian economic policy introduced and implemented a new economic strategy that included both conventional and unconventional elements and was based on the coordinated operation of fiscal and monetary policy. Mutually complementary and sequential steps were able to stabilize the Hungarian economy's financial situation, restart growth, and ensure the smooth operation of financial intermediation; in the meantime, social acceptance of reforms was maintained. However, for economic convergence to be sustainable, a turnaround in competitiveness is still required (Virág, 2018).

### 3.4 Poland

The terms related to social security and fiscal policy are especially important; uncertainty shocks have long-term effects on unemployment in Poland. Researchers how regional indices can be used to study the impact of uncertainty on local economies ( Bartha, & Bontempi, 2022).

Table 4: The reasons for Economic policy uncertainty and its impacts in Poland

Author/s	Reason of EPU	Impact/s
Bartha, & Bontempi, (2022).	Fiscal policy shocks	Impacts local economy
Soliman, (2020).	Investment in SMEs	Having greater potential in Poland
OECD (2007)	A strategy of applying mixed policies	Boosting science and technology human resources, and improving the innovation system's governance.
Ozcelebi, & Izgi (2023).	stock markets volatility	economic policy uncertainty (EPU) index of the US on the exchange rates and stock returns of Korea, Mexico, and Poland.
Hołda, (2019).	Fiscal policy uncertainty and stock market movements	Affects the corporate assets or financial market
Mroczek-Dąbrowska, & Matysek-Jędrych, (2022).	EPU relates to Brexit	Brexit has caused a visible disruption in the Polish companies operating in British markets.
Guney (2019).	Macro-economic uncertainties on private investment	The real exchange rate, inflation, and growth uncertainties affect private investments negatively in Poland.

Authors (2023).

Poland's innovativeness is primarily perceived through the lens of large business entities, owing to the greater resources that can be allocated to research and development, as well as higher qualifications and human capital associated with a more matched offer of large academic centres operating in areas with greater potential. Furthermore, the persistence of the innovation stereotype understood as breakthrough changes, which are frequently important not only for a given entity but for the entire sector, makes innovative actions in the small and medium-sized enterprise sector deserving of the label "hidden ", (Soliman, 2020).

According to OECD (2007), Poland pursued a policy mix strategy, such as strengthening the scientific and technological foundation, prioritizing excellence and critical mass, increasing the incentives for corporate R&D and innovation, boosting science and technology human resources, and improving the innovation system's governance. However several EPU's can be observed recently in Poland, such as Brexit has caused a visible disruption in the so far fairly unobstructed segue to regional integration. Our research is based on a survey of Polish companies operating in British markets and aims to see how companies responded to the changes caused by Brexit and whether certain groups of companies exhibit similar characteristics in response to the observed uncertainty (Mroczek-Dąbrowska, & Matysek-Jędrych, (2022), Macro-economic uncertainties on private investment (Guney 2019), fiscal policy shocks (Bartha, & Bontempi, 2022; Hołda, 2019).

#### **4 Conclusion**

The importance of the impact created by different uncertainties in the policies on the overall economy of a country or a region cannot be denied. The Visegrád Group (V4 countries, including the Czech Republic, Hungary, Poland, and Slovakia) has certain political and cultural alliances and a significant economic influence in both central Europe and the European Union. Importantly, post-covid years are attempting to overcome the prior policy uncertainties to sustainably strengthen economic conditions. Slovakia is an intriguing example of a country with high economic growth but low research, technology, development, and innovation levels. Where the Czech Republic invested in innovation based on the application of digital technologies to streamline the functioning of all sectors of the financial market, improve its financial service provision, and foster a stronger and more resilient Czech Republic real economy. However, the Hungarian FinTech market tends to lag behind its peers in the central European region. Finally, the study found out that Poland's innovativeness is primarily perceived through the lens of large business entities, owing to the greater resources that can be allocated to research and development, as well as higher qualifications and human capital associated with a more matched offer of large academic centres operating in areas with greater potential

To understand the true nature of economic uncertainty in financial innovation in the Visegrad economies, the researchers conducted a systematic literature

review on the background of economic policy uncertainty and financial innovation in the Visegrad economies. PRISMA 2020 has been updated to include more detailed and accurate systematic literature reviews that were previously ignored. These economies share characteristics in their transition from planned to market economies, particularly in Slovakia and the Czech Republic. Fiscal policy uncertainties, stock market volatility, exchange rate fluctuations, and political uncertainty all contribute to the EPU in these economies. However, the rapid innovation priority and emphasis on R&D development have a significant impact on the economy's ability to rapidly converge with the EU.

### **Abstract**

The Open Innovation (OI) increases knowledge flows, accelerates the innovation processes and increases the benefits produced by the innovation itself. It is generally considered as a fundamental tool for the development of the circular economy.

In line with this, the aim of this study is to investigate the possible connection between knowledge management (KM) and circular economy (CE), within the open innovation practices.

---

<sup>1</sup> This paper was produced while attending the PhD programme in Sustainable Development And Climate Change at the University School for Advanced Studies IUSS Pavia, Cycle XXXVIII, with the support of a scholarship financed by the Ministerial Decree no. 351 of 9th April 2022, based on the NRRP - funded by the European Union - NextGenerationEU - Mission 4 "Education and Research", Component 1 "Enhancement of the offer of educational services: from nurseries to universities" - Investment 4.1 "Extension of the number of research doctorates and innovative doctorates for public administration and cultural heritage".

To accomplish this aim, we adopted the Grounded Theory (GT) approach to investigate OI practices linked to CE, partnerships and benefits declared by companies.

Italian firms have been adopted as a research context. Those selected for the analysis have started to redesign their production systems or carried out radical innovations to achieve the goal of obtaining the decoupling of economic growth from the depletion of natural resources. The results of the study show that the selected firms apply collaborative innovation practices, confirming the existence of a relationship between OI and the EC. The size does not seem to affect the type of OI, while with reference to the industrial businesses, OI practices are concentrated on few ones.

By far, the OI coupled practices are the most numerous and it emerges that there are more companies that introduce innovation into the external context than those that use the external environment to acquire knowledge. In addition, findings show a difference in the benefits achieved on the basis of the category of partners involved in the innovative initiatives. According to the results, we identified three research hypotheses which will be explored in a second step of the analysis.

The paper deals with an emerging issue and can foster a better understanding of the drivers, in terms of KM practices, for the development of the circular economy through the OI. Although this study is an explorative analysis of a sample of Italian circular firms, it offers academic and institutional implications regarding the debate on the circular economy at a micro-level. Understanding the experiences that companies are already having can represent a further step for the achievement of a new economic model, stimulating and fostering the implementation of the circular economy at a micro-level, and leading to policies that support the development of circular innovation.

## 1 Introduction

The circular economy (CE) represents a new paradigm aiming at achieving the sustainable development (Bakker et al., 2021; Korhonen et al., 2018; Ghisellini et al., 2016), this differs from the linear economy (LE) (extract, produce, consume) replacing the concept of “end of life” with the so-called 3Rs framework “reduce, reuse and recycling”, (Jesus and Jugend, 2023).

The need to reconfigure production processes in a sustainable way, highlighted by numerous international actors, (i.e. OECD, 2011), determined a growing attention to the circular economy (Ghisellini et al., 2016), since, achieving the sustainable development requires the consideration of environmental, economic and social aspects, as well as the interaction between them (FAO, 2002; Ren et al., 2013), and the CE pursues sustainability in all these aspects (Birat, 2015; Ellen

Macarthur Foundation, 2013), operating at micro (companies, consumers), meso (industrial symbiosis networks, eco-industrial parks) and macro (cities, regions, national or global governments) levels (Kristensen and Mosgaard, 2020; Kirchherr et al., 2017).

At the micro level, companies, to answer to the growing demand for circularity, have started to develop circular business models (Ferasso et al., 2020) that manage to increase value for consumers, while solving economic, social and environmental challenges (Bocken et al., 2016). Different categories of actors must cooperate to make the CE model work at each stage of the product life cycle, coordinating innovation activities to understand how to adapt or create new systems to generate circularity (Brown et al., 2020). Circular business models activate products and processes innovation and innovate the company's value proposition (Geissdoerfer et al., 2017). This recalls the Open Innovation approach, that can represent a potential guide for the realization of innovative business models (Jesus and Jugend, 2023) as it increases knowledge flows, accelerates the innovation process and increases the benefits produced by innovation itself (Chesbrough, 2003). The OI appears as a fundamental tool for the development of circular economy initiatives, although the integration and interaction of the two approaches is scarcely investigated, as well as the contribution that can be provided by the OI to a more sustainable economy (Jesus and Jugend, 2023).

In line with the above, the aim of our study is to understand the relations between OI and CE, considering, as a research context, some Italian circular economy companies. To accomplish this aim, we adopted the Grounded Theory (GT) methodology (Jensen and Jankowski, 1991). In detail, in the present paper is presented the first step of the study (exploration phase), that starts from the description of each company to identify the presence of OI practices related to CE practices. In particular, the phenomena to be detected and analysed are the different practices of OI, the different categories of partners and the advantages listed by the circular economy companies.

The research sample is represented by 114 circular companies located in northern Italy. Prior to the empirical investigation, a review of the literature on the concept of Open Innovation and its possible role in the circular economy is presented in the second paragraph. Then, the third paragraph illustrates the methodological process adopted and clarifies the phases of data collection and analysis for the empirical research; in the fourth paragraph the results are presented; finally, in the last paragraph the discussions and implication are

presented, with the identification of three research hypotheses to be deepened in the further phases of the analysis.

## **2 Open Circular Innovation**

The OI breaking with the classic idea of the innovation built within the company walls, represents a new way of innovating that involves the use of ideas, knowledge and technologies both internal and external to the company (Chesbrough, 2006; Lee et al., 2010).

According to the scientific debate, the increasing mobility of talented employees among companies of different countries (that began in the twenty-first century), made it difficult to protect knowledge, favouring the development of OI. However, OI has not to be considered as a defect in the company's innovation process, on the contrary, to date the openness of companies and their innovative process are considered by many to be a necessary aspect for innovation in the market (Bigliardi et al., 2021). In addition, the increase in academic courses number has brought specialist knowledge out of research centres (Chesbrough, 2006), favouring the innovation of market dynamics.

It is possible to group OI knowledge flows into: outside-in, inside-out and coupled. The outside-in knowledge (also called inbound knowledge flow) involves the search for knowledge outside the company to expand the internal one, so as to improve the innovative capacity of the company (Chesbrough, 2017; Enkel et al., 2009); on the contrary, the inside-out knowledge (also called outbound knowledge flow) provides to bring the knowledge out of the company's walls by making it available to the external environment. This could occur through technological license agreements or the creation of start-ups and spin-offs, can also represent an additional source of profit from business knowledge otherwise fruitless for the company or in any case with a return lower than that thus generated (Barham et al., 2020). Finally, the coupled open innovation (combining knowledge inflows and outflows) is characterized by the simultaneous presence of outside-in and inside-out knowledge flows (Enkel et al., 2009).

OI practices have also been described as a useful tool for overcoming obstacles to the CE (Jesus and Jugend, 2023). Innovation is central to drive the transition to a circular economy and a sustainable development (De Jesus and Mendonça, 2018), and to generate reuse circuits (through restructuring and reproduction), recycling processes (reconstruction of inputs and remodelling of outputs) and

renewal initiatives (using clean energy and eliminating waste), so creating the so-called "eco-innovation" (Sáez-Martínez et al., 2016). Eco-innovation in a circular economy perspective expands the basic concepts, too focused on the final phase of the product's life, and includes waste prevention, sharing/leasing, repair, remanufacturing, and recovery, these concepts also include other stages of the life cycle, such as the design and use phase (EIO, 2016). Bogers and colleagues (2020) describe this kind of innovation as "a distributed innovation process which is based on purposively managed knowledge flows across organizational boundaries, using pecuniary and non-pecuniary mechanisms in line with the organization's business model, thereby contributing to development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Bogers et al. 2020, 1507).

It is characterized by the objective of reducing, slowing down and closing resource circuits, but clashes with the problem of dispersion of capacities and infrastructures for its realization among the different market players (Blomsma, 2018). Collaboration and knowledge management, therefore, play a fundamental role, as every phase of the product's life and, consequently, each involved actor must adopt a shared approach with partners, innovating together to adapt or create new systems to generate circularity (Brown et al., 2020).

### **3 Methodology**

As mentioned above, the main aim of our study is to propose a model to explain this relationship between OI and CE through the GT method. To accomplish this aim, 114 circular companies located in the northern Italy have been analysed. We decided to consider only companies located in the North of Italy in order to analyse the business choices in circumstances as homogeneous as possible – namely companies belonging to the same territory and cultural context, although from different sectors (Hilgers and Ihl, 2010; Roper et al., 2013; Yun et al., 2020) - having at the same time a large sample.

Has to be underlined that the present paper represents a preliminary phase of the whole research process, namely the exploration phase, since the research process started with the analysis and description of each single company, to detect any reference to the OI. In addition, in this phase will be also introduced three research hypotheses that will be further analysed in the future steps of the

study through the Grounded Theory approach. Survey items of the exploration phase are illustrated in Figure 1.

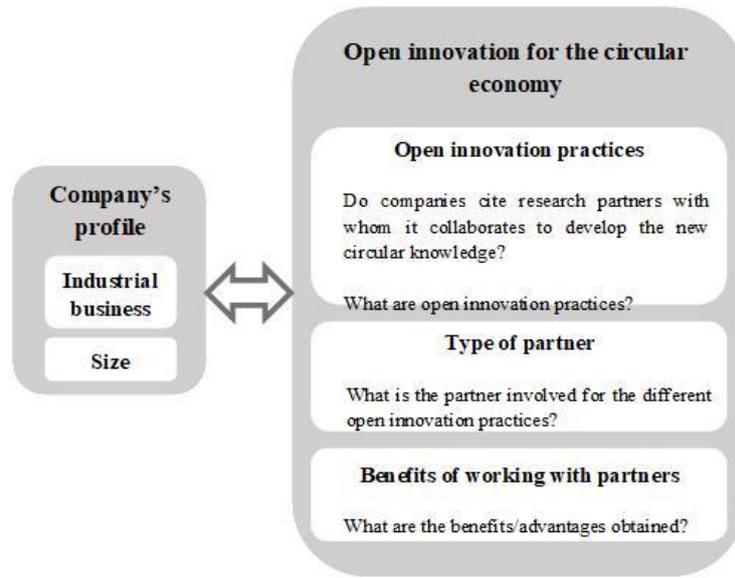

Figure 1: Survey items

### 3.1 Data collection

Data are mainly collected from the Italian Atlas of the circular economy website ([www.economicircolare.com](http://www.economicircolare.com)), namely an interactive web platform, created by the Environmental Conflict Documentation Center of the Association Sud ([www.asud.net](http://www.asud.net)) with the support of Erion, and born from the experience of two Italian WEEE consortia (waste from electrical and electronic equipment).

The Italian Atlas platform has been chosen to collect data since it is considered as a tool to map territorial realities according to the circular economy initiatives implemented by local firms and it is continuously updated through the monitoring of a scientific committee.

We selected data related to firms located in the Northern Italy, the most numerous of the Italian firms listed in the Atlas and in particular in the following regions: Valle d'Aosta, Piemonte, Lombardia, Trentino-Alto Adige, Veneto, Friuli-Venezia Giulia, Liguria, Emilia-Romagna Romagna. Data collection lasted 7 months (from May 2022 to November 2022).

The firms are categorized by the region, the business area, the level of circular initiative implemented or planned (circular production model; circular product; secondary raw material; circular service; enabling technology; circular economy research research project), the category (profit; non-profit; research institution; public sector) and the target (B2C; B2B). To avoid any bias and to guarantee the methodological consistency, we chose to collect more data from the official websites of the companies. And, in particular, we collected data on the organizational characteristics, such as the size and the sector in which they operate, and strategic characteristics related to the adoption of the OI approach in implementing CE initiatives, such as the presence of innovative initiatives, the type of OI, as well as the partners with whom the company collaborates, and the related advantages declared.

#### **4 Results**

The results show that 72% of the companies analysed apply collaborative innovation practices (Appendix 1), this confirms the relationship between OI and CE. Firms' OI initiatives have been classified according to Chesbrough and Bogers (2014) proposal, namely inside-out, outside-in and coupled process.

Only 6% of the companies realize exclusively outside-in OI collaborations; 22% exclusively realize inside-out OI collaborations, mainly represented by partnerships; finally, 44% of the sample realize coupled OI initiatives.

The size of companies does not affect the kind of initiative implemented (Figure 1): in fact, 60% of large companies, 62% of medium-sized companies, and 69% of small companies declare to implement outside-in OI and coupled OI initiatives; while 100% of large companies, 77% of medium-sized companies, and 92% of small companies declare to implement inside-out OI and coupled OI initiatives.

In general, it emerges that, regardless of size, there are more companies introducing innovation into the external context than those that use the external environment to acquire knowledge. This means that circular innovation does not necessarily have to be driven by large companies, on the contrary, small firms manage to be more profitable in innovation, with special reference to radical innovation (Lee et al., 2010). This suggests a great innovative capacity of companies which represents a research trajectory to be further investigated.

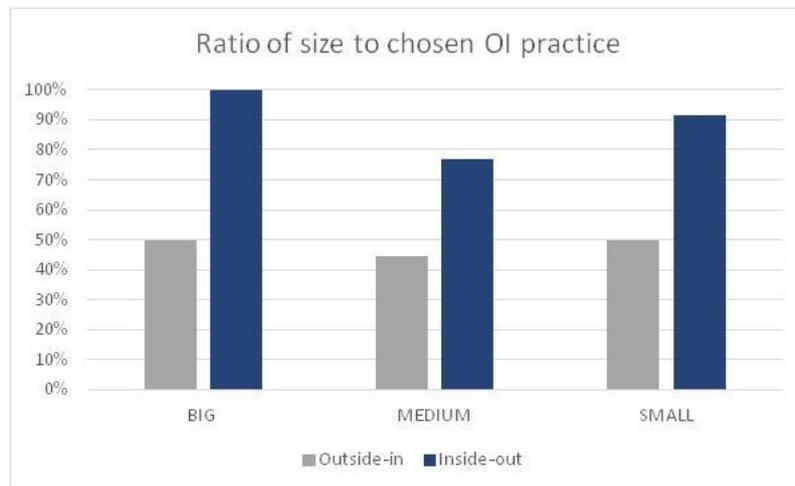

Figure 2: Outside-in and inside-out OI initiatives by firm size

According to the documents we analysed, the benefits deriving from the implementation of OI initiatives are, in descending order: acquisition of new knowledge, encouraging the adoption of a sustainable approach, spreading principles of circular economy, costs reduction, costs sharing, time-to-market reduction (see Appendix 1).

By comparing the benefits and the way in which the OI initiatives are implemented, it emerges that companies that collaborate with different categories of stakeholders have a more diversified portfolio of advantages, managing, in many cases, to acquire new knowledge (69%), spread the principles of the circular economy (54%) and encouraging the adoption of a sustainable approach (73%) (Figure 3).

The second most mentioned aspect is the relevance of the collaboration with different actors in the realization on OI initiatives.

The very logic of OI offers a clear explanation of this phenomenon, where, especially in SMEs, even two competing companies find it more convenient to collaborate and co-create than to close themselves off and not feed the innovative process (Radziwon and Bogers, 2019). The "partner companies" were divided into two groups on the basis of the sector in which they operate, we also paid attention to the selection of partners operating in the same sector. In general, the benefits are very similar, differing only in the frequency with which these benefits occur, lower for the "companies in the same sector" category.

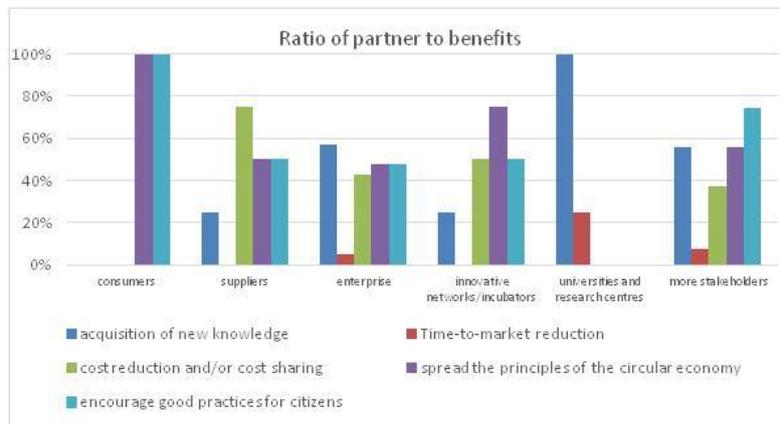

Figure 3: The frequency of benefits in relation to the partner they collaborate with.

The third most mentioned aspect is the relevance of partners as universities and research centres; in fact, 25% companies recognize universities and research centres as the best entities with whom cooperate with special reference to the acquisition of new knowledge; anyway, apart from the acquisition of knowledge, the collaboration with these categories of partners is not considered as very advantageous, least of all to reduce the time-to-market.

The collaborations with other categories of partners are less numerous; for example, only three companies state to collaborate with consumers, declaring, as expected benefits, the dissemination of CE principles and the promotion of good practices for citizens, while collaborations suppliers are considered useful with reference to cost reduction or sharing.

Finally, innovative networks / incubators represent 6% of the categories of partners mentioned, the benefits associated to this category of partners are mainly cost reduction and sharing, as well as the dissemination of circular economy principles and the promotion of good practices for citizens.

As concerns the sectors (Figure 3), companies analysed are mainly from textile, clothing, leather, footwear and accessories sectors (18%), followed by furniture and furnishing companies (12%); finally, companies operating in waste management represent the 11% of the dataset, as well as companies producing secondary raw material, also representing the 11%. Although the dataset does not allow to determine a relationship between the specificities of the various sectors and their influence on the adoption of circular practices and OI, it is nevertheless

relevant that there are sectors not represented at all in our dataset, like “Mobility, transport, and logistics” or “Energy production and distribution”.

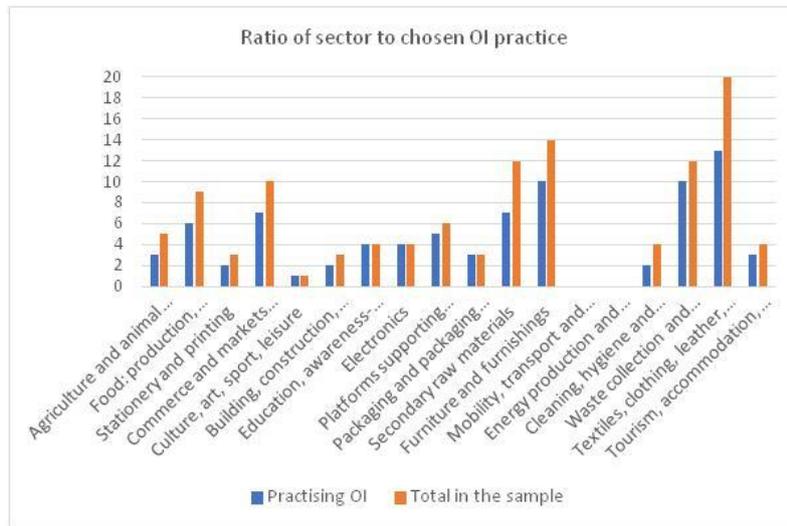

Figure 4: The frequency of realities adopting OI practices in relation to the sector in which they operate.

## 5 Discussion and implications

The results highlight the existence of links among the different phenomena investigated, within the relationship between OI and CE, this led us to identify three research hypotheses to be explored in a further step of the investigation:

*H1. The benefit pursued by the company determines the type of IO initiative and the partners to be involved.*

Data show that benefits can change if the partners involved change. Then, would the search for a specific benefit determine the category of partners to be involved in the implementation of OI initiatives? This aspect poses a further question on the presence of specific partners and their willingness to collaborate and share their knowledge and skills.

Our results are aligned with the model proposed by Jesus and Jugend, (2023), representing an empirical confirmation of their study, especially as concerns to the implications/benefits noticed with reference to "consumer awareness" and "organizational performance": in fact, collaborations with consumers have as main effect the dissemination of a new awareness, while the collaboration with the

different actors brings improvements on the operational performance of the companies.

Interesting theoretical implications derive from the first hypothesis: focusing on the relationship between benefits and partners and investigating this relationship more deeply would shed light on a completely new perspective on the influence of OI and, consequently, of knowledge management in circular companies (Chesbrough, 2003; Brown et al., 2020). This perspective would make it possible to circumvent (1) a possible "internal obstacle" for the company, related to the lack of awareness of the benefits that can be achieved through collaborative forms, and that can favour the development of circular innovation; (2) a possible "external obstacle" related to the presence of partners and their willingness to collaborate. Future studies on the relationship between benefits and partners would make it possible to make the various players aware of the centrality of their role in supporting the birth and development of circular processes: an example is represented by the so-called University's Third-Mission that can support the circular transaction of production systems and, at the same time, obtain rewards for having supported applied research.

Also interesting are the implications for institutions in considering the relationship between IO, partners and achievable benefits: on the basis of these relationships and the benefits to be obtained, institutions would identify the necessary partners. In particular, actions could be put in practice to ensure that the partners are from the same territory and are willing to collaborate; this could be part of a policy for the development of the circular economy. Furthermore, policymakers could intervene in raising awareness and educating the various stakeholders on the circular economy.

*H2. Local culture and characteristics of the sector can represent a barrier/stimulus to OI and CE.*

In the approach to CE and in the implementation of OI initiatives for circular innovation, our research shows clear differences in the behaviour of companies with respect to the territorial characteristics and industrial business (Hilgers and Ihl, 2010; Roper et al., 2013; Yun et al., 2020). The analysis of the key factors that determine these differences can constitute an interesting research trajectory to understand the influence of OI in circular companies, that could also lead further research on the obstacles to OI and the development of circular innovations in some industrial sectors.

*H3. The CE through OI is an opportunity for SMEs.*

Small firms manage to be more profitable in innovation, with special reference to radical innovation (Lee et al., 2010). Data show that the size of circular companies does not affect the tendency to carry out more inside-out OI than outside-in OI initiatives. The presence of small innovative firm that adopt an OI approach in implementing CE initiatives, could be useful and perhaps needed for the diffusion of the circular economy in the Italian territory. The debate underlines that the specificity and flexibility of SMEs accelerate innovation (Lee et al., 2010), innovation sharing can represent a relevant business opportunity and a lever for the development of new markets that small businesses can enter.

In conclusion, the phenomena we investigated and the preliminary results emerged from this first phase of the analysis represent a starting point for future investigations to confirm or confute the research hypotheses proposed above. The future steps of the research will be carried on through an empirical analysis adopting the Grounded Theory approach.

### Abstract

There are many types of uncertainties that the contemporary working life – including public and private sector organizations – needs to cope with to operate successfully and to maintain their competitive advantage. Worldwide crises, shortage of labour, and the need to adjust quickly to the changing environment call for a new type of organizational resilience. We propose that in addition to being able to bounce back from adversities, which is the traditional viewpoint for organizational resilience, organizations need to invest in developing their proactive organizational resilience. It is suggested that leadership and management activities play a key role in building and fostering proactive organizational resilience. It is expected that knowledge management practices, such as increasing change capability and creating a continuous learning environment are important elements in improving proactive organizational resilience. As a way of identifying the crucial leadership and management processes in developing proactive organizational resilience, a systematic literature review on recent research literature is currently being carried out. This is still work-in-progress but based on interim results of the systematic literature review, this conference paper presents some key perspectives and discussions together with main research findings. In addition, some interesting future research prospects are described.

**Keywords** – Organizational resilience, Proactive organizational behavior, Systematic literature review, Management, Leadership

**Paper type** – Academic Research Paper

## 1 Introduction

The working life is facing several profound challenges in the near future. A recent report by the Finnish Institute of Occupational Health lists massive shortage of workers, uncertainty caused by recent worldwide crises, and difficulties in operating the welfare state as three most important problems for managing the working life in Finland (Ranki, 2023). It is very likely that Finland is not alone in dealing with these problems. At the same time, the concept of resilience has become the buzz word in popular press along with newspapers and magazines – as well as in academic literature. According to the Scopus database, during the first quarter of 2023, over 6,000 scientific publications dealing with some forms of resilience have already been published.

Resilience belongs to the core constructs of positive organizational behavior (Hartmann et al, 2020). At the individual level, it is a malleable (i.e. developable) capability to bounce back from adversities (Luthans, 2002). Resilient individuals are able to function despite crises and stressful situations. At the organizational level, resilience has traditionally been firmly connected with crisis management (Williams et al., 2017). In contemporary organizational settings, such reactive resilience is not sufficient to guarantee sustained high performance, but a certain amount of proactive change capacity is also needed. Therefore we propose proactive organizational resilience as a multidimensional concept including at least interpreting the current situation, anticipating future events and responding proactively, as well as continuous learning. The goal of proactive organizational resilience is flexibility, not just in reacting to what has happened but in being at least one step ahead of what is going on in the organization and the world around it. While the need for resiliency has been well recognized across many academic disciplines and consequently related research is burgeoning, there seems to be a lack of overarching frameworks focusing on the proactive side of resiliency, especially from a managerial point of view.

Then what is it that we currently do know about leading and managing resilience at the public sector and in private organizations? To answer this question, we are in the process of conducting a systematic literature review on the topic. We are currently going through a set of 333 research articles on organizational resilience which we have identified through a review protocol explained in detail in the methodology section of this conference paper.

The importance of being able to lead and manage resilience proactively has become extremely important for both the public and private sector organizations because they all need to cope with a constant stream of unanticipated large-scale changes, which ultimately shake the very tenets of their existence. Hence all kinds of organizations must be able to make renewals on operational, tactical and strategic levels. The conference paper will contribute to a practical understanding of what are the key facets of leadership and management of a proactive type of organizational resilience. From the academic perspective, the forthcoming paper contributes to building an improved understanding of the current state of the literature concerning proactive organizational resilience and its leadership and management. The paper will outline the key perspectives and discussions in the current literature, methodological choices, and main findings, and will also point out a set of topical future research questions to be tackled.

## **2 Building organizational resilience**

Given the abundance of research articles on organizational resilience, it is surprising how few of them focus on building, that is, leading or managing resilience effectively. Thus, the focus of supporting employees in their attempts to cope has largely been neglected (Richard, 2020). Conceptualizing organizational resilience has been the focus of numerous recent literature reviews but only few of those (Britt et al., 2016, Fisher et al., 2019, Hartmann et al., 2019, Hillman and Guenther, 2021; Koerber et al., 2018; Linnenluecke, 2017; Vanhove et al., 2016) have dealt with resilience with emphasis on the working life context, and even fewer from a proactive viewpoint.

Some researchers argue that to demonstrate resilience requires the presence of adversity (Hartwig et al., 2020). Previously, workplace resilience has been defined as employees' ability to manage and positively overcome adverse events at work (Fletcher and Sarkar, 2013). However, Stoverink et al., (2020) point out that the greatest influence on building organizational resilience takes place before an adversity is imminent. Hartwig et al. (2020) identify three key themes regarding organizational resilience: the dynamic nature of resilience, a positive adaptation to adversity, and a sustained organizational viability. To us, these describe the building blocks of proactive organizational resilience.

Borg et al. (2022) explored how resilience can be built across organizational levels and found that psychosocial mentoring and peer coaching are effective means for bolstering workforce resilience. Vanhove et al. (2016) found in their meta-analytic approach that one-on-one delivery format, such as coaching, was

the most successful method in resilience-building programmes. Therefore, there seems to be a strong link between resilience building and management practices. Nevertheless, in her review of resilience in business and management literature, Linnenluecke (2017) contends that literature has provided contradictory recommendations for how resilience should be built into organizations, and hence the topic is worthy of further inspection.

### **3 Methodology**

The objective of the systematic literature review in this conference paper is to describe what is currently known about leading and managing organizational resilience and what are the main trends suggested for future research. With our research question 'What do we currently know about leading and managing resilience at the public sector and in private organizations?' in mind we created a review protocol with the following criteria. After some initial experimental literature searches, we limited our search on the Scopus database as it offers an extensive coverage of titles publishing research on life, health, and social sciences. We then defined our search criteria to ["organi\* resilien\*" AND lead\* OR manag\*] mentioned in the article title, abstract or keywords. This search produced 964 documents initially. As we are interested in the current state of affairs with a focus on managerial activities, we further limited our search to documents published during 2018-2023 and in the subject areas of 1) Business, Management, and Accounting, 2) Social Sciences, and 3) Psychology. This search decreased the number of documents to 399. We finally limited our search to articles or reviews written in the English language thus excluding conference papers, book chapters, and the like, for the purpose of emphasizing peer-reviewed documents. This final limitation brought us down to 333 articles or review articles on organizational resilience.

In the second stage of the literature review process, we omitted articles which were published in journals that have no AJG (Academic Journal Guide) ranking as an implication of research quality and integrity. After this, we carefully went through all the remaining abstracts, excluding articles where lead\* or manag\* did not refer to organizational managerial activities, where the research focused on nonwork settings, or where the main focus of the article was otherwise off from our research question. The final number of articles to be gone through in detail will be around 70-80. We are currently in the middle of this process, and consequently describe our findings so far, based on 35 articles, in the remainder of this conference paper.

## **4 Findings**

Our findings so far concentrate on three aspects of organizational resilience. We first summarize how organizational resilience has been defined in contemporary research literature. We then proceed by taking a look at key perspectives and discussions and the methodological choices within these current articles and describe their key findings. Finally, we point out some interesting topical future research suggestions.

### ***4.1 Definitions of organizational resilience***

The most common definition of organizational resilience deals with the process of recovering or overcoming an adversity. This definition originates from Sutcliffe and Vogus (2003) and has been found in several literature review articles. Along a similar idea is the definition of resilience which describes the ability to bounce back from a setback or failure (originally from West et al., 2009). A more proactive look on defining resilience can be found in Stokes et al. (2019), who describe resilience as the ability to withstand challenges through cultivation of organizational capacities and in McEwen (2022), who defines resilience as being proactive in positioning future challenges.

### ***4.2 Key perspectives, discussions and findings***

By far, most of the current research articles on organizational resilience are quantitative in nature. There are also some literature reviews and conceptual papers, but these represent a clear minority.

On the softer side of management activities, well-being oriented human resource management practices increase resilience through influencing group feelings and social climate (Cooper et al., 2019). Leaders also need to personally invest resources that build their own resilience in order to foster resilience in teams they lead (McEwen, 2022). Trust, reciprocity, and clarity play a vital role in cultivating employee resilience (Kakkar, 2019), and a learning organization positively effects employee resilience (Malik and Garg, 2020).

Preparedness to unexpected events and a proactive resilience perspective can be found in Branicki et al. (2018) and Casprini et al. (2023). Mitsakis (2020) adds that strategic human resource development is a proactive response to unexpected events.

Several scholars conceptualize organizational resilience through an adaptive capability for internal or external organizational alignment (e.g. Mithani, 2020;

Chowdhury et al., 2019; Martinelli et al., 2018) which results in bounce-back or bounce-forward (proactive) resilience. Leadership can support organizational resilience by fostering a belief in group capabilities (Fernandez et al., 2022).

A process perspective to organizational resilience is introduced in several articles. According to Yang et al. (2021) there are three phases: preparation, response and development, while Akgün et al. (2022) list anticipating, preparing for, responding, and adapting as the four phases of this process. Finally, Mithani (2020) sees five phases, those of avoidance, absorption, elasticity, learning, and rejuvenation.

Branicki et al. (2018) make a difference between everyday resilience and resilience in extreme conditions and bring into discussion micro-processes that link individual resilience and organizational resilience. Finally, managerial resilience is seen as collective persistence and recovery (Ranucci and Wang, 2022).

#### **4.3 Future research questions**

A few articles call for new resilience measures in response to the fast-changing context of work. In addition, the role of contextual or organizational practices in explaining resilience (Hartwig et al., 2020) needs clarification. On the softer side, looking at optimism, cynicism and humour in connection with resilience (Stokes et al., 2019) adds to the trend of seeing personal resources as building blocks of not just employee resilience but also organizational resilience.

## **5 Conclusions**

This paper addressed the highly topical issue of organizational resilience with the aim to better understand how organizational resilience can be supported by leadership and management activities. We discussed the need to approach organizational resilience not only as the ability to recover from emergencies and crises (Lee et al. 2013), but also as the ability to proactively renew the organization (Välikangas, 2010). In specific, this paper examined leadership and management of proactive organizational resilience by exploring the current research knowledge on the topic with systematic literature review method.

As the systematic literature review process is still ongoing at the time of writing this conference paper, we reported the interim results. They demonstrate that while many research articles still define organizational resilience reactively as bouncing back from adversities, there are several scholars who call for a more proactive approach to organizational resilience. Many scholars emphasize

adaptive capabilities as a key resource for organizational resilience. Well-being, trust, and in general a positive learning environment are suggested as human resource management-oriented practices to foster proactive organizational resilience.

There are some limitations in this literature review. First, we only looked at a limited number of articles through a single database, and it is likely that we have overlooked some relevant articles. We are in the process of rectifying this shortcoming in our review by updating our reading list as we proceed with the original articles. It is probable that if an article is cited several times in the articles we have so far read, it is worth looking into by us as well. Second, we are still in the original stages of our systematic literature review and have thus far benefited little from researcher triangulation. However, in the next stage of our review process we will jointly go through and discuss the relevance of our findings so far.

### **Abstract**

The increasing importance of agility in healthcare organizations and the fact that there are no studies in the field of agile management in healthcare in Slovenia led us to the decision to prepare research that includes a Delphi study on the importance of adopting agile and flexible business models based on the digital transformation of business in Slovenian health organizations. Knowledge management ensures long-term quality care and provides support in the decision-making process. Most of the knowledge that healthcare professionals learn during their training needs to be renewed during their working period, which is why they need to be agile in their thinking and behavior. The fundamental goal of the study is to answer the research question, what organizational changes need to be implemented in Slovenian healthcare organizations to develop the foundations for

creating an organizational culture that will enable the emergence of organizational agility in Slovenian healthcare organizations in the future? The research is focused on organizational adoptions and changes that are necessary for the healthcare organization to become agile. The purpose of this exploratory study is to investigate the consensus among employees in healthcare organizations regarding new pragmatic approaches based on knowledge management that will enable the implementation of organizational culture. We are interested in researching the evolution of organizational agility, where we will discuss organizational culture, models of organizational culture, and the changes it is currently under. We also emphasize how to overcome the resistance towards change to enable acceptance of agility in healthcare organizations. We describe agility as a competence that enables innovation. We highlight the factors that influence a healthcare organization's agile functioning. Our research objective is to present a finished study of knowledge management, and agility management in healthcare organizations.: The methodology used is the Delphi method. Our research empowers healthcare professionals with new management and leadership concepts, such as agile management, and different leadership development methods in healthcare. Sustainable leadership influences healthcare organizations' distribution of human and financial resources. The impact of sustainable leadership is leading healthcare organizations and their stakeholders towards sustainable development according to UN Global Goals. However, this is many times challenging to do. The emergence of a new organisational culture will also contribute to the efforts of employees, which are necessary to ensure the successful transformation of a healthcare organization into an agile one.

## 1 Introduction

In theory and modern managerial practice in healthcare organizations, the question arises as to why organizational agility is important for healthcare organizations and its role. Based on analyses of texts by authors such as Kitzmiller (2006), Mak et al. (2020), Marashi and Hamidi (2018), and Moon (2020), it can be concluded that organizational agility is a concept that enables healthcare organizations to adapt their operations to disruptions and remediate their consequences faster. In practice, healthcare organizations must be prepared for: the adoption of technological changes, the emergence of digital transformation, changes within the healthcare supply chain, disease outbreaks and crises such as the one caused in the healthcare system by Covid-19, changing customer needs, competitor responses, and regulatory guidelines. The agility concept aims to ensure that implementing changes does not require a complete restructuring of the organization.

What organizational agility means for a healthcare organization is easiest to demonstrate based on the evolution of the concept and with theoretical examples from production organizations. Organizational agility initially became a critical factor that points to how competitive an organization is and whether this enables it to survive in more volatile market conditions. After 2000, the importance of agility in the organization also moved to the individual, strategic, and organizational levels. Agility is thus in the second decade of the 21st century. has become a complex research area. It is going about research in the field of agility in areas such as management, business logistics, marketing, computer science, business information systems, digital transformation, and increasingly also healthcare (Stenbeck and Mix, 2019). Hoelbeche (2018) justified the fundamental mission of agility as encouraging the organization to learn and discover changes in the environment as opportunities, respond to them quickly, and use them to its advantage, which gives the organization a competitive advantage in the market. More and more studies are focusing on researching the importance of agility in the service sector, as in our case, healthcare. In 2006, Kitzmiller and co-authors (2006) pointed out that adopting an agile concept in a clinical system improves the implementation of a conventional process implementation plan. Pipe et al. (2012) believe that resilience and agility are increasingly valuable in a healthcare environment that is changing rapidly and unpredictably. Davies and Drake (2007) surveyed home care in the UK. They found that it was only awarded to those providers who met strict criteria and met the selection criteria and were able to introduce significant organizational changes that have resulted in the quality and increased range of services offered and increased agility. Krishnamurthy and Yauch (2007) suggested that it is necessary to analyze essential dimensions in the healthcare field, within which the authors classified social systems, organizational culture, and employee attitudes.

The increasing importance of agility in healthcare organizations and the fact that there are no studies in the field of agile management in healthcare in Slovenia led us to the decision to prepare research that includes a Delphi study on the importance of adopting agile and flexible business models based on the digital transformation of business in Slovenian health organizations.

The fundamental goal of the study is to answer the research question, what organizational changes need to be implemented in Slovenian healthcare organizations to develop the foundations for creating an organizational culture that will enable the emergence of organizational agility in Slovenian healthcare organizations in the future?

The research is focused on organizational adoptions and changes that are necessary for the healthcare organization to become agile. The purpose of this exploratory study is to investigate the consensus among employees in healthcare organizations regarding new pragmatic approaches based on knowledge management that will enable the implementation of organizational culture. The goal of developing and implementing an organizational culture must be based on the fact that it must positively influence the development of the phenomenon of an agile healthcare organization. The emergence of a new organisational culture will also contribute to the efforts of employees, which are necessary to ensure the successful transformation of a healthcare organization into an agile one (Jovanov Oblak, 2022).

## **2 Methodology**

### ***2.1 Delphi study and scenario planning***

Using the Delphi study, we set out to investigate the development of the organizational culture model in Slovenian healthcare organizations until 2027. The very purpose of the research is to obtain insight into the state of the organizational culture and subsequently determine what changes would be necessary for organizations to achieve an agile business model or transform from classic to agile organizations. The empirical results obtained in this way allow us to build a scenario for the most likely future of changes in organizational culture, to ensure the successful implementation of agility concepts in the context of medium-term strategic planning. Created scenarios will serve managers in preparing new strategies and challenging already established ones. Researchers can use the scenarios as a starting point for further studies on the development of organizational culture, which enables and ensures the transformation of a healthcare organization from classical to agile.

As part of the Delphi study, we designed a questionnaire. A questionnaire is based on predicting future scenarios of the development of organizational culture and organizational agility. The future is considered uncertain and often unpredictable. Part of this uncertainty is technological development, which increasingly dictates the speed and pace of organizational change. Thus, there is an increasing need for all stakeholders to manage this change and uncertainty by acquiring new knowledge (Branson et al., 2002). Forecasting studies, however, are complex and, of course, not consistently accurate in depicting the future. They can only try to predict future developments as best as possible (Saritas and Oner,

2004). The basic idea of forecasting as a tool for long-term planning (Courtney et al., 1997) is to guide decision-makers in specific directions within political, economic, socio-cultural, and technological developments and to support them in times of high uncertainty (Powell, 1992). At the same time, forecasting methods should facilitate discussion between decision-makers and current experts to understand better the paths and possible futures that result from technological development and population aging in the field of healthcare.

The questions were sent via the 1Ka platform. Thus, the concrete Delphi study will be based on the statistical processing of collected opinions obtained from employees in healthcare organizations who perform various tasks related to healthcare and are employed at different organizational levels.

The experts answered the questionnaire in two rounds. The goal of conducting two rounds was that the second round would allow for more unified positions. In this case, a study is appropriate because it is based on the search for consensus. Participating experts could independently express their views and give their ideas and proposals. With the help of a questionnaire, in the first round, we obtained the views and opinions of employees in healthcare organizations about the level of agility, the importance of agility, the need and possibility of changing organizations to agile, and the importance of organizational culture in this regard. After the first round of surveying, we analyzed all the data obtained and sent them with a questionnaire to the respondents in the second round. In the second round, the respondents were asked to check the results of the first survey and judge them again. Thus, in the second round, we tried to influence the respondents to unify their answers as best as possible, following the results of the first round.

### *2.1.1 Sample*

15 employees in Slovenian healthcare organizations took part in the survey. Thirteen of them were female, and two were male. Of these, seven were between 35 and 45 years old, four people were between 46 and 55 years old, and four people were between 56 and 60 years old.

The average age of women was 45 years and of men 48 years. The educational structure of the employees was as follows: 1. Bologna level - 7 respondents; 2nd Bologna level – 5 respondents and 3rd Bologna level – 3 respondents.

The structure of the respondents according to their position in the healthcare organization is presented in Table 1.

Table 1 Respondents' workplace

<b>Workplace</b>	<b>Frequency</b>	<b>Percentage</b>	<b>Cumulative</b>
Head of the unit	1	7	7
BA in health care - work with emergency patients at the secondary level of health care	2	13	20
Medical doctor	2	13	33
Administration in a healthcare facility	1	7	40
Work coordinator	2	13	53
BA in health care - in the intensive care unit	1	7	60
BA in health care – specialistic ambulatory	4	27	87
BA in health care - work in the field of endoscopy	2	13	100
Total	15	100	

Table 2 shows the organizational forms in which the respondents are employed.

Table 2 The structure of the organizations in which the respondents are employed

<b>Organizational form</b>	<b>Frequency</b>	<b>Percentage</b>	<b>Cumulative</b>
Hospital	6	40	40
Private health ambulatory with concession	2	13	53
A private medical institution with a concession	7	47	100
	15	100	

### 3 Results

The first scenarios were related to organizational culture agility. The results show that a maximum of 40% of respondents think that it is necessary to introduce processes in their organizations in the next five years that will stimulate organizational changes and learning (acquiring new knowledge). The standard practice must become the managerial acceptance of employee mistakes. Consequently, these changes must lead to greater trust in employees. 27 percent of those polled believe that by 2027 in their organization, it will be necessary to ensure that the importance of the dynamics of development focuses on a growth mindset, using failure for innovation and strengthening resilience. Due to the increasing digitalization of work processes, it will be necessary to focus on the perception of technology in the direction of enabling the increase of human abilities, but not its replacement. It will also be necessary to increase the appreciation of empathy itself. 20 percent of respondents believe that by 2027, it will be necessary for the organization to ensure that the presence of elements of organizational culture, such as fear and lack of communication, which hinder

agility, will be rare, minimal, if not even zero. Management must therefore take care to reduce control over employees and increase their availability and level of cooperation and communication. At least 13 percent of respondents think that in the next five years, it will be necessary to decentralize decision-making in the organization. Respondents believe that making partial decisions should be left (within their professional competence) to agile teams. While the respondents reached a unanimous consensus that in their organizations until 2027, it is not necessary to bring decision-making processes as close as possible to employees and thus increase cooperation between employees.

In the context of the second scenario, we assumed that by 2027 there will come changes in organizational culture competencies. Only these will lead to organisational changes that are important for the growth of the organization and the satisfaction of both employees and customers. 67 percent of the respondents believed that by 2027 organisational processes will have to be transformed. Processes will have to be transformed into easier, less detailed ones and may vary within the organization depending on the context the organization will face. Organizational values will have to become: transparency, learning, openness, teamwork, improvement, ownership, responsibility, self-reflection, and self-leadership and empowerment. 20 percent of respondents believe that by 2027, the development of an agile culture will need to bring a greater focus on people in their organization – which includes customers, stakeholders, and the people who deliver the services. Thus, the importance of creating added value for all stakeholders will come to the fore. Only 13% of respondents think that by 2027 they will have regular or frequent and transparent communication in the organization become a normal phenomenon. In the next five, it will also be necessary to ensure that organizational processes are based on trust with minimal (if any) control and minimal bureaucracy. Measures will thus have to be based on results and not on methods. It will be necessary to establish risk tolerance in the organization. The importance and attitude towards learning and continuous improvement of work processes will also have to increase. None of the respondents believes that by 2027 it is necessary to ensure that organizational goals are expressed as relative and dynamic – the shorter the period, the more variable they will be. This would allow objectives and key results to replace performance indicators. Likewise, no one expressed the need to transform the role of personnel and management in the organization. The roles of personnel and management should go in the direction of coaching. The role of managers should more closely resemble the role of a trainer of agile employees.

In the context of the third scenario, we assumed that by 2027 there will be an increase in employees' willingness to change. Increased readiness will enable organizational changes to occur, which are essential for the growth of the organization and the satisfaction of both employees and customers. All three assumptions received the same number of, i.e., 33% of respondents' suggestions. Thus, the respondents believe that there should be organizational changes in their organizations in the following years as a result of the complexity and variability of the healthcare situation. As well as that by 2027 their organizations will be able to implement the changes necessary to transform into an agile organizations. Thus, the characteristics of an agile organization, such as maintaining solid teams and the breakdown of work, and the transfer of work to teams, will also apply to my organization. And that by 2027 it will be possible to introduce organizational changes and change the organization to an agile one in the following cases: By increasing people's abilities and helping management to change its thinking and the nature of practices paradigmatically. Management must move from management processes that include planning, directing, telling, and coordinating to management that focuses on creating the conditions and establishing bases of practice with which employees can develop skills and competencies within their framework and in a mutual partnership. important to the vision and goals of the organization.

In the context of the fourth scenario, we assumed that by 2027 steps will be taken that will lead to agility in the organization. The establishment and execution of steps will lead to the emergence of agility, which will enable the further growth of the organization and affect the increase in satisfaction of both employees and customers. At most, 47% of respondents believe that by 2027, their organization will transition to agile only if the very top of the organization accepts agility as its goal, and the management team will thus work in a more agile way. The management must stop interfering too often in the work of the departments because by doing so, they can cause a departmental war. All managers at all organizational levels must communicate and work following the commitment to the strategic direction of the organization. 33% of respondents believe that by 2027 the organization will transition to agile, provided that agile transformation will mean not only technological development and adaptation of employees to new technological work guidelines but also the transformation of the importance of employees, who must be defined as human capital (social capital) of the organization in which it is necessary to invest. This will increase efficiency and profitability. As can be seen from the analyzed results, 20% of the respondents

believe that the organization will become agile by 2027 if the management of the organization commits itself to the processes of agile transformation and insists on the implementation of the processes. The results are visible in actual actions. Management will also have to focus more on creating new skill sets for employees. However, none of the respondents predicted that by 2027 their organization would transition to agile if it focused on improving overall results rather than specifically on agile techniques.

In the context of the last, i.e., the fifth scenario, we assumed that by 2027 there will be the implementation of measurements (performance) and evaluation of the implementation of steps that will lead to agility in the organization. Measurements and evaluations will help to increase the organization's growth and make it possible to adopt further organizational changes and adjustments based on the criteria and evaluations of the satisfaction attitudes of both employees and customers, which will make it possible to increase the satisfaction of both employees and customers. Based on the analysis of the results, it can be seen that 40% of respondents believed that by 2027 they will implement the following evaluation criteria in their organization: 1. Indirect cultural indicators based on the survey analysis, including teamwork culture, improvement culture, culture imperatives, a culture of vision and a culture of focus. 2. Analysis metrics include process efficiency (e.g., value-added effort as a proportion of total time). 3. Direct quantitative metrics such as period distribution, replenishment frequency, and release frequency. Likewise, 40% of respondents believed that by 2027 customer satisfaction should become a key criterion in their organization. Satisfaction must also be reflected in their opinions and willingness to return. Another criterion will be employee satisfaction. The third criterion will include an approach to innovative solutions and the introduction of modern technologies. At least 20% of the respondents believed that by 2027 in their organization, if they want to become agile, it will be necessary to ensure a distinction between what "is" measured and what "should" be measured.

#### **4 Discussion and Conclusions**

As part of the study, a Delphi study was conducted among employees in Slovenian healthcare organizations. The goal of this was to enable the acquisition of views and opinions of the respondents based on the questionnaire, which will lead to an answer to the research question, what kind of organizational changes need to be implemented in Slovenian healthcare organizations, to enable the development of the foundations for the creation of an organizational culture that

will enable the emergence of organizational agility in Slovenian healthcare organizations in the future?

However, what needs to be mentioned first, and what this study also shows, is the paradox of Slovenian healthcare organizations, which can be seen in the chaotic state, poor organization, lack of knowledge about management processes and the fundamentals of management, mobbing, burnout of medical staff, increasing staff shortages, waiting for lines, etc. (Fortuna, 2017; Night, 2021). According to Fortuna 2017, Slovenian healthcare is in crisis due to poor management. This leadership crisis results from political staffing and the lack of highly educated personnel in managing healthcare organizations at reputable global universities. Slovenian health care has thus fallen into clientelism, nepotism, and corruption. The commitment to conduct business under international standards for ensuring safe and high-quality medical care, such as the international standard for hospitals AACI and ISO standard 9001:2015, does not help to solve the situation.

The results of our study, which was carried out both in public healthcare and in private healthcare organizations, show that in healthcare organizations, it is not possible to talk about agile processes at this moment, and even less that healthcare organizations are agile. The employees also do not think that healthcare organizations can be defined as attractive to a work environment oriented towards sustainable development at a given moment.

The study results, based on a scenario that should be introduced in Slovenian healthcare organizations in the next five years, show the actual state of Slovenian healthcare organizations in 2022. The results highlight all the shortcomings in the organizations, which, according to the respondents, stem from the management of organizations. Thus, in the framework of the open question, where the respondents were asked to give their views on the processes of agility in their organization, only they gave different opinions. Thus, most individuals find that agility processes are only minimally present in their organization, or that they are still in their infancy, and employees perceive them only in individual moments. The respondents emphasize that it would be necessary to educate the management about agility, and only then would it be possible to hope for fleeting changes. In their opinion, agility processes are necessary for the appropriate development of process implementation because of ever-increasing requirements - digitization, higher quality of work, etc. Respondents further state that their organizations try to be innovative and flexible, but not enough. Although this area is changing slowly with the introduction of new technology, no

investment is being made in educating personnel who could use it. According to the respondents, management should detail how they plan to implement changes regarding agility processes in their organization.

The critical weaknesses of the current management of healthcare organizations are also shown by the fact that as many as 67 percent of the respondents believe that their organizations will have to transform organizational processes in the next five years. The processes must thus become more accessible and more straightforward, not so detailed, and it will be possible to differentiate them according to the context the organization will face at a given moment. It is also evident that, at the moment, the values of healthcare organizations are not based on learning, openness, teamwork, responsibility, and self-reflection; the management and empowerment of employees are also lacking. The ownership of health organizations is also open because a certain degree of privatization of state institutions is also open. This should be based on the co-ownership of employees and not only on health insurance companies. This would solve the complex problem of poor management and thus enable a faster adaptation of the health system to the requirements of solving internal and external organizational challenges (Fortuna, 2017).

The results of the study show that Slovenian healthcare organizations are not agile. This is also indicated by the fact that none of the respondents expressed the need for their organization to move to agile by focusing on improving overall results and not specifically on agile techniques. Indeed, we perceive the need to introduce agile techniques and processes. This can only be introduced through changes in the organizational culture, which must ensure that employees become aware of the importance of agile processes and acquire appropriate competencies that will enable organizational changes and adjustments that will lead to agility in the organization. Here, it is necessary to emphasize that the management of organizations will first have to acquire appropriate skills in the field of agility and then enable employees to acquire the skills necessary for implementing agile processes as part of lifelong learning. This is indicated by the views expressed in the context of the respondents' open questions about the agility of their organization. As part of the analysis of the results of the survey itself, it can be seen that:

- There is a need to promote organizational change and organizational learning in healthcare organizations. It is necessary to ensure that accepting employee mistakes and offering help to employees becomes standard practice. However, we must also emphasize that in healthcare

organizations, it is necessary to ensure the greater trust of the management towards the employees.

- Digitization of work processes requires the management to perceive technologies as a tool that will increase human abilities, not their replacement.
- That empathy is not sufficiently valued in healthcare organizations, which will need to be changed.
- Top management must embrace agility as their goal. It is necessary to stop too frequent interference in the work of departments. All managers at all organizational levels must perform interpersonal communication and work following the commitment to the strategic orientation of the organization.

Within the framework of the study, we thus addressed the issue of agility in Slovenian healthcare organizations and, at the same time, answered the research question, which represents the fundamental goal of the master's thesis. In the end, we must emphasize that it will be necessary to assign a more significant role to agility in Slovenian healthcare, both in the context of scientific research work and in the field of management, the course of operational management processes, the development of human resources and the very attitude of work within healthcare organizations. In the last years, the economic and management literature has primarily stressed the importance of knowledge assets for company's competitiveness. Grounded in the knowledge-based view of the firm, which interprets the NPD as a cognitive process characterized by the use, development, and management of knowledge assets, this paper, utilizing a multi-case studies analysis, stresses the importance of considering knowledge assets as value drivers that can support NPD process performance improvements.

### **Abstract**

This article discusses the growing popularity of software that simulates the energy consumption of buildings, Energy Plus, Insight, Green Building, and Revit. These programs allow you to model and analyze different scenarios to optimize the energy efficiency of a building. The use of biomaterials, such as straw and raw earth, is also gaining traction as a sustainable alternative to modern building materials. The Nebraska-type building system is a self-supporting structural design that uses interlocking blocks of straw bales and wood to reduce materials and energy consumption. The article presents a case study in Querétaro, Mexico, demonstrating the benefits of using bioconstruction with the Nebraska

system. With Revit, a simulation is developed as an analysis-diagnosis using the complement of Energy Plus, Insight, and Green Building. The qualitative and quantitative method is used to contrast the results with the support of the Energy Modeling of Buildings (BIM) program. The double consumption of resources is evident if it is done with traditional materials such as brick and concrete, being less economical, which also means a more significant impact on the environment from its manufacture abortion to annual energy consumption. Bioconstruction consumes 10,670 KWh per year, and conventional construction 24,417 KWh. The results for the simulation were as follows: a) The maximum value of the cooling load was 12,064 W in bioconstruction and 13,479 W in the building with conventional materials b) Maximum value of the heating load for the simulation of bio construction was 11,351 W of consumption was obtained and for conventional construction a consumption of 12,429 W when using the Software described. SolidWorks and the simulation corresponding to thermal analysis are also used to analyze the heat convection of the primary materials used, consolidating the reliability of Bioconstructions. The simulations showed that bioconstruction provides greater thermal comfort than conventional materials. It is concluded that a bioconstruction is an eco-sustainable option that reduces the direct impact on the environment and can be implemented in multiple construction systems based on straw and bamboo for sustainable buildings with low economic cost.

**Nature of proposed paper:** Practical Paper and Academic Research Paper

## 1 Introduction

In recent years, constructions repave represented advances in the area of sustainability. However, their acceptance could be more convincing. This article presents a case study in Querétaro, Mexico using the Nebraska-type building system compared to emerging energy consumption technologies that use the software as monitoring. The Nebraska-type system combines wood and straw to build ecological and sustainable houses, where wood is the prim material straw structures were made of bales by hand de t the strength and flexibility of their intrinsic fibers, which were gradually used in construction from and easy-to-handle packaging that was later industrialized. Its constructive origin is due to the European immigration of the Missouri River that was in a land lacking construction material, such as trees and stone, which abounded in their countries of origin; even the availability of mud for adobe was complicated since they did not have fuel to cook them (Kahn, 1979). It was after the westward expansion due to regulation requiring the construction of permanent housing for land acquisition that the peat clod technique was developed (Kahn, 1979).

This technique was first used in 1846 when Mormons arrived in Nebraska. Peat block construction is based on extracting brick-shaped earth blocks from swampy areas, which are then used to build walls (Kahn, 1979). The result of these buildings is the Nebraska style—a true style—a true stylized by self-sufficiency, used from 1915 to 1940. At the same time, in Europe, thatched roof buildings began in the 20th century and ended at the same time (Nitzkin, 2021). It is believed that the building system came to Europe from Canada first to France, then spread to England, and was used to reconstruct areas after World War I. System o It is still used today with a system of wooden posts and beams, filled with straw and inexpensive means, 2010Itltt is an accessible process that makes it ideal for a self-construction process available to everyone without needing much-bowled knowledge).

In Mexico, buildings form a relationship with context. The physical expression and structure of nature native to Mexico are related to natural resources. The construction methods used throughout the house seemed to result from ancient oral or practical experience passed down from generation to generation. Today the use of emerging technologies through software is a reality compared to simulations of the energy consumption of buildings. Energy Plus, insight, and Revit are complementary and innovative technologies and fundamental tools for planning and managing woncerconcernannual energy consumption in buildings.

An alternative material thermal and acoustic insulator, which works as a moisture regulator. Within the construction, it is a material that adheres easily with clay and lime and has a low economic cost and a low environmental impact.

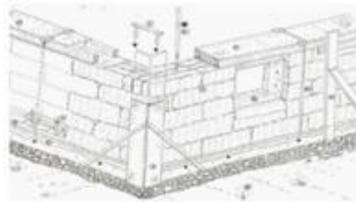

Figure 1. Simonton House, Nebraska 1908. Source: [construccionbalasdepajauax1](https://construccionbalasdepajauax1)

<sup>1</sup> Simonton House, Nebras 1908. In: *Construction with straw bales [web] Spain: Marta Revuelta, 2015 [Accessed 12 May 2016]* Available in: <https://construccionbalasdepajauax.files.wordpress.com/2015/02/simonton-house-nebraska-1908.jpg?w=676> in <https://construccionbalasdepajauax.wordpress.com/2015/07/07/un-poco-de-historia/>

The current green building in the US is not simply a phenomenon. At the beginning of the twenty-first century, it was a movement that represented a set of non-industrialized construction technologies mainly used for residential uses. (Carro Castro, F. 2007)

## 2 Materials

For the manufacture of straw bales for the construction of houses (See fig. 2a and fig. 2b), wheat, spelled, rice, and rye straw are mainly recommended. The straw bales are made in various formats: the smallest have measures ranging from 32cm to 35cm x 50cm x 50 to 120 cm, although the width of 50 cm can be somewhat smaller. In production, balers develop a pressure of between 80 and 120 kg / m<sup>3</sup>; Bales made with lower pressures are unsuitable for construction. Large bales, 70 cm x 120 cm x 100 cm at 300 cm or even more significantly, are more significant for the signification of load-bearing walls since they generate larger wall widths and, because of their greater weight, can only be moved with forklifts. The baling pressure ranges from 180 to 200 kg/m<sup>3</sup>. (Rivero Nogueiras, V., 2016)

Figure 2. a) Nebraska Wall – Maren Termens from the book *Straw Houses*. b) Drawing of corner staple – Maren Termens from the book *Straw Houses*. Source: Romans Torres (2014)

### 2.1 Structural walls

In load-bearing walls, straw bales directly support the roof's weight without any other structural support, such as wooden poles or cement columns. (See Figure 3a). To make the baled walls form a continuous connection between the foundation and the roof plate, tensioners arise from the foundation, pass through

the pass raw bales, and end up tied to the roof structure. That is why this tensor must be firmly attached to the foundation. When tensioners are not used, the viable option is to occupy smooth construction iron rods of 6 or 8 mm. in diameter and 15 cm. (see Figure 3b) (Rodríguez Vivanco, C. 2007)

 Figure 3. a) Stacking of bales, b) Tensile cables attached to the Foundation. Source: *Construction with Bales an Alternative for the Araucanía Region*. Author: Rodríguez Vivanco, C. 2007

## 2.2 Eco-innovation for Today in the Reality of Latin America and Europe

The material we study, packed straw, plays a fundamental role in energy efficiency. Its characteristics make it advisable to place it in areas where you want to limit heat losses, especially in the facades facing north (in the northern hemisphere). In these facades, glazed surfaces should be avoided or limited as much as possible since they represent an area of low gain but outstanding excellence. On the other hand, in the south, you can use larger glazed surfaces or even enclosures with other features such as heat accumulation. (Carro Castro, J., 2006)

The confrontation tradition/modernity is universal and is reflected in the change of the roofs of the houses. According to A. González (2001) "*The traditional, the pre-industrial past is considered before the arrival of capitalist material culture as a symbol of opprobrium that must be denied.*"

## 3 Methodology

For this case study, energy efficiency is measured in four phases. The first three are empirical, and the fourth is theoretical-practical. The first phase: Starts with brick walls and straw walls, which are planted on a stone base, and joined with

clay mortar, lime, and sand, to later stack them together and give the function of the load-bearing wall with a thickness of 0.50 meters. In the second phase: it is used as a coating gypsum made with raw earth, clay, water, and organic waste. In the third phase: A bamboo structure based on the geometry of a dodecagon is used to distribute the loads towards the load-bearing walls made of straw, unifying the bamboo sections; Potential problems related to water runoff and natural lighting are also resolved. In its last phase, a simulation is developed as an analysis-diagnosis through the complement of Energy Plus, Insight, and Green Building, with Revit, where the qualitative and quantitative method is used.

### ***3.1 Modeling and Configurations in Software***

It is essential to configure the modeling and configuration of materials for Revit software such as SolidWorks, yielding data for analysis and digital interpretation in favor of good contains preconfigured materials, facilitating and streamlining the development of any modeling. SolidWorks lacks preconfigured sustainable materials; however, it has a section benefiting from the development simulation regarding the convection of the heat flow of the materials used.

Revit and SolidWorks were used for this case study, modeling two buildings simultaneously with different materials; the first model was with a conventional system and materials in Mexico, such as brick and a concrete slab. The second model uses the Nebraska-type system based on straw bales and bamboo.

Regarding the SolidWorks Software and the directed orientation, the same methodology will be used for modeling as Revit; the only difference will be the orientation of the study, focusing on the efficiency of heat convection in both construction systems covering the roofs of the models with bamboo and a concrete slab, concerning walls the models will be simulated one with solid brick and the other model with straw bales again using Revit. The forum software above buildings simulates the materials that make up each construction system to be studied to obtain an analysis of the energy consumption of the building. Figure 4 shows the methodology developed to elaborate from the modeling in three dimensions, its configurations, and parameterizations to reach the results of the simulations using the different software, complements, and plugins to obtain desired results.

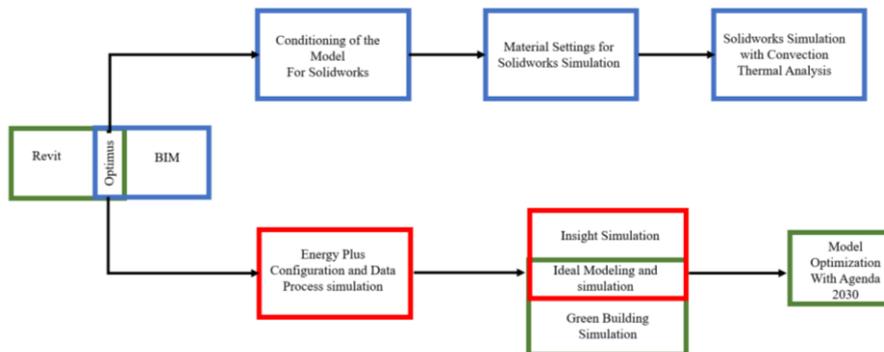

Figure 3. Methodology for modeling and simulation processes. Source: Authors.

### 3.1.1 Revit and BIM

For the modeling of any building and to carry it out properly, it is necessary to analyze the project, know the material and construction systems, and make their configuration in the software, obtaining an ideal modeling configured entirely with BIM. For this article, a building was modeled in duplicate, one model using Biomaterials and another using construction materials for conventional use in Mexico. Some materials were found preconfigured in the factory software, and others were configured manually, above, due to their non-existence in the software and the need to complete the BIM modeling of both mod; Figure 4, the "bamboo" material is shown, configured in Revit. In what corresponds to the constructive materials of conventional use in Mexico, the software has all the required materials preconfigured, streamlining the workflow for this type of boatbuilding its BIM modeling in Revit, in Fig. 5, the material "Brick", pre-established in Revit, is shown. Figure 4 shows the "bamboo" material, edited manually in Revit.

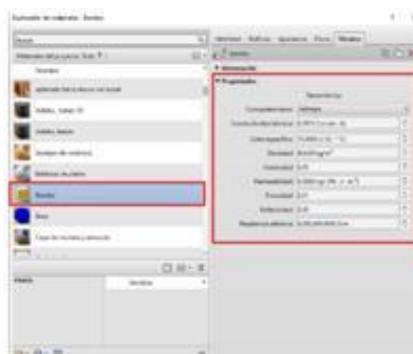

Figure 4 Bamboo Configuration

Table 1 shows the structure of both models to be developed and organizes them correctly according to each construction system.

Table 1 Materials and Process to both Models

<b>Building area</b>	<b>Conventional system</b>	<b>Nebraska-like system</b>
Foundation	Stone masonry foundation fathoms to 80 cm depth glued with mixture Cem. Arena Prop 1:4:5	Fathom stone masonry foundation 80 cm deep glued with lime-sand mortar prop 1:3
Walls	Capuchin wall of annealed red partition 30 cm thick, glued with mixture cem-cal-sand prop 1:3:5	Straw bale 45 x 60 x 90
floors	Jalcreto firm, jal-sand-lime prop 1:5:6, cement leveling paste sand ceramic floor, glued with gray adhesive.	Floor system opus signum based on earth and ceramic pieces and sealed with linseed oil.
Covers	Reinforced concrete slab and lock 12 cm thick, finished with shade brick and waterproofing top 10 Comex.	She is armed with a bamboo structure with a crushed bambosheetset, polyurethane foam as insulation, natural wax, and linseed oil to waterproof the cover.
windows	1st pine wood frame and 6 mm tinted glass, shaft, and structural wood girder.	1st pine wood frame and 6 mm tinted glass, shaft, and structural wood girder.
Doors	Shaft and girder of structural wood, wooden frame, and wooden stave.	Shaft and girder of structural wood, wooden frame, and wooden stave.
Initial coating (walls)	Flattened based on cement mortar sand, prop 1:4	Flattened earth base with long straw and horse or cow manure.
Final coating (walls)	Multiple kinds of pasta from Cemex finished stucco.	Pasta based on sifted earth, quicklime, and cactus slime with natural dyes.

### 3.1.2 SolidWorks and Sustainable Materials

The SolidWorks software is software designed for the modeling of parts for physical/mechanical analysis in the present study, the same building developed in Revit was modeled in duplicate for the thermal analysis of heat convection through a heat power induced at one end of the materials, simulating the model with the materials of the traditional type system, as well as the biomaterials of the model in Nebraska type system. The software does not have a wide range preconfigured to use and simulate like Revit software. Figure 5 shows the selection of the type of study and configuration of materials in SolidWorks concerning their physical/mechanical properties.

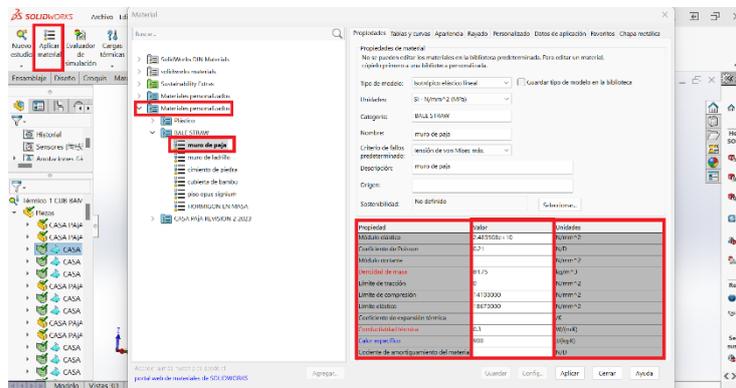

Figure 5 Configuration of Materials in Solids Works.

Regarding the properties of Elastic Modulus, Shear Modulus, Mass Density, Compression Limit, Elastic Limit, and Thermal Conductivity of Bamboo, the results of Martínez García (2015) were used. Also, Viera et al.'s (2020) results were used for the simulation, comprising the Elastic Modulus, Poisson Coefficient, Mass Density, Compression Limit, and Elastic Limit. The properties that were used for the simulations of the annealed red brick were; Elastic Module, Shear Module, Mass Density, Compression Limit, Thermal Conductivity, and Specific Heat products obtained by Sánchez-Tizapa et al. (2013), and for the mass concrete, the simulation was developed with the Mass Density, Thermal Conductivity and Specific Heat published in the CONTART 2016 ("Thermal and Acoustic Properties in Walls and Projected Earth Coatings and their Compliance in the CTE", 2016).

### 3.2 Parameters and Simulation of Models with Software

In order to perform any simulation, regardless of the software to be used, the different methodologies developed to obtain the results to be needed must be understood; the above depends on each software, its needs, and requirements. Revit and Solidworks use different methodologies for their configuration, parameterization, and production of results, which range from the use of weather stations and their information, as well to mathematical models and advanced mathematics such as the finite element method, each software, and its development is described below.

#### 3.2.1 Revit and Energy Plus

When modeling and configuring materials in Revit (BIM), it is possible to use the Energy Plus add-on to create the different "zones" to be analyzed energetically and concerning the square meters of the building without taking

into account the users who would use the spaces or "zones" previously defined, as shown in Figure 6. This is essential for the production of data and information regarding the model and its volumes to later use the Insight or Green Building plugins. Once the above is done, it is imporessentialelect a weather station, preferably the closest to the study area,s o that Revit and the associated servers can perform the corresponding analysis; Figure 7 shows the weather station used for this work.

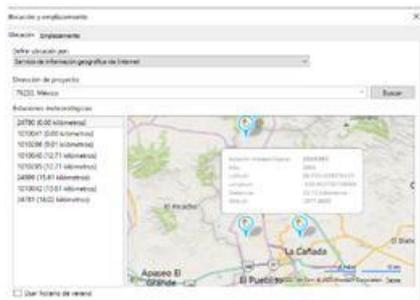

Figure 6 Selection of Weather Station for the Simulation

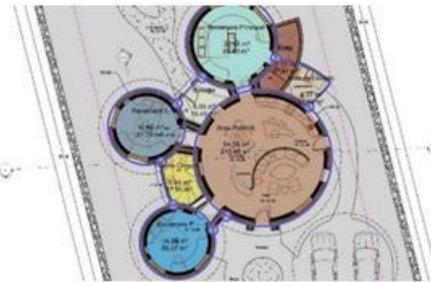

Figure 7 Classification of "Analysis Zones in Revit"

### 3.2.2 Simulation with Insight and Green Building

Having the tabulators of spaces, energy zones, and consumption generated by Energy Plus with the Revit BIM model develops the simulation of Insight and Green Building to obtain energy consumption considering the spaces and energy "zones" occupied by inhabitants; the above is shown graphically in Figure 8. Insight performs analysis templating the energy costs of the building concerning materials, orientations, type of windows, and sun and hand as the comparison between the energy models analyzed or previously modeled. According to Insight for Revit, the 9th section shows the recommended suggestions for making the building more efficient.

Figure 8 Analysis areas designated for calculation1

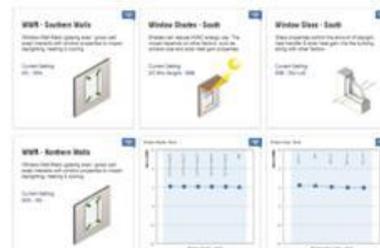

Figure 9 Software recommendations for improving model performance

### 3.3 Simulation of Thermal Analysis in Solid Works

Having the model made, the materials configured and saved in SolidWorks, the simulation corresponding to "Thermal Analysis" is configured, and the configuration of the necessary parameters for it is carried out, these being those shown in Fig. 10

Materials are only assigned to elements that theoretically have that component; then, the model is taken as a fixed union by the type of model to be simulated. The parameters of "loads" are assigned these the heat output on the inner surface of the material and the outside as convection in order to simulate the heat convection efficiency of the materials, performing four simulations in total concerning two different systems and construction materials, the first; A construction with traditional materials, using the concrete slab cover and solid brick walls 0.50 cm. thick, to obtain the convection data of the material. The second, with the same model but with biomaterials, simulated the cover covered bamboo and the walls with a Nebraska straw wall of .50 cm thick. The configuration for all simulations follows the same order described above, shown in Figure 11 and enclosed in red; only the parameters of the materials for convection analysis change using heat load shown in tTable2 to obtain results.

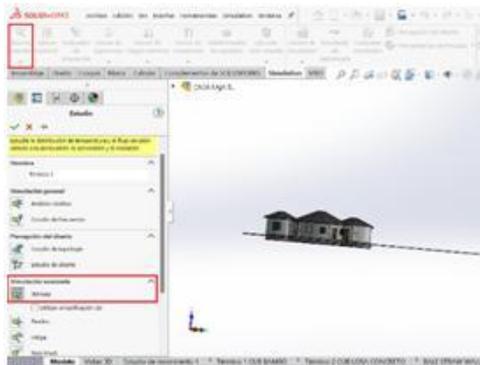

Figure 10 Analysis Type Selection in Solid works

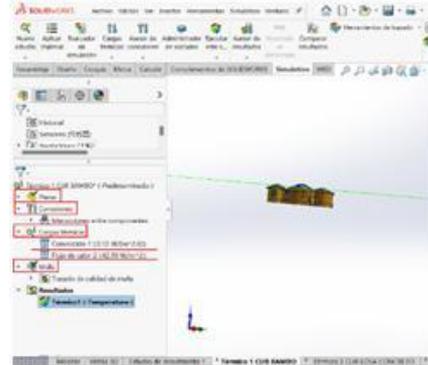

Figure 10 Configuration of simulation by Convection

The differences in the configurations only cover the parameters of the materials for convection analysis using a heat load shown in Table 2 for obtaining results and a simulation time of 5 seconds with the preset heat flow for 5 seconds and sampling every .5 seconds, respectively.

## 4 Discussion and Results

### 4.1 Revit and Energy Plus

Once the energy simulation and analysis have been carried out, Energy Plus and Revit produce several results, among which the energy load stands out, showing the quantities in a unit of Watt necessary to cool or heat the model, shown in Table 3, in addition to the general energy analysis producing as a result of lower energy consumption the Nebraska type construction system compared to the conventional system according to the simulation executed in the software described above, shown in Table 3.

Table 3 General energy consumption of both model systems.

<b>General Energy Consumption of both Buildings by Energy Plus</b>		
Type	Parameters	Watts
Nebraska System	Total maximum refrigeration load value	12,064
	Total maximum heating load value	12,429
Traditional System	Total maximum refrigeration load value	13,479
	Total maximum heating load value	11,351

## 4.2 Insight and Green Building

Once the Energy Plus analysis is done, it is possible to simulate with Insight which produces the energy cost for the traditional system in dollars per m<sup>2</sup> per year. Also, the simulation provides recommended suggestions based on the analysis of model information for the use of solar energy and natural ventilation to improve the performance and use of natural resources, all based on model information, information from the nearest weather station, and information provided by Energy Plus, this is shown in Figure 11a.

Figure 11a. Insights cost results and optimization suggestions.

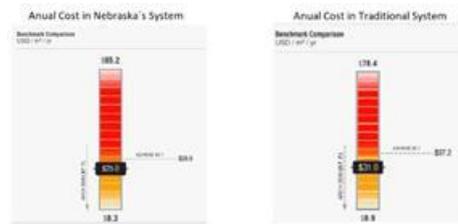

Figure 11b. Comparative analysis of the energy costs of both Systems

Based on all the above, the results of the simulation are produced, and a comparative review of the Nebraska and conventional construction systems Ares made on the costs of using the building in dollars on an annual basis, Figure 11, shows the annual costs of the simulated buildings for a better appreciation of the results produced.

Concerning Green building, it also shows an analysis of actual annual total costs from the analyses produced by Energy Plus, producing through formal tabulators and without the possibility of adopting improvements to the model and its conditions, the annual energy costs of the model, CO<sub>2</sub> emissions, life cycle of electrical energy, etc. A comparative analysis of the simulations produced for both modeled systems and their annual costs is carried out. (See Table 4)

Table 4 Overall results and costs of both systems.

Global Results of Green Building Simulation		
Parameters	Nebraska's System	Traditional System
Energy, Carbon, and Cost Summary	\$2,532	\$4,634
Annual CO <sub>2</sub> Missions	5.7 mg	7.5 mg
Lifecycle Electric Energy	10,670 KWh	24,417 KWh
Annual Energy	1,763 MJ/m <sup>2</sup> /year	2,049 MJ/m <sup>2</sup> /year

Green building also quantifies energy costs, building, CO2 emissions, energy life cycle, and energy uses in the building graphically, corresponding to the simulations developed and the information collected; figure 12 shows the information described above graphically for the Nebraska System.

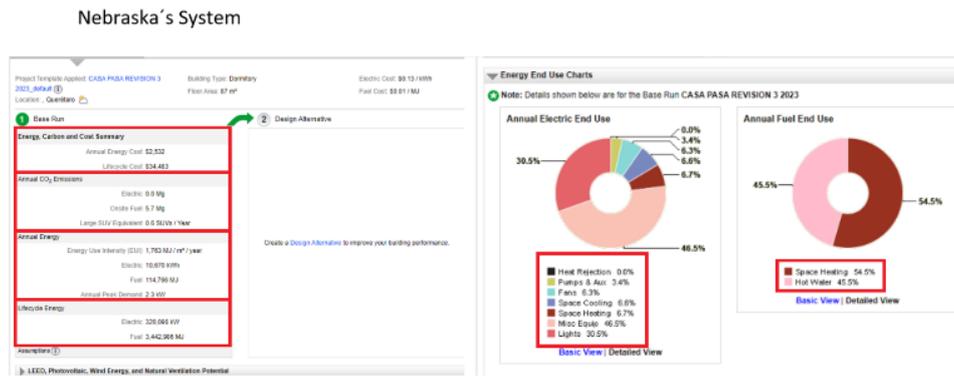

Figure 12 Green Building Energy Cost and Consumption Results for the Nebraska System

It is also possible to appreciate the results obtained for the conventional system graphically, shown in Figure 13.

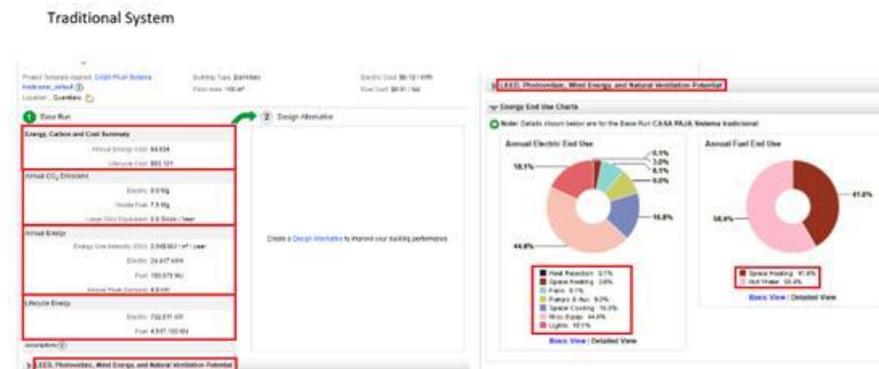

Figure 13 Cost and energy consumption outcomes of green building for the traditional system.

### 4.3 SolidWorks

The product of the four simulations carried out in SolidWorks is represented by the Software quantitatively and graphically; the simulations configured as heat power are executed in an analysis in time, showing the temperature that the material would arrive under the assumption of constant flow without any logical, physical reaction of the simulated material, obtaining very high or shallow measurements. However, this result does not affect the purposes of this research

due to the interest in analyzing the simulation and specifying the convection properties of the simulated materials, regardless of whether walls or roofs. Figure 14 shows the simulation of the bamboo roof.

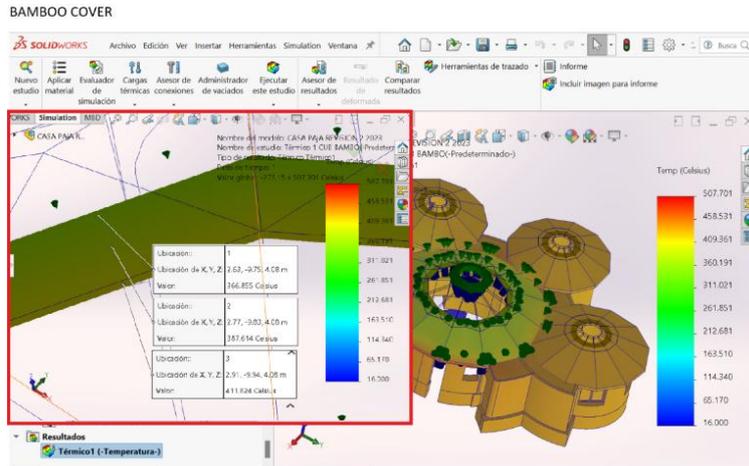

Figure 14 Results of the roof bamboo simulation.

The roof with a concrete slab is shown in Figure 15, representing quantitatively and graphically in color scale the results of the convection analysis in the simulation.

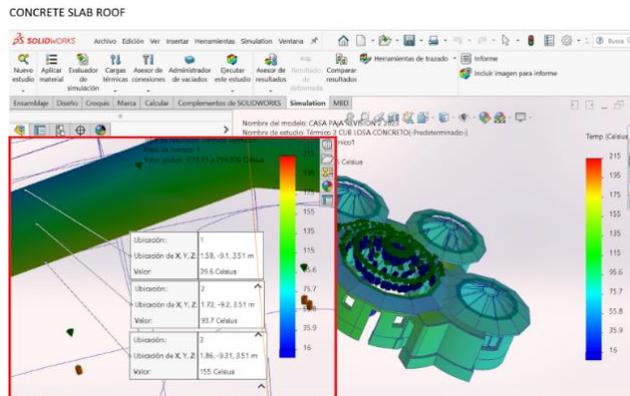

Figure 15 Results of the simulation of the concrete slab roof.

Regarding the simulation of materials in walls for the Nebraska system they are shown in Figure 16.

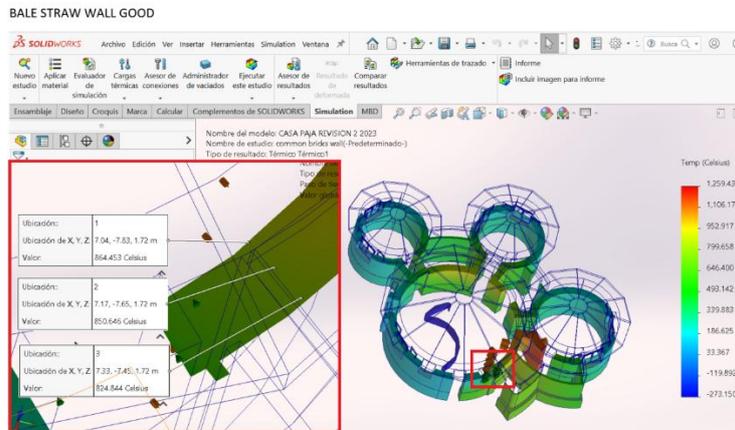

Figure 16 Results of the bale straw wall convection simulation.

Finally, Figure 17 shows the results obtained in the simulation of the conventional system with brick wall and its results of convection analysis.

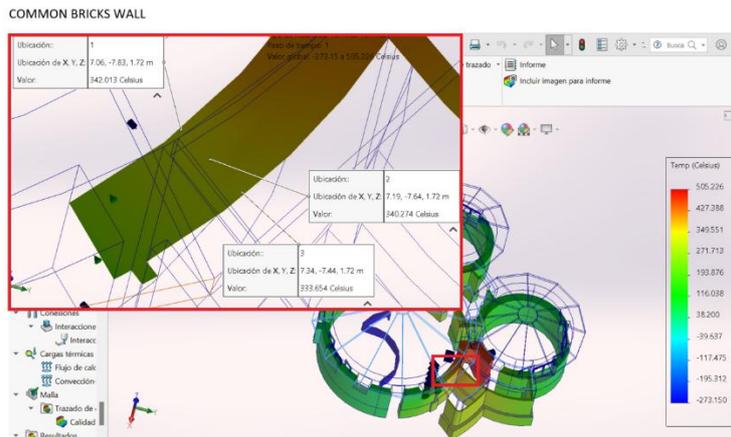

Figure 17 Results of convection simulation of common brick walls.

Table 5 shows the results of all the simulations developed in SolidWorks, enabling the comparative analysis between them and the convection efficiency of the materials proposed in the multisided systems.

Table 5 Overall results and costs of both systems.

SolidWorks measures of convection analysis simulation on materials					
Analysis Section		Material	Measure 1	Measure 2	Measure 3
Walls	Nebraska's System	Bale Straw	864.453 °C	850.646 °C	824.844 °C
	Traditional System	Common Bricks	342.013 °C	340.274 °C	333.654 °C
Covers	Nebraska's System	Bamboo Cover	366.855 °C	387.614 °C	411.824 °C
	Traditional System	Concrete Slab Roof	39.6 °C	93.7 °C	155 °C

## 5 Conclusions

In the present research, it was used and diversified in software and methodologies. Regarding Revit and Energy Plus, they offer the possibility of generating a BIM model and its quantification, making time and resources more efficiently. Insight and Green Building complement the study, based on the data generated between Revit and Energy Plus, theoretically obtaining the energy expenses and costs of the model generated when conditioning the spaces by heating or cooling. Concerning the recommendations of Insight, they are interesting for obtaining better thermal comfort and use of natural lighting and ventilation, reducing the consumption of resources shown in the tabulators and comparisons of this work. Although designed for modeling and simulation of industrialized parts, SolidWorks was functional for the expected result. However, it involved more work time to use it due to the configuration of custom materials; however, when simulating the convection of the materials, high temperatures occurred in both bamboo and straw bales, checking the high heat propagation in the materials for their thermal characteristics, Benefiting the model concerning natural thermal comfort and consequently to the environment, due to the type of material theoretically used.

### Abstract

This paper aims to explore the interconnection between megatrends analysis, future research, and the role of think tanks. Think Tanks are presumed to drive megatrends discourses and make significant contributions to future research and strategic foresight. However, relatively little attention has been paid to think tanks explicitly or implicitly working on megatrends and future research. This paper analyses discourses on megatrends and looks at the evolving global landscape of think tanks. It shines a spotlight on seven think tanks from different countries and world regions that apply diverse strategies of knowledge dissemination and policy advice. Policymakers, business leaders, and asset managers have shown a growing interest in megatrends analysis and future research which is leading to increased visibility for some think tanks. Furthermore, the dynamics of international cooperation and geopolitical developments have also contributed to the expansion and growing diversity of the think tank landscape, including in the Global South.

**Keywords** – megatrends, future research, think tanks, strategic foresight, policy advice.

**Paper type** – Practical Paper

## 1 Introduction and methodology

The main objective of this paper is to improve the understanding of the dynamic discussion around megatrends, as well as the essential characteristics of future research. Additionally, the paper seeks to highlight the contributions of think tanks in fostering future literacy and conceptual frameworks addressing major challenges for humanity.

Academic literature that is reflecting on the role and challenges of think tanks is relatively limited. One of the more recent books is an edited volume by James McGann (2021) who has been in charge of the flagship reports of the Global Go To Think Tank Index (GGTTI) of the Think Tank and Civil Society Programme (TTCSP) hosted by the Lauder Institute at the University of Pennsylvania for many years but ending in 2021 (TTCSP, 2021). McGann invited leading think tank professionals to reflect on critical issues affecting the work of think tanks. The reflections of some authors of the book are worth quoting to introduce the relevance of the topic and the opportunities and challenges think tanks currently face.

*“Often, academic work is far away from political realities. It can also be unsuited in its approach if it ignores institutional, legal, and governance constraints. Therefore, think tanks can play a role in translating findings as well as practicing applied research with a more policy-oriented focus that complements more academic work” (Wolff, 2021: 54)*

*“Midway between academia and politics, these centres of thought have transferred rigorous studies to political praxis, both in terms of public discourse and policy. But is this link still valid at times of increased political contestation and of traditional power structures?” (Morillas, 2021: 59)*

*“Think tanks are currently caught in a paradox. From environmental and climate injustice, to extreme inequalities and global pandemics, the world faces an extraordinary set of challenges that think tanks can contribute significantly to addressing. Yet, they must do this at a time when profound disruptions such as rapid technological advances, shifting centres of global power, decreasing levels of trust in experts, democratic disorders, and fake news are providing a myriad of new threats and opportunities that challenge the ways in which they currently operate.” (Leach, 2021: 107).*

To begin, section two of this paper explains how megatrends analysis, future research and strategic foresight relate to and complement each other in understanding future developments while also pointing to some features which distinguish them from each other. Section three of this paper discusses the

definition and the evolution of megatrends analysis and future research and explores how megatrends discourses and future research gained traction over the past decades. Section four defines think tanks and comments on the evolution of the global landscape of think tanks. With a purpose to illustrate the work of think tanks related to megatrends and future research in different ways, section five introduces seven diverse think tanks from different countries and world regions which either explicitly or implicitly engage in megatrends analysis and future research.

This paper seeks to fill a gap in academic literature by analysing the evolution of megatrends and future research which has received limited attention. The limited interest of the profession to document and analyse its historical evolution could probably be attributed to an inherent preference of megatrends experts and futurists to looking forward rather than backward.

This paper references landmark publications in think tank analysis, particularly the TTCSP's "Go To Think Tank Report" series (TTCSP 2021), which maintained a global database of over 8,200 organisations from various countries and regions but is currently discontinued. It is referenced by leading media, especially in the United States of America (U.S.) (Chafuen/Forbes, Feb. 15, 2021).

The rankings are based on surveys. The list of almost 4000 voters includes university faculty and administrators, journalists, policymakers, think tank players, and donors. TTCP data set does not include a category for think tanks working explicitly on megatrends or engaging in future research. Furthermore, this paper gathers diverse evidence from various other sources to demonstrate the rising attention paid to megatrends analysis and future research and the growing number and diversity of think tanks in various parts of the world. Evidence includes academic papers, reports, and interviews with experts.<sup>1</sup>

The methodology also includes semi-structured interviews with leaders of various think tanks in different countries and world regions. While it is not a representative sample, attention was paid on criteria of diversity. Interviewed think tanks included organisations from different countries and world regions and organisations of different size and thematic focus. The interviews cover organisations with an explicit focus on megatrends and future research, while we

---

<sup>1</sup> We have also made inquiries on the influence of megatrends discourses and think tanks to ChatGPT, an artificial intelligence language model developed by OpenAI (ChatGPT, Version March 14, 2023). We are aware of the ongoing discussion in academia to ban the use and citation of ChatGPT in academic works. We believe that the discussion has not come to an end. While we refrain from quoting our inquiries in the main text of this paper, we would like to draw attention that ChatGPT response are currently biased toward mainstream U.S. American think tanks as ChatGPT collects its artificial knowledge and intelligence from big data analysis and the large majority of openly available reference to think tanks is found in the U.S.

have also included some others which do not explicitly use such frameworks, but are in fact doing analysis that is relevant to megatrends and future research discourses. Interview partners were also selected on the basis of their expressed interest in participating in the project.

## **2 Megatrends, future research, and strategic foresight**

Megatrends, future research, and strategic foresight are interconnected and can provide a comprehensive understanding of future developments. However, there are also notable differences between them. While megatrends analysis is more explicitly based on factual data, future studies and strategic foresight rely more on methodologies that involve specific expert input and the use of tools like horizon scanning, road mapping, and scenario development.

Megatrends analysis focuses on identifying major trends and forces that will shape the future over the next decade and beyond, including how these trends intersect with one another. This approach aims to provide deep insights into the dynamics of global trends based on the analysis of data, discourses, and agendas of influential political, academic, and business institutions, social forces, and the media. On the other hand, future research is primarily focused on methodological approaches to forecasting, such as horizon scanning, scenario development, backcasting, and predictive modelling. Both address challenges for humanity and aim to create awareness for the relevance of future literacy.

Strategic foresight, meanwhile, is a more proactive approach to preparing organisations, companies, groups, or individuals for change. It involves a structured and systematic process of exploring and creating possible futures, and developing robust strategies and plans that can handle a range of different scenarios. Strategic forecasting is influenced by a variety of tailor-made business approaches of different organisations and companies, which makes it difficult to generalise on its significance for addressing challenges for humanity and promoting the common good.

## **3 Definition and evolution of megatrends analysis and future research**

Global megatrends are trends that strongly influence different spheres of life in many countries and at different levels, covering political, economic, natural environmental, social, and cultural dimensions. They describe large-scale, long-term shifts with wide-reaching effects across different localities and world regions

that attract attention from global leaders in politics, business, academia, media, and social affairs.

In their book “Global perspectives on megatrends” Kuhn and Margellos (2022) applied five criteria to prioritize big trends: (1) level of coverage by research activities, (2) level of political attention, (3) level of interest to global investors and business communities, (4) level of media coverage, and (5) attention paid by social movements. They adopted a comprehensive, global approach to megatrends, including political and social trends, such as rising inequality and migration.<sup>1</sup>

Figure 1: Pentagon Model Global Megatrends (Kuhn & Margellos, 2022).

John Naisbitt was a pioneer of megatrends and future studies. His book “Megatrends: Ten New Directions Transforming Our Lives” was first published in 1982 (Naisbitt, 1982). It focused mainly on the United States but also attempted to present a global outlook. Naisbitt accurately predicted the change from industrialized to information societies. Megatrends was published in 57 countries and sold more than 14 million copies. Subsequently, Naisbit worked for several academic institutions and founded the China Naisbit Institute at Tianjin University in China in 2009.

<sup>1</sup> The 12 megatrends identified in the book are: climate action and sustainability; digitalization; inequality; demographic trends, urbanization and smart cities; health and nutrition trends; green economy; sustainable finance; multipolar world order and the future of multilateralism; democracy and governance innovations; civilizational developments (diversity, individualization and loneliness, gender shift, and identity politics); and migration (Kuhn & Margellos, 2022).

Today, a large number of academic institutions, think tanks, researchers and analysts engage in learning, analysing, and forecasting future developments. Asset managers of many big investment funds show a keen interest in megatrends research. Major consulting firms, including McKinsey, PwC, Deloitte, Roland Berger and many others as well as major think tanks like the World Economic Forum, Bertelsmann Foundation and Brookings conduct rigorous analyses of global risks and trends. Many other non-profit institutes, individual experts, but also international organisations like the International Labour Organisation (ILO) and national-level Ministries engage in future research. Megatrends and future research are also of vital interest for multinational corporations and asset managers. The German car-manufacturer Volkswagen runs a unit staffed with 27 future research experts. The number of academic publications on megatrends and future research has been steadily increasing over the years<sup>1</sup>, as has the number of consulting firms and other organizations using foresight and scenario planning. We have also observed a growing interest in future-focused events and a rising popularity of foresight and scenario planning.

Though not explicitly related to megatrends, the United Nations 2030 Agenda for Sustainable Development and the 17 Sustainable Development Goals (United Nations, 2015) exhibits strong connections to megatrends discourses and is worth mentioning because it attracts widespread attention by think tanks and futurists. The 2030 Agenda covers aspects of economic, social, and environmental development and stresses the importance of multi-stakeholder partnerships at different levels (SDG 17). The 17 Goals were adopted by all member states of the United Nations in 2015. The German Agency for International Cooperation, die Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ), states that "Global megatrends provide the backdrop for the 2030 Agenda for Sustainable Development. (GIZ, 2017).

The differences between the 2030 Agenda for Sustainable Development and megatrends frameworks lie in the degree of formality. The 2030 Agenda has been adopted by states and consists of detailed and hierarchically-structured goals and processes, including defined roles of custodian agencies and formal arrangements for monitoring and reporting on 232 indicators associated with 169 targets. The megatrends framework is more fluid and anarchical and focuses more on opportunities rather than highlighting problems or pointing to deficits, especially when used by consulting firms.

---

<sup>1</sup> According to Web of Science, the number of articles published on the topic of "megatrends" has more than doubled from 2010 to 2021.

#### 4 Definition and evolution of think tanks

The term think tank was first used in military jargon. According to Ladi (2023) it was first used during World War II to describe a safe place where plans and strategies could be discussed. There is no uniform definition, and the meaning has changed over the past decades, especially in the context of the proliferation of private non-profit policy research organizations in the United States. The Merriam-Webster Dictionary describes a think tank as “an institute, corporation, or group organized to study a particular subject (such as a policy issue or a scientific problem) and provide information, ideas, and advice” (Merriam Webster Dictionary, 2022). The United Nations (2014) has published a report, “Thinking the Unthinkable: From Thought to Policy—The Role of Think Tanks in Shaping Government Strategy.” Which refers to the increasing complexity and technical nature of policy problems, which play in favour of think tanks aiming to become more important in influencing policymaking.

However, “*what matters is not the label but the function, or functions, that think tanks fulfil*” (Mendizabel, 2021). Think tanks typically conduct research, engage in policy dialogue activities, and provide advice. More specifically, “they inform and educate decisionmakers and the public, promote ideas, advocate for change, hold decisionmakers to account, train the next generations of decisionmakers and create and nurture spaces for informed debate on matters of public interest” (Mendizabel, 2021: 1). In many countries, especially in the United States and in the United Kingdom but as well as at the level of the European Union, think tanks have developed into prime actors shaping agendas of policymakers and influencing decision-makers in business and finance. While it has been acknowledged that focused intellectual groups have played an influential role in governance for centuries (royal courts, elite societies, and business clubs, for example), think tanks are considered “a distinctly 20th century invention.” (Barham & Barham jun., 2021, 1).

The Center for China and Globalization (CCG), a leading think tank in China and well-networked in the global think tanks community, describes the function of a think tank as follows:

*“Through research reports, seminars, forums and meetings, as well as symposiums and proposals, think tanks play a role in setting agendas and conducting policy interpretation and research in the public arena. They also reflect public opinion and provide policy recommendations to the relevant government agencies through national consultation and democratic mechanisms.” (CCG, 2021)*

Think tanks are sometimes perceived as elitist lobby organisations whispering recommendations to policymakers. Rand Corporation in the United States or Chatham House in the United Kingdom are two examples who have contributed to such images of think tanks among the general public in Germany and other countries. Whether or not think tanks are considered elitist organisations can depend on various factors such as their funding sources, their areas of focus, and the level of access they have to policymaking processes. Some argue that think tanks are elitist organisations because they are often funded by wealthy individuals or corporations, and their research and policy recommendations may not always align with the interests of the general public. Additionally, some think tanks may have a limited pool of experts who come from elite academic backgrounds or have ties to political elites. On the other hand, we have witnessed a proliferation of think tanks staffed with experts from diverse backgrounds which provide valuable research and analysis to help inform policy decisions. Many think tanks also prioritize engaging with a broader range of stakeholders and the public through events and publications. While recognising the growth of the think tanks sector, it is important to understand that the analytical capacity of many think tanks often depends on one or a few leading experts. In the field of future studies, the Association of Professional Futurists (APF) was founded in 2002 and has more than 500 members which act as analysts, consultants, and speakers and are affiliated to diverse think tanks, University departments and consulting firms.

Typologies of Think Tanks have been proposed by, among others, Weaver and McGann (2000) and Thunert (2006) who distinguished between (1) Academic Think Tanks, (2) Advocacy Organisations, and (3) Party Think Tanks. For example, in Germany, as in many European and Asian countries, academic think tanks are the dominant group while in countries of the Anglosphere private think tanks which are registered as nonprofits play a more important role. Such findings of Thunert (2006) on the difference between the think tank landscape in continental Europe and countries of the Anglosphere is still valid according to our observations and talks with experts. private advocacy organisations play a less significant role than in countries of the Anglosphere (Thunert 2006). In Germany, political foundations also play a significant role. They are affiliated to parties represented in the German Parliament and are largely funded by the Government and exercise different functions, including implementation of development cooperation projects as well as managing scholarships. For example, Konrad Adenauer Foundation which is affiliated to the long-time ruling Christian

Democratic Party (CDU), calls one of its five departments, the Department Analysis & Consulting, a “think tank” while considering itself “more than a think tank”.<sup>1</sup>

While the authors’ own observations and exchanges with experts suggest that most established think tanks, are not much affected by the burgeoning megatrends discourse and analysis of future scenarios, there are some notable exceptions, such as the Bertelsmann Foundation in Germany, a leading private think tank, which has set up a Future Challenges team and publishes on megatrends (Bertelsmann Foundation, 2020).

More recently, we see a trend that non-profit organisations engaged in policy-oriented work prefer to work under the label of think tank rather than advocacy-organisations because advocacy work, especially involvement in campaign work, has become under scrutiny from government administration and courts in some countries, especially in the Global South and when it involved foreign funding. India and China are prime examples for this development. However, even some advocacy non-profit organisations in Western Europe face legal challenges. The Association pour la Taxation des Transactions financières et pour l’Action Citoyenne (Attac), an activist organisation originally created to promote the establishment of a tax on foreign exchange transactions, lost its tax privileges in Germany due to its involvement in political work (Beck Aktuell Januar 28, 2021).

The TTCSP (TTCSP 2021) has published the most authoritative report on Think Tanks over many years until the project was discontinued around the year 2021 when lead author James McGann tragically passed away. The TTCSP’s GGTTI Report was designed “to identify and recognise centres of excellence in all the major areas of public policy research and in every region of the world.” (TTCSP, 2021). The report provides the following definition of think tanks:

*“Think tanks are public-policy research analysis and engagement organizations that generate policy-oriented research, analysis and advice on domestic and international issues, thereby enabling policymakers and the public to make informed decisions about public policy” (TTCSP, 2021).*

The number of think tanks included in the TTCSP GGTTI database has increased steadily over the years, from just over 5,000 in 2012 to over 8,000 in 2020. Growth was also significant outside the U.S. which still hosts by far the largest number of think tanks of any country in the world. Barham (2021, 2023) published a list of the most influential think tanks in academic influence which includes only one

---

<sup>1</sup> Talk with Ariatani Wolff, a KAS scholarship holder on March 30, 2023.

organisation in the U.S. among the top ten. Brookings, The Heritage Foundation and the Council on Foreign Relations (CFR) top the list.

We have witnessed a growth of think tanks in the Global South, especially in emerging markets and in countries which are looking to assert themselves in international relations. The Chinese government started to promote think tanks with Chinese characteristics soon after Xi Jinping took over as President in March 2013. Most Chinese think tanks are affiliated to single Ministries, but there are also more independent think tanks registered as non-profits and working on a variety of issues, with different Ministries and government agencies, especially on global issues. Xue, Zhu & Wanqu (2018) argue *"that the success of Chinese think tanks has been driven primarily by greater official recognition of their value, due to increasingly complex domestic and international problems stemming from a fragmented decision-making system...consequently, by late 2015, the new policies led to the selection of twenty five 'pilot high-end think tanks' and the establishment of the management system of think tanks in China."* (pp. 49). Khan & Köllner (2018) analysed the growing role of Think Tanks in India and pointed out that *"India's foreign policy think tank sector has gained in visibility and vibrancy due to new demand in the wake of India's expanding international stakes..."* Other reasons for the rise of think tanks in India include better funding and access to information, especially in the case of the Ministry of External Affairs (MEA). (Khan & Köllner. 2018).

The landscape of think tanks in a country often reflects characteristics of the political system of this country. Many ruling parties or coalition governments across the world interact closely with think tanks. Chile and two of its major think tanks, Centro de Estudios Públicos (CEP) and "Libertad y desarrollo" (LyD), are prime example for close political ties.

Many of the leading think tanks in the world, including Brookings (Washington D.C.), Bruegel (Brussels), Carnegie (Washington D.C.), Chatham House, (London), the Center for China and Globalization (Beijing), the World Economic Forum (WEF), and many others, have global outreach and focus more on global agendas than on national policy issues. The World Economic Forum (WEF), for example, has more than 13,000 members in 150 countries and supports the Global Shapers Community, a network of young people under the age of 30 working together to address local, regional, and global challenges. It convenes the Davos Forum and publishes the widely referenced Global Risks Report which has been extensively quoted by experts working in the field of megatrends analysis and future research.

Since the 1990s, we have seen a growing number of think tank reports and academic publications dealing with future analysis and megatrends. There are now many smaller and medium-sized institutes and associations that explicitly address megatrends, future research as well as strategic forecast. The Association of Professional Futurists (APF) was founded in 2002 and has more than 500 members. It emerged as a network of practicing futurists who act as analysts, consultants, and speakers.

However, the TTCPS (TTCSP 2021) does not offer a category of think tanks with the thematic focus on megatrends, future research, or strategic forecast. There are many leading think tanks which employ a variety of methods and approaches to megatrends analysis, future research, and strategic foresight, and they play a critical role in shaping policy debates and influencing the direction of public discourse on the future

The number and diversity of organisations engaging in megatrends and future research is increasing. Expert opinion gathered in the context of our research also suggests that big data analytics and growing ICT capacities much facilitated megatrends analysis and future research and motivated smaller organisations to also engage with it. For example, we have come across a business case for developing AI based self-learning taxonomies for megatrends analysis. The Berlin-based start-up company Anacode is venturing into megatrends analysis based on big data and targets the financial industry and larger corporations with their product (Anacode, 2023).

## **5 Spotlights on diverse think tanks**

This section introduces seven diverse think tanks from different countries and world regions which either explicitly engage in megatrends analysis and future research or work on issues highly relevant for megatrends analysis and future research. We selected the think tanks based on criteria of diversity related to regional, thematic, and methodological focus and dependent on their interest in participating in this research.

Interviews were conducted with the following think tanks:

- The Millennium Project (MP), Washington  
MP is an established global think tank with a strongly decentralized network of Nodes and an explicit focus on future research which is involved in the United Nations 2024 summit on the future.
- Copenhagen Institute of Future Studies (CIFS), Copenhagen.

CIFS is one of the earliest European think tanks with high-level expertise on future research and strategic foresight and is implementing projects with diverse stakeholders as well as offering training courses.

- Green Economy Coalition (GEC), London.  
GEC is the world's largest alliance for green and fair economies and has 60 organisational members including trade unions, businesses, NGOs, United Nations agencies and citizen's groups and established eight green economy hubs in Brazil, India, Mongolia, Peru, Senegal, South Africa, Uganda and Caribbean region.
- Center for China and Globalisation (CCG), Beijing.  
CCG is a well-established, globally recognised and well networked independent nongovernmental Chinese think tank with a broad agenda which focuses on economic, trade, and geopolitical issues and is engaged in dialogue with leading Chinese companies, universities and government departments of several ministries.
- Centre for Civil Society (CCS), Delhi  
CCS is an established and internationally well-networked advocacy-oriented non-profit organisation, and is shaping policy discourses in the field of social and economic development and influenced law-making processes in India.
- Cultural Infusion (CI), Melbourne  
CI is considered a global leader in diversity research and is working on cultural issues in cooperation with many organisations and big companies, including UNESCO.
- 4Sing, Hamburg  
4Singh is a for-profit think tank that offers consulting and coaching services in foresight and strategy development in the field of security and sustainability governance for public and private sector organisations across the world.

We examined their involvement in megatrends analysis and future research and their work on issues related to major discourses relevant for megatrends analysis and future research. We learned about their different orientations, approaches and changes in their strategies. The scope of this paper does not allow to present the work of these think tanks in detail. Thus, only brief summaries are provided focusing on how these organisations position themselves thematically and within

the landscape of global think tanks and which strategies they adopt to maximise their impact.

### **5.1 Millennium Project (MP), Washington**

MP has an explicit focus on megatrends analysis. Its 15 Global Challenges provide a framework to assess the global and local prospects for humanity and contribute much to knowledge dissemination on megatrends. The description of the trends is updated each year, since 1996.

MP, under the leadership of Jerome Glenn, puts a lot of emphasis on having a truly global approach, “a global representation” and aims to avoid ideological or country/region bias. MP works through and with “Nodes” (currently 71 across the globe) which enable the MP to quickly access intelligence and to collect analysis and assessments from around the world. It is involved in the preparation of the United Nations Summit of the Future in 2024 and has a strong motivation to guide and lead organisations and experts in providing policy advice in the field of megatrends and future studies.

### **5.2 Copenhagen Future Institute, Copenhagen**

CIFS work contributes towards democratising future thinking and working for common goods. It stresses its ability to convene broadly and to engage with diverse stakeholders and is currently putting emphasis on engaging more with ethical dimensions of future developments. New projects relate to bringing future thinking principles to young people, inserting them into educational systems and developing open-source products for young generations. In cooperation with companies, CIFS stresses the importance of integrating anticipatory leadership thinking in corporate cultures rather than just creating well-designed but gimmick-like foresight tools. CIFS considers itself as a pioneer organisation in future research. It is aware of the current boom in forecasting and megatrends analysis which may provide opportunities for networking but also some quality related risks for the profession. CIFS hosts a UNESCO Chair in Anticipatory Leadership and Futures Capabilities.

### **5.3 Green Economy Coalition (GEC), London**

GEC is an influential green economy network of organisations promoting the green economy and just transition to a sustainable future across countries and

regions. Under the previous leadership of Emily Benson and the current leadership of Oliver Greenfield, the work of the coalition relates to the megatrends framework and to system risks. GEC puts a special focus on the intersection of megatrends. The organisation and its network contributed to make the Green Economy a megatrend in itself, and they aim to pro-actively shape megatrends by forging new alliances. Knowledge management is centred around its informative website which comments on recent developments, e.g., reflections on IPCC climate science reports. The GEC realises that policymakers will probably not move beyond incremental change. Thus, their strategy focuses more on new mechanisms of citizen engagement with a purpose to renegotiate social contracts for the green and just transition. GEC is realising that the climate imperative poses challenges to inclusive and democratic governance. Thus, it is crucial to find solutions addressing big social and political divides between and within countries for progressing with the sustainability transition and addressing systemic risks.

#### ***5.4 Center for China and Globalisation, Beijing***

CCG has a broad agenda relating to many global megatrends and topics of future research with a focus on economic and trade policies. In the context of extended and sharpened interest in geopolitics and geoeconomics, CCG has got growing global recognition as a non-governmental Chinese think tank and is considered to have a huge knowledge base on internal relations. It benefited from the interest of the Chinese political leadership in policy-oriented academic work on global issues but considers itself as politically independent organisation. CCG is organising many dialogue events, contributes to books publications and publishes newsletters which reach a large audience in China and other countries. Policy advice is provided in the context of many high-level conferences and through direct contact to policymakers. CCG entertains good relations with the Chinese governments and works with several ministries and large companies. Under the leadership of co-founder and President Wang Huiyao, CCG has much contributed to disseminate the concept of think tank work in China and beyond.

#### ***5.5 Centre for Civil Society, Delhi***

CCS's mission is to "advance social change through public policy..." Its work is based on three pillars: education, livelihood, and governance. CCS provides policy training with the purpose to promote choice and accountability across the private

and public sectors. To translate policy into practice, CCS engages with policy and opinion leaders through research, projects, and policy training.

Under the leadership of Chief Executive Officer (CEO) Lakshmi Sampath Goyal who previously served as the CEO of the India Sanitation Coalition, the organisation has further strengthened its relationship with think tanks and other non-profit organisations networking on the national and international level.

CCS has influenced many policy-making and law-making processes in India, and closely follows and guides economic, social, and political discourse on India's future. While CCS has no explicit focus on megatrends, future studies, or strategic foresight, it is interested in such topics and familiar with leading discourses related to megatrends. CCS emphasises that it always aims to stay on top of the agenda of key social and governance issues in India. It is internationally well-networked due to affiliations with various organisations, including liberal think tanks and foundations in the West which have provided funding support to CCS.

### **5.6 Cultural Infusion**

Peter Mousaferiadis founded Cultural Infusion in Melbourne in 2002. The organisation has attracted some outstanding talents and established a good track record in the field of intercultural understanding. By 2015, Cultural Infusion expanded into the digital world, releasing award-winning apps, *Joko's World* and *Sound Infusion*. CI developed and promotes the *Diversity Atlas*, an online survey which is used as part of training programs to assess and monitor diversity within companies and organisations by measuring demographics and intersectional data across the four interconnected cultural diversity pillars: (1) Religion & Worldview (7,900+ religions, branches and denominations); (2) Country of Birth (UN list of countries and independent territories); (3) Language (7,900 + all spoken languages worldwide); and (4) Ethnicity & Race (8,000 + different global ethnic groups). It is developing comprehensive data sets on diversity and cooperation with governments and multinational corporations in their effort to more adequately recognize and promote diversity. CI has made contributions to promote the global megatrend of diversity and has participated in a megatrends project.

### **5.7 4Sing, Hamburg**

4Sing is a network of foresight experts working in different countries and guided by Adrian Taylor, a foresight expert, strategist, change agent and business

coach with extensive and diverse international experience. 4Sing works about equal parts for the government and non-profit clients. 4sing experts focus on strategic foresight and strategy development targeting different industries, including the energy, utility, chemical, and automotive industry. 4Sing has worked in different countries across the globe, especially in Europe and Asia. It uses technological tools to enhance and visualise its scenario and system development work. While its scenario and strategic foresight work with public sector or non-profit clients sometimes involves external parties or is organised as a multi-stakeholder event, the more strategy-focussed consulting work with the private sector usually just involves different departments within one company as strategy development is sensitive in a competitive business environment. 4Sing cooperation and networking partners include organisations working in the field of design thinking, horizon scanning, action research and strategic foresight, especially EIDOS, the Global X network, Cognitive Edge, Futurescaper, futuribles, shapingtomorrow and 4strat.

## **6 Conclusion**

Today it is easier to learn, analyse, and forecast future developments in different parts of the world as we live in a much more globalised world with better access to data, information and quick survey and networking tools. Thus, we are witnessing a significant growth of larger and smaller think tanks engaged in explicit analysis of megatrends, future studies, and strategic foresight or working on issues which would qualify as megatrends issues. The many diverse think tanks are using different conceptual frameworks, methodologies, and tools. This may, at least in the long run, lead to a proliferation of new methodologies and enhance the quality of megatrends analysis and future research. Future literacy is likely to receive more attention by international organisations as well as universities and the education and consulting industry.

The majority of established think tanks, however, are not deeply affected by the burgeoning megatrends discourse and does not specifically engage in future studies or uses strategic foresight tools. There are some notable exceptions like the Bertelsmann Foundation, a large German think tank, which has recently taken-up megatrends analysis and forecasting.

Most of the leading think tanks are situated in the United States and EU countries but other parts of the world are catching up, including China and India. The knowledge management and policy advice strategies of think tanks usually follow their function and are diverse. Many of them concentrate on producing

analytical reports including data analysis and policy recommendations, engaging in multi-stakeholder exchanges, and organising conferences and other dialogue events. The UN future summit 2024 reflects the growing attention paid by international organisations to future research and their interest to engage with think tanks and megatrends experts in exchanges and dialogue events on the future of humanity.

### Abstract

In the era of technological progress, it is necessary to have a skilled workforce with abilities to react to market changes. The empirical literature relies almost exclusively on school attainment measures of human capital, such as years of schooling. As lifelong learning programs may increase the skills of a labour force, the research on the participation of labour force in lifelong learning programs and its impact on income, wages, and productivity should contribute to the existing literature. The aim of this study is to estimate the impact of the participation of labour force in lifelong learning programs on income, wages and productivity, as empirical analysis shows high heterogeneity in the participation rate among European countries. Descriptive statistical analysis of a sample of 35 European countries for the period 2006-2021, shows that, on average, 10.8% of the EU (27) population aged 25-64 years participated in education and training programs in 2021, with Finland and Sweden having the highest participation rates in 2021 (30.5% and 34.7%), while the Balkan countries have the lowest participation rates (1.8 in Bulgaria and 4.8% in Serbia in 2021, 2.7% in Montenegro and 2.6% in North Macedonia in 2020). Applying the OLS model to the sample of thirty-five European countries and the period from 2006 to 2021, with growth in the participation rate in education and training (persons in the labour force, 25-64 years) as an independent variable, while the growth in GDP per capita, labour productivity, and wages are dependent variables, we show that growth in the participation rate in education and training by one percentage point leads to GDP per capita growth by 6 percentage points, nominal labour productivity growth by 5.5 percentage points, and wages growth by 2.6 percentage points. Productivity growth is a prerequisite for long-run economic growth in all countries, and it is not possible without investment in knowledge, either in education or investment in research which will result in innovation and technological progress. Lifelong learning is an important part of the overall system of education and increases human capital, and should be given the highest relevance in the

overall education process. For medium-income European countries, to converge to the income level of developed European countries, it is necessary to increase its technological readiness, quality of the workforce, and productivity. The growth in human capital is therefore indispensable, not only through formal education but through lifelong learning also.

**Keywords:** Lifelong learning, Income, Wages, Productivity, Europe

**Paper type:** Academic research paper

## 1 Introduction

In the era of technological progress, frequent job changes, and fluctuations in the labour market, it is necessary to have a workforce that has the skills and abilities to react to market changes. Traditional skills and knowledge are changing workers' values and importance and younger staff have the advantage of having the skills needed to react to the changes. This trend is observed in all economies of the world, both developed and developing. International Labour Organization - ILO (2021), concluded that "skills mismatches are a growing challenge in today's labour markets, with many consequences for workers, businesses and the future of work.

The solution to the lack of a workforce that has skills and abilities in compliance with existing technological achievements can be seen in constant education and training, through various forms. The empirical literature relies almost exclusively on school attainment measures of human capital, such as years of schooling. Therefore, the research on the participation of labour force in lifelong learning programs and its impact on income, wages, and productivity should fill the existing research gap.

As emphasised by the ILO (2021), "skilling, reskilling and upskilling throughout all stages of life is the precondition and an accelerator for people to access decent work opportunities and enable smooth transitions into labour markets and within labour markets". Further, they conclude that skill development and lifelong learning are fundamental enablers of decent work, productivity, and sustainability that can raise the value and output of labour, empowering the lives of workers and enriching societies.

An empirical analysis of a sample of 35 European countries for the period 2006-2021 shows that, on average, 10.8% of the EU (27) population aged 25-64 years participated in education and training programs in 2021, with the highest participation rate observed in Finland and Sweden (30.5% and 34.7%), and the

lowest in the Balkan countries (1.8 in Bulgaria and 4.8% in Serbia in 2021, 2.7% in Montenegro and 2.6% in North Macedonia in 2020). Based on the same sample and the period, the research shows that a high heterogeneity was observed in GDP per capita, annual wages, and labour productivity. Therefore, it is of immense importance to investigate determinants of income, productivity and wages, so countries with lower income may converge to more developed countries. Lifelong learning may contribute to income convergence.

At the European Union level, lifelong learning is recognized as an important determinant of productivity and income growth. The European Commission defines lifelong learning as "all learning activities undertaken during life with the aim of improving knowledge, skills and competences at the personal, civic, social, and/or employment level". It involves the acquisition of all kinds of interests, abilities, and qualifications from pre-school age to post-retirement age, through formal and informal learning, to encourage continuous development and improvement of professional and personal plans. Important determinants in the development of the lifelong learning policy and legislative framework in Europe include the Bologna process, numerous initiatives of the European Union within the framework of the Lisbon strategy, and increasing participation in the financing of lifelong learning programs. In line with the headline target of the European Pillar of Social Rights Action Plan, 60% of all adults are expected to participate in training every year by 2030. Actions and initiatives at the European level provide support to national institutions and individuals to increase adult's participation in learning and training activities. They enhance understanding of how to respond to challenges in the field of adult learning and enable better exchange of knowledge and experiences between countries.

A resolution adopted by the Council of the European Union (EU) on 29 November 2021, on a new European Agenda for Adult Learning, highlights the need to significantly increase adult participation in formal, non-formal, and informal learning. The Agenda outlines a vision of how adult learning should develop in Europe by 2030 in the following five priority areas: governance of adult learning – with a strong focus on whole-of-government national strategies and stakeholder partnerships; supply and take-up of lifelong learning opportunities with sustainable funding; accessibility and flexibility – to adapt to the needs of adults; quality, equity, inclusion and success in adult learning – emphasizing the professional development of adult learning staff, the mobility of both learners and staff, quality assurance, and active support to disadvantaged groups; and green and digital transitions and related skill needs.

The policy framework and support for the lifelong learning concept are provided through the following documents: The Lisbon Strategy (2000) – includes a program for the modernization of higher education through the emphasis on knowledge and innovation and the introduction of instruments aimed at strengthening the European research area; Charter of the European Association of Universities on lifelong learning<sup>1</sup>; the Copenhagen process (2002), aimed at establishing the recognition and transparency of the standards and content of professional qualifications, compatibility between the qualification frameworks of member states, and the introduction of quality assurance measures for mutual recognition of qualifications and linking of knowledge acquired in any period; Education and training in 2020, a document containing a framework with the spectrum of education and training from the perspective of lifelong learning; The European Qualifications Framework, a reference framework for lifelong learning, which enables the comparison of educational and professional qualifications in European countries by linking degrees, diplomas, and education in countries with a common European framework.

The study is comprised of five sections. After the introduction, in the second section, the most relevant findings from the literature were presented. In the third section trends in lifelong learning in Europe are analysed. The methods and empirical results of the study are presented in the fourth section, followed by a discussion and a conclusion.

## **2 Literature review**

The literature on relevance of human capital for productivity and economic growth is waste, but relies almost exclusively on mandatory forms of education. Still, several studies analyse the significance of lifelong learning.

Becker (1993), pointed out that workers increase their productivity by learning new skills and improving old ones while employed, and discuss general and specific trainings. He concluded that training has an important effect on wage and income. Aceleanu (2012), studied lifelong learning in Romania and found that implementing lifelong learning programs, can recover the gaps compared to developed countries, and improve work efficiency and employment. Barış (2019), states that it is imperative that lifelong learning at the forefront of lifelong

---

<sup>1</sup> The European University Association (EUA) unveiled a 'European University Charter for Lifelong Learning' at its autumn conference in Rotterdam, the Netherlands, on 25 October 2008. Written after consulting some 800 universities and 34 conferences of university rectors that are members of the EUA, the charter aims to back universities in Europe in developing their special role as institutions for lifelong learning.

and supporting methods be incorporated into the programs of the countries and the development and implementation of educational policies. Economic strengthening is possible through the training of qualified personnel. Wiederhold (2015), emphasizes that "It is essentially undisputed that the human capital of a nation accumulated through schooling and lifelong learning is crucially important to the economy's innovative capacity and ability to compete in the globalized world of the 21st century. A substantial body of research has shown that human capital has positive effects not only on individuals' success in the labour market, but also on their general well-being. However, the empirical literature relies almost exclusively on school attainment measures of human capital, such as years of schooling. Due to differences in the quality of schooling over time and across countries, these measures might be poor approximations of effective human capital. Moreover, measures of educational attainment just reflect an individual's human capital at the end of formal schooling, which may not be good indicators of effective human capital when individuals need to constantly adapt their skills to structural and technological change throughout their entire working life." He pointed out that several studies showed that a good governance framework of the school system and effective teachers are important for achieving high levels of skills among students. However, continuing structural and technological changes in the economies require skill adaptations and the process of lifelong learning after school. This puts focus on policies that ensure that skills are effectively retained and used. Furthermore, skills also accumulate through regular practice. This learning-by-doing seems to develop skills at a faster rate when there is substantial novelty and challenge in the scope of the everyday activities undertaken by employees. Brine (2006), found that low-knowledge-skilled learners are at "risk", in opposite to high-knowledge-skilled learners. Chiam, Norbaini and Nur (2011) show that human capital and learning by doing play significant role in economic growth, and are powerful catalyst that promotes economic growth. Aleandri and Refrigeri (2013) pointed out that a promotion of efficient lifelong learning requires financial and economic incentives, also a widespread cultural change.

### **3 Lifelong learning, income, labour productivity and wages in Europe – an empirical analysis**

An empirical analysis of a sample of 35 European countries for the period 2006-2021 was conducted based on indicators and data presented in Table 2. The analysis shows that, on average, 10.8% of the EU (27) population aged 25-64

years participated in education and training programs in 2021, which is 38% higher than in 2006 (7.8%). The highest increase in the participation rate was observed in Romania (217%), Portugal (207%), Estonia (183%), and Luxemburg (116%), while in the United Kingdom, it decreased by 54% in 2019 compared to 2006, in Denmark by 24% in 2021 compared to 2006 and by 14% in Iceland (Table 6-annex).

Finland and Sweden have the highest participation rates in 2021 (30.5% and 34.7%), while the Balkan countries have the lowest participation rates (1.8 in Bulgaria and 4.8% in Serbia in 2021, 2.7% in Montenegro and 2.6% in North Macedonia in 2020).

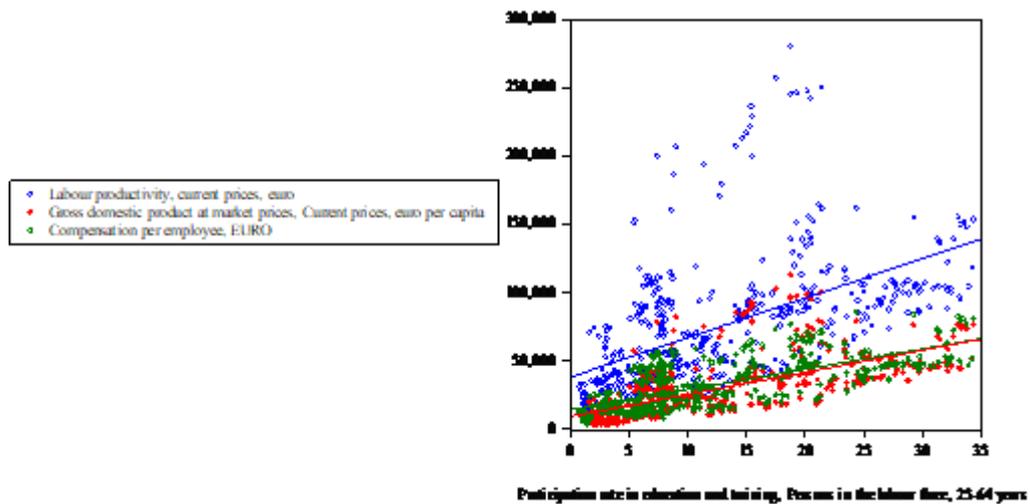

High heterogeneity was observed in GDP per capita, annual wages, and labour productivity among European countries from the sample (Table 1). Descriptive statistics analysis for 35 European countries and the period from 2006 to 2021, shows that, although the average GDP per capita (PPP) was 28.6 thousand €, at the individual country's level, it ranges from 8.9 thousand € (minimum) to 88.4 thousand €. The same was observed for GDP per capita (current €), labour productivity, and percentage of labour participating in training.

Table 1. Descriptive statistics for selected indicators, panel mean (35 European countries, 2006-2021)

	<b>GDP per capita, PPP €</b>	<b>GDP per capita (current €)</b>	<b>Labour productivity (current €)</b>	<b>Wages (annual), current €</b>	<b>Participation in training</b>
Mean	28681.36	30120.79	73725.37	32302.11	12.11858

## 4 Data and methodology

### 4.1 Data and sample

In this study, we used data from thirty-five European countries, from 2006 to 2021. The data have an annual frequency. The indicators used in this study are listed in Table 2.

Table 2. List of variables

Indicator	Source		Date extracted
Participation rate in education and training, Persons in the labour force, 25-64 years	Eurostat	Participation rate in education and training (last 4 weeks) by sex and labour status [trng_lfse_02]	Oct-22
Gross domestic product at market prices, Current prices, purchasing power standard (PPS, EU27 from 2020) per capita	Eurostat	Main GDP aggregates per capita [nama_10_pc]	Oct-22
Gross domestic product at market prices, Current prices, million euro	Eurostat	GDP and main components (output, expenditure and income) [nama_10_gdp]	Oct-31
Employees national concept, Thousand persons	Eurostat	Population and employment [nama_10_pe]	Oct-31
Compensation per employee, EURO	European Commission	Labour productivity and unit labour costs [nama_10_lp_ulc]	Oct-22

Source: Author's compilation

## 4.2 OLS estimation

To estimate the impact of lifelong learning on the growth in standard of living, we estimated OLS where an annual change in GDP per capita (PPS, EU27 from 2020) -  $\Delta GDP_{pc,t}$  is the dependent variable, while growth in the participation rate in education and training (persons in the labour force, 25-64 years) -  $\Delta L_{pt,t}$  is an independent variable (Equation 1).

$$\Delta GDP_{pc,t} = f(\Delta L_{pt,t}) \quad (1)$$

The estimated results are presented in Table 3.

Table 3. OLS estimation - Equation 1

Variable	Coefficient	Std. Error	t-Statistic	Prob.
$\Delta L_{pt,t}$	0.060960	0.0111012	5.535784	0.0000***
C	0.025737	0.002176	11.82942	0.0000***

\*\*\*  $p < .01$ , \*\*  $p < .05$ , \*  $p < .1$

Source: Author's estimations

The estimated results show that growth in the participation rate in education and training by one percentage point leads to GDP per capita growth by 6 percentage points.

To estimate the impact of lifelong learning on the growth in nominal labour productivity per employee (GDP per total number of employees, current prices, €), we estimated OLS where nominal labour productivity per employee growth -  $\Delta LP_{pc,t}$  is the dependent variable, while growth in participation rate in education and training (persons in the labour force, 25-64 years) -  $\Delta L_{pt,t}$  is an independent variable (Equation 2).

$$\Delta LP_{pc,t} = f(\Delta L_{pt,t}) \quad (3)$$

The estimated results are presented in Table 4.

Table 4. OLS estimation - Equation 2

Variable	Coefficient	Std. Error	t-Statistic	Prob.
$\Delta L_{pt,t}$	0.055788	0.013309	4.191662	0.0000***
C	0.025367	0.002633	9.632433	0.0000***

\*\*\*  $p < .01$ , \*\*  $p < .05$ , \*  $p < .1$

Source: Author's estimations

The estimated results show that growth in the participation rate in education and training by one percentage point leads to nominal labour productivity per employee (current prices, €) growth by 5.5 percentage points.

To estimate the impact of lifelong learning on the growth in wages (compensation per employee), we estimated OLS where wages -  $\Delta W_{pe,t}$  is a dependent variable, and growth in the participation rate in education and training (persons in the labour force, 25-64 years) -  $\Delta L_{pt,t}$  is an independent variable (Equation 3).

$$\Delta W_{pe,t} = f(\Delta L_{pt,t}) \quad (3)$$

The estimated results are presented in Table 5.

Table 5. OLS estimation - Equation 3

Variable	Coefficient	Std. Error	t-Statistic	Prob.
$\Delta L_{pt,t}$	0.026896	0.012985	2.071299	0.0389**
C	0.028840	0.002598	11.10002	0.0000***

\*\*\*  $p < .01$ , \*\*  $p < .05$ , \*  $p < .1$

Source: Author's estimations

The estimated results show that growth in the participation rate in education and training by one percentage point leads to a 2.6 percentage point increase in wages.

## 5 Discussion and conclusion

Economic theory provides strong evidence that points to a strong link between the expansion of scientific and technical knowledge that enables productivity and income growth in the long run. Becker (1993), pointed out the importance of investing in human capital (education, training, and improvement of employees) for the growth of productivity and income. Romer (2001), in his analysis of the impact of knowledge accumulation on economic growth, pointed to the possibility that one of the reasons for the low level of income in less developed countries is their inability to use already developed technologies. Empirical findings by Denison (1985), show that growth in the level of education of the workforce in the USA contributed to a quarter of the total economic growth achieved in the period from 1929 to 1982.

Productivity growth is a prerequisite for long-run economic growth in all countries, and it is not possible without investment in knowledge, either in education or investment in research which will result in innovation and

technological progress. Lifelong learning is an important part of the overall system of education and increases human capital, therefore should be given the highest relevance in the overall education process. The goal of EU policies and development documents is to **achieve 60 percent participation of employees in training programs** by 2030.

For medium-income European countries, to converge to the income level of developed European countries, it is necessary to increase its technological readiness, quality of the workforce, and productivity. This affects the growth of earnings, the growth of the company's profitability, and the prosperity of the country as a whole. The growth in human capital is therefore indispensable, not only through formal education but through lifelong learning also.

### Abstract

The paper is conceptual as it aims to extend the well-known Nonaka's spiral model in order to develop a model of knowledge creation (MKC) using information technology. The need of developing the MKC is due to the increasing ubiquity of information technology in the field of knowledge management. The three grounds of the MKC development are considered. The first is human-computer symbiosis combining the automatic (computer) and expert stages of goal-oriented new knowledge discovery. The first ground determines the usage of three media of different nature (mental, informational, and digital ones) during knowledge discovery. The second ground extending Nonaka's model is the specification of digital potential sources of new knowledge which should be relevant to the goal of its discovery. The third ground is explicit linkages between new concepts (individual and group) and their digital sources. To define the MKC the paper describes some notions (knowledge, concept, mental data, sensory perceived and digital information, sensory perceived and digital data, and digital knowledge representations). The MKC covers three processes of Nonaka's model (internalisation, socialisation, externalisation), its modified fourth process (combination), and includes new processes for discovering new concepts in digital potential sources of new knowledge. The principal feature of the MKC is encoding knowledge dynamics in computer system knowledge bases fixing individual and group concepts, their digital sources, and concept generation time points. The proposed model is the foundation of evolving previous version of the DIKW hierarchy because the MKC processes clarify linkages between data, information, and knowledge.

**Keywords** – Knowledge creation, Knowledge dynamics, Spiral model, DIKW hierarchy

**Paper type** – Academic Research Paper

## **1 Introduction**

In 2015, a report was published with a forecast of technological development (WEF, 2015). It was prepared under the auspices of the World Economic Forum. Approximately 800 experts and executives from the information and communications technology sector contributed to this report. The report containing the results of their survey includes the list of new information technologies which predetermine the fundamental nature of the social and economic transformation, called the "Fourth Industrial Revolution" (Schwab, 2016).

Modern information technologies that control the processes of production and consumption generate huge amounts of digital data, which are positioned as potential sources of creating new knowledge. According to Di Maria et al. (2018), "The rise of network technologies allows organisations to acquire and manage knowledge from a wider set of sources within and beyond the organisational boundaries <...> the Industry 4.0 revolution stresses the huge potentialities in data generation related to a) a wider set of processes, including operations and consumption; b) a more detailed level as well as a higher volume of data than before". According to Manesh et al. (2021), "to truly benefit from this digital transformation, organizations should improve their KM approaches so they can scan and detect meaningful pieces of information and develop more sophisticated uses of this knowledge".

Huge amounts of digital data necessitate reconsidering the field of knowledge management in its theoretical core and developing methods and models of knowledge creation using information technology. The purpose of the paper is to develop the model of knowledge creation (MKC), extending the well-known Nonaka's spiral model (Nonaka, 1991; Nonaka and Takeuchi, 1995), and to create the medium version of the DIKW (data, information, knowledge, wisdom) hierarchy. The principal aim of developing the MKC is to describe goal-oriented discovery of new knowledge in digital data.

## **2 The spiral model and its extending**

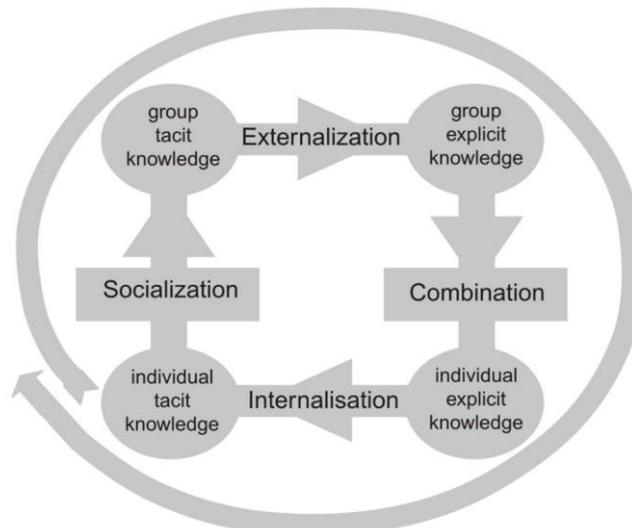

### ***2.1 The spiral model and its variants***

To create the MKC, we will first briefly describe the spiral model and its variants. At present, the spiral model of knowledge creation (= SECI model) is one of the most popular. Two categories of knowledge are determined in this model:

individual knowledge and group knowledge. Each of these categories is divided, in turn, into two sub-categories: explicit knowledge and tacit knowledge. The spiral model includes the following four types of knowledge (Nonaka, 1991; Nonaka and Takeuchi, 1995):

- Individual tacit knowledge
- Group tacit knowledge
- Group explicit knowledge
- Individual explicit knowledge

In the model, besides these four types of knowledge, the following four transformation processes are defined: Socialisation-Externalisation-Combination-Internalisation (SECI). By definition, each spiral turn of knowledge creation includes the sequence of processes (Fig. 1): socialisation → externalisation → combination → internalisation → socialisation (as the beginning of the next spiral turn).

*Figure 1. The spiral model (Nonaka, 1991)  
(this diagram was taken from (Wierzbicki & Nakamori, 2006))*

According to C. Bratianu (2019), “The SECI model does not contain time as an explicit variable. <...> The model contains time implicitly since any transformation needs time, but it is a generic time without any possibility of measuring it”. Therefore, in this qualitative model, one can already see three dimensions of the processes of knowledge creation:

- The socialisation dimension has two nominative categories (individual and group)

- The temporal dimension is implied in the spiral turns of knowledge creation
- The explicitness dimension also has two nominative categories (tacit and explicit)

Some models describe knowledge dynamics with another number of nominative categories in the socialisation dimension and with one or two explicit temporal dimensions. For example, Nissen (2006) extended the spiral model to integrate two temporal dimensions: "*life cycle* and *flow time*. *Life cycle* refers to the kind of activity (e.g., creation, sharing, application) associated with knowledge flows. *Flow time* pertains to the length of time (e.g., minutes, days, years) required for knowledge to move from one person, organization, place, or time to another". The socialisation dimension identifies three nominative categories (individual, group, and organisation). All four dimensions (socialisation, two temporal, and explicitness) for characterising knowledge flows can be employed collectively to visualise the spiral turns of knowledge creation. One name is changed here for clarity (i.e., Nissen uses the term *reach* instead of *socialisation*).

Another model with more nominative categories in the socialisation dimension was proposed by Wierzbicki and Nakamori (2006, 2007). Like Nissen (2006), they also offer three nominative categories, but instead of organisation knowledge, their model (hereafter the WN model) includes conventional knowledge:

- individual knowledge,
- group knowledge,
- conventional knowledge (knowledge of humanity).

Wierzbicki and Nakamori also subdivide each category into tacit and explicit knowledge, thus obtaining six knowledge types. They define nine transformation processes that provide knowledge creation, including socialisation, externalisation, combination and internalisation. Eventually, to build their knowledge creation model, they operate with six types of knowledge, three emotion components (individual, group, and conventional), and identify nine types of transformations of knowledge types. Eight more transformations of three emotion components, as well as between knowledge and emotions have been defined. For example, between individual tacit knowledge (individual intuition in the WN model) and individual emotions, they defined two transformations, namely, motivation: individual emotions → individual intuition and determination: individual intuition → individual emotions (Wierzbicki and Nakamori, 2006: p. 75).

Before describing the MKC, we list the principal features of the models briefly discussed above. Their strengths are that they explicitly or implicitly use three or

four dimensions to describe the dynamics of knowledge. For all models in the explicitness dimension, two nominative categories are defined (tacit and explicit). If we add conventional knowledge from the WN model to the three Nissen's nominative categories (2006), then in the socialisation dimension we get four nominative categories (individual, group, organisational, and conventional). The weakness of all models is that any sources of new knowledge are not defined.

## **2.2 Extending the spiral model**

The most appropriate approach to create the MKC is to join the model of an information system storing and processing digital potential sources of new knowledge with the spiral model describing the dynamics of knowledge (= digitalising the spiral model). Earlier, the ITO model was created during the digitalising the spiral model for solving two problems of new knowledge generation based on this approach (Zatsman, 2021):

- Discovering new meanings of language units in question
- Discovering new terms for creating and updating the medical knowledge base of terminological profiles of diseases

The approach to digitalising the spiral model is to use three media of different nature (Fig. 2):

- The mental medium includes concepts as parts of tacit knowledge in the minds of people
- The informational medium includes explicit knowledge as perceptual forms of concepts which are the parts of texts, diagrams, formulae, tables, etc.
- The digital medium encompasses digital potential sources of new knowledge, computer codes of concepts and their perceptual forms in networks, databases, etc.

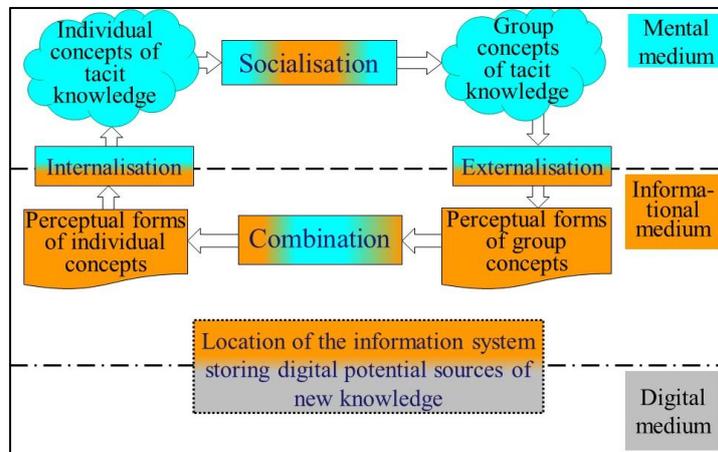

Figure 2. The spiral model processes and the location of the information system

According to the first two stages of the spiral model digitalisation described in (Zatsman and Khakimova, 2021), we distribute the four types of knowledge of the spiral model among two media: concepts of tacit knowledge are in the mental medium, and explicit knowledge as perceptual forms of concepts is in the informational medium (Fig. 2).

Note that the processes of socialisation and combination embrace the types of knowledge of both media, but to simplify Fig. 2, we will place these processes in different media. Such placement of these processes in media corresponds to the initial and final stages of them: the initial and final stages of the socialisation process refer to the mental medium, and the initial and final stages of the combination process refer to the informational medium. The processes of internalisation and externalisation begin and end in different media. Therefore, we place them on the boundary between them (Fig. 2).

As mentioned above the spiral model does not embrace any sources of new knowledge. To digitise the spiral model, the digital medium with the potential sources should be added to the mental and informational media. The main idea of the spiral model digitalisation is to aggregate the processes of the spiral model and the processes of the information system storing digital potential sources of new knowledge. For integrating the spiral model with the digital potential sources, we have added three processes of the information system: potential source retrieval, their visualisation, and interpretation (Fig. 3).

The task of the first process (retrieval) is to find potential sources of new knowledge that are necessary to achieve the goal of discovering new knowledge. For example, if the goal is to update the terminological profile of a certain disease with new terms, then the database of medical papers is searched for works

describing this disease and containing potentially new terms that are not in medical dictionaries and the current version of the terminological profile (Zatsman and Khakimova, 2021).

The task of the second process (visualization) is to convert the digital codes of the found potential sources into a sensory perceived form on the screen of an expert who performs the third process (potential source interpretation). The expert's task is to analyse potential sources of new knowledge and identify genuinely new sources from his individual point of view. In the above example of updating the terminological profile, the expert analyses potential new terms and their contexts in the found papers and divides the genuinely new terms and new synonyms of the terms which were already presented in the terminological profile of a disease. Such division of potentially new terms reflects the individual point of view of only this expert. Individual new terms and synonyms are added to the terminological profile by the combination process (Zatsman and Khakimova, 2021).

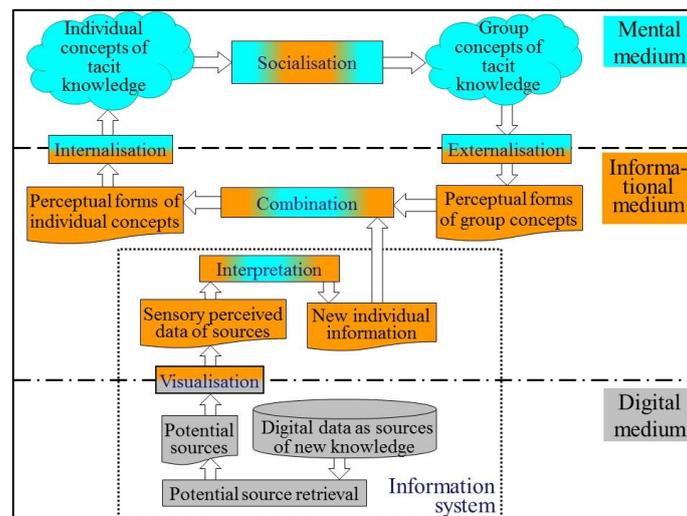

Figure 3. The spiral model aggregated with the digital potential sources and processes of the information system

When performing the combination process, in the general case, individual information is aggregated with group information (as perceptual forms of group concepts). The input of the process of internalisation is individual information (as perceptual forms of the expert's individual concepts) in the context of the already obtained group information. Then the processes of socialisation and externalisation are carried out according to the spiral model, perceptual forms of

new and/or updated group concepts are generated, and the next cycle begins with the process of potential source retrieval in the information system. The time points of creation of new individual information are fixed in the system.

### 2.3 Encoding knowledge dynamics

Aggregating the processes of the spiral model and the processes of the information system makes it possible to implement three functions: to fix the time points of generation of new (updated) group information, encode knowledge dynamics and mark during the decision-making process exactly the new knowledge that was used in each specific case. To implement these three functions, we add to the information system two knowledge bases for representing new knowledge in the digital medium, as well as the following processes of encoding (Fig. 4):

- Individual concepts and their forms
- Group concepts and their forms
- Knowledge dynamics

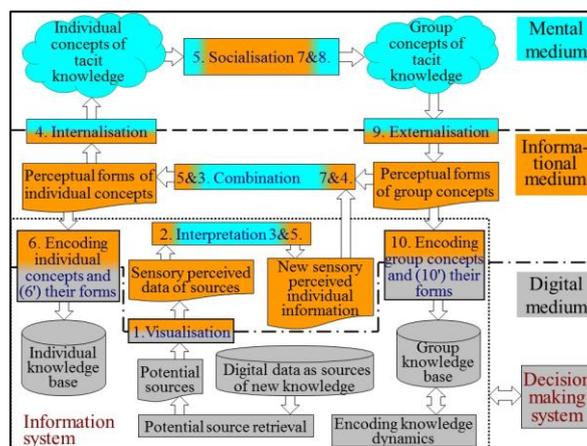

Figure 4. The model of knowledge creation (MKC)

Thus, retrieval, visualisation, interpretation and encoding processes, which are executed by the information system, are added to the four processes of the spiral model. Some processes include one or more numbered transformation stages, which will be described below. The outcomes of encoding concepts and their representation forms are stored in two knowledge bases.

The base of individual knowledge stores a description of new concepts of individual knowledge created and described by an expert, as well as the time

points of their entry into this knowledge base. The group knowledge base stores a description of new or updated concepts of group knowledge, agreed upon and described by the team of experts, as well as the time points of their entry into this knowledge base.

Fixing these time points by the information system makes it possible to see the dynamics of growth, the processes of socialisation and change of new knowledge (Zatsman, 2020), as well as to link the decision made to the knowledge used and mark its sources. To link the decision made to that knowledge, it is necessary to integrate the information system with a decision-making system. In this case, it will be possible to store the history of the decisions made, linked to the used knowledge generated according to the MKC, and its sources.

### **3 Evolving the DIKW hierarchy**

#### ***3.1 Previous framework of the DIKW hierarchy***

In 1989, Russell Ackoff introduced the notion of "DIKW hierarchy" (data, information, knowledge, wisdom) and described the linkages between them as follows:

"Wisdom is located at the top of a hierarchy of types, types of content of the human mind. Descending from wisdom there are understanding, knowledge, information, and, at the bottom, data. Each of these includes the categories that fall below it — for example, there can be no wisdom without understanding and no understanding without knowledge" (Ackoff, 1989).

Note that when using the DIKW hierarchy, only four of its levels (data, information, knowledge, wisdom) are often considered, and a separate level is not singled out for understanding (Rowley, 2007). Sometimes they confine themselves to considering the first three terms – data, information, knowledge – and describing linkages between them (Chen et al., 2009).

When Ackoff says that higher terms include lower ones, he is talking about the processes of their transformation, and not about the inclusion of their semantic content, which is described by subsumption relations or other hierarchical relationships. Jennifer Rowley draws attention to this feature of the description of the DIKW hierarchy in the review of works devoted to the DIKW hierarchy. According to Rowley (2007, p. 163), the DIKW hierarchy "is one of the fundamental, widely recognized and 'taken-for-granted' models in the information and knowledge literatures". The main conclusion of her scrutiny of the literatures is that:

“Typically information is defined in terms of data, knowledge in terms of information, and wisdom in terms of knowledge, but there is less consensus in the description of the processes that transform elements lower in the hierarchy into those above them, *leading to a lack of definitional clarity* (italics supplied)”.

The need for more definitional clarity is due to the fact that the same word can have several meanings (for example, information) and sometimes denotes entities having mutually exclusive properties (Newman, 2001). Thus, it is proposed that different meanings are expressed lexically when describing the processes of knowledge creation and encoding of its dynamics in time points of when new concepts appear or existing concepts change. The Fig. 4 distinguishes between sensory perceived (informational medium) and digital information (digital medium), sensory perceived and digital data as sources of new knowledge (digital medium), knowledge, concepts (mental medium) and their digital representations in knowledge bases (digital medium).

### **3.2 Evolving the DIKW hierarchy based on MKC processes**

The MKC uses different meanings of the first three notions of the DIKW hierarchy (data, information, knowledge), leading to further definitional clarity. As a theoretical basis for constructing the MKC, five articles were used that describe the spiral model and its variants (Nonaka, 1991; Nonaka and Takeuchi, 1995; Nissen, 2006; Wierzbicki and Nakamori, 2006; Wierzbicki and Nakamori, 2007). The fundamental novelty of the MKC is that it includes digital sources of new knowledge, which should correspond to the goal of generating new knowledge.

The first principle of constructing the MKC is to employ three media of different nature: mental, informational, and digital ones (Fig. 2-4). The second principle of constructing the MKC is to embrace digital sources of new knowledge which are visualised, interpreted and combined with perceptual forms of group concepts (Fig. 4). In other words, the combination process has two inputs in each spiral turn: new sensory perceived individual information as the output of the interpretation process and perceptual forms of group concepts as the output of the externalisation process.

The MKC processes can consist of one, four, five or six transformation stages. Five processes (visualisation, encoding individual concepts, internalisation, externalisation, and encoding group concepts) include one stage of transformation with numbers 1, 4, 6, 9 and 10, respectively. The socialisation process has four stages (5, 12, 7, 8 in Fig. 5; the stage 12 is not shown in Fig. 4). The interpretation process has five stages (2, 11, 14, 3, 5 in Fig. 5; the stages 11

and 14 are not shown in Fig. 4). The combination process has six stages (4, 7, 13, 15, 3, 5 in Fig. 5; the stages 13 and 15 are not shown in Fig. 4).

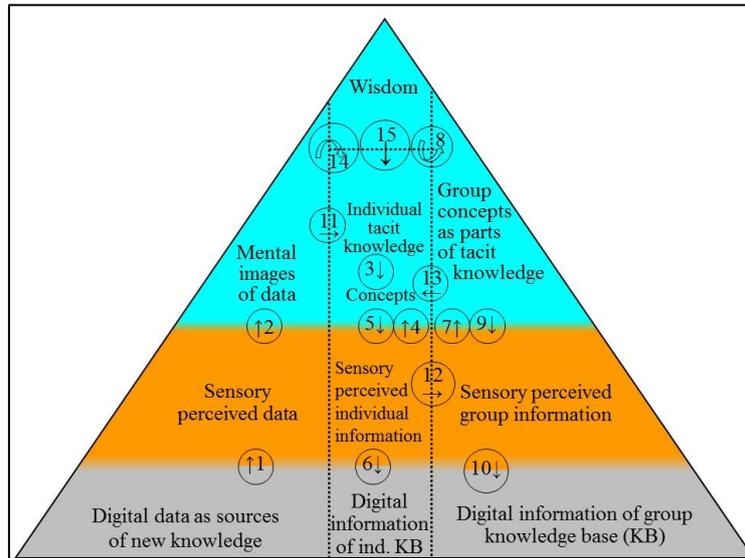

Figure 5. The medium version of the DIKW hierarchy

These 15 stages became the basis for the creation of the medium version of the DIKW hierarchy (Fig. 5), which describes the mutual transformations between sensory perceived and digital data, sensory perceived and digital information, individual/group concepts, knowledge, and wisdom. The use of MKC processes' stages in the DIKW hierarchy that transforms entities located in three media, on the one hand, complicates the DIKW hierarchy, on the other hand, leads to greater clarity on processes that transform entities of the DIKW hierarchy (the lack of clarity was noted by Jennifer Rowley (2007)). Let us briefly describe the stages numbered from 1 to 15.

1. Visualization is the stage of converting digital data into sensory perceived data performed by a computer (in general, it can be performed in both directions).

2. Creating the mental images of sensory perceived data by a person is the first of five stages of the interpretation process.

3. The division of individual tacit knowledge into concepts using a sign system is the fourth of the five stages of the interpretation process of sensory perceived data (see below the second, third, and fifth stages under numbers 11, 14, and 5), and the fifth of the six stages of the combination process.

4. Internalisation is the spiral model process (Nonaka, 1991; Nonaka and Takeuchi, 1995), and the first of six stages of the combination process.

5. Representing individual concepts of tacit knowledge in sensory perceived forms (i. e. individual information) is the last of the five stages of the interpretation process, the first of four stages of the socialisation process, and the last of the six stages of the combination process.

6. Encoding sensory perceived individual information is the process of their representation by computer codes in the digital medium.

6'. Encoding individual concepts of tacit knowledge is the process of their representation by computer codes in the digital medium.

7. Creating group concepts is the second of six stages of the combination process (see below the third and fourth stages under numbers 13 and 15), and the third of four stages of the socialisation process.

8 (optional). Refining group concepts of tacit knowledge based on previous persons' experience of coordinating their individual concepts is the last of the four stages of the socialisation process (see below the second stage under number 12).

9. Externalisation is the spiral model process, i. e. representing group concepts of tacit knowledge in sensory perceived forms (i. e. group information).

10. Encoding sensory perceived group information is the process of their representation by computer codes in the digital medium.

10'. Encoding group concepts of tacit knowledge is the process of their representation by computer codes in the digital medium.

11. Interpreting mental images of sensory-perceived data by a person is the second of five stages of the interpretation process.

12. Generating sensory perceived forms of group concepts based on sensory perceived forms of individual concepts is the second of four stages of the socialisation process.

13. Creating individual concepts based on group concepts as parts of tacit knowledge is the third of six stages of the combination process.

14 (optional). Refining individual concepts of tacit knowledge based on previous person's experience of interpreting mental images of sensory perceived data.

15 (optional). Refining individual concepts of tacit knowledge based on previous persons' experience of joining outcomes of stages 4 and 13.

During the creation of the medium version of the DIKW hierarchy, the transformation stages from the MKC were used. At the same time, in order not to

complicate Fig. 5, it does not show the stages of encoding individual and group concepts, which are labelled 6' and 10' in Fig. 4. Previously, the paper (Zatsman, 2019) showed that stages 6' and 10' can be implemented technologically if stage 6' is aggregated with stage 6, and stage 10' with stage 10. The medium version, which reflects the aggregation of these stages, is shown in Fig. 6 (in order to show aggregation, we swapped around data and individual information).

One more stage 16 is also added for dividing group knowledge into concepts, similar to stage number 3. It makes the proposed medium version of the DIKW hierarchy more universal (other stages are not shown in Fig. 6).

#### **4 Conclusions**

There are four main differences between the MKC and the spiral model (Nonaka, 1991; Nonaka and Takeuchi, 1995). First, the MKC distinguishes between two representation ways of knowledge: by sensory perceived information, e.g. words (see the interpretation and externalisation processes in Fig. 4) and by computer codes (see encoding concepts and their forms). Second, the MKC processes can include transformation stages. Third, the MKC includes digital potential sources of new knowledge, which should correspond to the goal of generating new knowledge. And finally, aggregating the processes of the spiral model and the processes of the information system makes it possible to encode knowledge dynamics and mark during the decision-making process exactly the new knowledge that was used in each specific case.

The MKC is the foundation of evolving previous version of the DIKW hierarchy because its processes and their stages establish linkages between data, information, knowledge, and wisdom. The use of MKC processes' stages that transform entities located in three media leads to greater clarity on processes that transform entities of the DIKW hierarchy. The medium version of the DIKW hierarchy (Fig. 5) reveals the spectrum of the stages that need to be implemented in information technology of discovering new knowledge in digital sources (Fig. 4 shows far from all the processes' stages).

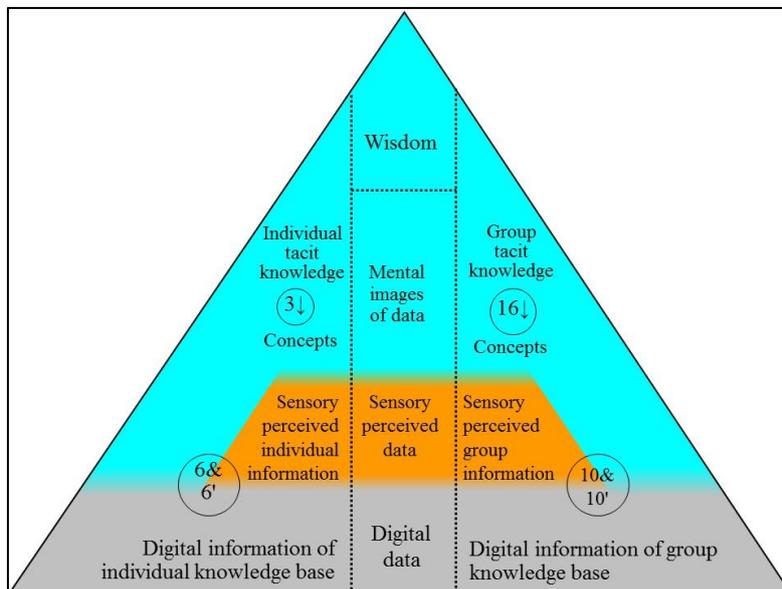

Figure 6. The medium version of the DIKW hierarchy: encoding concepts as parts of tacit knowledge

Previously, particular cases of the MKC were created, which were used in the development of information technologies for the goal-oriented discovery of new linguistic and medical terminological knowledge in scientific documents (Zatsman, 2021; Zatsman and Khakimova, 2021; Zatsman et al., 2022), but without usage of new knowledge in decision-making systems. Having completed the work on the creation of the MKC, we plan to integrate the processes of discovery, socialisation of new knowledge and decision-making processes within the corporate information medical system.

### **Abstract**

Organizations have become aware of the need to expand their objectives beyond traditional economic issues. Thus, since the concepts of Corporate Social Responsibility (CSR) and Corporate Sustainability (CS) were introduced, more and more managers introduce social and environmental objectives in their decision-making process. Additionally, organizations focus their efforts on the development of their intangible assets to achieve better performance, since these guarantee their survival, value creation and improvement of competitive advantage. The set of intangible assets that an organization possesses constitutes its Intellectual Capital (IC).

The existing literature has repeatedly illustrated different concepts and dimensions of IC from various perspectives. However, the terms "green", "social" and "sustainable" IC have recently been incorporated into the academic literature on the management of companies' social and environmental responsibility, representing the fusion between two key aspects for the future success of organizations: (1) the management of intangibles and (2) sustainability.

In order to increase the knowledge in the field of intangibles management from the perspective of sustainability, the purpose of this work is to carry out a systematic review of the scientific literature around a very new topic: Sustainable Intellectual Capital (SIC). The research questions that arise are: (1) How has the scientific production on the SIC evolved? and (2) What are the fundamental characteristics of this type of study?

To answer the research questions formulated, a systematic review of the literature was carried out according to the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses methodology (PRISMA, 2022).

Data collection was carried out between January and July 2021 through the Web of Science and Scopus databases. After eliminating duplicate papers and those that did not coincide with the topics of interest, the final sample consisted of 32 articles.

The results obtained shed light on the following aspects: (1) 71.87% of the papers on the SIC have been carried out in the years 2019, 2020 and 2021; (2) The scientific production analysed has been divided into eight blocks: the relationship between the green management of human resources and Green Intellectual Capital (GIC), the relationship between the GIC and green innovation, the conceptualization and analysis of the SIC construct, the link between logistics and management of the green supply chain with the GIC, the effect of organizational environmental awareness and environmental regulations on the GIC, the effect of the GIC on the competitive advantage of the organizations, the impact of the GIC on the CS and the role of information and communication technologies and the GIC in the achievement of the CS; (3) The use of quantitative methodologies predominates over qualitative ones. In particular, the use of Structural Equation Modelling (SEM) stands out; (4) Most of the studies have focused on the analysis of companies in the secondary sector, more specifically, manufacturing firms.

**Paper type** – Academic Research Paper

## 1 Introduction

Organisations have become aware of the need to expand their objectives beyond traditional economic issues. Thus, since the concepts of Corporate Social Responsibility (CSR) and Corporate Sustainability (CS) were introduced, more and more managers introduce social and environmental objectives in their decision-making process (Bansal, 2005). Both concepts have as a common denominator the search for well-being in society and the environment through business activities.

Additionally, organisations focus their efforts on the development of their intangible assets to achieve better performance, since these guarantee their survival, value creation and improvement of competitive advantage (Khan, Yang and Waheed, 2019). The set of intangible assets that an organisation possesses constitutes its Intellectual Capital (IC), so companies with a richer and more sophisticated IC can obtain greater advantages than those with a poor IC (Ahmad and Ahmed, 2016).

The existing literature has repeatedly illustrated different concepts and dimensions of IC from various perspectives. However, the terms "green", "social" and "sustainable" IC have recently been incorporated into the academic literature on the management of companies' social and environmental responsibility, representing the fusion between two key aspects for the future success of organisations: (1) the management of intangibles and (2) sustainability.

In order to increase the knowledge in the field of intangibles management from the perspective of sustainability, the purpose of this work is to carry out a systematic review of the scientific literature around a very new topic: Sustainable Intellectual Capital (SIC). The research questions that arise are: (1) How has the scientific production on the SIC evolved? and (2) What are the fundamental characteristics of this type of studies?

The structure of the paper is as follows: after the "Introduction", a literature review of the terms CSR, CS and SIC is carried out. The methodology to be used and the data collection procedure are described below. Subsequently, findings and their discussion are shown. Finally, the main conclusions, contributions and future lines of research derived from the study are presented.

## **2 Literature review**

### **2.1 Corporate Social Responsibility (CSR)**

Since the 1950s, various definitions have been proposed around the concept of CSR, both by academics and by national and international institutions and, although there is no consensus on its definition, there are some common characteristics in all of them.

First, CSR is voluntarily applied by companies (Eilbert and Parket, 1973; Jones, 1980; Van Marrewijk, 2003; CSR Observatory, 2014; Sarkar and Searcy, 2016), which links it to the idea of going beyond strict compliance with legal requirements raised by Waldam et al. (2006) and the Forum of Experts in Corporate Social Responsibility (2007).

Second, while Walton (1967), Van Marrewijk (2003), Hopkins (2004) and the European Commission (2011) show the close relationship that the company must maintain with their stakeholders, David and Blomstrom (1966) and Waldman et al. (2006) focus on meeting the needs and expectations of the different stakeholders.

Third, several authors highlight that CSR's actions transcend the economic interests of the organisation (Davis, 1960; Davis and Blomstrom, 1966; Eells and Walton, 1974), since the underlying idea is to integrate social and environmental concerns into activities developed by it (European Commission, 2001; Van Marrewijk, 2003; Ismail, 2009; Aguinis and Glavas, 2012; CSR Observatory, 2014).

Fourth, another common characteristic refers to the responsibility of organisations to mitigate the negative externalities generated by their activity (Fitch, 1976; Mohr, Webb and Harris, 2001; Forum of Experts on Social Responsibility, 2007; European Commission, 2011; CSR Observatory, 2014).

## **2.2 Corporate Sustainability (CS)**

The concept of sustainability firstly became known globally through the report *Our Common Future* of the World Commission on the Environment, known as the *Brundtland Commission*. This commission related sustainability to environmental integrity, social equity and economic prosperity, coining the term sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987, p.43).

According to Schwartz and Carroll (2008), originally CS was considered solely from an environmental point of view and social aspects were gradually incorporated. Agenda 21, approved at the United Nations Conference on Environment and Development (UNCED) in 1992, can be considered a milestone in such incorporation (Steurer et al., 2005), since in Agenda 21 addressed both social and environmental variables, even though most member countries had a biased view of the concept towards purely environmental issues (Giddings, Hopwood and O'brien, 2002). Under this approach, Doyle (1998) argued that social issues should be a priority in thinking about CS. Similarly, the concept of sustainability developed by Gladwin, Kennelly and Krause (1995) also focused on social aspects, defining CS as "a process to achieve human development in an inclusive, connected, equitable, prudent and safe way" (p. 878).

Later, the economic dimension was introduced. However, it did not reach its maturity until Elkington (1999) introduced the concept of the Triple Bottom Line

(TBL). According to this author, sustainable development implied the simultaneous search for economic prosperity, environmental quality and social equity. Therefore, organisations pursuing CS need to act not only based on financial results, but also on environmental and social results.

However, there is some ambiguity in the literature as to whether CS should be a three-dimensional (economic, social and environmental), two-dimensional (social and environmental) construct or a synonym for environmental management.

### **2.3 Sustainable Intellectual Capital (SIC)**

In the knowledge society, organisations focus their efforts on developing their intangible assets to achieve better performance (Agostini, Nosella and Filippini, 2017), since these guarantee the survival of an organisation (Obeng, Robson and Haugh, 2014), they foster value creation (Edvinsson and Malone, 1997; Berezinets, Garanina and Ilina, 2016) and enhance their competitive advantage (Khan, Yang, and Waheed, 2019). As stated in the "Introduction" section, the intangibles of an organisation constitute its IC (Alcaniz, Gomez-Bezarez and Roslender, 2011).

The integration of IC with sustainability is rare and both academics and practitioners have paid little attention to this relationship. Faced with this situation, the IC "green", "social" and "sustainable" terms have recently been incorporated into the academic literature on the management of social and environmental responsibility. Under the TBL approach, it is possible to affirm that the term Green Intellectual Capital (GIC) focuses on environmental issues (Chen, 2008; López-Gamero et al., 2009), the term Social and Environmental IC focuses on social and environmental issues, the Social and Economic IC focuses on social and economic aspects and the SIC on environmental, social and economic issues (Zaragoza-Sáez et al., 2020).

Chen (2008) first introduced the concept of GIC, defining it as "the total stock of all kinds of intangible assets, knowledge, capabilities and relationships, etc. about environmental protection or green innovation at the individual level and the level of the organisation within a company" (p. 277). Nikolaou (2019) introduced the concept of social and environmental IC to address the sustainable intangibles of the company not only from an environmental point of view, but also from a social point of view. However, despite incorporating the social dimension of CS, it does not introduce a holistic vision of it.

With the aim of combining economic, social and environmental perspectives, Zaragoza-Sáez et al. (2020) introduced the SIC construct in the academic

literature, defining it as "the set of human, structural and relational intangibles that a company can take advantage of to carry out economic, social and environmental management, which allows it to achieve competitive advantages" (p. 4). Thus, in keeping with the TBL approach, the authors break down the SIC into two dimensions: GIC and Social and Economic IC (SEIC). On the one hand, as already explained, the GIC is made up of intangible human, structural and relational capital linked to the conservation and management of natural resources. On the other hand, SEIC is made up of the intangible human, structural and relational capital linked to the impact that the company has on the social system in which it operates and to the generation of wealth through its economic activity. The definition provided by Zaragoza-Sáez et al. (2020) surpasses the previous conceptualisations, to the extent that it provides a broader and more complete vision of the concept.

After reviewing the literature and given the novelty of the SIC topic, two research questions arise: How has scientific production on SIC evolved in recent years? and (2) What are the fundamental characteristics of this type of studies?

### **3 Methodology**

To answer the research questions formulated, a systematic review of the literature was conducted according to the Preferred Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines between January and July 2021. This methodology is based on a 27-criteria checklist and a four-step flowchart that aim to improve the quality of systematic review protocols by providing authors with a roadmap for conducting systematic reviews (Moher et al., 2015).

The motivation of this research is based on two basic premises. Firstly, the development and dissemination of the SIC allows the company to identify to what extent it has accepted environmental responsibility for the impacts caused by its activity. Secondly, the SIC facilitates the realisation of sustainable activities thanks to the knowledge acquired.

#### **3.1 Data collection**

Data collection was carried out between January and July 2021 through the Web of Science and Scopus databases. The articles analysed in this review were selected based on the following two criteria: (1) articles in scientific journals and (2) published between 2008 and 2021. On the one hand, only scientific articles were included since publications in scientific journals they are, compared to other

forms of communication, certified knowledge (Callon, Courtial and Penan, 1993). On the other hand, the year 2008 was chosen as the starting year because it was when Chen (2008), through his seminal article, introduced the GIC construct, giving rise to a new field of research within the academic literature on IC. Once the search was carried out, the studies were filtered according to the category of Management and only the papers written in English were selected. The search equation applied was the following:

*( [ "green intellectual capital" OR ("green human capital" OR "green structural capital" OR "green relational capital" ) ] OR [ "sustainable intellectual capital" OR ("sustainable human capital" OR "sustainable structural capital" OR "sustainable relational capital" ) ] OR [ "environmental intellectual capital" OR ("environmental human capital" OR "environmental structural capital" OR "environmental relational capital" ) ] OR [ "social intellectual capital" OR ("social human capital" OR "social structural capital" OR "social relational capital" ) ] OR [ "social intellectual capital" OR ("social human capital" OR "social structural capital" OR "social relational capital" ) ] OR [ "social and environmental intellectual capital" OR ("social and environmental human capital" OR "social and environmental structural capital" OR "social and environmental relational capital" ) ] OR [ "social and environmental intellectual capital" OR ("social and environmental human capital" OR "social and environmental structural capital" OR "social and environmental relational capital" ) ] OR [ "social and economic intellectual capital" OR ("social and economic human capital" OR "social and economic structural capital" OR "social and economic relational capital" ) ] ) )*

A total of 110 papers were obtained from the search. After eliminating duplicate articles and those that did not coincide with the study topics, the final sample consisted of 32 papers.

#### **4 Findings**

From the papers selected for the systematic review and based on four criteria (main objective of the study, methodology used, industry and field of the activity) the results are shown in Table 1.

Table 1. Scientific production on SIC (2008-2021)

Author(s)	Fundamental information	Methodology/Method	Industry / Country	Variable
Chen (2008)	GIC construct is proposed and results show that it has a positive and significant effect on the competitive advantage of firms.	Quantitative / ANOVA	Electronic Industry / Taiwan	GIC
López-Gamero et al. (2011)	Importance of Green Human Capital (GHC), Green Structural Capital (GSC) and Green Relational Capital (GRC) in the accumulation and use of ecological knowledge.	Qualitative / Multiple case study	Several industries / Spain	GIC
Huang and Kung (2011)	Environmental awareness has an indirect impact on competitive advantage through GIC investment.	Quantitative / Structural Equation Modelling (SEM)	Manufacturing sector / Taiwan	GIC
Baresel-Bofinger et al. (2011)	Knowledge Management (KM) and GIC improve the quality of organic knowledge and are important for the application of organic supply chain management practices.	Qualitative / Multiple case study	Several industries / Greece	GIC
Chang and Chen (2012)	CSR and environmental awareness have positive effects on GIC. In addition, environmental awareness mediates the relationship between CSR and GIC.	Quantitative / SEM	Manufacturing sector / Taiwan	GIC
Chen and Chang (2013)	Corporate environmental ethics have a positive effect on the results of the GHC, GRC and Green Innovation (GI).	Quantitative / SEM	Manufacturing sector / Taiwan	GHC GRC
Delgado-Verde et al. (2014)	The GIC has an indirect impact on the GI through the GSC.	Quantitative / SEM	Manufacturing sector / Spain	GIC
Chang (2016)	The environmental commitment of the companies influences positively and directly on GI and indirectly through the Green Adaptative Ability (GAA). However, GHC does not directly affect GI results, but indirectly through GAA.	Quantitative / SEM	Manufacturing sector / Taiwan	GHC
Jirawuttinunt (2018)	Green Human Resources Management (GHRM) practices have a positive impact on GIC. Companies can accelerate GHRM to improve GIC and gain competitive advantage.	Quantitative / Regression analysis	Several industries / Thailand	GIC
Xu (2019)	GHC and GSC influence GHRM.	Quantitative / SEM	Manufacturing sector / China	GIC
Yong et al. (2019a)	GHC and GSC influence GHRM. However, GHC is not significantly related to GHRM.	Quantitative / SEM	Manufacturing sector / Malaysia	GIC
Yusoff et al. (2019)	Of the three dimensions that make up the GIC, only the GSC and the GRC have a positive and significant relationship with the CS.	Quantitative / SEM	Manufacturing sector / Malaysia	GIC

Bag and Gupta (2019)	The availability of GHC positively influences the adoption of reverse logistics and the performance of manufacturing operations.	Quantitative / SEM	Automotive industry / South Africa	GHC
Nikolaou (2019)	Theoretical framework under the approach based on corporate knowledge and IC to explain the interrelationship between some mediating components of the environmental and financial results of companies.	Qualitative / Narrative review of the literature	N/A	N/A
Yong et al. (2019b)	The four key factors influencing GHRM adoption are stakeholder pressures, relative advantage, top management commitment, and GIC.	Qualitative / Case study	Manufacturing sector / Malaysia	GIC
Yusliza et al. (2020)	There is a positive influence of the GIC on economic, environmental and social performance.	Quantitative / SEM	Manufacturing sector / Malaysia	GIC
Malik et al. (2020)	Both GHRM and GIC practices have a positive effect on CS.	Quantitative / SEM	Manufacturing sector / Pakistan	GIC
Song, Yu, and Xu (2020)	The GHRM positively influences the GI, and the GHC mediates the link between both variables.	Quantitative / Regression analysis	Several industries / China	GHC
Zaragoza-Sáez et al. (2020)	Findings do not support the hypothesis that the SIC directly influences the performance of hotels. However, it is confirmed that CSR and KM mediate the above relationship.	Quantitative / SEM	Hotel industry / Spain	SIC
Shoaib et al. (2021)	A positive and significant effect is observed between GHRM and organisational commitment. In addition, the GHC mediates the effect between both variables.	Quantitative / SEM	Food industry / Pakistan	GHC
Ma, Chen and Ruangkanjanes (2021)	This study examines the determinants of GHC and job satisfaction. Only kindness and openness have a positive and significant impact on the GHC.	Quantitative / SEM	Several industries / China	GHC
Mansoor, Jahan and Riaz (2021)	There is a mediating effect of GHRM on the relationship between GHC and environmental performance. In addition, two dimensions of the GIC (GHC and GSC) are positively related to environmental performance.	Quantitative / SEM	Manufacturing sector / Pakistan	GIC
Amores-Salvadó et al. (2021)	The role of the GSC is diverse and depends on the manifestation of the GSC analysed.	Quantitative / Regression analysis	Manufacturing sector / Spain	GSC
Ullah et al. (2021)	There is a positive and significant effect of GIC on CS. In addition, the moderating role of ICT between the GIC and CS is observed.	Quantitative / SEM	Manufacturing sector / China	GIC

Rehman et al. (2021)	Findings show that neither the GIC nor the GHRM are directly related to environmental performance. Instead, they show that GI mediates the relationships between GIC, GHRM, and environmental performance.	Quantitative / SEM	Manufacturing sector / Malaysia	GIC
Trevlopoulos et al. (2021)	There are positive relationships between environmental results and the level of compliance with environmental legislation by companies, as well as between companies' GI and environmental results.	Quantitative / SEM	Metallurgical industry / Several countries	GIC
Ali et al. (2021)	The GHC and GSC significantly increase GI adoption. However, the GRC does not have a significant impact on the GI.	Quantitative / Regression analysis	Manufacturing sector / Pakistan	GIC
Albertini (2021)	The managers of the main European companies develop ecological associations to face the challenge of the energy transition by modifying their manufacturing processes and improving their SIC.	Qualitative / Analysis of the lexical and thematic content of the letters.	Several industries / Several countries	SIC
Wang and Juo (2021)	The three constructs of the GIC positively affect economic performance, ecological performance and GI, respectively.	Quantitative / SEM	Tech sector/ Taiwan	GIC
Agyabeng-Mensah and Tang (2021)	GHC has significant influence on financial results. However, it does not have a significant influence on social performance and green competitiveness.	Quantitative / SEM	Manufacturing sector / Ghana	GHC
Jirakraisiri, Badir and Frank (2021)	The green strategic intention of a company has positive effects on the three dimensions of the GIC. In turn, the three dimensions have positive effects on GI.	Quantitative / SEM	Several industries /Thailand	GIC
Shah et al. (2021)	There is a significant association between GHC and GRC with environmental performance. Likewise, a strong association between responsibility and environmental performance is demonstrated.	Quantitative / SEM	Hospital industry	GIC

## 5 Discussion

The discussion of the results is shown below, depending on the objective of the study, the methodology used and the sector of activity analysed:

### 5.1 According to the main objective of the study

It is possible to identify the following topics and relationships:

- First, 9 papers address the *relationship between the GHRM and the GIC*. Three of them analyse the effect of the GIC on the GHRM and point out the existence of a positive relationship between both variables. However, there are differences when it comes to identifying which dimension of the SIC affects GHRM (Xu, 2019; Yong et al., 2019a, 2019b). Jirawuttinunt (2018) analyses the opposite relationship, considering the GHRM as the driver of the GIC and identifying a positive and significant relationship between both variables. Malik et al. (2020) demonstrates a positive effect of GIC and GHRM in CS. Three other works contemplate the GIC and the GHRM as mediating variables in the proposed models. While Song et al. (2020) and Shoaib et al. (2021) consider that the GIC mediates the GHRM-GI relationship and the GHRM-organisational commitment, respectively, Mansoor et al. (2021) identify the GHRM as a mediating variable between the GIC and environmental performance. The remaining work examines the GIC determinants that facilitate the GHRM process (Ma et al., 2021).
- Second, 7 papers investigate the *relationship between GIC and GI*. Chen and Chang (2013), Delgado-Verde et al. (2014), Chang (2016), Ali et al. (2021) and Jirakraisiri et al. (2021) analyse the GI as a dependent variable, introducing the GIC as an independent or mediating variable in the proposed models. Chen and Chang (2013) demonstrate a positive and significant relationship between GIC and GI performance. Instead, Chang (2016) states that GIC does not directly affect GI, but indirectly through GAA. Delgado-Verde et al. (2014) point out that the GIC has an indirect impact on the GI through the GSC. Ali et al. (2021) show that GIC and GSC increase significantly with GI adoption. Jirakraisiri et al. (2021) show that the three dimensions of the GIC positively and significantly influence the adoption of the GI. In the works of Wang and Juo (2021) and Rehman et al. (2021) do not analyse the GI as a dependent variable, but rather as a mediating variable in the relationship between the GIC and environmental performance.
- Third, 4 papers address the *concept of SIC*. Two of them, López-Gamero et al. (2011) and Albertini (2021) only refer to environmental aspects. Instead, Nikolaou (2019) creates and analyses the social and environmental intellectual capital construct, made up of social and environmental intangibles, and Zaragoza-Sáez et al. (2020) concentrate the three dimensions of the TBL in the IC.

- Fourth, 3 papers deal with *logistics and green management of the supply chain*. Baresel-Bofinger et al. (2011) demonstrate the existence of a positive relationship between the GIC and the implementation of green management practices in the supply chain. Bag and Gupta (2019) state that GHC is a critical element for reverse logistics adoption, and Agyabeng-Mensah and Tang (2021) find that green logistics practices mediate the relationship between GHC and green competitiveness.
- Fifth, 3 papers analyse the *effect of the organisation's environmental awareness and environmental regulations on the GIC*. Chang and Chen (2012) verify that environmental awareness mediates the effect between CSR and GIC. Shah et al. (2021) demonstrate the existence of an indirect effect between GIC and environmental performance through the mediating role of environmental responsibility. Trevlopoulos et al. (2021) demonstrate the existence of a positive effect between environmental regulations and the three dimensions of the GIC.
- Sixth, 2 papers analyse the *effect of the GIC on the competitive advantage of organisations*. Chen (2008) demonstrated the existence of a positive and significant relationship between the GIC and competitive advantage, while Huang and Kung (2011) demonstrated the mediating role of competitive advantage in the relationship between environmental awareness and GIC.
- Seventh, 2 papers address the *impact of GIC on CS*. Yusoff et al. (2019) find that only GSC and GRC positively and significantly influence CS, while Yusliza et al. (2020) demonstrate how the GIC positively affects economic, social and environmental performance.
- Eighth, 2 papers analyse the *role of ICT and GIC in achieving CS*. While Ullah et al. (2021) demonstrate the moderating role of ICT between the GIC and the CS, Amores-Salvadó et al. (2021) find that the impact of the green technological distance on the adoption of proactive sustainable strategies depends on the manifestation of the GIC in the organisation.

## **5.2 According to the methodology used**

The existence of a greater number of studies that use quantitative methodologies (27) compared to qualitative ones (5) stands out. In relation to

quantitative methods, the use of SEM predominates in 81.5% of the cases. Other quantitative methods have been regression (14.8%) and ANOVA (3.7%). The software most used to process the data obtained in quantitative research is SmartPLS, used in 7 of the 22 studies, which shows the relevance of this tool in research on the SIC.

The multiple case method has been the qualitative methodology tool used in 3 of the 5 qualitative studies. The other two qualitative investigations have used the narrative review of the literature and the lexical and semantic analysis of letters.

### **5.3 According to the sector and field of activity**

The predominance of papers focused on a single sector (24) is observed as opposed to several sectors (7). Of the 24 publications focused on a single sector, those from the secondary sector predominate (83.3%) compared to the tertiary (8.3%), with only one work on the primary sector. The industry with the greatest weight in the analysed sample is manufacturing, with a total of 17 publications.

The countries with the largest number of studies are Taiwan (6) and Malaysia (5), representing 31.25% of the studies. Regarding the countries of origin of the companies analysed, the investigations tend to focus more on one country (28) than on several (3). The relationship between the sector and the country deserves special attention, since the investigations focus on the idiosyncratic sectors of each country. Proof of this is the case of the electronics sector in Taiwan (Chen, 2008; Wang and Juo, 2021), the manufacturing sector in China (Ullah et al., 2021), or the hotel sector in Spain (Zaragoza-Sáez et al., 2020).

## **6 Conclusions**

One of the first conclusions drawn from the systematic review of the literature is the notable increase in the number of publications that address the SIC in the last three years analysed, given that 71.87% of the research has been published in this period. This confirms the statement of Yong et al. (2019a), who consider that the SIC "has not emerged as an important field of study until recently". It is also noteworthy that, of the 32 articles, almost 47% were published by the publishers Emerald and Elsevier in one of the journals in their catalogue, among which stand out due to the number of contributions the *Journal of Intellectual Capital* and the *Journal of Cleaner Production*. These results could be of interest to researchers who are in the process of identifying potential journals for publication of their results.

Most of the studies have dealt with analysing the GIC, leaving the Social and Economic IC in the background. The importance of developing GIC is because it can not only lead to increased productivity, but it can also enable organisations to charge relatively high prices for green products, thus gaining a competitive advantage (Chen, 2008). However, companies have recognised the need to balance social responsibility and economic performance in their operations (Wang and Juo, 2021), so social and economic IC should continue to be addressed in the academic literature, integrating its study under a new organisational paradigm: *the vision of the firm based on SIC*, in which environmental, social and economic intangibles are considered.

The scientific production analysed has been divided into eight sections which determine the future challenges of research around the SIC. Regarding the methodology, the existence of a greater number of studies that apply quantitative methodologies compared to qualitative ones stands out, constituting the SmartPLS software a relevant tool in research on the SIC. Regarding the sector and field of activity, the selected studies have focused on the analysis of companies in the secondary sector, more specifically manufacturing companies, despite not being the most intensive in knowledge. This can be explained by the interest aroused by this sector, given its ability to generate employment and wealth in the economy.

The systematic review carried out has three main implications for theory and practice. First, it provides a solid foundation for the study of SIC, integrating green, social and economic IC under the TBL approach. Second, the review offers a unique insight into the topic, since, to our knowledge, no previous work has conducted a literature review in this field. Finally, the eight commented blocks determine the current lines of research on the SIC, so that researchers can use this classification to know the current research fronts as well as future research challenges around the SIC, being therefore a fundamental guide both for experienced scholars in the field and for those who want to start their study.

### **Abstract**

In this paper we conduct a qualitative case study on how knowledge management occurs within a regulated safety context that seeks to make its knowledge sustainable. Thus, organizations, which operate in this context, try jointly, to create, share and, above all, sustain this knowledge for a long time. The most effective way to meet their objectives is to redesign their inter-organizational architecture into a non-competitive knowledge ecosystem. The back and forth between the research field and the theory, led us to ask the following research question: how a regulated safety context should evolve into a non-pre-competitive knowledge ecosystem? To answer this research question, we adopted an organizational perspective, integrating knowledge management and organizational innovation streams. Our results show the emergence of a non-pre-competitive knowledge ecosystems where actors' interactions are strictly collaborative due to its main goal: sustainable and inter-organizational knowledge management. This emergence is enabled by internal and inter-organizational innovation, i.e., the development of a knowledge management process. Organizational innovation is articulated within the actors' own (intra-organizational) knowledge systems, but also through the knowledge flow that is exchanged at the inter-organizational level. To achieve this, ecosystem governance is ensured by a focal actor (through regulatory legitimacy) who assumes the role of orchestrator, to sustain the knowledge flow through coordination and collaboration of ecosystem members.

## 1 Introduction

Knowledge ecosystem has gained attention in the strategic, innovation and entrepreneurship management literature. The concept is mostly mobilized to study how a network of actors collaborates to create knowledge for value creation and exploration. Defined as a meta-organization, knowledge ecosystems are organized around joint knowledge search that can differ in terms of nature and target (Järvi *et al.*, 2018). Beyond the traditional question of what a knowledge ecosystem is, and how it differs from other ecosystems' type (Valkokari *et al.*, 2015; Cobben *et al.*, 2022), a focus has been on how a knowledge ecosystem transfers to a business ecosystem, how it enables the emergence of a business ecosystem or how it facilitates the development of entrepreneurial activities (Clarysse *et al.*, 2014; Attour and Lazaric, 2020). More recently, in line with Van der Borgh *et al.*, (2012), the management literature sheds light on how knowledge ecosystems are organized (Jarvi *et al.*, 2018; Öberg and Lundberg, 2022); and how knowledge is created and shared for value creation within such type of ecosystems. Some of these works paid attention to specific knowledge ecosystem they conceptualized as patent ecosystems (Schillaci *et al.*, 2022). But, whatever the specificity of the knowledge ecosystems studied, they have a common characteristic: ecosystem members (such as universities, public research institutions, and for-profit firms) collaborate to create and share knowledge (to create value) in a pre-competitive context of innovation (Järvi *et al.*, 2018). That is because the ecosystem outputs collectively generated is innovation (Thomas and Autio, 2020).

Innovation in such ecosystems refers to outputs of innovative processes (i.e., products, services, processes, business models, and knowledge) as well as to the process itself. It occurs in pre-competitive setting, where actors' activities are far from downstream activities that seek to exploit and commercialize newly generated knowledge (Valkokari, 2015). Such setting is thus a pre-commercialization one (Järvi *et al.*, 2018). Collaboration is dominant at that stage. It remains however framed by the easily anticipated competitive tensions that will take over once the pre-commercialization phase is over. Most often technological,

product or service, innovation is indeed the ultimate goal sought by the actors of the knowledge ecosystem. Moreover, knowledge creation and share fostered by the precompetitive knowledge ecosystem is a catalyst for these innovations. In other words, pre-competitive knowledge ecosystems support innovation in its exploration stage through research activities involving the creation of new knowledge, recombination of existing knowledge and inventions to be applied to new products, technologies, and services (Järvi *et al.*, 2018).

This paper sheds light on the inverse relation: how innovation supports knowledge management. We identified such a relation by studying the case of a non-pre-competitive knowledge ecosystem, which are unstudied by the literature. We define a non-precompetitive knowledge ecosystem as the gathering of heterogeneous actors mobilized to create and manage sustainable knowledge. The output here is therefore not innovation, but the sustainability of knowledge. Innovation occurs however, but in an organizational setting. Organizational innovation deals with the creation of new knowledge related to innovative organizational methods, practices, and structures, in contrast to existing ones that were established to achieve the organization's goals (Birkinshaw *et al.*, 2008).

The aim of this paper is therefore to introduce the concept of non-pre-competitive knowledge ecosystems by understanding how it may emerge. To answer this research question, we adopted an organizational perspective, as suggested by Jarvi *et al.*, (2018). As section 1 of this paper presents it, we integrate two separate streams of research: knowledge management and organizational innovation. We furthermore believe this study is the first to consider the specific case of non-precompetitive knowledge ecosystems. For that purpose, we conduct an exploratory case study of a regulated safety context that seeks to make its knowledge sustainable, as section 3 details it. Our results show that, within this context, safety is a matter of life or death (Halgren *et al.*, 2018). Thus, organizations, which operate in this context, try jointly, to create, share and, above of all, sustain this knowledge for a long time. To this end, actors need to innovate their intra-organizational architecture by building first a knowledge management system within their own organization. As well as through the knowledge flow within a knowledge management community. We develop these results in section 4 and derive three theoretical contributions discussed in this section. We conclude that our case study revealed the significance of non-pre-competitive knowledge ecosystem, its main characteristics and highlighted its role in effective inter-organizational knowledge management. We provide

recommendations for organizations on how to effectively manage and utilize knowledge within this specific knowledge ecosystem.

## **2 Literature Review**

Both, management literature and business communities recognize knowledge as a critical resource for organizations (Prahalad and Hamel, 1994; Nonaka, 1994). More precisely, knowledge is perceived as an enabler of innovation and a facilitator of the value proposition of a company. And, knowledge management (KM) is defined as the process of creating, using, sharing, storing, coordinating, recombining, and managing knowledge and information within an organization to achieve its objectives (Alavi and Leidner, 2001; Sambamurthy and Subramani, 2005). Those processes are described as a complex social process. When knowledge is held by several actors or is located outside the boundaries of a single organization, a knowledge exchange mechanism is required (Kogut and Zander, 1992, 1996; Nahapiet and Ghoshal, 1998). Such a mechanism relies on several elements, such as: the opportunity and capacity to exchange and combine knowledge, the anticipation of the value created, the motivation of the actors in this process, the social interaction between the different actors, a common understanding and the accumulated experience favoring knowledge transfer through common routines, culture and language (Kogut and Zander, 1993, 1996; Teece *et al.*, 1997). From there, KM is understood as a set of principles and practices that aims to improve collaborative and cooperative interactions that occur within a particular intra and inter organizational environment. Interactions between individuals, organizations and knowledge artefacts are the primary enablers of knowledge processes.

To understand knowledge management mechanisms and processes within and inter-organizational environment, some recent works examined and/or mobilized the concept of knowledge ecosystems (Van der Borgh *et al.*, 2012; Järvi *et al.*, 2018; Öberg and Lundberg, 2022; Cobben *et al.*, 2022). Knowledge processes and, particularly knowledge development and transfer, are studied as the objective goals of the ecosystem. Two reinforcing mechanisms for knowledge development in the knowledge ecosystem are identified: structure and openness (Öberg and Lundberg, 2022). Structure describes a linear knowledge transfer accomplished through the ecosystem members who need to develop their capabilities to generate knowledge, rather than to develop the content of knowledge. Openness describes how ecosystem members interact and achieve common or shared purposes, how knowledge is developed and, how ecosystem expands its

knowledge base through collaborations with parties outside its own boundaries (Van der Borgh *et al.*, 2012; Järvi *et al.*, 2018). Those collaborations are made by firms rather than by a focal actor playing the role of coordinator (orchestrator) or than a public institute such the one of university. Indeed, in this literature, knowledge ecosystems are defined as "*heterogenous set of knowledge-intensive companies and other participants [ , such as universities, regional system networks, etc.], that depend on each other for their effectiveness and efficiency and as such need to be located in close proximity*" (Van der Borgh *et al.*, 2012, p. 151). From that view, knowledge ecosystems focus on the development, transfer and integration of knowledge among parties (Cobben *et al.*, 2022), in pre-competitive settings where the output of knowledge processes is innovation (Järvi *et al.*, 2018).

A distinction is furthermore made between pre-competitive knowledge ecosystems searching for a knowledge domain and those searching within an identified knowledge domain, respectively characterized as prefigurative and partial forms of organizing (Järvi *et al.*, 2018). While in prefigurative ecosystem elements of organizing are absent but sufficiently predictable to be introduced later; in partial organized ecosystem, regulation and monitoring are present. They structure the organization logic of the ecosystem, as they are in use for coordinating the participants and their knowledge creation activities. But, as observed by Järvi *et al.*, (2018), despite the identification of the two organizational logics, the variety of knowledge ecosystems involves different configurations of search processes, because of a movement of back and forth between the two types of searches (for and within a knowledge domain). While the authors explain this movement thanks to a problem-solution pairs mechanism in reference to Von Hippel and Von Krogh (2016), we assume that the organizational logic of a knowledge ecosystem is itself subject to innovation. We do here reference to organizational innovation defined as "*changes in the organization's structure and processes, administrative systems, knowledge used in performing the work of management, and managerial skills that enable an organization to function and succeed by using its resources effectively*" (Damanpour *et al.*, 2009, p. 655). Based upon this definition Fernandes Rodrigues Alves *et al.*, (2018) identified several activities they classified as organizational innovation, such as brand management, divisional structure, leadership development, decentralization, the balanced scorecard, intellectual capital measurement and Six Sigma. All these activities are however emblematic to a business logic of organizational innovation, where the objective goal is business performance and the firm's environmental context is

competitive. One can here ask if organizational innovation matters in non-competitive environment. This paper addresses this gap by examining the case of the emergence of a non-precompetitive knowledge ecosystem.

### **3 Methodology**

#### **3.1. Research context: Kronos ecosystem**

For the purpose of our research question, we conduct an exploratory case study of a regulated safety context, applying a thematic analysis method (Gehman *et al.*, 2018; Williams and Moser 2019). A qualitative approach is appropriate for exploring the characterizing observed phenomena (Yin, 2008). Due to confidentiality issues, we will refer to the studied case under the code name Kronos. Kronos is an ecosystem form by various organizations in the energy field. These include (see table 1): public industrial and commercial establishments (Alpha, Eos, Helios), multinational companies (Daedalus, Talos), public companies (Icarus), professional federations (Perseus), administrations (Atlas, Sisyphus), and public institutions (Orpheus). Evolving in a safety-regulated context, the main objective of Kronos is to establish a sustainable knowledge for safety-related activities. This safety purposes within the ecosystem will be driven by certain standards and regulations to achieve a common public objective which requires strong technical know-how. Contrarily to traditional knowledge ecosystem, this objective is thus not hampered by individual positioning strategies of the actors. There is no competition between actors neither in upstream nor in downstream phases of the ecosystem's life cycle (emergence and existence). This stress the need to understand how a non-pre-competitive ecosystem emerges.

#### **3.2. Data collection**

We collected primary and secondary data during a period of sixteen months (from 2021 to 2022). Primary data were collected from 42 semi-structured interviews we conducted with members of the studied regulated safety context (see Table 1). It represents approximately 60 hours of recording for 700 pages of transcripts. Primary data were extended with secondary data from multiple sources; archives (mainly internal documents and public ones representing approximately a total of 1300 pages), frequent interactions with field actors (including regular meetings and informal exchanges) and observations through participation in various events. Data collection and analysis were conducted

iteratively between field and theory (Suddaby, 2006; Eisenhardt *et al.*, 2016; Gehman *et al.*, 2018).

Semi-structured interviews were conducted to have access to the experience of the ecosystem's various actors (Langley and Meziani, 2020), in order to expand our understanding of the studied phenomenon. We progressively identified the relevant informants through various exchanges with field actors and preliminary interviews. The interview guide on which we based our data collection was gradually built around several themes identified as the study progresses (e.g., intra- and inter-organizational KM, ecosystem, dynamics of interactions and collaborations, KM process, organizational structure and architecture).

Table 1: Interviews

<b>Organizations</b>	<b>Typology</b>	<b>Number of interviews</b>	<b>Interviewees</b>
Alpha	Public industrial and commercial establishment	28	Knowledge manager (1), Knowledge engineer (2), Safety manager (5), Safety engineer (4), Scientific and technological manager (3), Scientific and technological engineer (3), Memory manager (1), Strategic manager (2), Engineer (4), Archivist (2)
Eos	Public industrial and commercial establishment	1	Knowledge manager (1), Knowledge engineer (1)
Helios	Public industrial and commercial establishment	3	Knowledge manager (1), Project manager (2)
Icarus	Public company	1	Project manager (1)
Talos	Multinational company	2	Project manager (1), HR manager (1)
Daedalus	Multinational company	2	Knowledge manager (2)
Atlas	Administration	2	Senior official (1), Archivist (2)
Sisyphus	Administration	1	Archivist (1)
Orpheus	Public institution	1	General archivist (1), Archivist (2)
Perseus	Professional federation	1	Project manager (1)
<b>Total</b>	3600 min (60h) / 700 pages of transcripts (400,000 words)		

### **3.3. Data analysis**

In order to bring out different explanatory mechanisms, the main data (the interviews) were fully transcribed and analyzed in several stages with thematic

analysis method (using Nvivo software for qualitative data analysis) to gradually construct meaning (Williams and Moser, 2019). Following Gioia *et al.*, (2013) systematic approach to qualitative data analysis, several codes emerged inductively from the data (Gehman *et al.*, 2018).

Initially the analysis is conducted through an abstract process of open coding (Strauss and Corbin, 2003). Then, during the analysis process we categorized the different information directly from the field (at the 1st order level of informants). And we compared these different categories allowing themes to emerge that would allow us to begin to explain and understand the phenomenon under study (at the second-order level of theoretical themes) (Gioia, 2021). Finally, we organized and structured these emergent themes into global dimensions to be able to build and support our theorizing at a higher level of abstraction (Gioia *et al.*, 2013; Williams and Moser, 2019).

## **4 Results**

Our results highlight that Kronos is a non-competitive knowledge ecosystem emerging from two specific contexts aiming to satisfy recent political regulations (4.1). This new knowledge ecosystem differs from traditional knowledge ecosystems in the conditions of its emergence. The non-competitive knowledge ecosystem Kronos emerges through organizational innovation materialized at the internal and external level. Organizational innovation takes the form of development of knowledge management systems. In the case Kronos, such development is operated at the internal (4.2) and the inter-organizational level (4.3).

### ***4.1 The emergence of a new form of ecosystems***

Kronos is in the process of emerging following three main pre-existing conditions: two context specificities, that are (i) safety context and (ii) non-competitive context; and (iii) a focal actor able to orchestrate activities and KM processes generating sustainable knowledge.

#### ***4.1.1 A regulated safety context***

Organizations involved in Kronos evolve in a context very constrained by regulations to ensure a long-term perspective of safety-activities (i.e., the activities and their objective are envisaged over a long period, corresponding to several decades). This objective is materialized by the ability of ecosystem members of Kronos to control and/or apply safety standards.

*"There are management measures that guarantee long-term operation (...) What is important for us is that we have a device that is operational and that lasts over time." (#32)*

Indeed, in this type of context, organizations are forced to demonstrate their ability to control security. For these purposes, they must provide written and formalized evidence. This evidence is subject to validation by regulatory bodies. Thus, the day-to-day operational procedures are not subject to the law of "chance". Every procedure must be authorized before being put in place. These validation and control processes between the operating organizations, on the one hand, and the organizations having the role of control, on the one hand, produce a huge number of interactions.

*"[Ecosystem actors] have [safety] requirements, which are prescriptions of means, and they also have prescriptions of objectives. In fact, it's a mix, they have objectives to follow and, in some cases, for some particular things, means to follow as well. And so, that, we [public authorities] check all the time." (#32)*

#### 4.1.2 Non-pre-competitive context

Here there is no competitive logic between the actors. They are, as they describe it, in *"the same boat"*. The survival of their business depends on their joint effort to collaborate and achieve the safety objective jointly. Due to the context and its specificities, actors of Kronos are interdependent, and they have predefined roles (see figure 1), and their main activities are contractually or legally defined.

*"We all work together for a common goal and a common vision; beyond that we also have common projects." (#40)*

Those activities materialize sustainable and inter-organizational knowledge flows within Kronos. Those activities are composed of complex and varied knowledge and know-how (including more than 50 domains of expertise), through several projects (sometimes over decades). It implies collaboration and coordination between Kronos actor which in turn generates inter-organizational knowledge share, combination, and creation. This collaboration and coordination mechanisms ensure the sustainability of shared, combined and created knowledge. The value proposition materialized by Kronos is thus the flow of sustainable and inter-organizational knowledge within the ecosystem. Such main goal of Kronos characterizes its non-pre-competitive context orchestrated by Alpha.

*"Multilateral interactions are strongly driven by [Alpha], necessarily (...) globally, it is still pretty structured, with committees that exist, participants who are more or less designated, and all of this is driven by [Alpha] according to the challenges of the upcoming schedules (...) there is always this management by [Alpha] and this centralization by [Alpha]." (#37)*

However, the inter-organizational knowledge flow within Kronos is composed of various knowledge typologies: scientific knowledge (required by R&D for innovation), technical knowledge (for the development and achievement of projects), practical knowledge (on the products and services provided), organizational knowledge (all the knowledge of the organizations and their members, required to perform the activities) and know-how (tacit knowledge of organizations' members). This implies interactions between actors, to align with the safety regulated system. Such alignment is enabled through a focal actor that is Alpha.

#### 4.1.3 Orchestrating external and inter-organizational knowledge management

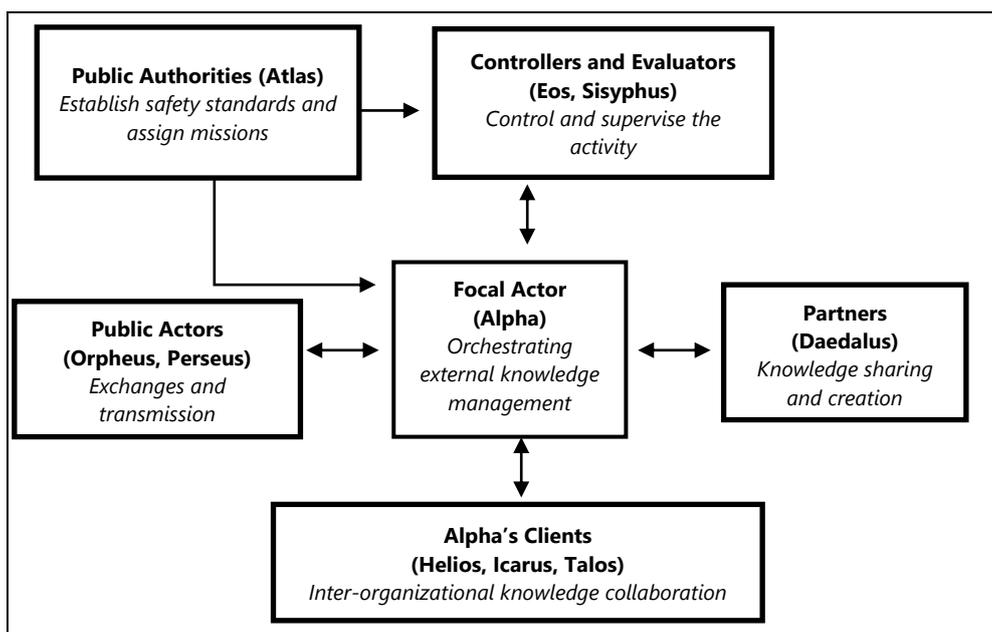

Figure 1: Kronos ecosystem

As shows it figure 1, interactions induced by the regulated safety context materialize between three groups of Kronos's members: public authorities that establish safety standards and assign missions (Atlas), controllers and evaluators

who control and supervise the activities from a safety perspective (Eos Sisyphus), and a focal actor (Alpha).

Alpha appears as a focal actor of Kronos as it is positioned as an orchestrator between actors achieving control processes and three other groups of actors. The first other group of actors includes members of Kronos who are concerned by knowledge transfer (Orpheus and Perseus), those who are concerned by knowledge generation (Daedalus), and those who are concerned by knowledge collaboration (Helios, Icarus, Talos). Both three groups must comply with its standards in their knowledge management processes. The focal role of Alpha is then characterized by its capacity to ensure the flows between knowledge management processes and enforcement of regulatory standards. In other words, Alpha is the focal actor of the ecosystem, because it is in charge of ensuring the coordination and collaboration among all groups of actors.

*"Afterwards, at the national level, I consider that everything must come from [Alpha]. It is the official actor who is in charge of [the ecosystem activity] and it must come from [Alpha], not to formalize knowledge, but to establish rules. And then, of course, it also comes from [Alpha] through [a common knowledge base], etc. To have a level of knowledge and capitalization of knowledge that is somewhat the basic foundation. After that, it's up to each actor to build on this base, to develop methods and elements of standardization and knowledge management within the organization. This is what we do, in a more or less formalized way." (#33)*

However, sustainable knowledge creation also requires organizational innovation in the form of the development of a knowledge management system at both intra and inter organizational level.

#### **4.2. Organization of knowledge management process at the internal level**

To create and share sustainable knowledge, the actors of the ecosystem must implement an inter-organizational knowledge system. To this end, actors must first innovate in their intra-organizational architecture by building a knowledge management system within their own organization.

To take part in the inter-organizational knowledge flows within the ecosystem, actors must each have a knowledge management system at the intra-organizational level. In the case of Kronos, some actors did not have internal knowledge management systems, or their knowledge management systems were not sufficiently well organized to meet the objectives of inter-organizational knowledge management at the ecosystem level. To fill this gap, progressively, the

main actors in the ecosystem have initiated different approaches to manage their knowledge internally.

#### 4.2.1 Organizing internal knowledge management through four stages

This was done through different stages that lead to the construction of different knowledge systems. We named these stages as follows: (1) Needs, (2) Means, (3) Objectives, (4) Structuring.

At the first stage, actors identify the knowledge management (KM) needs.

*"[Helios] has become aware, [Helios] became conscious of the fact that KM was important and that it would not be bad if we had a centralized management and at least a common methodology and that we could share, since as I said, each one was doing their own thing in their own corner, which does not mean that it was not good, but simply that it is true that it is perhaps more interesting if we can have an extended model that can be used by the whole organization." (#40)*

Organizations in the ecosystem have gradually become aware of the need and interest in managing their knowledge, through various factors and triggers related to the regulated safety context or to internal organizational needs. At the regulated safety context, there may for example be external institutional pressures (e.g.; new standards or recommendations). At the internal level, there is for example the need to fill the risk of knowledge loss or to codify individual knowledge of experts from organizations likely to leave the ecosystem (for retirement, or a new job, etc.). Those needs can be identified at the hierarchical level of the organizations (the board of directors).

*"I can confirm that this is a common problem for all the actors within [the ecosystem] (...) retirements (...) are a problem for [the ecosystem]". (#40)*

At stage two, organizations give to itself the means to enable the implementation of KM processes. This requires some organizational changes or evolutions within their own organization to initiate a global internal knowledge management process.

*"[The support of the board of directors] is absolutely essential because we are in activities that have a lot of difficulty measuring their value (...) And so, either there are heads who are convinced of this and who think that there is a close association between general knowledge or shared knowledge and performance in general, or to avoid nonsense. Well, if they believe it, that's fine. If they don't believe it, it's very hard to prove it to them. There are ways to get around it. At the end of the day, you have to*

*have metrics, you have to bring metrics. You have to give confidence.”*  
(#31)

At stage three, organizations set the targets to be achieved in terms of KM. They implement knowledge management processes within their borders according to different purposes and to reach several objectives. In the short term, these objectives consist of filling the need to codify tacit knowledge at risk of loss. In the long term, it is about improving performance, facilitating organizational innovation, and creating a knowledge memory.

*“Knowledge management must meet your needs and your operational goals. It is even a guarantee of a more solid anchoring than a theoretical approach that would be diffused.”* (#38)

And at stage four, actors’ structure intra-organizational KM processes. They progressively built and organized their knowledge management process in a systemic way.

*“[At Daedalus] we have defined a matrix [of the knowledge system] with different themes. So, we have five themes: knowledge transfer, knowledge sharing, capitalization, storage and distribution. And for each of these themes, we have identified three topics, and so the objective for us in the knowledge management program is to transform employee knowledge into corporate knowledge and make it accessible to everyone when needed.”*  
(#41)

#### **4.3. Moving towards the emergence of a non-precompetitive knowledge ecosystem through the development of an inter-organizational knowledge management system**

As Kronos’s actors evolve in a non-precompetitive but safety regulated context, the organizational innovation operated at the intra level also contribute to the development required at the inter-organizational level. Kronos emergence is materialized by the development of an inter-organizational knowledge management system facilitated through three enablers and three mechanisms of emergence.

##### *4.3.1 Enablers of emergence*

The first enabler of Kronos emergence is the sharing of KM approaches between actors. The different knowledge management approaches of organizations will lead to be shared and disseminated in the context of their interactions. The second enabler is the sharing of knowledge bases and KM tools

between actors. Because of their cognitive proximity in terms of knowledge management, actors are led to share and have a certain number of common KM devices and tools. And the third enabler is the sharing of good practices between actors. In their operational interest and to reach the goals of their knowledge management approach, actors share their good practices and their feedback on knowledge management.

*"We have a very strong ecosystem with companies to which we are closely linked. And it is essential that these companies know how to keep their knowledge to ensure the quality and monitoring of manufacturing. So, we intervene. We regularly intervene with partners to help them capitalize on their know-how, on their technical gestures or things like that." (#30)*

#### 4.3.2 Mechanisms of emergence

The organizational innovation operated at the intra-level results in an improvement of actors' practices which in turn serve at the inter-organizational level. This leads them to organizational innovation in the way they organize and operate at the ecosystem level. Three inter-organizational KM mechanisms facilitate the emergence of Kronos. First, in the context of their activities and regulatory obligations, actors are led to exchange, combine and create knowledge in a sustainable way. The first mechanism is then knowledge processes between actors. The second mechanism is the development of common KM practices and issues within the ecosystem. Due to a common culture, actors have a certain cognitive proximity, which in terms of knowledge management translates into shared practices and issues. And, the third mechanism relay on actors' continuous learning to improve their practices and way of doing things through regular exchanges between them. The regular interaction of actors in charge of knowledge management in different organizations leads to the improvement of their practices and way of doing things through continuous learning.

*"There are many aspects, subjects that concern us, but also [the ecosystem activity] itself, that are actually learning and are in a continuous learning perspective. And so, the more we learn and the more we develop practices, we identify best practices. These identified best practices are able to change the organization. And our goal is to do this continuously. And we are perfectly aware of different aspects that the organization modes or certain current practices are not the best or in any case, it could be better. There are avenues on this too, there is work, anyway, that aims to seek better ways of doing things, on all subjects." (#36)*

#### 4.3.3 Obstacles

There are however two obstacles to face during the emergence process of Kronos ecosystem. First, the ecosystem actors are gradually moving towards inter-organizational knowledge management despite the challenges and difficulties identified. Second, the initiation of systemic shared knowledge management between ecosystem actors, lead the ecosystem to move towards systemic inter-organizational management.

*"Today we have a basic foundation and a process that is established by [Alpha], but today we do not have a common rule (...) I would say that today we have methods and processes for knowledge management, through for example everything that is [shared knowledge base]. This is the foundation. And these processes are then declined in the knowledge file, knowledge control and [product] processes. But there is still a part, a part where we don't have, we remain at the macro level (...) But certainly for me, we would have feedback to share, that is, we take the best [products] of all, and we all do the same, that would be great. But today, it's not like that. We don't have fine centralized management, nor our technical processes, and therefore not our knowledge management processes." (#33)*

## 5 Conclusion

This paper examined the case of the ecosystem Kronos. It aimed to understand what type of knowledge ecosystem Kronos is. And to specifically study how such a new type of knowledge ecosystem emerge. The paper shows that Kronos is a non-pre-competitive knowledge ecosystem where actors' interactions are strictly collaborative due to its main goal: sustainable and inter-organizational knowledge management. The ecosystem's activities are organized through the development of projects involving long-term knowledge collaboration, where the role and missions of the actors are predefined. The regulated safety context structures furthermore the interactions between the ecosystem members in two ways: control (of security and safety) and collaboration. Emergence of the ecosystem is enabled by internal and inter-organizational innovation, i.e., the development of a knowledge management process. Organizational innovation is articulated within the actors' own (intra-organizational) knowledge systems, but also through the knowledge flow that is exchanged at the inter-organizational level.

To achieve this, ecosystem governance is ensured by a focal actor (a legitimate state actor), which is different from the focal actor of pre-competitive knowledge

ecosystem (a leading firm, or a research institute). In a non-precompetitive knowledge ecosystem, the focal actor assumes the role of orchestrator such as pre-competitive knowledge ecosystem. However, they differ in that, in non-precompetitive knowledge ecosystem (Alpha), orchestration activities are mainly ensured through regulatory legitimacy. The goal is to ensure the sustainable flow of knowledge through coordination and collaboration of ecosystem members.

## Abstract

This study takes the British equity crowdfunding platform Crowdcube as the research object, and explores the impact of the persuasive language style on the final performance of equity crowdfunding. This study uses the Linguistic Inquiry and Word Count Dictionary (LIWC) to carry out classification and frequency of vocabulary in the text. The results show that emotional language style has a significant positive impact on equity crowdfunding performance, which demonstrates that using positive emotions of entrepreneurs can most arouse investors' empathy and then invest. Besides, social discussion provides positive signals for investors and is positively associated with equity crowdfunding performance. However, there is no significant impact on emotional language style on the crowdfunding performance. Finally, the study suggests writing styles of project content for entrepreneurs who raise funds through equity crowdfunding to reduce information asymmetry with investors, and at the same time use rhetorical techniques to improve their persuasive language and improve their fundraising performance. For example, it is suggested that entrepreneurs should make more use of emotional rhetoric when writing ideas, which can improve empathy and reduce psychological distance, so that investors can be more sure of the value of equity crowdfunding projects and attract more investment.

**Keywords** – Equity Crowdfunding, Information Asymmetry, Persuasive Language style

**Paper type** – Academic Research Paper

## 1 Introduction

Crowdfunding is a new channel for start-ups to obtain capital financing. Previous research has focused on reward-based crowdfunding, and less research

has been focused on equity crowdfunding. Investing in equity crowdfunding campaigns, investors receive not only a portion of dividends but also capital appreciation in the future. Therefore, information asymmetry is a serious problem in the context of equity crowdfunding (Vismara, 2018).

To overcome these asymmetries, entrepreneurs can communicate quality information to investors through the information provided in the project description. Related research discussing the determinants of equity crowdfunding is mostly based on the effects of product category, quality of signals, or entrepreneurs (Chan, Park, Patel, & Gomulya, 2018). However, information overload on the Internet causes decisions to be made quickly. Generally, investors browse the summary of fundraising projects quickly, and only if they are interested will they further research this fundraising project or invest further. Therefore, how the persuasive style of abstract text affects crowdfunding performance is the question explored in this study.

Studies discussing persuasive style language are only on reward-based crowdfunding (Angerer, Niemand, Kraus, & Thies, 2018; Kraus, Richter, Brem, Cheng, & Chang, 2016), and there are a few studies aimed at exploring the relationship of style language and performance of equity crowdfunding. Aristotle's Rhetorical Theory of Persuasion states that the persuasiveness of language changes attitudes and ultimately leads to differences in behavior. In general, following the rules of language use elicits a positive response from the recipient and increases persuasiveness. Persuasion is the process by which we try to change the attitudes of others (Mehran & Mahdii, 2016), and the role of persuasive language in advertising and communication has been extensively studied (Wright, Friestad & Boush, 2005). For example, Wang, Chen, Zhu, & Wang (2016) explored the influence of persuasive language on reward-based crowdfunding activities, and used Kickstarter to demonstrate that persuasiveness in the text is one of the important factors affecting investment decisions.

The language styles reveal the sentiment of human beings, and usually reflect the personality and psychological status. Some studies have found that language represents different dimensions of personality, such as Francis (1993), Kahn, Tobin, Massey, & Anderson (2007) and Joksimovic, Gasevic, Kovanovic, Adesope, & Hatala (2014).

In the business field, some studies from marketing aimed at the influence of social media on customer mindset (Kübler, Colicev, & Pauwels, 2020), and some studies focus on the relationship between linguistic style and crowdfunding success (Parhankangas & Renko, 2017). Although linguistic style has been

discussed in previous studies, what kind of language style and in what way for entrepreneurs and equity crowdfunding projects is still vague in the literature. Therefore, this study explores the relationship between language style and performance of equity crowdfunding, and employs the data from Crowdcube for empirical study.

## **2 Literature Review and Hypotheses Development**

Equity crowdfunding (ECF) is a special kind of crowdfunding that involves offering shares issued by a fundraiser to investors and is therefore often subject to traditional securities laws and other regulatory restrictions. Access to financial resources is a fundamental challenge for entrepreneurs (Cassar, 2004; Gompers & Lerner, 2004). Previously, only wealthy individuals, venture capitalists and business angels could invest in startups. Therefore, startups have relied on financing from professional equity investors, especially venture capitalists (VCs) or business angels (BAs) to achieve early growth (Harrison, 2013). Emerging equity crowdfunding platforms democratize the investment process by opening the doors to a larger pool of potential investors, known as the "crowd". Over the decades, equity crowdfunding has evolved into a viable alternative to early established forms of equity financing (Block, Fisch & Praag, 2016). This form of funding allows startups to raise capital from many private investors in exchange for equity or profits through intermediary online platforms (Ahlers, Douglas, Christina & Denis, 2015).

In the context of equity crowdfunding, information asymmetry is a serious problem (Vismara, 2018). To overcome these asymmetries, entrepreneurs can communicate quality information to investors through the information provided in the project description. For example, studies have shown that equity retention, information and human capital can increase the likelihood of successful equity fundraising (Piva & Rossi-Lamastra, 2018; Vismara, 2016; Ahlers et al., 2015). These signals are usually provided by the entrepreneur and do not change during the crowdfunding campaign.

For crowdfunding activities, entrepreneurs use written materials on the platform to prove that their products or services are competitive and have great potential for future development, so as to convince investors to invest in them. Therefore, the persuasiveness of words in crowdfunding projects has a great impact on crowdfunding performance. This is similar to word-of-mouth marketing in the field of marketing. Traditional marketing scholars believe that word-of-mouth has two effects; perception effect (awareness) and persuasion

effect (persuasiveness) (Pang & Lee, 2008 ; Järvinen, Tollinen, Karjaluoto & Jayawardhena, 2012 ). The influence of the perceived effect of word-of-mouth on product sales comes from the description and transmission of basic product information in the text. However, there are few literatures that systematically study the persuasive effect of word-of-mouth marketing, especially the persuasiveness of language from the perspective of text analysis.

As an important supplement to word-of-mouth marketing, in addition to providing basic information on the quality of crowdfunding projects, its persuasive effect will have a significant impact on the investment behaviour of participants, and ultimately affect whether crowdfunding projects can successfully raise funds (Wang et al., 2016).

Reward-based crowdfunding projects can be seen as an appeal from entrepreneurs to investors, who are often emotionally inclined. Chen & Thomas & Kohli (2016) found that emotional information has an overall positive impact on successful fundraising goals in reward-based crowdfunding. Wang et al. (2016) research results show that appealing to emotion has a positive impact on the performance of reward-based crowdfunding activities. And studies have shown that emotional appeal is more important for hedonic products (Armstrong, 2010). Xiang & Zhang & Tao & Wang & Ma (2019) studied the kaishiba.com crowdfunding platform in China and divided supporters into two types: consumers and investors. Consumers support projects in the expectation of remuneration for the product et al., while investors seek financial returns. Research shows that emotional appeal has a greater impact on consumers than on investors.

Therefore, this study proposes the following hypothesis:

*Hypothesis 1: Emotional language style is positively related to equity crowdfunding performance.*

Appealing to logic means that the speaker gives a speech in a logical deduction method, which is an effective means to smash certain rumors (Gentes & Selker, 2013). It falls into the category of appeals to reason in Aristotelian rhetoric. Rational appeals follow awareness, knowledge, likes, preferences, beliefs, and buying patterns. It may include detailed information about the product such as specific features, durability and value. Advertisements with rational rhetoric can make people more sure of the value of the product, and ultimately make a purchase. Rational appeals mainly persuade consumers through fact-based information and influence (Wang, Qiu, Kim, & Benbasat, 2016). Therefore, consumers usually make purchase decisions based on their

personal sense of logic and reasoning. Successful rational appeals depend on how persuasive they are or how persuasive their arguments are. The logic system of advertising display also has a significant impact on advertising effectiveness. Information that evokes logical judgments is likely to attract more investment (Smith & Berger, 1996). Studies have pointed out that in the 13 most successful crowdfunding projects, the initiators used logical language expressions in project descriptions to varying degrees (Tirdatov, 2014). Therefore, this study hypothesizes as below:

*Hypothesis 2: Logical language style is positively related to equity crowdfunding performance.*

Studies on marketing research have proven that online reviews are positively associated with sales volume or sales intention. Ahani, Nilashi, Ibrahim, Sanzogni, & Weaven (2019) predict that online hotel reviews are evaluations of product quality for other customers. For those who are searching for products or services, online reviews play an important role in judging the advantages or disadvantages based on the experience of reviews.

In a systematic review of e-marketing activities of star-ups, Chakraborti, Dutta, & Jana (2022) found that customers rely on online reviews for further purchasing. The behaviour may result from a signal theory that the new customers collect related information before decision making (Siering, Deokar, & Janze, 2018). More discussion in the fundraising projects shows more investors interested in this project, which may lead to successful performance (Ahlers, et al., 2015). Therefore, this study hypothesizes as below:

*Hypothesis 3: Social discussion is positively related to equity crowdfunding performance.*

### **3 Methods**

#### **3.1 Data**

The data for this study collected from the fundraising target, corporate philosophy and business plan is from the period from August 1, 2021 to August 1, 2022 on the Crowdcube website. The data collection process follows the rules as below. First, the interception of the data is at the end of the project. Second, the items of the last day for each project are summarized into a list. Third, project content includes company name, release date, target amount, final fundraising amount, idea, business plan, etc. are collected. There are finally 241 projects in the data pool.

Francis & Pennebaker (1993) conducted text analysis on the text data that people usually write. They classified the words, and then compiled a dictionary of words after calculating the words by programming. A text analysis application called Linguistic Inquiry and Word Count (LIWC) has been well developed after that.

This study used the fifth version of LIWC (LIWC-22), consisting of nearly 6,400 words, word stems, and curated emoji. The LIWC program includes the main text analysis module as well as a set of built-in dictionaries. After the processing module reads and counts all the words in the given text, it calculates the percentage of the total number of words that match each dictionary category. For example, if LIWC analyzed 2,000 words and compared them to the built-in LIWC dictionary, it might find that 150 pronouns and 84 positive emotion words were used. It converts these numbers into percentages; 7.5% for pronouns and 4.2% for positive emotional words.

This study mainly focuses on the language style analysis of the "idea" part in each equity fundraising project, for the following reasons. First, the idea is located in the first category of the webpage of crowdfunding projects, mainly used for project overview, and attracts investors' interest with short text. When investors are interested in the content presented in the concept of the company, they will apply to the company for its plan and other internal materials. Therefore, a convincing idea is very important for crowdfunding projects. Second, the team qualification is mainly for the personal introduction of entrepreneurs, and fewer rhetorical techniques will be used. Third, there are many complicated texts in the business plan and other content, which may result in errors in the processing process. The content of the idea is streamlined, and the consistency and accuracy of the also higher for all projects.

### **3.2 Variables**

#### **Dependent variable**

*Equity crowdfunding performance.* The performance of equity crowdfunding is defined as the success rate of fundraising on the last day of the crowdfunding project.  $\text{Fundraising amount on the last day} / \text{target amount} \times 100$ .

#### **Independent variables**

*Emotional language style.* This variable uses all the vocabulary categories related to emotion in the LIWC dictionary, which includes the categories of positive emotional tone (tone\_pos, emo\_pos). The sum of the percentages of LIWC's final use of emotional words is calculated.

*Logical language style.* In this study, the words which are related to logic are classified into the lexical categories of logic in LIWC, including conjunction words (conj), insight words (insight), and causal words (cause). The sum of the percentages of LIWC's final use of these categories is calculated.

*Social discussion.* The variable of social discussion refers to the amount of discussions that investors or members of Crowdcube publish regarding the focal company. The variable indicates the signals that investors are interested in this company. The natural logarithm of the variable is calculated.

**Control variable**

*Risk assurance.* In England, the government provides income assurance projects, including the Enterprise Investment Scheme (EIS) and Seed Enterprise Investment Scheme (SEIS), encouraging investors to invest in new ventures. EIS and SEIS are used as a measure of risk assurance variables, and are recorded as 1 if the fundraising project has been included in EIS and SEIS, otherwise recorded as 0.

This study used SPSS 22 to test the internal consistency of all variables, and hypothesis testing was performed through multiple linear regression analysis.

**4 Results**

Table 1 illustrates the correlation coefficients of all variables used in the regression analysis.

Table 1 Descriptive statistics and Pearson correlation matrix

Variable	Means	S.D.	1	2	3	4
1 Equity crowdfunding performance	1.46	0.82	1			
2 Risk assurance	0.78	0.42	0.05	1		
3 Emotional language style	3.52	2.03	0.07	0.00	1	
4 Logical language style	8.02	2.43	-0.04	-0.03	-0.06	1
5 Social discussion	2.52	0.76	.447**	0.02	-.162*	-0.02

Note: n =241, \*: p<0.05, \*\*:<0.01, \*\*\*:p<0.001

Table 2 shows the regression results in this study. All independent variables and control variables were used in the regression model. The results show that the F-value is 16.043, reaching a significant level (p<0.01). Therefore, the regression model is predictive. The R-square in this model is 0.22, which is less than 0.7. It may result from the limitation of data collection. We suggest future research may collect other kinds of data to enlarge the dataset.

Table 2 Regression Model

Variables	Y=Equity crowdfunding performance
Risk assurance	.014 (0.118)
Emotional language style	0.140** (0.024)
Logical language style	-.026 (0.020)
Social discussion	0.469** (0.065)
F value	16.043***
R-squared	0.22
Adjusted R-squared	0.207
N	241

Note:

1. standard errors are in brackets

2. \*:  $p < 0.05$ , \*\*:  $p < 0.01$ , \*\*\*:  $p < 0.001$

In Table 2, the coefficient of risk assurance is 0.014, which is positive but does not reach a significant level. The coefficient of emotional language style is 0.140, which is positive and reaches a significant level. The results show that emotional language style and social discussion are positively correlated with equity crowdfunding performance, but logical language style is negatively correlated with equity crowdfunding performance but fails to reach a significant level. Therefore, hypothesis 1, that emotional language style is positively associated with equity crowdfunding performance, hypothesis 3, that social discussion is positively associated with equity crowdfunding performance are both supported. However, hypothesis 2, that logical language style is positively associated with equity crowdfunding performance, fails to support it.

## 5 Discussion and Conclusion

This study has several contributions. First, this study enriches the literature on equity crowdfunding activities in the field of signaling theory. Most of the previous literature on crowdfunding focused on incentive-based crowdfunding. Although most of the research on equity crowdfunding was based on signaling theory (Ahlers et al., 2015; Vismara, 2016), the research was focused on making crowdfunding campaigns through tangible products or entrepreneurial factors. In contrast, from the perspective of text content, this study tries to explain how the language styles affect the results of equity crowdfunding, and confirms that social discussion has a significant impact on crowdfunding performance.

Second, this study confirms the impact of a persuasive language style on equity crowdfunding, extends Aristotle's rhetorical theory to the field of equity crowdfunding, and finds that emotional expressions are important rhetoric for equity crowdfunding.

Third, the results show that the more the number of investors that investors publish regarding the project, the higher the equity crowdfunding performance. The results demonstrate that the more discussions about the new ventures seem to provide a signal for other investors.

The findings of this study have important implications for entrepreneurs of start-ups in equity crowdfunding platforms for writing project content. Correct and effective text content can help entrepreneurs communicate their ideas to investors, let investors better understand the content of equity crowdfunding projects, and improve their investment desires. The results suggest that consideration of the following recommendations may increase the success rate of equity crowdfunding campaigns. First, this study can guide entrepreneurs in generating attractive text descriptions. It is suggested that entrepreneurs should make more use of logical and emotional rhetoric when writing ideas, which can improve persuasion and reduce psychological distance, so that investors can be more sure of the value of equity crowdfunding projects and attract more investment.

Second, businesses with EIS and SEIS should pay more attention to the interpretation of risks. Because EIS and SEIS only protect the rights and interests of British investors and reduce their investment risks, but for investors in other countries, they can only be used as a reference. The specific investment risks need to be understood through other content in the crowdfunding project. Therefore, entrepreneurs who have EIS and SEIS need to be prepared for danger in times of peace, not only rely on this risk protection factor, but also send other risk protection quality signals to investors to attract more investment from non-UK investors.

### **Abstract**

The need for environmental awareness and green management in business and management arenas has led to green becoming a vast field that needs to be parcelled out to identify the green shoots. Knowledge is emerging as the key factor in developing a green awareness in companies, which has come to be called green intellectual capital (GIC). The objective of this research is therefore twofold. First, to identify and map the existence of active research fronts in the field of green through a bibliometric analysis (bringing green shoots to the surface); and second, to analyse in depth the GIC research front previously identified in this paper (one of the green shoots that emerged) and to offer new insights into it. We analysed 4,180 articles (4,142 for the identification of green research fronts and 38 for GIC) from WoS published between 2008 and 2022. Amongst the potential contributions made by this study include characterising 19 of the most active research fronts on green in business and management, as well as to know what advances have been made (and what remains to be done) in the literature on GIC.

**Keywords** – Green, Business and management, Green intellectual capital (GIC), Bibliometrics, Bibliographic coupling analysis (BCA).

**Paper type** – Academic Research Paper

## 1 Introduction

Green issues have become a topic of interest for both academics and practitioners in different spheres worldwide. The need for environmental awareness and green management evolves from a variety of wrongdoings that have transpired over time (Pane Haden et al., 2009). Business has not escaped this interest in green issues and in recent decades has become increasingly concerned with incorporating sustainability aspects into business management, through their corporate, competitive, and functional strategies. In this way, many organisations are trying hard to become more sustainable organisation (Yusoff et al., 2019), for example, by incorporating green business strategies (Leonidou et al., 2017), by developing green entrepreneurship (Silajdžić et al., 2015) or green business innovations (Lin et al., 2011) leading to green business models (Nair & Paulose, 2014). Although the introduction of green in business goes back several decades, business and management researchers have made considerable efforts to contribute new knowledge on green and environmental issues in recent years. Data provided by Web or Science (WoS) show that the production of scientific articles on green has quadrupled in the last decade (2012-2022), which gives an idea of the relevance and maturity of the field.

As a field or domain of research enters its stage of maturity, it fragments into different areas that are more specific or address particular problems. To use a recent analogy, as the Coronavirus matured, that is, as it spread as a pandemic among the world's population, new variants emerged, bringing with them new challenges and particular problems that consequently required new methods and strategies to be addressed by the scientific community. Similarly, the maturity of the green field in business may have led to the emergence of different lines or fronts of green research. Precisely, our first research question deals with this issue.

*RQ1: Has the maturity of green in business and management led to the consolidation of different research fronts in this area?*

To answer this research question, we conducted a quantitative literature review on "green" in business and management. There are different types of quantitative literature review methods, among which bibliometric analyses are outstanding due to their robustness and reproducibility. Some studies have used author co-

citation (ACA), document co-citation (DCA), or co-word analysis (e.g., Chen et al., 2010; Leydesdorff & Welbers, 2011; Zhao & Strotmann, 2011). Others have employed the bibliographic coupling analysis (BCA) (e.g., Boyack & Klavans, 2010; Chen et al., 2011; Glänzel & Thijs, 2011). There is yet another group of scholars who have jointly used some of these analysis techniques; ACA and co-word analysis (e.g., Zitt et al., 2011) or co-citation and text-based analysis (e.g., Saft & Nissen, 2014; Mora et al., 2019). This study combines BCA and SNA techniques to explore our first research question. For this purpose, a total of 4,142 scientific articles published over the last decade (2012-2022\*) were analyzed.

Once the research fronts on green have been identified, we focus on analysing one of the fronts that in recent years is arousing great interest among researchers and business practitioners, i.e., green intellectual capital (hereinafter, GIC). In the era of knowledge economy, the significance of intellectual capital has been increasing globally. Similarly, recent studies have focused on the importance of GIC in mitigating environmental degradation (Ali et al., 2021). The concept of GIC was introduced in the seminal work of Chen (2008) and has become a booming field today. The author defines it as "the total stocks of all kinds of intangible assets, knowledge, capabilities, and relationships, etc. about environmental protection or green innovation in the individual level and the organization level within a company" (p. 277), and his proposal considers three types of green intellectual capital: green human capital, green structural capital, and green relational capital. This concept emerged in the academic literature with the aim of emphasizing the importance of the environmental intangibles possessed by the organization to improve the organization's competitive position. Therefore, our second research question is related to the existing knowledge on GIC.

*RQ2: What progress has been made (and what remains to be done) in the literature on GIC from the emergence of the concept until now?*

To answer this research question, we conducted an in-depth analysis of the 38 articles published on GIC in WoS from the origin of the concept to the present day (2008-2022). We employ a combination of bibliometric analysis techniques that provide insight into the most relevant articles, journals, institutions, and countries, as well as a content analysis that offers new insights into the approach of the works, the type of analysis, the analysis technique used, the country in which the study was conducted, the industry analysed, the sample used, the way the GIC construct is measured and the relationships tested.

In sum, this research pursues a twofold aim: (1) to identify and mapping the existence of active research fronts in the field of green through bibliographic

coupling analysis (BCA) and social network analysis (SNA); and (2) to analyze in depth the GIC research front previously identified in this paper and to offer new knowledge about it.

This paper contributes to the previous literature at least in two ways. On the one hand, to the best of our knowledge, there is no review of the literature using bibliometric techniques that identifies research fronts in the field of green-related business and management, which provides a prospective approach on research (Verbeek et al., 2002; Vogel & Güttel, 2013). This is of value to researchers who wish to have a clear and structured map of the established lines of research in this field and thus be able to focus their efforts on one of these fronts or alternatively to develop new original proposals to existing ones. On the other hand, the detailed analysis of one of the fronts allows researchers concerned with GIC to have structured knowledge, to identify gaps that offer opportunities to develop high impact research and to know the road already travelled and the future research avenues.

The remainder of this article is organized as follows. Section 2 discusses the methodological design of the research. Section 3 reports the results obtained as well as their discussion. Finally, Section 4 shows the main conclusions and implications of the study.

## 2 Materials and methods

### 2.1 Research design

The methodological design employed in this study includes two clearly differentiated stages: (1) the identification and mapping of green-related research fronts and (2) the in-depth analysis of one of the previously identified research fronts (see Figure 1).

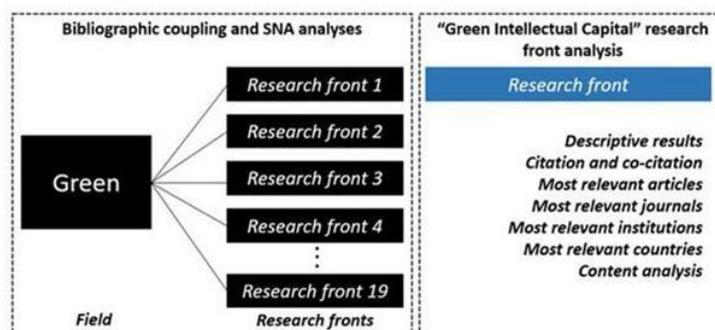

Figure 1. Methodological design.

### **First research stage: Bibliographic coupling and SNA analyses**

Since, as stated by some authors (Aria & Cuccurullo, 2017), science mapping is complex and unwieldy because it is multi-step and frequently requires numerous and diverse software tools, at the first stage of the research different analyses have been carried out and different software has been used. Particularly, for the exercise of identifying and mapping active research fronts two types of analysis have been conducted: bibliographic coupling analysis (BCA) and social network analysis (SNA).

Bibliographic coupling analysis, proposed by Kessler (1963), reveals the connection between documents based on overlapping bibliographic references (Bretas & Alon, 2021). Bibliographic coupling analyzes the similarity between two documents using the number of references shared by them (Elango, 2019; Sánchez-Famoso et al., 2020; Zupic & ˇCater, 2015). Thus, two articles citing a third publication, i.e., two "citing" documents, are coupled because high instances of mutual references in their bibliographies suggest an intellectual capital common to both (Xu et al., 2018; Khanra et al., 2021), a shared related topic (Maseda et al., 2022, p. 282), or a high thematic affinity (Kessler, 1962: 1963). Precisely, the interest of studies based on the application of BCA lies in the fact that documents connected by strong bibliographic coupling links can provide insights on the structure of research fronts within a field or academic discipline in terms of thematic relatedness (Vladutz & Cook, 1984; Peters et al., 1995; Jarneving, 2007a, 2007b).

In contrast to co-citation analysis, this technique by capturing the most recent contributions (Zupic & ˇCater, 2015) allows to detect current trends and future priorities reflected at the forefront of research (Vogel & Güttel, 2013), being therefore suitable for identifying "hot" research topics (Glänzel & Czerwon, 1995: 1996; Jarneving, 2007a, 2007b). Based on the above and given that the choice of method depends on the research objective, we chose the bibliographic coupling technique over other bibliographic techniques such as co-citation. We also used SNA to build, visualize and analyze the bibliographic coupling network.

### **Second research stage: GIC research front analysis**

The second research stage allowed us to gain a deeper understanding about one of the research fronts identified in the previous stage. Thus, in this stage we proceeded to the selection of one of the fronts to conduct an in-depth analysis of the topic addressed by that front. As mentioned above, in the era of the knowledge economy and sustainability concerns, the importance of green-related intellectual capital for reducing environmental damage (Ali et al., 2021) has

become increasingly important in recent years. For this reason, we selected the GIC research front.

We employ a combination of bibliometric analysis techniques and a content analysis to characterise the research front analyzed. The potential of content analysis lies in its combination with other methods (Gaur and Kumar, 2018), such as bibliometrics (Foguesatto et al., 2021). Bibliometrix® was used for data analysis and visualisation. This is an open-source R-package, developed by Aria and Cuccurullo (2017), which provides a tool for quantitative research in bibliometrics and scientometrics. Compared to most free software (e.g., CiteSpace and VOSviewer), Bibliometrix does not only focus on data visualization, but also on the correctness and statistical completeness of the results. Figures 3, 4 and 5 and tables 3, 4, 5 and 6 shown in the results section provide some examples of the output that can be obtained using Bibliometrix.

## **2.2 Data collection**

For rigorous bibliometric studies, data collection consists of three stages: (1) data retrieval; (2) data loading and conversion into a format suitable for the bibliometric tools used; and (3) data cleaning. To curate relevant research for this study, we limited our search to the Web of Science Core Collection™ database (WoS). Specifically, we used one of its indexes: the Social Sciences Citation Index (SSCI). Since the simultaneous use of different databases is unhelpful owing to duplication of records (Harzing & Alakangas, 2016) and WoS is considered the 'gold standard' database for measuring scholars' performance, WoS was our election.

From this database, only peer-reviewed academic journal articles in the English language were retrieved and excluded all other document types such as books, book chapters, conference proceedings or documents containing reviews or notes. According to some authors (Merton, 1973), only peer-reviewed academic journal articles can be seen as "certified knowledge", since the review process itself acts as a control mechanism to validate knowledge (Light & Pillemer, 1984; Ordanini et al., 2008). Moreover, the use of articles constitutes a common practice in these type of studies (e.g., García-Lillo et al., 2023).

The execution of the search equation in WoS, together with the criteria described above, yielded a dataset consisting of 4,142 articles on "green" published between 2012 and 2022\*. Once the data were obtained, they were prepared (data conversion and cleaning) for use in the BCA. Table 1a details the search criteria for the dataset that constitutes the first sample of our study.

<b>Time span</b>	2012-2022*
<b>Document type</b>	Article
<b>Language</b>	English
<b>Final sample</b>	4,142 articles

Once the research fronts were identified, another data collection was conducted, in this case, referring to the topic of the research front on which the in-depth analysis was performed. The procedure was like that used to obtain data from the first research stage. After establishing the search criteria for WoS, a total of 38 articles were obtained as a dataset representing the second sample of our study. Table 1b details the search criteria used.

## **2.3 Data analysis for bibliographic coupling and social network**

### *2.3.1 Treatment of bibliographic records, document selection and calculation of bibliographic coupling and proximity matrices*

The 4,142 articles analyzed were processed with Bibexcel®, a versatile tool for bibliometricians designed for the processing of bibliographic data. Bibexcel allows to extract the information included within a bibliographic record using any document's field or some combination of these fields. In this study, Bibexcel was not

only used to extract the reference list from each of the bibliographic records but also to quantify, for each pair of source documents, its coupling strength.

For BCA, we considered all those citing documents with a coupling strength of at least 27 shared references (tie strength  $\geq 27$ ) with at least one of the remaining documents in our dataset. BC occurs when two scholarly works cite a common third work in their reference lists. So, two documents are bibliographically coupled if they both cite one or more documents in common. The cut-off point mentioned above allowed us to obtain a bibliographic coupling matrix  $[C(c_{ij})_{n \times n}]$  of dimensions 252x252 with the amount of cited references in common between each pair of citing documents in the sample. Once a bibliographic coupling matrix  $C(c_{ij})_{n \times n}$  has been constructed the next step in the application of BCA consists of calculating a proximity matrix  $[S(s_{ij})_{n \times n}]$ .

### *2.3.2 Construction of the bibliographic coupling network*

Once the bibliographic coupling and proximity matrices were constructed, we performed a factor analysis (FA) as a further step in the application of the BCA. FA by means of principal component analysis (PCA) with varimax rotation applied on matrix  $S(s_{ij})_{n \times n}$ , led to the extraction of up to 108 factors with eigenvalue  $\geq 1$ . From these factors, only those comprising at least three (node degree  $\geq 2$ ) of the primary-source documents with loadings above 0.7 in absolute value were retained for further analysis. The reason for this way of proceeding was to remove all those sources documents –also known as citing documents– that did not significantly load in any of the extracted factors. Following the application of these criteria/parameters (tie strength  $\geq 27$ ; eigenvalue  $\geq 1$ ; node degree  $\geq 2$ ; and loadings  $\geq |0.7|$ ), the number of factors finally retained was nineteen, representing a total explained variance of 26.6%. In terms of documents, the final sample of primary source documents was reduced from 4,142 to 64 articles representing the BC network nodes.

Finally, we took the output of the preceding analysis as input for subsequent SNA using Gephi version 0.9.6. This is an open-source software (OSS) that utilizes a three-dimensional render engine to provide expressive and insightful visual illustrations of large networks (Jacomy et al., 2014). Specifically, we use the 'Force Atlas' algorithm provided by Gephi to compute the layout of the nodes of the BC network. This allowed us to visualize the research streams identified in this study. The SNA carried out conceptualizes the citing documents as nodes and their relationships to each other as lines between the nodes.

### 3 Results and discussion

This section shows and interprets the results of the BCA and SNA on green conducted in this study, as well as the in-depth analysis of the GIC research front.

#### 3.1 BCA and SNA results – Identifying research fronts

Figure 2 shows the layout of the BC network comprising the 64 citing documents mentioned above. For ease of understanding, the network was visualized in an aesthetically pleasing Force Atlas layout, which is a classic force-directed algorithm that uses the properties of the network to draw linked nodes closer and push unrelated nodes farther apart. This layout also allows consideration of edge weight for directed networks, such that the strength of different connections may be visualized at a glance (Cherven, 2015; Velden et al., 2017).

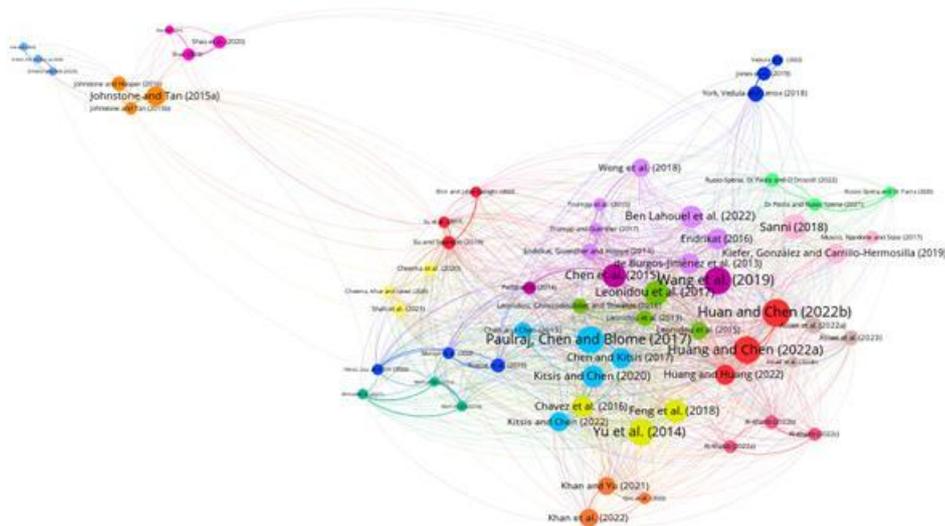

Figure 2. Bibliographic coupling network comprising the 64 citing documents included in the 19 research fronts identified in the study.

The color of each node in the network is indicative of the research front to which the citing document belongs among the 19 identified. In this research, the resulting groups of BC and SN analyses are defined, similarly to previous studies (García-Lillo et al., 2023), as "active research fronts" which shape the vanguard of knowledge and reveal current trends and future directions in the domain under

examination. The node diameters are scaled to their respective betweenness centrality degree, while the lines represent the relationships between nodes (i.e., the amount of overlap between the reference lists of each pair of such documents). Table 2 shows the 19 research fronts identified.

Table 2. Research fronts identified after the application of factor analysis upon Matrix S.

ID research front	Colour	Number of papers	Authors (year)
Research front 1		7 papers	De Burgos-Jiménez et al. (2013), Trumpp et al. (2015), Wong et al. (2018), Endrikat (2016), Trumpp and Guenther (2017), Ben Lahouel et al. (2022), and Endrikat, Guenther and Hoppe (2014)
Research front 2		4 papers	Leonidou et al. (2013), Leonidou et al. (2017), Leonidou et al. (2015), and Leonidou, Christodoulides and Thwaites (2016)
Research front 3		5 papers	Kitsis and Chen (2020), Chen and Chen (2019), Kitsis and Chen (2022), Chen and Kitsis (2017), and Paulraj, Chen and Blome (2017)
Research front 4		3 papers	Yu et al. (2014), Chavez et al. (2016), and Feng et al. (2018)
Research front 5		3 papers	Johnstone and Hooper (2016), Johnstone and Tan (2015a), and Johnstone and Tan (2015b)
Research front 6		3 papers	Al-Khatib (2022a), Al-Khatib (2022b), and Al-Khatib (2022c)
Research front 7		3 papers	Ahmad et al. (2021), Islam et al. (2021a), and Islam et al. (2021b)
Research front 8		3 papers	Asiaei et al. (2022a), Asiaei et al. (2022b), and Asiaei et al. (2022c)
Research front 9		3 papers	Russo-Spena, Di Paola and O'Driscoll (2022), Di Paola and Russo-Spena (2021), and Russo-Spena and Di Paola (2020)
Research front 10		3 papers	Huang and Chen (2022a), Huang and Huang (2022), and Huang and Chen (2022b)
Research front 11		3 papers	Hooi, Liu and Lin (2022), Roscoe et al. (2019), and Muisyo et al. (2022)
Research front 12		3 papers	Kiefer, González and Carrillo-Hermosilla (2019), Muscio, Nardone and Stasi (2017), and Sanni (2018)
Research front 13		3 papers	Wang et al. (2019), Paillé et al. (2014), and Chen et al. (2015)
Research front 14		3 papers	Cheema, Afsar and Javed (2020), Shah et al. (2021), and Cheema et al. (2020)
Research front 15		3 papers	Qin et al. (2022), Khan et al. (2022), and Khan and Yu (2021)
Research front 16		3 papers	Vedula et al. (2022), Jones et al. (2019), and York, Vedula and Lenox (2018)
Research front 17		3 papers	Shao et al. (2022), Shao et al. (2020), and Shao (2019)
Research front 18		3 papers	Shiri and Jafari-Sadeghi (2022), Su et al. (2017), and Su and

			Swanson (2019)
Research front 19		3 papers	Ertekin and Atik (2020), Atik et al. (2022), Ertekin, Atik and Murray (2020)

### 3.2 GIC research front results

The results of this section are not shown due to length limitations, for more information please contact the authors.

## 4 Conclusions

This paper has provided a review of the recent literature (2012-2022) on "green" in the areas of business and management, with the aim of identifying and mapping the existence of active research fronts through bibliographic coupling analysis (BCA) and social network analysis (SNA). Based on the analysis of 4,142 articles we were able to identify 19 of the most active research fronts in the field of green (see Table 2 and Figure 2). These results suggest that within the vast field of green, important research fronts are developing that have the potential to make advances in their respective areas. In many cases the new front involves the incorporation of the concept of sustainability or green into a topic already established in the literature. Examples include green supply chain management, green consumption behaviour, green human resource management or green intellectual capital.

Precisely, this paper has also provided an in-depth review into one of the previously identified research fronts, i.e., Green Intellectual Capital (GIC). For this, 38 articles published from the emergence of the concept to the present day were analyzed.

### Abstract

The process of synthesis is key for the consolidation of new insights from existing bodies of knowledge, information, and data. In connection to other knowledge processes, e.g., inspiration, research or analysis, synthesis – as an activity of connection and convergence – is central to creating meaning and understanding. It builds upon principles of integration, unification, and generalisation as prerequisites for the inference of reliable and replicable knowledge. Synthetic processes are significant when dealing with large data sets or disparate and heterogeneous information. Especially in explorative research projects, the synthetic integration of a multitude of inputs is crucial to generating valuable and applicable knowledge output.

As a key idea, the paper puts forward the concept of a Knowledge Synthesiser as a heuristic device to shape the knowledge generated in larger research programmes. Resting on general models of information processing and knowledge life cycles, the Synthesizer is conceptualised as a system that generates meaningful knowledge output by interconnecting different functional layers and modules, e.g., for knowledge collection, structuring, or integration.

The specific case at stake is the German funding priority “Sustainable Development of Urban Regions” (SURE). Ten projects with approximately 150 partner institutions generate a large body of research about urban sustainability and innovation. The Synthesizer has been conceptualised to facilitate the convergence and integration of this knowledge and

to create insights about the SURE funding priority and about future urban development in general. Specifically, the Synthesizer has various practical purposes for the research programme:

- Structuring and safe-keeping the results from the ongoing research
- Allowing easy access to the research findings
- Enabling deep analysis of the collected data and information
- Linking information to create new insights.
- Outlining future trends in urban sustainability research
- Supporting research policy-making.

In response to the overarching research programme and its purposes, a system architecture has been created to be implemented as a prototype tool for the SURE funding priority. From the variety of functional and technical requirements, an overall schematic design has been created that eventually led to a Minimal Viable Synthesiser concept – the outline for the technical implementation of the key features and functionalities the Synthesizer needs to supply to the SURE funding priority.

## 1 Introduction

Mathematician and science philosopher A. N. Whitehead (1967) stated that "knowledge does not last longer than fish". The statement hints at one key aspect of scientific research: knowledge creation is an ever-unfinished process. Knowledge needs permanent refreshment, update, and re-organisation. Every discovery may re-arrange the entire landscape of knowledge. There is a demand for continuous efforts in searching, hypothesising, analysing, and synthesising - and for the respective methodologies and devices that can support such an open-ended venture. Besides the strenuous activities of collecting data and assembling facts, producing scientific knowledge is a task of systematisation and integration that needs creative vision. A multiplicity of often contradictory findings needs to be structured, converged, and harmonised into a new unity. A multitude of facts, events and observations must be brought into a rational structure and drawn into a comprehensive picture. This holds true, especially for large-scale research programs generating a multiplicity of knowledge around a given single topic – which in turn need to be balanced, converged, and shaped into reliable scientific output.

The German funding priority "Sustainable Development of Urban Regions" (SURE) is such a case. The present paper revolves around the management and

synthesis of knowledge in this large research programme, bringing together almost 150 partner institutions around the topic of sustainable urban development. It tackles the difficult task of creating new (meta)knowledge from the vast landscape of "pieces of knowledge" in this programme. Comprehensive knowledge synthesis and consolidation are needed. Funded by the German Ministry of Education and Research (BMBF) between 2019 - 2025, ten intercultural and transdisciplinary research projects are generating a large body of research about urban sustainability and innovation, focusing on metropolitan regions and megacities in South-East Asia and China. In concert with the need for collaborative approaches that put people first in urban and rural developments and aligned with the SDGs localisation and the New Urban Agenda, SURE targets applied research, urban-rural innovation and transformative strategies.

Accompanying the SURE funding priority is the "Facilitation and Synthesis Research project" (SURE FSR), which supports the overall evolution of the ten projects and the programme itself and is supposed to consolidate the knowledge created in them. The SURE FSR conducts qualitative and quantitative meta-studies on the projects which conceptualise and test locally implementable solutions and strategies for the sustainable transformation of fast-growing urban regions. The SURE FSR project creates conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address the issue of sustainable urban development and contribute to transdisciplinary research knowledge. Further insights on the overall research architecture of the SURE FSR can be found in the IFKAD23 research paper (ID 231) by Katharina M. Borgmann titled "The Research Architecture for Transdisciplinary Knowledge Synthesis for an Urban Sustainability Programme – A Meta-Study Methodology". As a creative research project, it is mandatory to invent and explore new methods and instruments to effectively facilitate and integrate the vast research knowledge of the projects and the programme. The following sections establish the theoretical background, place the paper within the SURE framework, and set the research scope and boundaries.

## **2 Background**

### ***2.1 Sustainability Science***

The global demand for sustainable development has pressured academia to establish the field of so-called Sustainability Science. According to Komiyama and Takeuchi (2006), Sustainability Science is a comprehensive and holistic approach

to identifying problems and perspectives related to the sustainability of global, social, and human systems. It is characterised as a problem-solving discipline, a transdisciplinary effort driven by the interplay of knowledge and action in environmental and social-cultural systems towards a liveable future (Kumazawa et al. 2009; Rapport 2007; Clark 2007). Sustainability Science is a “use-inspired basic research” – here, fundamental knowledge and pragmatic application are equally relevant (Clark 2007; Kajikawa 2008). Its knowledge generation rests on abduction-based synthesis, that is: new insights derive from justified assumptions or speculative hypotheses, which require validation through experiment and empirical research. The SURE Facilitation and Synthesis Research project aims to create a comprehensive and holistic knowledge synthesis approach to structure and consolidate transdisciplinary research results within the SURE framework. Yoshikawa (2008) theorises that “action based on abductive reasoning and the logic of synthesis can produce new forms of knowledge that will contribute to the creation of artefacts” – we explore and internalize this theory through the SURE FSR Knowledge Synthesis methods and conceptual tool discussed in this paper.

Sustainability Science is a problem-driven and solution-oriented field, following a transformation agenda and providing a vision and methodology (Steinfeld and Mino 2009), to deal with the complexities of sustainable development and to instigate knowledge structuring through multi-, inter-, and transdisciplinary approaches. Transdisciplinary approaches focus on the integration of knowledge from multiple scientific and societal sources through collaborative efforts. The ten projects within the SURE framework are characterized as Mode-2, transdisciplinary research projects (Slawski et al. 2022) they generate a growing pool of transdisciplinary approaches and sustainability knowledge. However, this knowledge is often based on literature and personal experiences. It still requires further consolidation and evidence-based principles to become useful and reliable for scientists and practitioners (Defila et al. 2006). Lang et al. (2012) emphasise the need for synthesising and consolidating the existing conceptual, methodological, and empirical knowledge of transdisciplinary research through qualitative and quantitative meta-studies.

## ***2.2 Research framework and ambition of SURE***

This paper and its findings feed into the meta-analysis and knowledge synthesis carried out by the SURE FSR project for SURE. Constrained by the SURE framework (limited geographical scope, number of projects, sample size for content analysis), the SURE FSR systematically examines and interprets the

findings of the ten transdisciplinary projects with qualitative and quantitative approaches.

With the findings, the SURE FSR aims to consolidate the existing conceptual, methodological, and empirical knowledge of transdisciplinary research and contribute to sustainable urban development and Sustainability Science. The SURE FSR overarching synthesis research architecture is elaborated, and its goals, objectives, and methods are discussed in the accompanying IFKAD23 paper "The Research Architecture for Transdisciplinary Knowledge Synthesis for an Urban Sustainability Programme – A Meta-Study Methodology". Preliminary research findings induced the formulation of hypotheses, of which the three listed below have relevance to this paper:

- Developing new methods and practices for knowledge synthesis aided by digital technologies will improve the consolidation, integration and comprehension of the large pool of knowledge generated in urban sustainability research.
- Targeted modelling of project contents and topic evolution will help indicate future challenges and issues to be addressed in urban sustainability research and policy making.
- Cross-analysis of programme documents and project content will contribute to recalibrating funding and proposal evaluation criteria.

Although the overarching meta-study is ongoing, this paper can present initial findings and first scientific framings in support of further investigations by the SURE FSR in the future years, also reaching beyond the scope of the SURE programme. The synthesis research targets three main aspects: Scientific classification to establish a reference and impact monitoring framework. Synthesis of project contents and findings, elaboration of problems and issues to be addressed in the future. Provision of digital infrastructure for knowledge management and decision support. As its central argument, this paper puts forward the design of a comprehensive IT system (Synthesizer) and discusses its potential application. The system is intended to work as a versatile environment for the synthesis of knowledge by the SURE FSR and a decision-support tool for relevant stakeholders within the community of the SURE projects. Indicating the accompanying complexities in the development process of such a system, the text explains the opportunities and challenges such an instrument can bring for urban sustainability research.

### ***2.3 The Principle of Synthesis within the Knowledge Lifecycle***

The idea of the Knowledge Synthesizer takes its point of departure from discourses in knowledge theory and knowledge management, acknowledging that the topos of "synthesis" has long been a steady concern in the scientific literature. Throughout the history of epistemology and philosophy of science, various models have been proposed to conceptualise the dynamic evolution of knowledge that commonly leads from knowledge creation to knowledge sharing and diffusion. Recent knowledge and innovation management approaches advocate so-called knowledge lifecycles that model a dynamic process of knowledge creation, consolidation, and diffusion activities (Nonaka, 1991; Nonaka and Konno, 1998; McElroy, 2003; Dalkir, 2005).

Epistemologists, however, hold that the phases of knowledge creation, especially the interplay of hypothesis creation on the one hand and knowledge integration and consolidation on the other, are essential drivers of novelty and progress (Peirce, 1878; Polanyi, 1966; Popper, 2002). Not just since Kant's inquiry into the limits of knowledge (Kant, 1781), synthetic procedures are seen as the key to generating new insights from existing bodies of knowledge, information and data. In connection with other modes of knowledge processing, the very capacity to structure and unify the multiplicity of input data and information into a consolidated and validated "larger picture" is central to creating meaningful, usable knowledge.

Synthesis work – as an activity of integration and convergence – searches the fundamental connective principles that allow reliable expression and replicable application of gained insights. Synthetic processes gain special significance when dealing with large sets of information and data or disparate and heterogeneous knowledge bodies. Extensive explorative research programmes like SURE need to purposefully structure and integrate the variety of findings created across the programme and its individual projects. Accompanying synthesis research thus becomes essential to ensure meaningful results for future research, result application, and policy making. Knowledge structuring and organisation are essential parts of the synthesis research activities. Nevertheless, structuring methods and approaches originate from a vast domain that needs more detailing than the constraints of this paper permits. Hence, the paper highlights some of the applied guiding principles in knowledge structuring: reusability, versatility, and accessibility, that are relevant to the conceptual design of the Synthesiser.

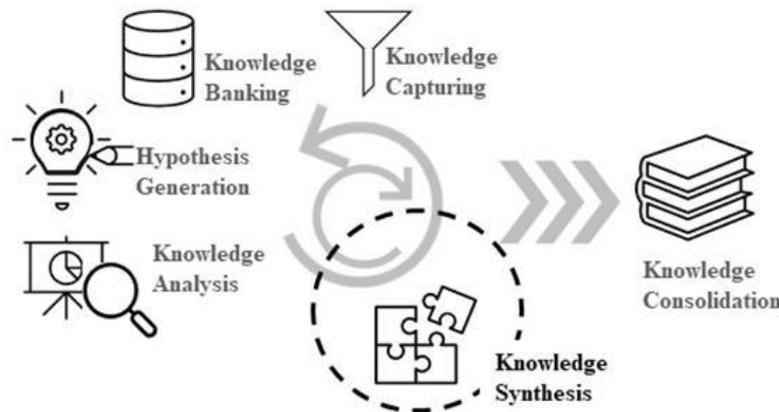

Figure 2: Synthesis processes within the knowledge life-cycle. Adaption of the knowledge management model of McElroy (2003) and Dalkir, (2005).

With a pragmatic perspective on the requirements for the synthesis research for the SURE funding priority, this paper – and namely the synthesizer concept presented in the following sections – assumes a simplified iterative process towards the synthesis and consolidation of knowledge (Fig. 1), adapted from established models in knowledge management (McElroy, 2003; Dalkir, 2005). It connects activities of knowledge capturing, hypothesis generation and rational analysis. Leaving the creative part of hypothesis generation (“abduction”) as well as the rational analysis and critical reflection on the human mind, the paper focuses on the eminent activity of knowledge synthesis, targeting its potential support with the new conceptual and technical device of the Knowledge Synthesizer. To this end, the following section is 2.3. We will line out relevant technical solutions and propose an overall conceptual design and technical system architecture in section 3.2.

## 2.4 Technical Solutions

Acknowledging that knowledge integration and synthesis of existing bodies of (scientific) knowledge is a cognitive activity on higher levels of complexity than data or information processing, it is still worthwhile to investigate the currently available technological means for synthetic knowledge engineering. Information technology is increasingly used in sustainable urban development to unlock insights from data, helping decision-makers and planners make informed decisions about resource use and development strategies. Platforms such as Google Big Query, Snowflake, and Azure Synapse Analytics offer large-scale data

analysis services that collect and log data from various systems, including numerical and textual data. With AI's help, these platforms provide data processing and querying services and outputs from charts, diagrams, and dashboards. Understanding the interdependencies among socio-economic and environmental systems to achieve sustainable urban development is crucial. Data analysis platforms allow researchers and urban planners to collect and analyse data from multiple sources, including sensors, surveys, and administrative data, to understand urban systems comprehensively. The Urban Observatory platform, for example, enables users to compare data on various urban indicators worldwide, such as population density, air quality, and water usage. This platform provides a valuable resource for decision-makers and planners to identify areas where improvements can be made to achieve sustainable urban development. Other technologies, like Machine Learning and Artificial Intelligence, can be powerful tools to model and simulate urban systems, enabling urban planners to test different scenarios and assess the potential impacts of different development strategies. Text-based data is prominent in sustainable development, including reports, research, policies, regulations, and guidelines. In recent years, cities, governments, and academia have shown a growing interest in leveraging natural language processing (NLP) techniques to generate valuable insights and help planners and decision-makers to understand the social, economic, and environmental issues affecting urban areas. NLP can assist in analysing large volumes of textual data, extracting meaningful insights and providing a deeper understanding of urban systems. For instance, the Echobox platform offers a valuable resource for urban planners to extract and monitor public sentiment on social media. By analysing data from social media, planners can identify areas of concern and gain a deeper understanding of citizens' concerns and priorities. This information can then be used to design more effective solutions and policies better aligned with the community's needs.

Commercial NLP engines have benefits and drawbacks when creating insights from data in a specific field of research. Our preliminary study using IBM Watson or Monkey Learn for text analysis in sustainable development had good results in identifying locations and organisations and assessing the sentiment of the text; however, both platforms showed low accuracy and failed to determine field-specific information. Hence, engine training and adaptation of these platforms are crucial for meaningful information and knowledge extraction. In addition to commercial platforms, we have identified various initiatives amalgamating data science and sustainability, such as the Global System for Sustainable

Development (GSSD) and open-source platforms like Apache Drill. The GSSD is an open-source database established by the Massachusetts Institute of Technology (MIT), which offers a comprehensive perspective on worldwide sustainability predicaments. The GSSD follows a rigorous knowledge structuring approach incorporating ontology engineering and collating data from multiple sources, including scientific literature, government reports, and NGO publications, to offer a holistic view of sustainability issues. A visualisation tool is also available within the GSSD, which facilitates knowledge structuring and information clustering for exploring sustainability data.

The aforementioned platforms provide powerful tools using and harmonising real-time data sets and extract insights to understand the complex interactions between urban systems and citizens, promoting more inclusive and equitable urban development. Nevertheless, data analysis platforms rely on the data's quality and accuracy, which may be compromised by missing, incomplete or inaccurate data sets leading to skewed insights. While text-based data analysis platforms may suffer from accuracy and bias issues as NLP use of unstructured data may only sometimes capture the nuances of language and context accurately. Our exploration shows an increasing trend of platforms that try to deal with information holistically and comprehensively; we highlighted only a few selected ones. We acknowledge these platforms as relevant examples for our system development to aid our synthesis research. Analysing these platforms shed light on challenges regarding knowledge structuring in sustainable urban development and existing technical solutions that can be used and incorporated into such a system.

### **3 Approach**

#### ***3.1 Conceptual Design of the Knowledge Synthesizer***

Based on the premise that technology and science are vital to enable sustainable transition, we put forward the concept of a "virtual thinking space" that provides a comprehensive visual representation of data from the SURE funding priority, projects and synthesis findings of dormant knowledge and topics in sustainable urban regions from Southeast Asia and China. As a point of departure, the idea of the synthesizer has served as a heuristic device to access, structure, and shape bodies of knowledge actively. Relating to general information and knowledge processing principles as well as platform architecture, the knowledge synthesizer represents – in the first stance – an instrument

supporting the generation of meaningful insights about and from the SURE FSR. It does so by processing knowledge output from various inputs through functional modules of knowledge harvesting, structuring, analysis, and representation.

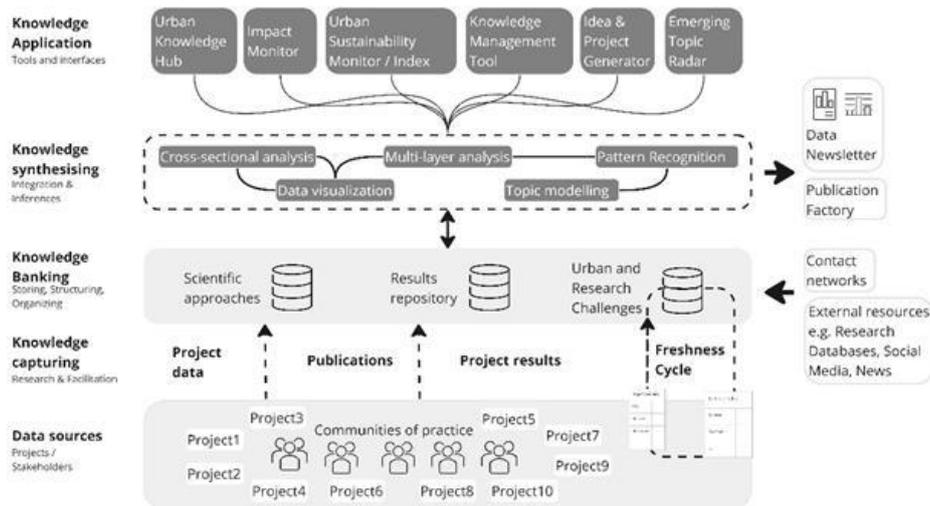

Figure 3: Maximum concept scheme of a "Knowledge Synthesizer"

Fig 2 depicts the initial conceptual design of the synthesizer – with a “Knowledge source” layer (primarily the projects facilitated by the SURE FSR), a “Knowledge collection” layer (indicating the content and input harvested and ingested in the system, e.g. qualitative and quantitative data from the research projects, their publications or through other facilitation activities, e.g. workshop, peer-to-peer meetings, project visits, interviews), and “Knowledge Banking” layer (the databases to structure, save, and make accessible the information and data gathered). A so-called “Freshness cycle” regularly updates the information and data collection as a routine task. On top of the “Knowledge Bank”, the “Knowledge Synthesizer” layer processes with several “intelligent” functionalities the given input, aiming to generate new insights with the materials from the layers below. Some of these knowledge products can be automatically channelled out in the format of visual or statistic reports (e.g. “Data Newsletter”). On the top, the “Knowledge application” layer provides the specific tools and instruments to actively work and pragmatically interact with the synthetic processes and their results. This generic scheme presents a maximum concept of a "Knowledge Synthesizer" applicable to accompanying projects like SURE FSR. Given

constraints and resource limitations, this initial concept needs a reduction to a pragmatic "Minimal Viable Synthesizer" (see section 3.2). However, the modular nature of this initial conceptual design provides for continuous extension and potential upgrades in future versions. Later editions of the synthesizer may incrementally scale up functionalities.

### **3.2 System architecture – Minimal Viable Synthesizer**

The specific system architecture of the Minimal Viable Synthesizer derives from requisite key functionalities and components needed to carry out the SURE projects and programme synthesis, impact monitoring and decision support. From the primary activities of the SURE FSR team – data linkage, statistical evaluations, thematic analyses, identification of topic networks, trend analyses etc. – the required functional layers for the Synthesizer can be determined. To access and explore SURE data efficiently, a number of databases (e.g. for project results, documents and contacts) and data services (e.g. for knowledge management, communication, and collaboration support) need to be provided. User-friendly interfaces are to present the knowledge output and gained insights – here, existing solutions from the realm of business intelligence (project dashboards, monitors, interactive cockpits) may be used. The system architecture thus comprises three main component layers (see fig. 3 "System architecture of the Minimal Viable Synthesiser: Functional layers and modules"):

- Data storage (data management, database, data lake, processing flows)
- Applications (intelligent processes and tools)
- User interface (single / multi-user, web-based, on-premise).

As input, the system gathers quantitative and qualitative data, scientific and non-scientific information from multiple sources such as projects, relevant organisations, the internet, social media, or the collaborative platform SURExCHANGE.

As SURE covers a wide range of domains, good data management and organisation are required to enable a subsequent systematisation and integration of knowledge and to discover concepts hidden in the data. The data storage and management layer collects, stores, and organises the generated and used data within the SURE framework. The layer includes a database and data lake optimised for fast queries, efficient data retrieval, and handling large volumes of data. It also ensures data accuracy and integrity through appropriate data validation and quality control measures.

The application layer comprises modules for processing user requests and generating responses based on the data stored in the database. Key applications are topic modelling, content comparison, results synthesis, and thematic clustering of solutions. Three specific functional modules are foreseen for the Minimal Viable Synthesizer: 1) a synthesis assistant, 2) an impact monitor and 3) a decision-support tool.

The interface layer provides user-friendly front-ends for accessing, exploring and interacting with the data, e.g. a web-based interface optimised for desktop and mobile devices or a stand-alone application designed for touch tables. To break down the complexity of SURE’s topics, rich and intuitive user experiences are envisioned using interactive visualisations and animations.

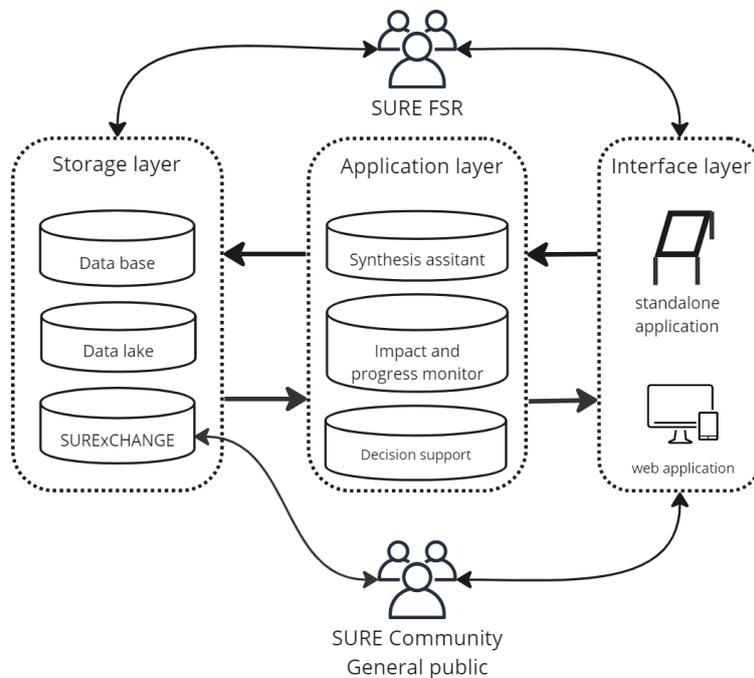

Figure 4 System architecture of the Minimal Viable Synthesiser: Functional layers and modules

### 3.3 Development Process of the Applications

The development process for the specific applications runs through stages of requirements definition, technical design and implementation, testing and deployment. An agile methodology is used to develop and implement all the modules, collaborate closely with stakeholders, and continuously improve the

applications at every development step. This agile process is essential for creating a synthesizer that meets user requirements and expectations while ensuring that it is stable, secure, and effective.

The first step of the agile process identifies user needs and lines out concrete use cases. Collaborative workshops with the project partners and the funding agency help to outline detailed "User Stories". So far, internal workshops have been conducted in the SURE FSR to map research needs (use cases) and identify objectives for module development. From the gathered requirements, clear and detailed design objectives and module specifications can be derived, enabling an in-depth design of the applications and functionalities in the following step, leading to a comprehensive system architecture and interface design. The technical implementation of the IT solution is followed by comprehensive testing in the next stage, where the application is thoroughly checked for mistakes and errors – first internally with the SURE FSR team and later by the entire SURE community through interactive workshops.

As a pivotal functionality to uncover and map the implicit (cross-cultural) knowledge within the SURE framework, to conduct cross-project content analysis and aid the synthesis research activities, an **NLP (Natural Language Processing) module** is envisioned. In the first stage, the NLP module will validate the list of synthetic focus topics the SURE FSR team has set up early in the project. The exploration aims to understand the text analysis and topic modelling of NLP models and train them for sustainable urban development issues. After refinement, the NLP application will assist in uncovering dormant knowledge ("Unknown Knowns"), identify open questions and problems ("Known Unknowns") and validate initial synthesis findings. The NLP module and first preliminary findings are described in more detail in a parallel paper handed in for this conference (Patel et al., 2023).

Next to the NLP module, an **Interactive Data Cockpit** is envisioned, allowing practical data exploration of the SURE funding priority. In the upcoming months, requirements-gathering workshops will be carried out with project partners and stakeholders to identify more modules to be implemented, such as a **Trend Visualiser** highlighting future development pathways or an **Impact Monitor** indicating the actual effect that SURE projects unfold in their specific context. The latter is based on the SURE Reference Picture developed by the SURE FSR partners at the Technical University of Lubeck (IFKAD23 contribution 209).

## 4 Conclusions

The SURE Knowledge Synthesizer is the **first conceptual and technical approach** to the ongoing challenge of integrating research findings in complex settings for urban sustainability research and to enable foresight on upcoming trends. The paper presented a conceptual design and system architecture for a Minimal Viable Synthesizer that responds to the essential requirements and functional demands deriving from such tasks. Being an ambitious venture in IT development and software configuration, however, the first technology mappings and technical explorations carried out by the FSR team suggest that solutions exist already that can effectively support knowledge management and decision-making processes in the context of sustainable urban development and policy making. Building upon existing solutions and using technology-assisted new methods and practices can facilitate the analysis and synthesis of the substantial data pool generated in sustainable urban development programmes like SURE. However, more intricate integration and in-depth research are needed to enable comprehensive knowledge synthesis in transdisciplinary urban sustainability research. On the path towards developing effective knowledge synthesis methods, the SURE FSR team acknowledges the challenges related to information organization and synthesis within an extensive research programme like SURE.

One of the significant challenges is to reduce complexity on the one hand while maintaining specificity and locality on the other. Regarding the SURE collaborative projects, region-specific topics (risk and flood management, nature-based solutions, urban planning) and culture-specific aspects remain prominent and versatile. In the process of Minimal Viable Synthesiser design, it is crucial that these aspects are reflected, and relatability by various groups of stakeholders is questioned - how to create a versatile and relatable system and generate reusable knowledge?

While the initial findings of the NLP module suggest its growing applicability in transdisciplinary research settings, the SURE FSR's direct project interactions have uncovered the vast tacit knowledge and the eminent influence of cross-cultural sensitivity. While such aspects are difficult to grasp with technological means such as the proposed synthesizer, they still form an essential part of the SURE projects and programme. They lead to a discussion on how far tacit knowledge can be mapped, measured, and translated into tangible, transferable knowledge. For an adequate analysis of program documents and project content, recalibration of funding and proposal evaluation criteria, and improvement research policy-making, further research of respective tools and methods are needed. By

exploring, testing and validating new synthesis methods, the modular synthesizer with functionalities such as the project content analyser or topic modeller may be a first step in such direction. Taking a tentative and systemic approach may uncover step-by-step the dormant knowledge and the future topics and challenges for sustainable urban research that is being inscribed in the SURE funding priority and projects already now.

### Abstract

This paper discusses the co-creation process that led to Dresden city's smart city strategy, channelling the contributions from various stakeholder groups – politics, administration, science, civil society, and industries – into one vision for integrated and sustainable digitalisation-based urban development. This co-creative strategy process aims to overcome technology-centred smart city approaches that often fall short of generating public value, and therefore lack of public support.

As part of the federal funding priority "Model Projects Smart Cities", Dresden's municipal administration and members of the Technical University Dresden started a 1-year strategy creation phase in 2021. The resulting smart city strategy forms the basis for a subsequent 4-year implementation phase during which specific measures and projects work towards an overall smart city vision. To this end, the strategy phase had to result in a

comprehensive innovation agenda for transforming Dresden towards a smart and sustainable city (i.e., Dresden's smart city strategy). Moreover, Dresden's application for the federal smart city programme centres on providing digital solutions to neighbourhoods to invigorate the urban society and locally create new qualities for living and working. Pursuing this goal requires a comprehensive strategy based on local stakeholders' needs and resources.

In the project's first step – the strategy phase – we devised a novel co-creative process that integrated approaches from innovation and creativity management ("Double diamond"), participation and co-creation research ("Quadruple helix"), as well as IT and software development ("Agility") into one methodology. This new approach effectively guided the strategy-making process from a comprehensive status quo analysis through creative "visioneering" towards an outline of strategic fields of action and specific measures. By combining these approaches, we ensured a dynamic, iterative process that a) effectively involves all relevant stakeholder groups, b) resulted in innovative concepts and implementation measures, and c) created a robust onward momentum leading to a feasible and context-sensitive urban development strategy in a short time.

**Keywords** – Smart City, Strategy Process, Participation, Urban Innovation

**Paper type** – Project Report

## 1 Introduction

Over the past decade, smart cities have become an increasingly prominent topic in urban development. Administrations and governments are pursuing the development of "smart" cities on global, national and local levels. Many countries, e.g., China, India, and the USA, have set up large-scale (funding) programs to use the opportunities of digital technologies in the urban realm.

However, during the decades since the concept's emergence, smart city development has been the target of substantial criticism. This criticism focuses on the corporate supply push by tech enterprises like IBM or Cisco, which was instrumental in creating the smart city concept and a comprehensive, fast-evolving and growing market of urban technologies (Kustra et al. 2017). However, while the corporate supply push in smart city development ensured economic value creation, these actors still face difficulties in implementing the smart city concept in ways that ensure the creation of public value (Kitchin 2014, Mello Rose 2022).

In Germany, this unclear generation of value for civil society and public sector actors and a lack of public support resulted in a feeble adoption of smart city concepts. Therefore, focussed research into the current development of smart cities is necessary to overcome the barriers to adopting smart city concepts.

In response, Germany's federal government initiated the funding priority "Model Projects Smart Cities"<sup>1</sup> (henceforth MPSC). This programme aims to support smart city development by focussing on urban planning and socio-spatial perspectives rather than technology-centred approaches. Furthermore, the MPSC in general, and its implementation in Dresden in particular, aim to address the uncertain public value creation and lack of public support by ensuring and providing scientific accompaniment. As part of an emerging smart or digital city science, researchers closely accompany the model project to support communities, administrations, and policy-makers in their ventures into smart city development. This way, the smart city model project from Dresden provided an outstanding opportunity to develop a smart city strategy with scientific support that integrated various scientific perspectives, especially from digital urbanism.

This article reports on this science-supported development of Dresden's smart city strategy. The "smart city strategy" is the primary outcome of the first phase of the city's smart city model project. As an official policy document, however, the strategy leaves little room for academic reflections on its conceptual and methodological basis. This article thus aims to provide the necessary academic description and reflection to support smart city developments. We do this by presenting and discussing the strategy process' conceptual and methodological building blocks (and their synergies) designed to overcome the barriers for creating public value and societal support in smart city developments.

## **2 Background**

### ***2.1 The Funding Priority "Model Projects Smart Cities" in Germany***

In 2019 the German Federal Government started the funding priority "Model Projects Smart Cities" to strategically support municipalities in using digital transformation for more integrated, sustainable and welfare-oriented urban development. The framework supports cities and municipalities in testing cross-sector digital strategies and exploring role models for distinct "Smart Cities made in Germany". In contrast to previous technology and infrastructure-driven missions, e.g., in China or India, the German programme aims to highlight and shape the spatial impacts of digitalisation on local, urban and regional scales. The funded projects are to show how the social-spatial qualities of the historical European city may be transferred to the age of digitisation. The future smart cities

---

<sup>1</sup> <https://www.smart-city-dialog.de/modellprojekte>

should fully exploit all the opportunities of information and network technologies for sustainable and integrated urban development while preserving the current qualities of compact, culturally rich and human-centered cityscapes.

Organised into three cohorts that started in a yearly rhythm, 73 model projects have been selected for the funding of a total of 820 million euros from the German federal government. Applicants needed to be municipalities – the funding programme thus attained an inclination towards city administrations. Explicitly named “model projects”, the supported ventures are supposed to have exemplary and replicative character. Running through a 1-year strategy phase and then through a 4-year implementation phase, they are supposed to inspire and lead a larger number of following cities in the future. The later reproduction of developed smart city strategies, measures, and solutions is built-in into the logic of each model project.

## **2.2 The Dresden Smart City Model Project**

The application of the city of Dresden – capital of the federal state of Saxony – was selected in July 2021 for funding within the third cohort.<sup>1</sup> The successful project proposal titled “IQ - Intelligent Quarters” was co-authored by Dresden’s municipal IT service provider Eigenbetrieb IT-Dienstleistungen (EBIT) in cooperation with our research unit at TU Dresden, the WISSENSARCHITEKTUR Laboratory of Knowledge Architecture. The basic idea for the proposal was to offer innovative digital services and solutions in city districts and neighbourhoods that would invigorate the urban society and create new urban qualities for living and working in the immediate spatial environment. On that premises the overall goal of our model project for a Smart City “made in Dresden” is to provide sustainable impetus for the long-term improvement of the socio-spatial conditions in the city and thus become a model for other municipalities in Germany and beyond.

At the beginning of 2022, we activated the first phase – “Strategy” – which concluded in spring 2023. The main target in the strategy phase was to translate the initial vision of a city composed of intelligent quarters and districts into an overarching strategic concept. This concept would serve as a long-term guideline for implementing specific projects in the subsequent 4-year phase until 2026.

The development of the strategy demanded input and broad participation of the city administration, civil society, science and business. To this end, we

---

<sup>1</sup> <https://www.smart-city-dialog.de/modellprojekte/smart-city-modellprojekt-dresden>

designed a novel strategy process that systematically led from a comprehensive status quo analysis to formulating a general vision and strategic goals. From here, we could derive concrete missions, action plans and measurements.

### **3 State of the Art**

#### ***3.1 Urban development strategies and Guidelines***

While tackling the relatively new challenge of urban digitalisation, any new smart city strategy needs to acknowledge existing and well-established frameworks for strategic urban development on which – in most cases – the long-term planning activities of cities are based. Without attempting to present a comprehensive literature review, however, the following paragraphs introduce the relevant frameworks and discourses in the German context.

On a most general level, the **Sustainable Development Goals** (SDGs) – namely goal 11 “Liveable Cities” – provide an overarching guideline and orientation for city planning (United Nations 2015). When the SDGs were formulated, however, the trend towards smart and digital cities was just gaining momentum. Thus, the original SDGs do not precisely reflect the role of digitalisation for urbanity (later editions and amendments tried to compensate that deficit). Still, the SDGs provide a holistic framework for the goal of strategically using the power of digital transformation for sustainable development.

On the European level, the **Leipzig Charter** established in 2007 and reviewed in 2020 (BBSR Bundesinstitut für Bau-, Stadt- und Raumforschung [Federal Institute for Research on Building, Urban Affairs and Spatial Development] 2021) provides a normative framework that aims to steer urban development towards the specific social and spatial qualities of the “European City” (e.g. centrality, diversity, preservation of cultural and historical assets). However, this charter does not relate specifically to smart or digital city discourses too.

As a key instrument for the coordination of plans addressing the various urban systems, **Integrated Urban Development Concepts** (IUDCs) have been established over the past decades (BMVBS Bundesministerium für Verkehr, Bau und Stadtentwicklung [Federal Ministry of Transport, Building and Urban Affairs] 2007). Based on participatory and deliberative approaches with multiple stakeholder groups, usually created and adapted in iterative loops over the years with a broad landscape of stakeholders, IUDCs do not methodologically reflect the advent and impact of smart and digital cities. Their approaches are, to a large extent, agnostic to digitalisation and new urban technologies. While envisioning

future scenarios is undoubtedly the overall goal of IUDCs, their focus is on integrating and re-framing *existing* concepts and strategies within a unified larger picture (DST Deutscher Städtetag [German Association of Cities and Towns] 2015; BMUB Bundesministeriums für Umwelt, Naturschutz, Bau und Reaktorsicherheit [Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety] 2016).

Acknowledging the growing demand for future scenarios with less path dependence on previous planning frameworks, the German government took a more vision-oriented approach with the large-scale program and competition titled “**Future City**” (**Zukunftsstadt**) (BMBF Bundesministerium für Bildung und Forschung [Federal Ministry of Education and Research] 2015-2022). While supporting exploratory experiments, living lab approaches and radically new forms of citizen engagement and participation, the program did not explicitly address digital urban challenges as well (Noennig et al. 2016).

In an attempt to relate future urban development strategies stronger to the ongoing digital transformation, the German federal government initiated a counselling process, eventually leading to the national **Smart City Charter** in 2017, which was subsequently updated (BBSR Bundesinstitut für Bau-, Stadt- und Raumforschung [Federal Institute for Research on Building, Urban Affairs and Spatial Development] 2021). The charter forms a fundamental guideline for future smart city funding priorities, innovation programs, and research projects to be implemented in Germany. While the Smart City Charter included and furthered key aspects of the SDGs or the Leipzig Charter (e.g., participatory approaches, urban sustainability measures), the practical value for guiding the implementation of smart city concepts and digital urban technologies is limited.

The initiative “**City of Tomorrow**” (**Morgenstadt**), run by the Fraunhofer Society since 2012, has assembled a range of companies, research institutions, and cities to build, explore, and experiment with platforms for digital urban technologies. Although multiple (not only German) cities joined the initiative, the initiative is shaped by a technology- and market-driven approach, rather focusing on urban performance indicators than socio-spatial qualities (Fraunhofer IAO 2016).

Being one of the first explicit digital city initiatives on federal level, the German government initiated the project “**Shaping the Digital City**” (Die digitale Stadt gestalten) from 2019-2022 to enable municipalities to create their digital city strategies and to set the stage for an upcoming, large-scale smart city funding priority. As a main outcome, the project issued a methodological guideline

supporting urban administrations struggling with making smart city strategies – a generic development process leaning on agile and participatory approaches (Jonas et al. 2021; Humann et al. 2022).

With a duration until 2027 at least, the German government finally started its own smart cities mission with the funding priority **“Model Projects Smart City”** in 2019, as introduced already in the previous chapter. It forms the main background for writing the smart city strategy for Dresden and, thus, for the present paper. To support and monitor the 73 individual model projects and to facilitate the knowledge exchange and technology transfer in the mission, a so-called Coordination and Transfer Agency (“Koordinierungs- und Transferstelle”) was established<sup>1</sup>. This agency forms the focus point and synthesiser for all relevant knowledge created in the ongoing German smart city model project, especially newly minted smart city strategies and the processes leading to them.

### **3.2 Gaps and Challenges for Smart City Research**

The previous paragraphs made clear that for the creation of smart city strategies, reliable frameworks are rare (Bauriedl & Strüver 2018). The digital revolution, on the one hand, progresses with high speed, making it difficult to catch up with normative guidelines or rules – so new developments may have easily surpassed any current state-of-the-art. The dynamics, effects and impacts of smart technologies, on the other hand, are especially hard to grasp and difficult to translate into conventional planning measures (Hick et al. 2018; Stelzle et al. 2021). This puts cities and communities under pressure when defining their attitudes and pathways towards digitalisation. Therefore, reliable strategic processes that can grasp the urban and spatial dynamics of digitalisation are in high demand (Noennig et al. 2016; Noennig et al. 2019).

Well-established frameworks fall short either by having few visionary components (as is the case with IUDCs) or by lacking orientation towards digital cities (Future Cities program). Business-oriented programs like the Morgenstadt initiative rather target corporate marketing and technological innovation than comprehensive urban development strategies with an all-inclusive societal and environmental point of view (Hick et al. 2019).

The co-creation of comprehensive strategies for a high-tech-related topic like smart or digital city development is hard to carry out with multiple players in urban administrations and civil society. The required level of technical knowledge

---

<sup>1</sup> <https://www.smart-city-dialog.de/modellprojekte/koordinierungs-und-transferstelle-modellprojekte-smart-cities-kts>

and the fast evolution of solutions make it hard to involve stakeholder groups who are not tech-affine – despite the availability of far-reaching digital media and instruments for digital participation (Münster et al. 2017; Kelber et al. 2019a).

Another main condition for the difficulty of creating smart city strategies is the absence of dedicated scientific research. Only a few authors systematically propose and discuss the practical steps for strategy development of digital cities (Piskorek et al. 2015; Schwegmann et al. 2021; Noennig et al. 2022). Although thorough reflection and critical discourses accompany the swift technological innovation of new urban technologies, methodologies and instruments are yet missing for the proactive and prospective planning of smart cities (Bauriedl & Strüver 2018). Notably, there is no well-established and reliable design science to target the digital urban transformation, or to strategically shape smart technologies for urban development. Moreover, existing smart city research rarely takes a planning perspective. As a result, participatory and co-creative methodologies – sufficiently complex enough already in the context of conventional urban planning – are lagging far behind in the case of smart city development.

## **4 Idea and Approach**

### **4.1 Ambition**

Acknowledging the demand for a systematic and scientific approach, the overall process towards Dresden's smart city strategy benefited from the specific opportunity that our research unit at TU Dresden – the Knowledge Architecture Lab – could provide scientific and methodological expertise not only in the field of strategic and integrated urban development but also in smart city technologies (Stelzle et al. 2017; Kelber et al. 2019b; Jannack et al. 2020). Targeting a process built upon the scientific state-of-the-art, the project leader at the City's IT Services Agency (EBIT) assigned the responsibility for the strategy development to our lab. By the end of the first project phase, a feasible, concise and context-sensitive smart city strategy was expected that would be yet open for further development and improvement in subsequent implementation phase. More specifically, the ambition was to devise a strategy-making process that would

- ensure the creation of innovative concepts and measures,
- effectively involve all relevant stakeholder groups,
- maintain a strong onward momentum and intrinsic dynamics.

Given the complexity of the tasks and ambition (e.g., dozens of administrative units had to be involved), the pre-defined 12 months timespan for the strategy-making was very short (eventually, the funding agency recognised this shortcoming and extended the strategy phase by half a year).

#### 4.2 Designing an Integrated Process

To achieve the above-mentioned targets, we envisioned a strategy-making process integrating elements from innovation and creativity management, participation and co-creation research, as well as IT/software development. By combining these approaches, we wanted to ensure that, on the one hand, a comprehensive involvement of all groups would be guaranteed and citizen-oriented, user-friendly solutions be created. On the other hand, we aimed to facilitate the creation of novel and ambitious ideas that could be further developed and improved in the later process. Specifically, we combined the following three approaches (Fig. 1):

Figure 1: Conceptual approaches for the smart city strategy process: Double Diamond, Agility, and Quadruple Helix. (Source: TU Dresden)

The *Double Diamond* from design thinking is a creative process that leads through successive divergence and convergence phases from the problem definition to the development of ideas to the creation of prototypes (Banathy 1996).

The principle of *Agility* from IT and software development describes an iterative step-by-step approach in which requirements and solutions are flexibly adapted in the continuous exchange between developers and customers to be able to react quickly to changes (Beck et al. 2001).

The *Quadruple Helix* from innovation and participation research supports the cooperation between four actor types – politics/administration, civil society, business and science – to make innovations economically, socially and ecologically sustainable (Carayannis & Campbell 2009).

Based on previous experiences in designing processes for citizen participation, we integrated these well-known components into a lean yet viable procedure

(Stelzle et al. 2020). We conceptualised a framework that followed the standard steps of most strategy-making approaches (status quo analysis ▪ future vision ▪ implementation roadmap). A new component, however, was to form a “driver” for the strategy process from those partners in the municipal administration (EBIT) and science (TU Dresden) who had been responsible for the project application – and were thus well acquainted not only with each other but also with the conditions of the funding program and relevant political smart city frameworks. Moreover, this “driver” team would bring a natural interest in furthering the project they themselves had initiated before. This dynamic momentum from this “driver” is represented in Fig. 2 by the horizontal grey arrow.

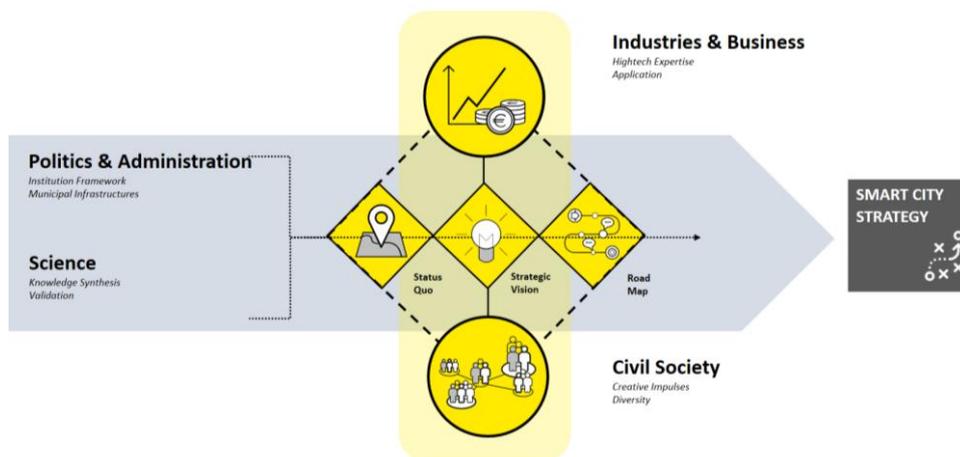

Figure 2: Procedural scheme #1 towards the Smart City Strategy: Onwards-moving “driver” (horizontal arrow) plus broader stakeholder participation (vertical bar). (Source: TU Dresden)

We acknowledged clearly that the complex and far-reaching strategy process needed broad participation and involvement of various stakeholder groups. Thus we completed the procedural scheme with a second lateral momentum (vertical yellow bar) which was supposed to introduce all relevant aspects “from the side” – that is: from civil society (individual persons but also organisations, associations, initiatives etc.) as well as from industries and business. From both sides, we expected valuable inputs and inspirations for the overall process.

While Fig. 2 – drawn early in the project’s first phase – gave us a guideline and orientation for the design of the overall procedure, the actual process eventually looked much different. Fig. 3 shows the process diagram as conceived at the end of the strategy phase. While the key conceptual elements (Double Diamond, Agility, and Quadruple Helix) remain discernible, the onward momentum

unfolded through complex and somewhat diffuse feedback/forward loops. They represent the necessary iterative cycles that concepts must pass to receive (in)formal acceptance, e.g., in bureaucratic admissions or public communication campaigns.

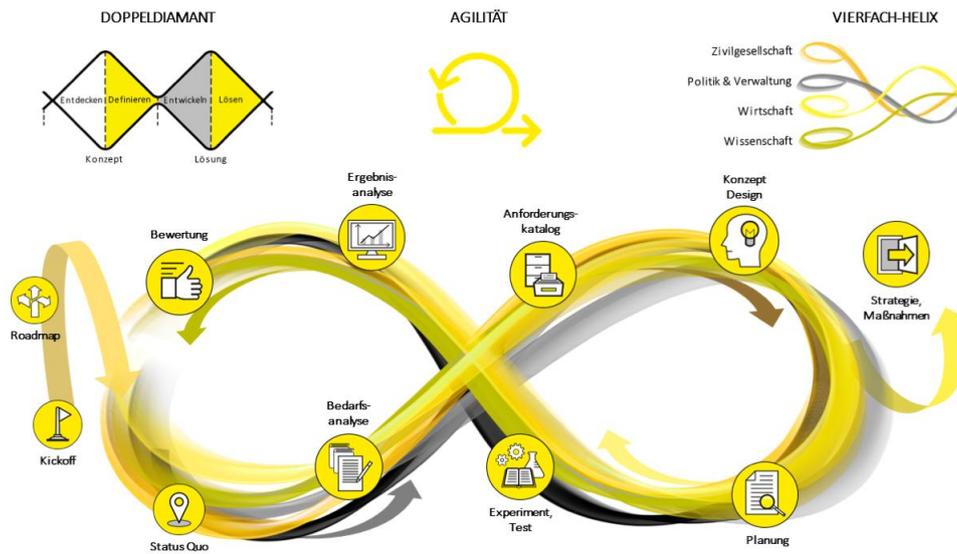

Figure 3: Procedural scheme #2: A complex and dynamic process based on iterative feedback/forward loops and defined milestones (Source: TU Dresden).

### 4.3 Roadmap for Strategy Making

The pragmatic implementation of this scheme and the multiple activities that it embraces resulted in a roadmap comprising multiple activities and events, especially participation formats. Fig. 4 shows the respective milestones that span from so-called first-hand data-collection with mayors and high-level deputies (“Leitplanken-Interviews”) to online participation campaigns (“Smart City Survey”), from in-depth workshops with research institutions (“Ecological Spatial Development”) to public promotions events (e.g. “Science Night”).

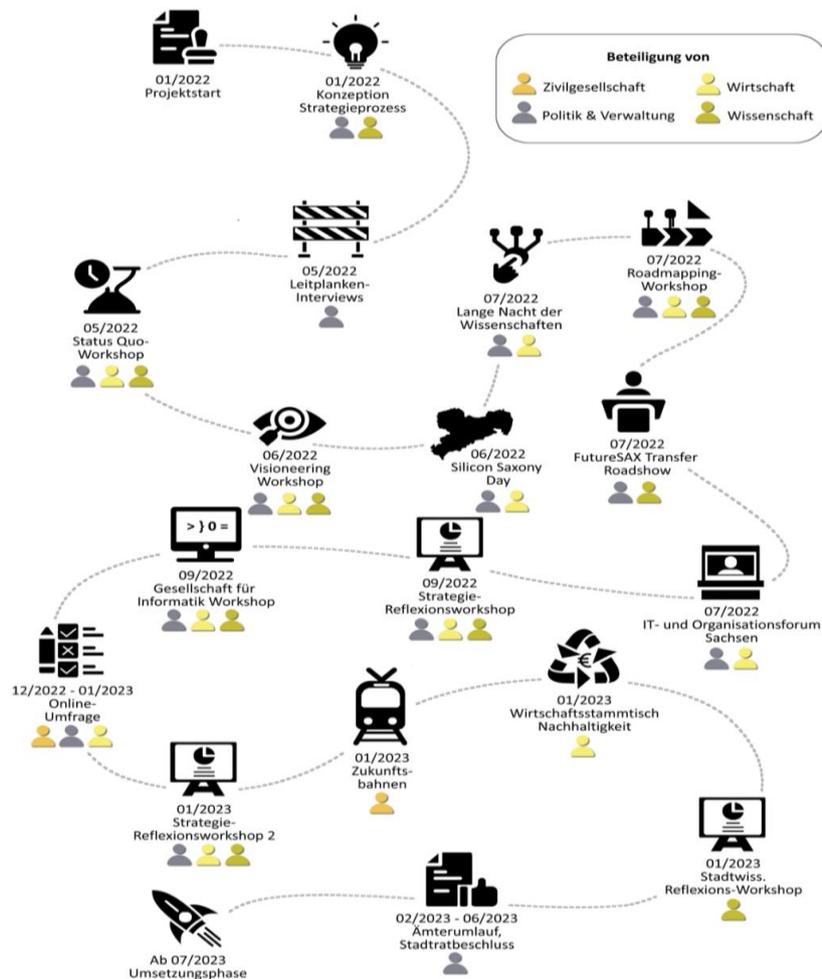

Figure 4: Roadmap through the strategy phase: Participatory events and activities with different stakeholder groups and actors. (Source: TU Dresden)

The intention of rolling out such a range of participation formats was to involve as broadly as possible the various stakeholder groups, to compensate the shortcomings of the single measures by the multiplicity and diversity of formats, and to collect thorough and deep knowledge about smart city projects and processes (impacts, risks, potential threats). While the temporal compression and partial parallelism of events were a challenge, the complementarity of formats and the respective findings ushered in surprising results (see section V).

#### 4.4 Participation in Smart City Strategy Making

Appropriate involvement of the various stakeholder groups – especially the civil society – was a quality demand stated by not only the funding programme but also by previous research (Stelzle et al. 2017; Stelzle & Noennig 2019). Hence, after co-creating initial ideas with experts from urban politics, administration, science and civil society in participatory strategy workshops, we enhanced these inputs at the end of 2022 / beginning of 2023 through various public participation campaigns and expert talks with representatives from the science and business sphere. In these formats, already running measures as well as existing thematic approaches relevant for the smart city context had been reviewed and checked for their potential to integrate into the model project. The goal was to create the most comprehensive possible synergies between the diversity of activities and actors, and to support the achievement of the city's overarching development goals.

Figure 5: "Zukunftsbahn" – Future Tram – ad hoc participation in public transportation. Tram lines become mobile laboratories for citizen engagement. (Source: TU Dresden)

In order to understand the tonality and attitude of the citizenship towards the idea of a smart city in general, and a Dresden-tailored strategy specifically, we engaged citizens by formats like the "Future Tram" (Zukunftsbahn) for which we remodelled public streetcars into rolling co-creation labs ("participation on wheels", Fig. 5) – or via an extensive online campaign. Based on previous research of "crowd listening" and discourse analysis (Holmer & Noennig 2017, 2018), the thorough analysis and synthesis of the results provided important guidance for the further design of the strategic process.

## 5 Results Discussion

As we accomplished the process of creating Dresden's Smart City Strategy in spring 2023, we cannot yet report on the strategy's long-term effects and impacts on the city's overall urban development and its neighbourhoods. However, the process itself and its key results allow first assessment, reflection and criticism.

### 5.1 Assessment of the Strategic Process

In the relatively short period of one year, the strategy team initiated, carried out and concluded a comprehensive strategic process based on a complex set of co-creative activities for a broad range of stakeholders. The effort finally led to a smart city strategy that was documented in two formats – a 70-page long version, from which a 15-page executive summary was condensed. Besides a comprehensive digest of the status quo analysis, the strategy includes a key vision (“mantra”), four overarching fields of activity, and nine specific measures and projects to be implemented in the subsequent 4-year project phase.

Due to lacking research and reliable methodologies (as described before), the overall process appeared somewhat obscure at the outset but soon consolidated into defined activities, formats, and results. We have successfully tested three key approaches that bear the potential to become part of a replicable model process:

1. The design and implementation of a set of **complementary participation measures**, targeting topics of smart city development and involving various stakeholder groups – to consolidate the local status quo as well as to collect creative input and critical feedback for the envisioned future strategy;
2. The conduct of a **complex concept synthesis**, mainly carried by the researchers at TU Dresden, who were in charge of streamlining and shaping the various stakeholder inputs into a concise vision picture and defined fields of activity by way of topic modelling and synthesis workshops;
3. The facilitation of a **simultaneous and iterative counter flow** of high-level vision-making on the one hand – as carried out within the process by key stakeholders and the strategy team – opposed by the pragmatic definition of concrete projects on the other hand, as resulted from ongoing activities and existing demands in the city administration of Dresden.

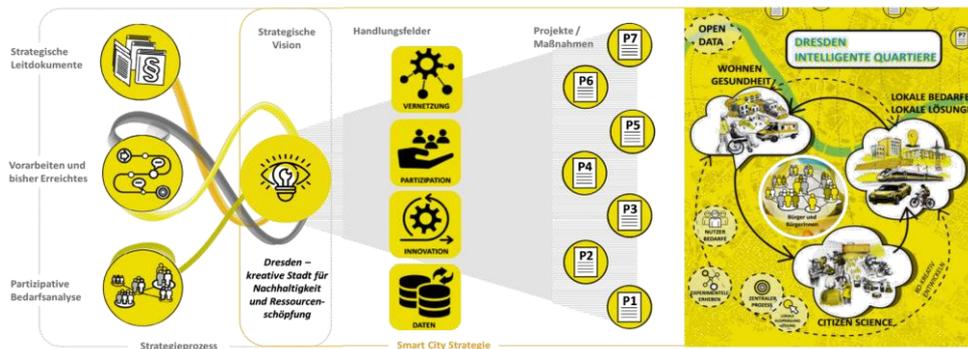

Figure 6: Counter flow of high-level strategy-making (left) and concrete implementation projects (right), connected by a strategic vision and general fields of activity (centre). (Source: TU Dresden)

To form a replicable model, we have systematised in retrospect the experimental and explorative procedure into a generic methodology (Fig. 6). It suggests a purposeful channelling of the strategic documents review, the survey of previous and ongoing local smart city activities, as well as the broad participatory demand analysis into one strategic vision (left side of the image). At the same time, concrete projects are being conceptualised for implementation in specific urban neighbourhoods (image right), feeding into overarching fields of activity (image centre) that directly support the vision.

Following the general agile approach, all past and future participants are encouraged to regard the present strategy as an open-ended, living document that demands continuous updates and revision in the future stages of the project.

## 5.2 Dresden-specific Results of the Strategic Process

In contrast to the presented generic process scheme, the specific results of Dresden’s smart city strategy process are location-bound and not necessarily replicable. To indicate the capacity of the new process for the specific urban development context, we will highlight some specific results in the following paragraphs.

The initial status quo analysis carried out in co-creative workshops led to a comprehensive mapping of existing smart city projects, themes, and actors (Fig. 7). Consolidated into an interactive collection of hundreds of project and institutional profiles, this so-called “Smart City Radar” provided a comprehensive knowledge base for synthesising the multitude of activities into coherent vision

and action – and will most certainly do so in the upcoming implementation phase too.

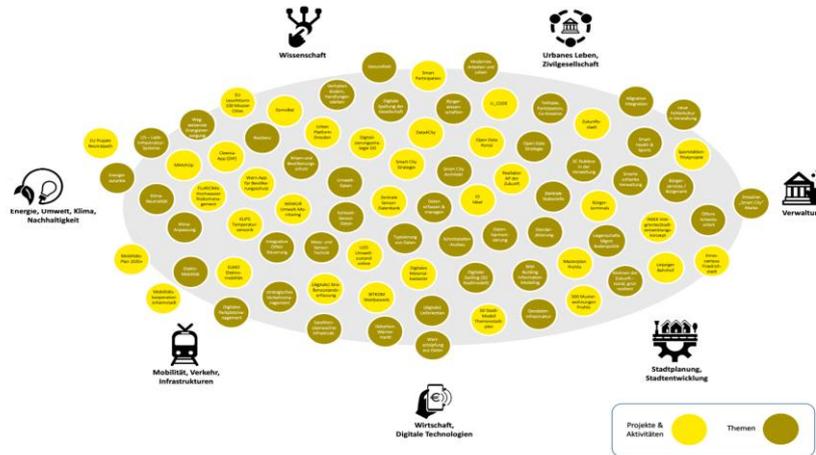

Figure 7: Smart City Radar – Visualisation of existing smart city projects (yellow) and themes (olive) in Dresden, arranged by sectors. (Source: TU Dresden).

The focus group workshops in Dresden’s so-called “Bürgerlabor” (Citizen Lab) – a public open facility on the ground floor of the town hall – brought strong conceptual impulses to feed into the later strategy process. Here, dozens of participants co-created high-flying visions (“Merging tradition and digitalisation”) and mission statements (“Networking actors to facilitate a maker culture”) for the long-term future, as well as ambitious challenges (“City Service Hubs”) and concrete project ideas (“Open Data Access”) to be tackled in the short run. These inputs have been carefully collected, synthesised and fed into the strategy activities.

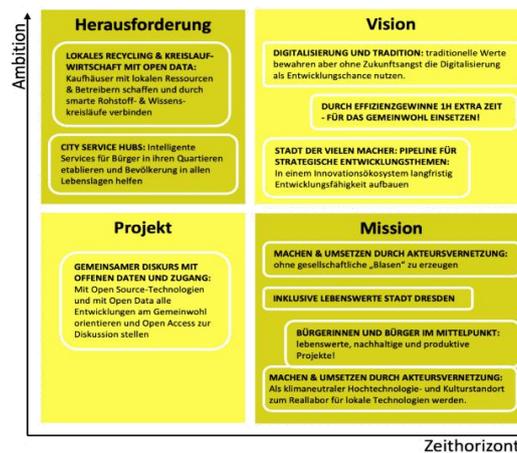

Figure 8: Matrix of co-created smart city visions / missions / challenges and projects for Dresden. (Source: TU Dresden)

The comprehensive collection of smart city challenges and demands through participatory campaigns (Future Tram, online survey) drew up an informative picture of the overall attitude of Dresden’s citizenship towards smart city themes. The online survey (Fig. 9) with more than 600 replies showed that mainly positive interpretations prevail within the population. At the same time, fears of surveillance and technocracy exist, even though they are not dominating. Meanwhile, visionary concepts co-created in participation workshops such as “Digital Service Points” or “Dresden as a testbed for innovative climate-protecting solutions” earned high agreement.

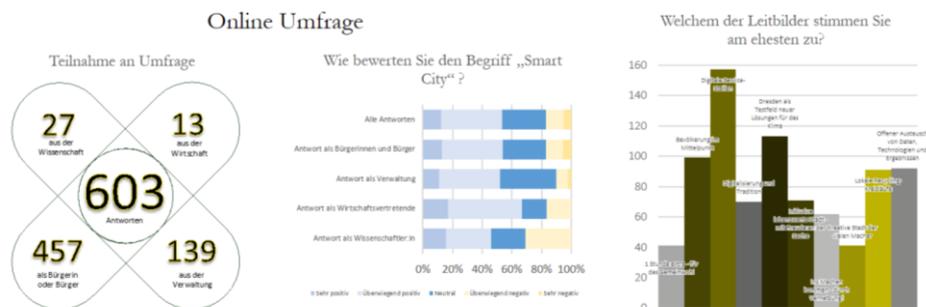

Figure 9: Results analysis of online survey: Participants count, positive/negative “Smart City” interpretation, preferred visions. (Source: TU Dresden).

The strategy process resulted in a portfolio of nine concrete projects, which – following the overall smart city strategy – are scheduled for implementation in the second phase of the model project. As thematic impulses mostly came from the city administration and authorities, their curation into coherent measures complying with the comprehensive new strategy has been a major activity throughout the strategy phase. Concrete measures include, for example, the establishment of a public platform (“Cleema App”) to trigger sustainable behaviour changes in the local population (Fig. 10). Each measure was carefully assessed as to their compliance with the UN Sustainable Development Goals and the national Smart City Charter, as well as their socio-spatial impacts according to Dresden’s Integrated Urban Development Concept (IUDC).

Figure 10: Project profile for smart project to be implemented: Cleema App for triggering citizen behaviour change towards sustainability. (Source: Cleema / TU Dresden).

## 6 Conclusions and Outlook

Within the specific context of the smart city model project for Dresden, and with an explorative and experimental approach, we have designed and tested a new methodology for creating smart city strategies. Based on state-of-the-art research in smart and digital cities, and in line with the overall ambition of the national funding priority “Model Project Smart Cities”, we have put forward a model process that appears replicable in other places too. The individual components of the process are easy to implement; local-specific adaptations are possible. The value of this process derives from the purposeful integration of conceptual key components into a co-creative logic enabling the effective formulation of strategic visions and actions.

By fusing approaches from innovation and creativity management (“Double diamond”), participation and co-creation research (“Quadruple helix”), as well as IT and software development (“Agility”), the new methodology was able to drive our strategy-making with high momentum. By combining these approaches, we ensured a dynamic process that a) involved all relevant stakeholder groups, b) resulted in innovative concepts and implementation measures, and c) created a strong forward movement that would rapidly lead to a feasible and context-sensitive urban development strategy.

Why are such strategies and visions important for smart and digital city developments? Arguably, they compensate for the high levels of insecurity that city administrations as well as civil societies face during the rapid digital transformation of their cities (Bauriedl & Strüver 2018). The opacity of urban futures creates a growing desire for normative visions. While any “future-telling” may be highly speculative by default, the outlining of strategic urban visions by way of iterative and co-creative problem-solving appears instrumental for

defining potential paths into agreeable and controllable futures. Anticipating possible future discourses and technological developments, they may become self-fulfilling prophecies.

### **Abstract**

This paper reports on results of the SURE facilitation and synthesis research (FSR) project for the funding priority SURE (Sustainable Development of Urban Regions) of the German Federal Ministry of Education and Research (BMBF). SURE engages ten collaborative projects which develop concepts and test locally implementable solutions and strategies for sustainable transformation of fast-growing urban regions in Southeast Asia and China. SURE aims to create conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address issues of sustainable urban development. The paper discusses the application of Natural Language

Processing (NLP) as one form of Artificial Intelligence (AI) to support data and knowledge synthesis in sustainable urban development research. The abundant urban data and recent advancements in the field of AI have the potential to transform how urban researchers perceive and tackle sustainable development-related problems of cities. The research team employs various NLP algorithms to assess text data with the goal to analyse patterns in order to explore intra-project synergies and research intelligence on future trends. NLP has exhibited an ability to digest copious textual data and improve the usability of urban corpora, improving study scope and reducing resources required for research. However, the implementation of NLP to study issues related to sustainable urban development is a relatively novel. Predominantly used NLP modules are unable to identify contextual relations amongst multiple words which is essential in urban region study. To overcome this issue, algorithms employed were trained to identify various word classifications related to urban study discipline for precise output. We discuss the preliminary results of the ongoing exploration and show how it could contribute to an understanding of large text-based data sets in urban knowledge management. We examine the possibilities and limitations of such an approach and discuss the implications of AI as part of a multi-methodological approach to carry out a synthesis of sustainable urban development research efforts across an entire region covered under SURE framework. The paper also gives an outlook on utilising new AI based algorithms to generate text-based data analysis channel as well as indicate the limits, successes, challenges and constraints of such approaches.

## 1 Background and Introduction

Rapidly growth of urban dwellings in cities located in South-East Asia and China has posed a challenge to scholars in dealing with complex issues threatening the societal livelihood of community and sustainable development. Researchers Kates et al. (2001), Binder et al. (2015), Zscheischler et al. (2014) discovered that dependency on inputs from single discipline is not enough to address intricate and complex problems related to sustainable development of urban and rural areas. Rather a transdisciplinary framework encompassing academics, non-academics and mutual learning amongst stakeholders is necessary to determine a practice-oriented solution that could be implemented locally. On such premise, the German Federal Ministry of Education and Research (BMBF) sponsors the funding priority SURE 'Sustainable Development of Urban Regions' that promotes transdisciplinary research towards SDG localization and an accompanying synthesis research with a primary focus to explore new

collaborative approaches that enable societal contribution, future topics and challenges in urban and rural development.

The SURE funding priority comprises ten collaborative projects oriented towards development of concepts and testing implementable solutions locally in fast-growing urban regions in Southeast Asia and China. These ten projects and funding priority are accompanied by the SURE Facilitation and Synthesis Research (SURE FSR) project that aims to create conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address the issue of sustainable urban development. Such framework enables vast tangible and intangible knowledge generation, that is captured from project documents (e.g. proposals, reports, results) and through facilitation activities (workshops, peer-to-peer meetings, interviews) to identify transdisciplinary and sustainable urban development challenges. The SURE FSR aims for transdisciplinary knowledge synthesis in sustainable urban research, with one of its pillars being 'Research intelligence ', where the team explores the digital tools and data science approaches to establish synergies between project via content comparison, topic modelling and exploration of future trends and challenges. This paper is embedded in the larger research effort of the SURE FSR, where the knowledge is being synthesized with the employment of AI tools. The IFKAD'23 paper by Agota Barabas et al., titled '*sustainable knowledge synthesizer: a modular tool for urban research*', from the HafenCity University Hamburg (ID 245) shows how databases, as well as data services for knowledge management and communication and collaboration, are provided, adapting solutions from business intelligence (e.g. project dashboard, monitors, cockpits), and then aggregated in the functional tool "Synthesizer". The paper discusses the concept of such a synthesizing system and its application in a meta-research environment of transdisciplinary sustainable urban development approaches, sheds light on the opportunities and challenges of the development of such a synthesizing tool, and draws a first picture of the complexity accompanying the development of a "synthesizer" as part of the SURE FSR.

Recent strides in the field of artificial intelligence (AI) and machine learning give an opportunity to analyse such tangible project outputs. AI applications has been prevalent in energy efficiency and mobility since early 2010s while recently developed AI tool's applicability in sustainability science has proven effective in various sectors including water management, sanitation, agriculture, pollution, urban development as well as tracking progress of sustainable development goals (SDGs) (Goralski & Tan, 2020; WU et al., 2022).

A sub-branch of Machine Learning, denoted as Natural Language Processing (NLP), has a capability of understanding human language structures and assist in analysing big text corpora. It is a form of computational algorithms which perform various tasks such as text analysis, text categorisation, sentiment analysis, topic modelling, network analysis, or text summarisation. In context of transdisciplinary research, NLP bears large potential to perform qualitative analyses on large volumes of data collected through interviews, focus groups, or survey responses as well as identify the main topics or themes within a large amount of text. Furthermore, NLP has wide applicability in field of sustainability research due to wide range of customisation and possibility of creating tailored neural networks in accordance to given research objectives. Such AI-assisted qualitative data analysis can help researchers identify patterns and trends that might otherwise go unnoticed, providing a more comprehensive understanding of the research topic. A bibliometric study conducted by Fosso Wamba et al., (2021) observed a significant increase in the utilisation of neural networks and other Machine Learning approaches for addressing ecosystem challenges, infrastructure management, and stakeholder management. Although trend of using AI-related tools to tackle challenges related to urban development is still in its infancy, researchers have applied NLP techniques in various topics related to urban governance and management, public health, land use and functional zones, mobility, and urban design (Cai, 2021). Li et al. (2023) demonstrated the capability of NLP using social media data to predict urban flood susceptibility in Chengdu, China; while Bardhan et al. (2019) developed a more sophisticated NLP algorithm capable of performing sentiment analysis as a mean to document various aspects in integrated urban planning of slum housing rehabilitation projects in Mumbai. Riding this wave of exploration of AI applicability relevance in area of sustainability and urban development, SURE FSR attempts to explore the sphere of content comparison and qualitative research in order to find cross-cutting topics and establish synergies between diverse topics. Exploring the applicability of AI in the area of sustainability and urban development, SURE FSR employs it for content comparison, to validate findings (e.g. focus topics), search for synergies between projects and knowledge synthesis. For this end, the SURE funding priority has been a rich source of tangible data to be analysed with NLP in order to create and test hypotheses.

## **2 Research Methodology**

### **2.1 Research Objective**

The SURE Facilitation and Synthesis research Project explores the challenges of synthesis research in cross-cultural settings and institutional set-ups, with a particular focus on sustainable development in the built environment in South-East Asia and China. The activity of this complex project is divided in two main “wings”: facilitation and synthesis research. The approach used in the SURE Facilitation and Synthesis research project is transdisciplinary, problem-driven, and solution-oriented. The project employs a meta-study methodology that synthesizes and consolidates existing conceptual, methodological, and empirical knowledge from literature and the ten collaborative projects within the SURE funding priority. Overall, the approach used in the SURE Facilitation and Synthesis research project is designed to support individual research projects and to systematically leverage the cross-project synergy potentials at the funding priority level. The goal is to create conceptual, theoretical, methodological, and translational innovations that integrate and move beyond discipline-specific approaches to address the issue of sustainable urban development.

The project looks to synthesize and consolidate existing conceptual, methodological, and empirical knowledge from literature and the ten SURE collaborative projects. This qualitative meta-study aims to contribute to the transdisciplinary sustainable research discourse by providing a scientific contribution to the third epistemic way (Lang, Wiek et al. 2012). The research project is designed to support individual research projects on the one hand and to systematically leverage the cross-project synergy potentials at the funding priority level based on the collected and structured knowledge from the projects and beyond. Conducting meta-research across disciplines and across cultural borders requires a management of knowledge that is sensitive towards these challenges (Ioannidis, Fanelli et al. 2015). Within the SURE facilitation and synthesis research approach, we developed a research and knowledge architecture that allows for constant reflection to improve the applied concepts. The overall structure of the SURE FSR is described in more detail in the IFKAD’23 paper ‘Meta-study: research architecture for sustainable knowledge synthesis’ (ID 231) by Katharina M. Borgmann et al. from the HafenCity University Hamburg.

Although the funding priority targets inherently non-linear development dynamics that are difficult to capture by computation, trained algorithms still may provide a substantial support. For this reason, we put forward the concept of a

technology-aided knowledge synthesizer and outline its conceptual design and technical implementation in a parallel paper to this conference (Barabas et al., 2023). The synthesizer is conceived as a digital infrastructure for knowledge creation and decision support, based on thorough project analysis and content elaboration. Assisting with scientific classification, among others, it aims to indicate future research topics and challenges in sustainable urban development. The system's idea is rooted in knowledge theory and knowledge lifecycles models with a focus on modes of knowledge synthesis – the integration and refinement of existing knowledge into new insights. The conceptual design of the synthesizer is composed of modules for the access, structuring and integration of knowledge captured from the transdisciplinary research projects in SURE.

This paper presents an exploratory inquiry's initial findings with NLP that is part of synthesizer's module development. This component is envisioned to conduct the cross-project content analysis and topic modelling to aid the synthesis research. Previously the SURE FSR team has synthesised and clustered without algorithmic support six focus topics based on projects and funding priority contents:

1. Urban-Rural Nexus
2. Resource Efficiency and Mitigation
3. Sustainable Behaviour and Practices
4. Ecosystem Services and Nature Based Solutions
5. Risk Management and Risk Reduction
6. Integrated Planning and Development.

Our initial exploration of NLP aims to validate these six focus topics generated in the researchers' previous discourse, and to understand the opportunities and challenges of automated text analysis and topic modelling within the overall process of knowledge synthesis. For the validation, we included the original documents of the BMBF funding call and project proposals that were used for the initial topic synthesis. In addition, we extended the document list with relevant policy frameworks and strategy documents to generate still better results.

Albeit the investigation is still embryonic, it provides valuable insights in development of topic modelling and discovery of future trends and challenges in sustainable urban development.

Table 1: Documents included in Dataset

Name	Type	Publication Year
Project 1	Project Proposal	2017
Project 2	Project Proposal	2017

BMBF - *Bundesministerium für Bildung und Forschung* (Federal Ministry of Education and Research)

## 2.1 Data – Proposals and Policies

The database of this study consists of proposals prepared by all ten projects and policies that has served as foundation for the SURE funding priority. Additionally, text extracted from webpage dedicated to all for proposals is also included in study. *Table 1* enlists documents included in analysis along with the publication years and other attributions. Due to privacy measures project names are not disclosed. The policy framework documents and SURE call for proposals are open-source and available online.

### **2.3 Data Preparation**

Eliciting textual data and pre-processing of documents for NLP analysis is necessary to remove the irrelevant information such as headers, footers, and references along with images. While manually pre-analysing the project proposal documents, irrelevant data without objective value were omitted. They include sensitive information such as partner information, personal details along with other numerical and graphical data.

## **3 Data Analysis and Results**

### **3.1 NLP Analysis**

#### *3.1.1 Document Cleaning*

Fig 1 illustrates the workflow of the methodology encompassing the step-by-step process for NLP analysis. The data pre-processing and removal of sensitive data from the documents has been conducted manually without any computation, resulting in converted pdf files to ensure better accessibility across various platforms. Python is chosen as a programming language to perform the research analysis, as a significant number of open-source algorithm libraries are offered in that language that are required at various stages of research. An iterative process is required to validate and check the compatibility at each stage of such analysis to ensure the accurate extraction of the desired output. Thus, in every stage of the process represented in decision tree (*fig 1*), a compatibility check is performed to maintain the homogeneity of the data.

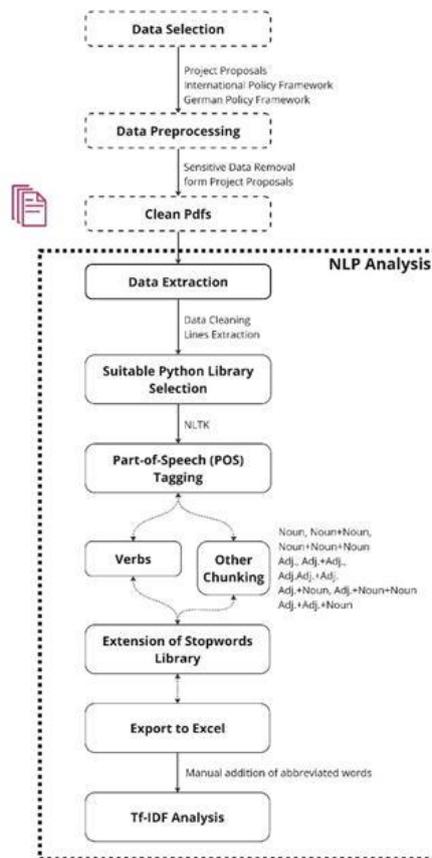

Fig 1: NLP Analysis Decision Tree

### 3.1.2 Approach and Customisation of the Natural Language Processing

Numerous open-source NLP libraries are available that are capable of performing basic tasks such as tokenisation, word tagging to advanced Machine Learning frameworks for natural language understanding and generation. Choosing a suitable library for required analysis could be a daunting task as these libraries offer specialised computation to perform specific tasks. Although the flexibility of Python scripts allows for the usage of multiple libraries in one algorithm, doing so also increases risk of errors and incompetence in analysis. Part-Of-Speech (POS) tagging emerged as essential process of computation from NLP analysis scope and output requirements study. One of the prominent complexities observed during an initial check is that word roots and its affixes usually hold contextually different meaning in the sentence formation of texts related to urban development and sustainability science (Jha et al., 2021). Thus, the standard linguistics processes of text lemmatisation and text stemming are

avoided in our algorithm to preserve the textual context as much as possible in NLP results. Versatility of the library also emerges as a deciding factor in the selection. As this study is to serve as basis for topic modelling and future challenges predication, the chosen library should offer tools and functionality to perform tasks such as named entity reorganisation (NER), machine translation, text classification and sentiment analysis. Primary requirement for this study is to perform an extensive POS tagging and identification of n-grams variations combining noun, adjective, adverb as well as long expressions. The Natural Language Toolkit (NLTK) was chosen as primary Python library to perform task related to NLP, as it offers tools to perform the afore-mentioned requirements and ease of customisation (Bird et al., 2009). In order to extract lines and sentences from the cleaned documents, removal of punctuations and word wrapping is necessary to achieve accurate results (Goralski & Tan, 2020). Python offers various pre-programmed libraries to perform line and sentence extractions from pdf documents. After conducting an iterative process conducted on assorted libraries and respective outputs, PdfPlumber library was chosen in the further computation as it offers better functionality in processing texts from diverse sources (GitHub, 2023). Due to diversity of data, it is observed that predefined stop words and punctuations used by the library are not adequate to provide satisfying results. Therefore, additional custom punctuations (see Annex 1) are amalgamated with existing stopword directory of NLTK after iteration.

To achieve the indicated research objective and uncover potential correlation between policy frameworks and the established project purpose, the NLP algorithm was trained to identify and extract keywords from each document. A bilateral approach was integrated in the Python script to differentiate POS tagging of verbs and various combinations of nouns and adjectives. While existing studies claim to have completely replaced traditional analysis methods in few fields of urban planning, existing models available for NLP analysis of text related to sustainability and related urban development lack cohesion of results (Cai, 2021; Kölbl et al., 2022). To avoid this, a rather novel approach is necessary that analyses the text holistically using an assorted combination of POS chunks to decrease the probability of overlooking phrases that determine the context. A NLP technique denoted as chunking is customised and assimilated in the algorithm. Chunking essentially identifies sequences of words that belong together in a sentence based on their grammatical role and extracts the contextually important sequences of words as units of meaning. Rather than utilising predefined rules and patterns, the algorithm is adapted to identify

grammatical combinations up to three consecutive words including noun, noun+noun, noun+noun+noun, adjective (adj.), adj.+adj., adj.+adj.+adj., adj.+noun, adj.+noun+noun adj.+adj.+noun. Initial iteration stages of NLP computation showed inadequacy in identifying different cases of alphabets and punctuations (see Annex 1). A computation loop was added to counter and identify same words in different case-sensitivity and avoid duplication of same keyword in output. A more coherent output is obtained in further iterations of the NLP algorithm runtimes after adaptive measures were added. In the final stages of the NLP process, a term-frequency (TF) analysis is carried out on identified keywords. In essence, TF measures the frequency of occurrence of each term in a document or corpus representing the importance of the term in the analysed document. It provides intrinsic value to each keyword that are necessary in an effort to establish correlation or to compare diverse set of documents with varying length and text structure. A well-structured output in spreadsheet format is obtained by using ExcelWriter library of Python for the further manual analysis and validation.

### *3.1.3 Manual Iteration of NLP output*

A manual interpretation of results obtained from NLP analysis is vital for a tenacious approach towards the establishment of topical synergies and correlations. A prominent discrepancy in frequent term analysis was discovered as the NLP engine lacked capacity to incorporate abbreviated words in the account. Notably the NLTK library requires extensive modifications before being able to consider and account for abbreviated wordings in documents. Thus, a rather simplified manual approach was chosen to avoid discrepancies in existing output from NLP analysis. Furthermore, an additional manual iteration was undertaken to indicate the relevance of each keyword within respective text of document. To define the relevance and assign a comparable scale with respect to other data extracted from document, a rather rudimentary version of TF-IDF (term frequency-inverse document frequency) approach was taken which involves proportionating the frequency of term in reference to total word count of corresponding document. The remaining manual iterations involved the sorting of data for the purpose of visualisation and convenience of usage.

## **3.2 Focus Topics**

The clarification of focus topics is an essential part of the SURE funding priority, as they serve as a foundation for subsequent knowledge exchange and

dissemination, as well as for the exchange of case studies and approaches across projects. By way of non-algorithmic analysis, the SURE FSR team had established six such focus topics, as being woven into each project’s efforts of developing locally adaptable solutions and strategies (see section 2.1). In that ‘non-technical’ attempt, a rather tenacious Grounded Theory-approach had been taken to identify and classify the most frequent keywords in each project proposal, and to derive an initial project ontology and list of focus topics (BMBF, 2023; FONA, 2023; Slawski et al., 2022; SURE, 2021).

### 3.3 Results of NLP Analysis

In the process of this NLP analysis, we used all ten project proposals and policies (see Table 1) to identify the most frequent keywords or topic clusters to determine the primary trends and foci of the respective documentation. Additionally, to explore potential links between project proposals and policy framework, a combined text of all proposals was created and analysed with the NLP algorithm to find most frequent terms and notions. Considering the vast number of keywords and their corresponding occurrence in documents, only the top 15 most frequently occurring keywords were retained from the project proposals for scrutiny, to establish consistency and reconcilability for critical analyse of findings. For the policy framework and analyses of all proposal texts, the top ten most frequently occurring keywords were retained.

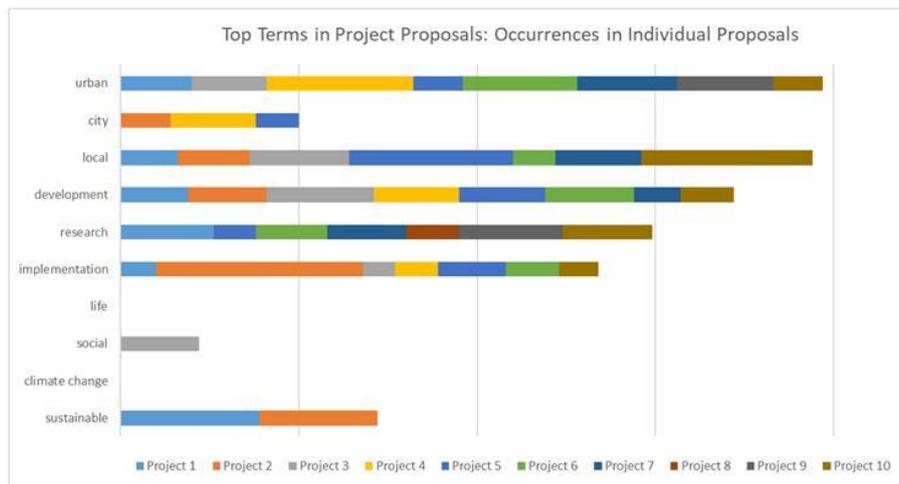

Fig 2: Top terms in Project Proposals: Occurrences in individual proposals

Fig. 2 represents a cross correlation between ten most frequent terms found in the combined text of the ten project proposals and their occurrences in the individual project proposal's 15 most frequent terms. The chart reveals several interesting traits and patterns. Most terms appear frequently in majority of project proposals, while terms 'urban' and 'local' are more prominent than others. Terms 'life' and 'climate change' are surprisingly missing from all ten project proposal's 15 most frequent terms. This could suggest these terms are mentioned as overarching topics and projects tackle them indirectly through their focus topic. Notably there are two outlier terms 'social' and 'sustainable' that appear in only one or two project proposals. Although since text lemmatisation and stemming is intentionally avoided in NLP analysis, other forms of root word sustainable such as sustainability, sustainable, sustainable development are interpreted differently. Thus, it could be that single word occurrence of these outlier terms is accounted differently in other project proposals. This comparison provides valuable insights into key themes and challenges that are undertaken by projects. For example, *project 2* emphasises 'sustainable' and 'implementation' while *project 1* puts more emphasis on 'sustainable', 'research' and 'development'.

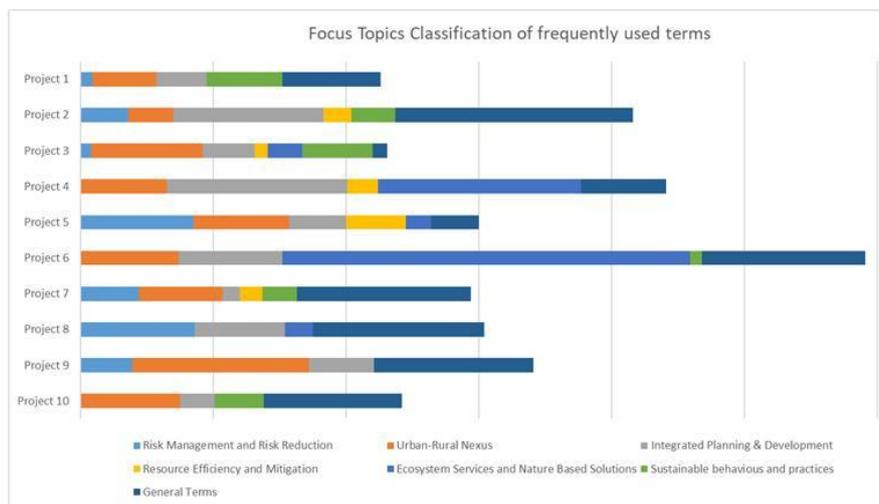

Fig 3: Focus Topics Classification of frequently used terms in project proposals

Fig. 3 illustrates the distribution of focus topic related terms in individual projects keywords. General terms were used to categorise keywords that are difficult to classify within the ontological boundaries of one single focus topic. Findings from Slawski et al., (2022) suggest that focus topics is reflection of BMBF's call for proposal and projects' thematic focus and skills. NLP analysis

provides a more detailed insight into each projects' focus. *Project 4* and *project 6*, for example, use 'Ecosystem Services and Nature Based Solutions' related strategies significantly higher than other projects, while all projects utilise 'Urban-Rural Nexus' related strategies in their quest for sustainable urban development solutions. As expected, targeted focus of each project varies greatly thanks to heterogeneous challenges undertaken by each project in combination with diversity in local and cultural environment.

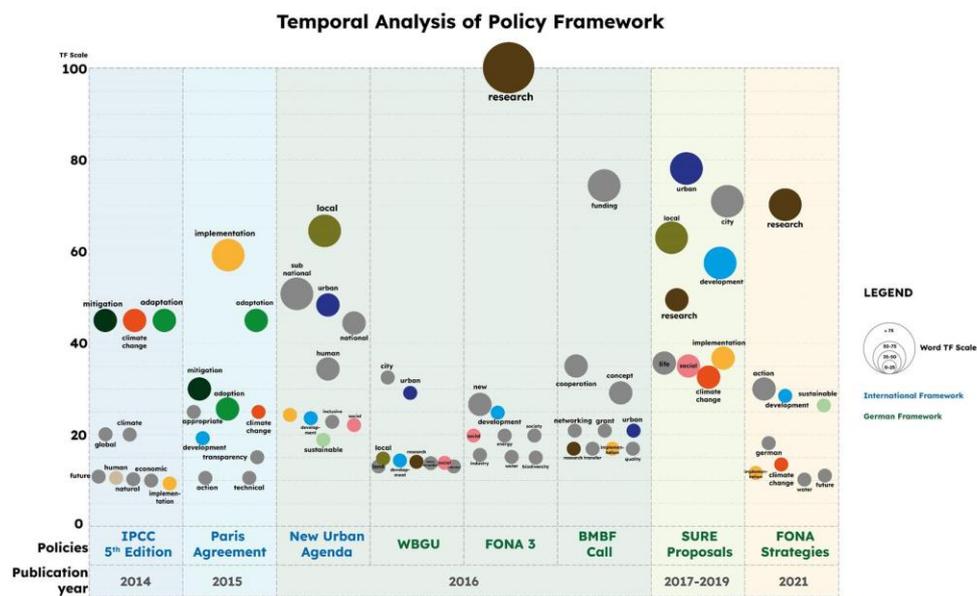

Fig 4: word occurrence over the years (Temporal Analysis)

Fig 4 shows the in-depth interpretation of output from all documents analysed by NLP. Ten Most prominent keywords from each document or webpage are represented according to their relative importance (TF-IDF). This visualization narrates the evolvement of foci of national and international policy framework and in what capacity the existing policy framework has influenced the challenges being tackled within SURE framework. The existing international policy framework has given priority to highlighting and narrating environmental challenges while German policy framework has shown more emphasis on research and development of solutions. The prominent words present in multiple policy documents are highlighted in graph by using bright colour theme while the other words are in grey.

## 4 Conclusions and Further Discussion

Transdisciplinary research is intrinsically complex, targeting multiple objectives simultaneously. The incorporation of innovative research directives along with traditional research methodology thus benefits the objective of achieving knowledge creation and dissemination across projects in the SURE funding priority. Although sustainable urban development related research puts emphasis on the local environment and context, an overarching and generic framework opens up valuable opportunities for the knowledge synthesis across the individual projects and the funding priority – for the currently running activities as well as for prospective future research. The explorative content comparison conducted via NLP techniques presented in this paper contributes to such objective. The linguistic analysis of project proposals highlights the priorities that each project gives to certain focus topics and challenges. An analogical NLP overview of the national and international policies that have led to SURE funding priority in the past, may line out the most prominent challenges overtime – as well as upcoming ones in the future.

The results show the application potential of NLP analytics in research related to urban development and sustainability science. The contextual preservation of identified keywords and chunks of words has been key for carrying out an effective and meaningful analysis of the given text corpora. The NLTK library has exhibited high confidence while performing POS tagging, chunking and context preservation when performing the preliminary text analysis with the relatively small set of given data from the SURE projects. Although the NLP analysis conducted in this paper is rudimentary, it has exhibited promising insights in projects' primary focus and challenges. The implications of AI in sustainable urban development research are significant, and our study underscores the need to continue exploring and evaluating the possibilities and limitations of such an approach. An NLP analysis of rich database containing more publications, research articles and other tangible outputs from projects could provide valuable insights and serve as testing platform for various hypotheses. SURE FSR aims to exploit the opportunity to explore various NLP applications including topic modelling and entity recognition. It would support the overall meta-study to consolidate existing knowledge from literature and collaborative projects. Furthermore, NLP model could be trained with enough manual data-tagging to

identify specific challenges in field of sustainable urban development potentially providing insights into most recent challenges and prediction of future trends.

### Abstract

Based on a multiple case study research, the paper aims at providing some first evidence on the adoption of Open innovation and sustainability practices by innovative startups. The focus is on the underlying motivations and the potential effect on startup success of the combined adoption of both types of practices. Following a literature review, an in-depth qualitative analysis has been performed based on five innovative startups based in the Romagna area (Italy) and in the Republic of San Marino. Results highlight that motivations

to Open Innovation adoption are classified in necessity-driven and opportunity driven, differentiating among the lifecycle phases. As for sustainability practices, two main attitudes are recognized in startups: reactive and proactive. Finally, no results on the interrelation between Open innovation and sustainability practices adoption can be found in the investigating sample, leaving room for further studies.

**Keywords** – Open Innovation; Sustainability; Collaboration; Startups; Startup success

**Paper type** – Academic Research Paper

## 1 Introduction

Following Steve Blank's (2010) definition, a startup is a temporary organization in search of a replicable and scalable business model that can take new ideas to market by transforming them into economically viable businesses. However, their small size entails significant difficulties for their development, translated into the concepts of liability of newness and smallness. The former refers to the risk of failure, which is very high in the initial stages of a venture creation, while the latter refers to the scarcity of resources, skills and capabilities (Hannan and Freeman, 1984). Since resources, both tangible and intangible, are a critical factor for startup success, it is necessary to counteract through the opening of business boundaries. In fact, collaborating with a network of external partners mitigates these liabilities as they can bring lacking resources and complementary know-how to the startup (Dickel et al., 2018). This approach has been defined by Chesbrough in 2003 as Open Innovation (OI) and it quickly gained the attention of researchers and practitioners. OI states that firms, especially startups, can and should leverage external resources, technologies and expertise by forming a network of strategic collaborations to cope with the lack of necessary internal resources (e.g., financial, technological, human, etc.). In support of this, recent literature on OI and entrepreneurship confirmed the effectiveness of an open approach marked by interorganizational collaborations in ensuring the success of a startup (Marullo et al., 2018).

In addition, startups have become increasingly aware of environmental issues in recent years, leading to a growing increase in investments on green economy and sustainability (e.g., de Faria et al., 2021). The origin of this trend can be traced back to the mid-1990s, where a wave of greening of industry in Europe and the industrialized world appeared (Freimann and Waltherm 2001). In the years since,

sustainability, declined in its three dimensions of environmental, social and economic, has become a priority for governments and companies worldwide. However, implementing more sustainable business practices in established companies requires considerable effort, calling for a total overhaul of organizational culture in most cases. In contrast, startups are more inclined to embrace sustainable approaches, often declined in the adoption of the Circular Economy concept to their businesses (Bigliardi and Filippelli, 2021). Based on these premises, it follows that the future of startups is inevitably geared toward sustainable innovation through the adoption of an open approach.

However, although numerous studies highlight the growing academic interest in testing the relevance of adopting OI and sustainability practices in startups, to date there is no scholarly work linking the combined adoption of both these practices to startup success.

For this reason, the present article aims to identify sustainability practices, with a specific focus on environmental and social ones, and OI practices adopted by startups in order to understand how they contributed to its success. This objective has been declined into specific research questions.

*RQ1. What are the motivations for a startup to resort to sustainability and OI practices?*

*RQ2. What are the characteristics of startups that adopt both sustainability and OI practices?*

Given the nature of the research questions identified and the phenomenon investigated, the study has been conducted using case study methodology (Yin, 2014). The use of qualitative research provides a better understanding of the dynamics of startups in adopting OI and sustainability practices. The study was conducted as part of the RESPONSE research project, sponsored by the University of the Republic of San Marino, therefore the sample analyzed is composed of innovative startups located in the area of San Marino and Romagna (Italy). The remainder of the paper is organized as follows: in section 2 the adopted methodology is presented, in section 3 review results are displayed while section 4 and 5 are devoted to multiple case study results and final discussion, respectively.

## **2 Methodology**

### **2.1 Research design**

A two-step methodology was used to answer the identified RQs: the first consisted of a literature review, while the second of multiple case studies. The literature review enabled the theoretical foundations of the topic under study to be traced (Green et al., 2006; Kafetzopoulos, 2022) and was a key starting point for answering the first research question regarding the motivations for a startup to employ OI and sustainability practices. For this purpose, a narrative literature review was conducted on the Scopus and Web of Science databases. Then, due to the qualitative nature of the research questions identified and the phenomenon investigated, the second part of the study leverages on the multiple case study methodology (Yin, 2003). The use of multiple case studies allows for the construction of a more robust and generalizable theory than a single case (Eisenhardt and Graebner, 1989). The selected unit of analysis was the individual innovative startup (or high-tech startup, as per the San Marino statute), based in the Romagna area (central-northern Italy) or the Republic of San Marino. A startup is defined as innovative if it meets at least one of the following requirements: (1) it incurs expenses in R&D and innovation equal to at least 15 percent of the greater value between turnover and cost of production; (2) it employs highly qualified personnel (at least 1/3 PhDs, doctoral students or researchers, or at least 2/3 with a master's degree); (3) it is the owner, depositary or licensee of at least one patent or the owner of registered software. Since the study is part of the RESPONSE Research Project sponsored by the University of the Republic of San Marino, the startups were selected from those incubated by San Marino Innovation, CesenaLab and Romagna Tech. This selection led to the identification of 5 cases. Data collection was carried out through semi-structured interviews supported by a research protocol consisting of both open and closed questions.

### **2.2 Case selection**

The innovative startups were selected from a sample of 50 startups involved in the larger RESPONSE research project. As Eisenhardt (1989) suggests in case study research it is preferable to select cases by applying specific criteria rather

than selecting a random number of units from a larger sample. Since the present study aims to generalize the results to understand the dynamics of innovative startups with respect to OI and sustainability practices, the cases were selected using the following criteria: startups (1) are at different stages of the lifecycle; (2) operate in different economic sectors; and (3) have different sizes (measured in terms of numbers of employees). The resulting 5 cases are presented in Table 1.

Table 1. The investigated sample of innovative startups.

<b>Case startup<sup>1</sup></b>	<b>Industry</b>	<b># employees</b>	<b>Stage of startup lifecycle</b>
<b>A</b>	Pharmaceutical	11-20	Market Launch
<b>B</b>	Healthcare	0-5	Product Development
<b>C</b>	Finance	>30	Growth and Expansion
<b>D</b>	Services	0-5	Market Launch
<b>E</b>	Services	0-5	Growth and Expansion

### **2.3 Data collection and analysis**

The researchers collected data about the types of implemented OI and sustainability practices and motivations (RQ1) through semi-structured interviews that took place through the Teams platform or by telephone. Respondents were preliminarily provided with the list of questions so that they could adequately prepare for the interview, collecting hard-to-obtain information if necessary. To enable triangulation of data (Yin, 2014), this information was compared and supplemented with analysis of official documents such as company websites.

Empirical data from the semi-structured interviews were analyzed using an inductive approach in which a list of OI practices, sustainability practices, and motivations was first identified for each innovative startup. The responses of the individual startups were compared and discussed among the researchers who conducted the study, thus applying researcher triangulation (Yin, 2014).

<sup>1</sup> For privacy issues, names of startups could not be shown.

### **3 Literature review**

#### ***3.1 Startups and OI practices***

Although the literature on OI is growing rapidly, studies focusing on startups are still limited. In fact, several authors (e.g., Bigliardi and Galati, 2018) have focused on SMEs, which share with startups the liabilities of smallness and newness. However, startups are unique entities that face a unique set of challenges, as they do not yet have established business processes, a solid customer base and reputation. This entails a difficulty in attracting investment, talents and consumers, resulting in tough commercialization of products or services.

The literature highlights the suitability of the OI approach to overcome liabilities of newness and smallness (Kraus et al., 2020). In fact, OI refers to a strategy in which companies actively seek resources from a variety of external sources, such as universities, research centers, suppliers, customers, other companies to improve their internal innovation capability (Chesbrough, 2003). Scientific research has identified two main modes of OI: inbound and outbound. Inbound OI refers to an organization actively seeking external resources, technologies or ideas to support the internal innovation process, while outbound OI occurs when an organization makes internally developed ideas and technologies available to external partners for further development and commercialization (Cassiman and Valentini, 2016). Both modes can bring significant benefits to startups, however they come with their own set of challenges and risks. Inbound OI allows startups to complement the owned resources with external ones, which are essential for fostering innovation, but at the same time it reduces control over internal expertise and weakens their knowledge appropriability (Cassiman and Veugelers, 2006.) On the other hand, outbound OI allows startups to leverage their ideas and technologies to generate additional revenues and create partnerships with external companies, however, this implies shared control over intellectual property and proprietary information (Von Hippel and Von Krogh, 2006). To mitigate these risks, startups must provide strong intellectual property protection mechanisms (Halt et al., 2017). There is also a third mode, called coupled OI, which involves the coupling of knowledge inflows and outflows and describes how parties collaborate on innovation, (e.g.,

through the establishment of long-term relationships, alliances, networks or consortia, etc.) (Hasche et al., 2017)

Since this approach requires additional effort to align the different actors involved, it is less likely to be undertaken by a company still in its infancy (Almeida, 2021). Many studies on OI adoption focus on the broad dimensions mentioned above, i.e., inbound, outbound, and coupled, while others go into more detail about the individual approach and consider one or more individual OI practices (e.g., Liu et al., 2020). Since the startup is an unstructured organization, often lacking a clear organizational structure and well-defined processes, it is more effective to consider the OI paradigm at the level of the individual practice to be implemented. This paper uses the definition proposed by Lu and Chesbrough (2022, p.1) who define OI practice as "the actual application or use of the ideas or methods based upon OI that companies implement for their innovation-related processes." Table 2 presents the main OI practices discussed in the literature. It shows that none of them is specific to startups, although they can be indiscriminately exploited by them as well. In addition, few studies contextualize the adoption of one or more OI practices in startups (e.g. Battistella et al., 2017) suggesting the need to expand knowledge with further studies.

Table 2. OI practices.

<b>OI practice</b>	<b>Description</b>	<b>Reference</b>
<b>Competitions/awards</b>	Participation to innovation challenges	Battistella et al. (2017); Chesbrough and Brunswicker (2014); Santoro et al. (2019)
<b>Networking</b>	Networking with different organizations without a formal contractual relationship, such as at conferences, to access external knowledge	Chesbrough and Brunswicker (2014); Santoro et al. (2019)
<b>University research grants</b>	Funding for research projects/fellowships/grants at universities to access outside knowledge	Battistella et al. (2017); Chesbrough and Brunswicker (2014)
<b>Publicly funded R&amp;D consortia/R&amp;D collaboration and technology alliances/consortia</b>	Cooperation between non-competing firms to pursue a common innovative goal (without shareholding)	Battistella et al. (2017); Chesbrough and Brunswicker (2014); Santoro et al. (2019)
<b>Contracting with external R&amp;D service providers</b>	Contracts with external service providers for dedicated R&D projects	Battistella et al. (2017); Chesbrough and Brunswicker (2014); Santoro et al. (2019)
<b>Dyadic co-creation/ co-development in the upstream</b>	Involvement of suppliers in the innovation process	Battistella et al. (2017); Chesbrough and Brunswicker (2014); van de

<b>network</b>		Vrande et al. (2009)
<b>Collection of information from external sources</b>	Range of informal activities aimed at acquiring and maintaining connections with external sources of knowledge	Battistella et al. (2017); Chesbrough and Brunswicker (2014); Oliveira and Alves (2014); Santoro et al. (2019); van de Vrande et al. (2009)
<b>Dyadic co-creation/ co-development in the downstream network</b>	Involvement of customers/end users in the innovation process	Battistella et al. (2017); Chesbrough and Brunswicker (2014); Santoro et al. (2019); West and Bogers (2014)
<b>Crowdsourcing</b>	Outsourcing an innovation task to an undefined crowd in the form of an open call	Almirall et al. (2014); Battistella et al. (2017); Chesbrough and Brunswicker (2014); Santoro et al. (2019)
<b>Specialized services from OI intermediaries</b>	Intermediary organizations that link companies needing OI support to a network of potential solvers	Chesbrough and Brunswicker (2013); Chesbrough and Brunswicker (2014)
<b>IP in-licensing</b>	Licensing of external intellectual property rights via formal licensing agreements	Chesbrough and Brunswicker (2014)
<b>Horizontal technology collaboration</b>	Competing or non-competing companies which join forces to pursue a common goal	Santoro et al. (2019)
<b>Joint venture</b>	Strategic and financial investments in independent joint ventures together with external partners	Chesbrough and Brunswicker (2013); Chesbrough and Brunswicker (2014)
<b>Corporate business incubation and venturing</b>	Business incubators or accelerators that help to develop potentially successful ideas and provide supportive environments for entrepreneurs	Chesbrough and Brunswicker (2014)
<b>IP out-licensing and patent selling</b>	Licensing of internal IP to external organizations via licensing agreements or selling via single payment	Chesbrough and Brunswicker (2014)
<b>Donations to commons or nonprofits</b>	Donations to commons or nonprofits (e.g., open-source communities) to support external R&D	Chesbrough and Brunswicker (2014)
<b>Spinoffs/ Academic spinoffs</b>	Investment in new ventures founded by company employees outside the boundaries of the organization or by academics willing to commercially exploit research results	Chesbrough and Brunswicker (2014)

### 3.1.1 Startups motivations

Startups benefit from such practices in ways similar to established companies, however, their motivations for using them are different and vary depending on the stage of the lifecycle the startup is in. The lifecycle of a startup can be summarized by the following broad phases: idea generation, development, market launch, scale and exit (i.e. growth and expansion), each characterized by

specific needs (Marcon and Ribeiro, 2021; Picken, 2017). The idea generation phase involves the generation of ideas and their subsequent evaluation to determine which possesses the greatest potential to become a viable business. The development phase corresponds to the realization of the service product, while in the market launch phase the startup focuses on expanding the customer base, building its brand, and optimizing operations to achieve sustained growth. Subsequent phases are concerned with the growth and expansion of the startup.

The motivations for startups to use OI practices can be grouped into two broad categories: necessity-driven and opportunity-driven (Table 3). The former stem from the startup's need to address specific challenges or find solutions to limitations to their operations. They relate to the lack of fundamental resources, in-house expertise or technologies that does not allow it to move its project forward and out of the initial idea generation phase. The second ones, on the other hand, stem from the intention to find new and innovative solutions, create new business opportunities, and leverage external resources and expertise to push its internal innovative capabilities. These motivations mostly arise in the market launch, growth and expansion phases, where the startup already possesses the essential resources for survival but needs the benefits of OI to scale.

Table 3. Startups motivations to adopt OI practices crossed with startup lifecycle stage

### 3.1 Startups and sustainability practices

Major social and environmental challenges are requiring companies to change current business models, adapting them to new needs that necessitate the generation of not only economic but also social and environmental value. In response to these needs and the pressures posed by the achievement of sustainable development goals, entrepreneurship has gained new challenges to face. As a result, there has been a growing interest from the scientific community in the topic of sustainability and sustainable development. Following the study by

Bansal et al. (2019), the concept of sustainability is often used to describe the ability to strike a long-term balance between economic growth, social progress and environmental protection. This definition is rooted in the "triple bottom line" approach introduced by Elkington and Rowlands (1999), according to which sustainability is developed on three distinct but intertwined levels: social, environmental and economic dimensions. At the corporate level, sustainability takes on the characteristics of a value creation process that takes shape through innovation activity (Weissbrod and Bocken, 2017). Specifically, the creation of sustainable value, that contemplates social economic and environmental values, is implemented through the adoption of sustainability practices (Sardana et al., 2020). Companies that adopt them aim to minimize negative impacts on people and the environment while maximizing economic effectiveness. This includes the need for responsible management of natural resources, use of low-impact technologies, protection of workers' and consumers' rights, business ethics and transparency (Epstein and Buhovac, 2014). Sustainability practices take many forms, depending on the industry and the company's specific situation. For instance, a manufacturing company may reduce its environmental impact by adopting low-carbon technologies, using recyclable materials, or improving energy efficiency (Bjørnbet et al., 2021). A service company can commit to providing services that respect workers' rights and promote diversity and inclusion (Govindan et al., 2021).

Table 4 shows the main sustainability practices, respectively environmental, social, and economic, implemented at the company level.

Table 4. Sustainability practices

<b>Sustainability practice</b>	<b>Sustainability dimension</b>	<b>Reference</b>
Reduced material use per unit of output	Environmental	Milana and Ulrich (2022)
Reduced energy use per unit of output	Environmental	Milana and Ulrich (2022); Schick et al. (2002)
Reduced CO2 'footprint' (total CO2 production) by your company	Environmental	Milana and Ulrich (2022)
Use of renewable sources of energy	Environmental	Milana and Ulrich (2022)
Use of 'closed loops' to re-use material waste for the generation of energy	Environmental	Schick et al. (2002)
Development of environmentally friendly products (i.e. recyclable products or products made from materials with low environmental impact)	Environmental	Schick et al. (2002)
Replaced materials with less polluting or	Environmental	Milana and Ulrich (2022)

hazardous substitutes		
Assessment of suppliers' environmental performance	Environmental	Khaksar et al. (2016)
Reduced soil, water, noise, or air pollution	Environmental	Milana and Ulrich (2022); Schick et al. (2002)
Recycled waste, water, or materials/waste sorting	Environmental	Milana and Ulrich (2022); Schick et al. (2002)
Used recycled input materials to manufacture primary products/services	Environmental	Milana and Ulrich (2022)
Compliance with environmental regulations	Environmental	Schick et al. (2002)
The offering of discounts for environmental and social groups	Environmental	Schick et al. (2002)
Increased health and safety aspects for your employees at the workplace	Social	Milana and Ulrich (2022)
Introduced product or service categories with improved health or safety impacts	Social	Milana and Ulrich (2022)
Provided additional training and/or assistance to upgrade employee skills	Social	Milana and Ulrich (2022)
New employee hires during the reporting period	Social	Milana and Ulrich (2022)
Implementation of fair labor policies, such as fair working conditions and fair wages for all employees	Social	Milana and Ulrich (2022)
Provide complain opportunities for customers or employees through formal grievance mechanisms	Social	Milana and Ulrich (2022)
Support for local and global sustainable development projects	Social	Patel et al. (2017)
Creation of jobs and training opportunities for local communities	Social	Scavarda et al. (2019)
Generated new sales	Social	Milana and Ulrich (2022)
Generated profit	Social	Milana and Ulrich (2022)
Opened new market and product/process opportunities for the firm	Social	Milana and Ulrich (2022)
Enhanced economic development in areas of high poverty	Social	Milana and Ulrich (2022)
Received financial assistance from a public authority	Social	Milana and Ulrich (2022)

However, implementing more sustainable business measures can be an arduous and lengthy process, especially if the company must change its existing organizational culture. In fact, because the adoption of sustainable practices should not be viewed merely as an addition to daily operating procedures, but as an integral part of the company's business model, they need to be integrated into the company's strategy and supported at the senior management level (Freimann and Walther, 2001). For these reasons, implementing such practices in startups

that are less structured companies where there is not already a rigid organizational culture may be a more promising approach. In new ventures, sustainability can be integrated from the idea generation stage, rather than being considered as an option to be added later. In addition, founders of startups are often more open to new ideas and innovations, providing greater flexibility and less organizational inertia (Terán-Yépez et al., 2020).

#### **4 Multiple case study results**

To present the results, the 4W model of OI proposed by Bigliardi and Galati (2018) has been adopted. It frames the OI process of SMEs, focusing on the object of OI (What dimension), the actors involved (With Whom dimension), the motivation (Why dimension) and the mode (How dimension). Since the present study analyzes startups, the When dimension was added to identify the lifecycle stage in which the startup resorted to OI.

Regarding the adoption of sustainability practices, in the present study we analyze the results by adapting the framework of Wu et al. (2018) and considering two main levels of corporate sustainability. The first level is determined by the current regulatory system, which acts along three main lines: it (1) prohibits behaviors that are harmful to the environment or people; (2) conditions certain production activities to comply with a given degree of environmental impact or social riskiness; and (3) incentivizes sustainable behaviors. The second level consists of strategies, investments, and activities that the company carries out to increase the social and environmental value, in an integrated way with the economic value, of its business.

##### **4.1 Open Innovation**

Startup A resorted to inbound OI practices by collaborating with universities, research centers and industry professionals (i.e., doctors). The collaboration with university and research center served in the experimental phase (i.e. idea generation and product development). Specifically, the startup A funded a fellowship at a university in central Italy to conduct specific research useful for ideating the product. The collaboration with professionals in the field was realized in the idea generation phase through a brainstorming activity aimed at circumscribing the specific need and in the market launch phase to later modify the product. The motivation for the startup A to resort to these forms of

collaborations is related to the lack of scientific expertise and the need to enter the market quickly.

Startup B resorted to external collaborations in the idea generation and product development phases to address the lack of specific knowledge regarding the medical industry. Since the startup provides tools to support medical personnel in managing patients with specific diseases, the founders felt the need to complement their expertise with specific medical knowledge. The startup B entered collaborative relationships with its suppliers, from whom it drew qualified human resources. In addition, discussions with users (i.e., patients) through brainstorming activities enabled the creation of a product as close as possible to their needs.

Startup C is the only one in the sample to use outbound OI: it patented three products under a single brand name that are made available to third parties to create innovative products in turn.

Startup D creates an innovative digital product that facilitates accounting management for Amazon resellers. The founders drew on the expertise of established enterprises and users. The former operates in the training business, providing the startup D with specific knowledge about how e-commerce works. The latter consists of users, represented by companies selling through the Amazon channel (B2B customers) who express specific needs considered by startup D must in product ideation and development. For these reasons, the startup D has resorted to collaborations with external parties in the stages prior to bringing the product to market, while soliciting feedback from users to improve the product already on the market in the growth and expansion stage.

The core business of startup E concerns making client companies' processes more effective through algorithms and artificial intelligence. The object of OI is intangible resources, such as missing technological knowledge and skills. To acquire it, the company work together with competing companies, research centers (CNR) and university. Specifically, it collaborated with the University of Bologna on the creation of a digital solution, later patented, to serve a client company. Competing companies and the research center, on the other hand, participated with the startup in a joint project to provide digital expertise to third-party clients. The aforementioned collaborations, which contributed positively to the process of inbound OI, took place mainly in the market launch and growth and expansion phase, enabling the company to expand its customer base and

consolidate its market position. An overview of the five cases is provided in Figure 1.

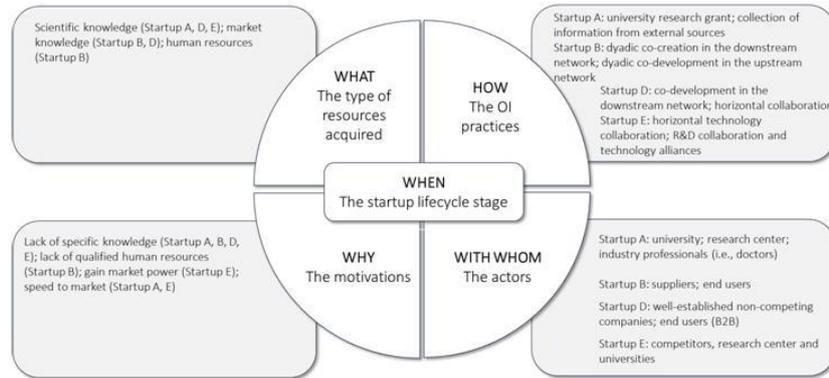

Figure 1. Sample cases represented through the modified 4Ws model.

#### 4.2 Sustainability

Startup A considers sustainability as a pillar of the company's vision and mission. The startup operates in the pharmaceutical sector and has manufacturing facilities. Regarding environmental sustainability, it currently adheres only to norms and regulations, but plans to implement strategies to lower the environmental impact of production as soon as it has more economic resources. In contrast, the startup shows a proactive approach to social sustainability as it has outsourced packaging production to a social cooperative based in the area while incurring a higher cost than in-house production.

Startup B does not have an avowedly sustainable purpose, nor does it have a sustainable or circular business model, yet sustainability is covered in the company's vision and mission. In fact, the innovative product offered has a positive impact on environmental and social sustainability. Regarding environmental sustainability, the product allows the patient to enjoy the necessary care at home instead of traveling to a facility, decreasing the emissions produced to get there. In addition, when evaluating suppliers, the startup's choice falls on the greenest ones. Regarding social sustainability, startup B displays a strong commitment to its community because the service it offers contributes positively to the well-being of its citizens. In addition, the startup plans to do corporate philanthropy by donating part of the proceeds to nonprofits organizations in the field of healthcare. This has not yet been possible because

the startup is still in the product development stage, so it does not have sufficient financial capacity.

Startup C contributes positively to social and environmental sustainability although the company's vision and mission were not designed with this goal in mind. In fact, the startup has created an innovative product for the middle east market (from Morocco to Vietnam), considered a developing area. The product allows the local population to benefit from banking services despite not having a bank account, thus it contributes positively to the social development of these areas. In addition, the product allows for a decrease in the consumption of physical resources (e.g., paper) as it ensures the digitization of banking services. It can be concluded that sustainability, both social and environmental, was an indirect consequence of the startup's core business.

Startup D approaches sustainability, both environmental and social, by simply fulfilling regulatory obligations. Specifically, by operating with Amazon the startup must be compliant with additional requirements imposed by the latter. Amazon, through its auditing activities, verifies the startup's ongoing adherence to them.

Startup E has a strategic approach to corporate sustainability incorporating the values of social and environmental sustainability into its vision and mission. Since its core business is an intangible product, the startup does not have a circular or sustainable business model, however, it actively strives for sustainability principles to underpin its business operations. From the perspective of environmental sustainability, startup E has a strict supplier selection process that is based on the level of environmental impact generated. Specifically, startup E only uses cloud service providers that claim to use renewable energy. Regarding social sustainability, the company is strongly committed to work-life balance by allowing its employees to benefit from agile working. An overview of the startups' sustainability practices is provided in Figure 2.

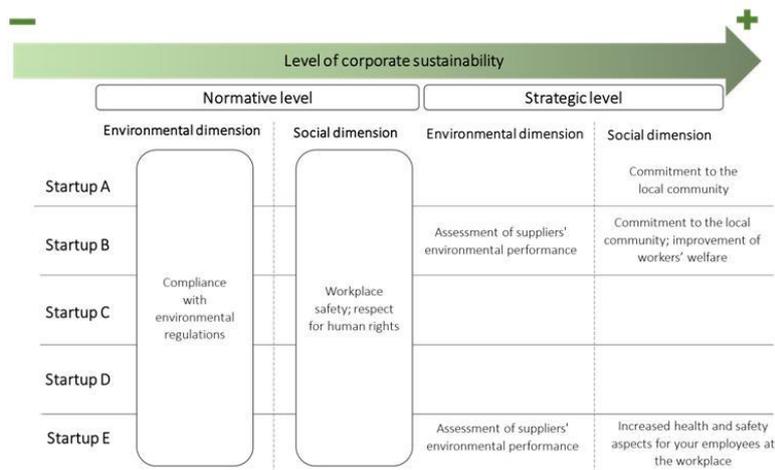

Figure 2. Startups sustainability orientations.

## 5 Discussion and conclusion

To answer the RQs, the results of the literature review were compared and integrated with that of the multiple case study. Regarding the motivations driving startups to use OI practices, two categories were recognized: necessity-driven motivations, found more in the idea generation and product development phases; and opportunity-driven motivations, more related to the market launch and growth and expansion phases. The sample startups exhibited necessity-driven motivations to a greater extent, and opportunity-driven motivations to a lesser one. As shown in Figure 3, the empirical evidence showed that in the preliminary stages of idea generation and product development, startups resorted to OI practices to complement the resources already possessed, in line with the findings of the literature review (Kraus et al., 2020). Specifically, out of five startups, only one realizes a physical product (Startup A), while the remaining have developed a digital innovative product (i.e. web application or software). Regardless of the type of product made, in the idea generation and product development stages the main motivation is access to missing resources. Specifically, these resources are mostly intangible, including scientific knowledge (i.e., technological and R&D knowledge) and market knowledge (i.e., information about the industry and the needs to be met) (Bigliardi and Galati 2018). In one case, the startup needed skilled human resources at the product development stage (startup B). In contrast, in the market launch and growth and expansion

phases, the motivations shift toward opportunity-driven ones, in accordance with what is inferred from literature. In fact, in these phases, the product is already on the market and the collaborations mostly serve to enable the organic growth of the startup, both in terms of size and market share. In the investigated cases, the main motivations are classified as rapid market access (market launch phase, startups A and E), increased market power, and improved product development processes (growth and expansion, startups D and E). Only startup E manifested necessity-driven motivation at a stage later than product development, due to a lack of sufficient technological expertise to modify the product once it was brought to market.

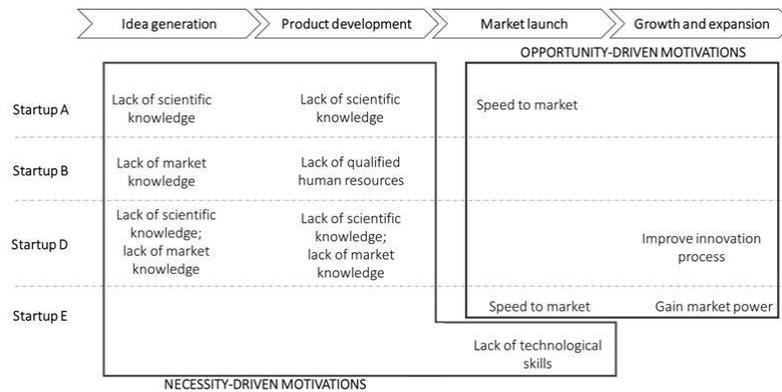

Figure 3. Startups OI motivations with respect to lifecycle stage: the why and when dimensions (Startup C is not displayed as it did not resort to inbound OI practices).

Regarding sustainability practices, two levels of corporate sustainability are recognized in the literature from which the startup's motivations for adopting them are derived. The two levels are summarized as: reactive attitude, in which the startup applies sustainability practices out of adherence to rules and regulations; and proactive attitude, when the startup invests in strategies to promote corporate sustainability, which is inherent in its vision and mission. Of the startups investigated, three take a proactive attitude (i.e. startups A, B and E) while the remaining manifest a reactive attitude.

In light of these results, however, a further distinction needs to be made. In fact, although some startups have not resorted to sustainability practices to comply with corporate vision and mission, they have nonetheless contributed positively to environmental or social sustainability. For this reason, a distinction

should be made between intentional sustainability and accidental sustainability. The former refers to startups having a proactive attitude toward sustainability while the latter refers to startups that, although they have manifested a reactive attitude, have had a positive impact on sustainability. To this second group belongs the startup C which has created an innovative product that, when used by third-party companies, enables them to increase their level of corporate sustainability. Such a startup can be regarded as a vehicle for sustainability.

Regarding the second research question, namely the profile of startups that resort to both OI and sustainability practices, the evidence from multiple case studies did not show an interrelation between them. The startups under study did not need to use OI for the specific purpose of implementing corporate sustainability practices, just as the use of OI practices did not have an intended impact on corporate sustainability. Indeed, in the literature, the link between OI practices and sustainability can be considered from two different perspectives: on the one hand, OI is the means by which the organization can implement sustainability practices; on the other hand, the use of OI is an indirect cause of sustainability. In the first case, an organization may resort to a network of collaborations for the express purpose of increasing corporate sustainability. In the second case, the organization resorts to OI for different reasons (e.g., lack of internal expertise; lack of qualified personnel, etc.), but it can still achieve a positive impact on sustainability: for example, it can select collaborators based on their level of sustainability, or it can help make third parties (e.g., its customers) more sustainable by producing an innovative product thanks to external collaborations. Consistently to previous studies (e.g. Kraus et al., 2020), our paper points out how external collaborations helped founders of innovative startups to make up for lack of relevant resources in both idea generation and product development phases, as well as to boost their growth in the subsequent stages.

Moreover, relevant findings are obtained on the sustainability side, highlighting a tendency of digital-based startups to operate as sustainability-accelerators, or vehicles, for other organizations.

## ***5.2 Limitations and future research avenues***

Despite expectations, there is no relationship between sustainability practices and OI practices adopted in the sample investigated. A distinguishing feature of this phenomenon is the core business of the investigated startups, which is

represented by the creation of a digital product, thus intangible (except for startup A). In this regard, future studies may replicate the analysis on a more heterogeneous sample to test whether core business influences the interrelationship between OI practices and sustainability. In fact, our sample consisted of innovative startups, most of which are configured as digital. Broadening the sample to manufacturing startups could reveal different trends. This further analysis could highlight factors enabling or hindering the use of OI practices to support corporate sustainability, and vice versa. Some limitations of this study should be noted. First, the small number of cases analyzed, and the geographical location limited to the area of Romagna (Italy) and the Republic of San Marino do not allow generalization of the results. The same is true for sector specificity effects; in fact, our study is mostly based on innovative startups making web or software applications; further research is needed to explore the phenomenon in other low-tech sectors.

### **Abstract**

This paper deals with a case of organisational change triggered by a process of digital transformation. It describes the management of change activated in the Supreme Court of Cassation in Italy. The project involved different actors and one of the main criticalities to deal with was the need of communication among people with different background and languages. We analysed how external consultants acted as knowledge brokers to facilitate the knowledge transfer process in a team. The consultants acted in facilitating the

alignment of different languages and lenses using visualising tools and focusing on boundary-spanning activities.

**Keywords:** Digital Transformation Project, Knowledge brokering.

**Paper type** – Academic Research Paper

## 1 Introduction

In the public sector much of the discussion, both in the academic and in the empirical fields, is focused on the opportunity to introduce technology in order to get better services by increasing efficiency and transparency, and improving accountability (Cordella & Bonina, 2012). Critical and urgent problems affected the justice domain where the need of the adoption of ICT is considered a priority in many countries (Agrifoglio et al., 2016).

The main goals for the Courts are to improve services and to be more efficient in the consumption of resources, and to improve transparency and accountability of court activities (Seepma et al., 2021).

This paper discusses a change management process in the Supreme Court of Cassation due to the introduction of online civil trials (Telematics Civil Process). The focus was on the use of electronic tools and communications that enable change from a paper-based to digital flow of information.

In September 2019, the CRUI Foundation (Conference of Rectors of Italian Universities) entrusted the Department of Economics at the University of Campania Luigi Vanvitelli with the implementation of activities within a project on development and organisational change in the services of the Supreme Court of Cassation.

It was to be carried out with the administrative staff of the Supreme Court of Cassation, in collaboration with the Ministry of Justice, especially the Directorate General of Automated In-formation Systems (DGSIA) within the Ministry.

In this digital transformation process, a peculiar role is played by knowledge management, as critical issue in making possible that people making from different perspectives could communicate. During this process, consultants (interpreted as knowledge brokers) can play a key role in facilitating the way people involved in the project interact.

The paper contributes to the literature on knowledge management, and adds to understanding about the role of (and practices developed by) consultants as knowledge brokers in managing a digital transformation team.

## **2 Managing knowledge in a Public Sector Project**

In the public sector, the concept of digital transformation is quite controversial, and it is adopted with regard to different kind of technological initiatives. As many other change projects, a key factor to manage is the capacity of building up new solutions making the different actors interacting.

This issue is a relevant one in the knowledge management literature. For example, Rajalo and Vadi (2017) studied boundary mechanisms adopted to facilitate communication and build a common framework among partners. Collaboration between different actors from diverse organisations often implies knowledge transfer. All the involved actors have their own language, background and expectations of new solutions (Sandberg & Tsoukas, 2015).

To facilitate knowledge transfer, actors need to work together to overcome their individual and organisational interests and needs, and collaborate to achieve a common goal (Canonic et al., 2020). External consultants could play a specific role in making possible people communicate and interact. In this sense, according to our perspective they act as knowledge broker, specialists who enable knowledge transfer across different organisational actors. They mediate between different disciplinary perspectives, facilitating communication, and creating a shared understanding of the problem or issue (Ishiyama, 2016). They act as liaison, gatekeepers, coordinators, representatives, and itinerant brokers. Previous studies have shown that group members can act as knowledge brokers among different groups. We would like to investigate how it is possible to build up a shared language even between people belonging to different organizations.

The aim of our paper was therefore to investigate how knowledge brokers act in a inter-organizational complex project, when the main goal was to find new and common solutions.

## **3 Methodology**

This empirical study was based on a qualitative investigation. We carried out the analysis iteratively using a semi-grounded approach, and our data informed the selection of theories (Van Maanen et al., 2007). We wanted to provide insights

from a unique case that was a valid candidate for theoretical sampling (Yin, 2003). The aim was to support the theoretical analysis of how “academic” knowledge can influence and facilitate knowledge translation and knowledge transfer processes in a project related to digital transformation in an Italian public sector body.

Choosing a single case can be a good way to explore how specific processes and complex issues take place within that case (Yin, 2003). In this study, the case was a digital transformation project triggered by the introduction of the Telematics Civil Process in the Supreme Court of Cassation in Italy.

The case study provided a consistent, differentiated and information-rich setting for studying the relationship between knowledge brokering and knowledge translation. Three data collection techniques were used: documentary analysis, participant observation and semi-structured interviews. First, data were gathered from documentary sources, such as internal reports, the organisation’s website, and reports by the Ministry of Justice on the impact of the Telematics Civil Process in the courts of first and second instance. Participant observation was the main source of data for the rest of this study (Canonico et al., 2017). Two of the authors were directly involved in the project team. This insight was used to explore the role of “academic” knowledge broker within the project team. During fieldwork, the two authors spent one day a week at the Court for one year. They had free access to the Court premises, and were able to make both formal and informal contacts and become relatively familiar with the management.

Finally, semi-structured interviews were conducted with the administrative head of the Court of Cassation, two executives from the Ministry of Justice co-involved in the project and three Court clerks. Each interview was conducted by two authors of this paper to reduce interviewer bias (such as first-impression error, nonverbal influences or negative emphasis).

#### **4 Case description**

Digital governance of the civil process involves the need to adapt to new forms of language and new practices and activities to replace those traditionally carried out by lawyers, judges, and administrative officers/clerks. The rationale for the introduction of the Telematics Civil Process is to simplify the process requirements for lawyers, magistrates and court clerks. It allows practitioners and offices to exploit the potential of delocalisation and management in

dematerialised form of the various procedural activities, as well as remote consultation of telematic files.

The process has already been tested in Italy in the courts of first and second instance. It is a “systemic” technology, replacing operational practices based on paper-based information exchange, not replaceable and enabling new functions and services. Its systemic characteristic requires strong integration in input–output processes. This implies that there is an ongoing need to verify that upstream and downstream processes meet the needs of those involved, and improve the efficiency and effectiveness of the work of the various professionals involved, both public and private.

The new process was introduced in the courts of first and second instance in 2014. The level of effectiveness and quality of processes and outcomes has been very different across courts, depending on how this technological innovation has been “implemented” and managed, and particularly whether the approach was strictly technological, or also incorporated an organisational perspective.

The experience of the courts of first and second instance has made clear that it is essential that the process of design and implementation of Telematics Civil Process technology systems is not developed using a purely top-down logic. Instead, it needs to be “built” through a collaborative approach of sharing knowledge, practices and experiences of the various stakeholders involved in the process, both internal and external to the courts. The acquisition of “digital” knowledge and skills, for example, cannot be achieved through mere participation in a training course on software features. It requires effective practice, participation and involvement of people in the assessing and redesign of workflows.

The project developed by the University of Campania was based on a scientific approach of “research–intervention”. It aimed to develop and implement design solutions and practices that would solve problems within an organisational and social system (Burton et al., 2015). The aim was to achieve the following macro-objectives:

- To assess models and practices of work organisation in the Supreme Court of Cassation linked to the previous technological equipment used by clerks and judges;
- To upgrade the archiving and document management information system in line with the needs and specificities of the Supreme Court of Cassation’s stakeholders; and

- To carry out an organisational redesign of the Court's activities and workflows, especially administrative activities and work carried out by the clerks, based on the potential offered by the digital filing of documents related to project implementation.

The project began in September 2019 and ended in early 2021. It was divided into two work packages:

- WP1. Assessing of the status quo (AS IS) (Goodhue & Thompson, 1995) of the Supreme Court of Cassation.
- WP2. Organisational redesign of work practices because of the introduction of the electronic filing and management of documents following both the planning and the implementation of the Telematics Civil Process (TO BE).

The objective of analysis at the first stage (WP1) was to reconstruct, describe and assess the work organisation of the Supreme Court. The start of WP2 coincided with the signing of the memorandum of understanding between the Supreme Court, the Ministry of Justice, the Attorney General's Office, the National Forensic Council and a software house. The framework of the protocol saw this as the start of an experimental phase in the implementation of the Telematics Civil Procedure from October 2020 to upload and test the new information system.

## **5 Discussion and conclusions**

One of the elements that emerged strongly during the kick-off meeting of this design and implementation phase of the projects was related to the critical issues originated by the differences in background and language adopted by the different stakeholders involved in the process.

The researchers therefore proposed to create two separate sub-teams: an operating committee of some clerks, lawyers and technicians from the software house, and a steering committee composed of internal Court personnel. To facilitate communication and organisational coordination, the researchers were part of both sub-teams.

The operating committee had the goal of developing the information system designed by the software house, drawing on the survey provided at the end of the WP1 that upgraded and verified the functionality of the "recommendations". The group provided for the systematic use of meetings and gatherings (including telematics), using a procedure to establish their frequency and content.

The knowledge broker pushed participants to adopt formats and languages that then became common assets of the sharing and collaboration by the use of visualisation tools. Clerks, magistrates and computer technicians have different languages and styles and may fall into the trap of thinking that their knowledge is “correct”. This makes it harder to understand another point of view (Sandberg & Tsoukas, 2015). Each person is knowledgeable about specific tools and methods and is often suspicious of other perspectives. In this case, the knowledge broker dynamically built and processed visualisation tools in both the first and second phases of the project. Second, inter-organisational and inter-professional collaboration between project team members created the need for boundary spanning. These were actions and behaviours that aimed to connect separate knowledge, needs and practices by managing interactions and negotiating the meaning and terms of the relationship between project team members. They also facilitated the sharing of knowledge across intra- and inter-organisational contexts (Kislov et al. 2017; Edelenbos et al., 2018).

The paper focused on a case study of organisational change triggered by a digital transformation process, in this case, the introduction of online civil trials in the Supreme Court of Cassation in Italy. The paper highlights the importance of knowledge transfer in a process like this, particularly between different actors and settings, and emphasises the need for mutual understanding and relevance. We showed that external consultants acted as knowledge brokers to facilitate the knowledge transfer process in a team.

### **Abstract**

Megaprojects stimulate and challenge public opinion mobilizing wide citizens' reactions. Given their ability to increasingly attract public attention, they may exert an influence on public participation to collective choices and on political decision making. These issues are relevant for the evaluation of a project, but unfortunately, they are rarely debated in the managerial literature. Our paper wishes to open up a debate related to social issues and how they could be considered according to a more managerial discussion.

**Keywords** – Mega-projects; sustainability; social evaluation

**Nature of proposed paper** - Academic Research Paper

## 1 Introduction

The diffusion of megaprojects worldwide represents an interesting field both for researchers and practitioners alike. Megaprojects are usually large-scale interventions, such as infrastructures, requiring billions of dollars investments (Brookes & Locatelli, 2015) and long-term perspective to be analysed (Flyvbjerg, 2014). The possibility to meet constraints in terms of budget, time and benefit known as "iron law" (Flyvbjerg B., 2017), in the last decades has been associated with sustainability issues. Research on the sustainability of megaprojects is still not only limited to few geographical areas (such as Eastern China, Western Europe, and Eastern United States), but also suffers the frequent underestimation of the two non-economic pillars, the environmental and the social ones (Wang et al., 2020). Given the emergence of the environmental dimension in the last few decades (Silvius & Tharp, 2013), we are nowadays witnessing the increased awareness for issues of social responsibility. This is "the reason why" we consider the better understanding of the interactions between megaproject and social impact assessment disciplines crucial (Esteves, 2012). In particular, significant effort has been devoted to the understanding of possible causes of megaprojects failures. Megaprojects have often an underestimated effect on local communities and residents that might be affected by a (temporary or permanent) change in terms of their livelihood conditions or life quality (Abdullah & Rahman, 2021). Crisis are more frequently related to project managers responsibility and forecasting ability (Wang et al., 2020) nor, in the cases of the industrialization development focus, with repercussions on the liveability of the local area. Literature has pointed out that there are even cases where an environmental impact analysis has been carried out, the overall project performance has not been effective due to the exclusion of the other social dimension within the perimeter of analysis. Ho et al., (2020) pointed out the disrespect of procedures or increase the dissatisfaction of local participants as possible causes of failure, but this is particularly evident in also the case of "Not In My Back Yard" (NIMBY) infrastructures or facilities with respect to local residents. Marcelino-Sádaba et al. (2015) proposed as research agenda the proposal of "tools that we might call social-design, helping to include social aspects in the project". This issue seems to be still urgent and a current open field for future works, also according to the evolution of the concept of project manager. Current literature aims to encompass this role, extending the analysis of the impacts to the broader concept

of stakeholders and local communities impacted by the project. The aim of this paper is to review the literature related to the interactions between megaproject and social evaluation, trying to reconstruct the existing fragmentation in extant studies. Therefore, for this purpose, previous mapping and systematisation of the social impact of mega-projects was sought. Priorly, Di Maddaloni & Davis (2017), reviewed the influent role of local community in major public infrastructure and construction projects. Moreover, they suggested frequent underestimation of external stakeholders in managerial practices and a focus on primary stakeholders able to control project resources. The applied mixed methodology is the result of the combination of a systematic and inductive approach.

At first we used for the systematic approach the Scopus database to select those works that contains in the title and abstract "Social Impact" AND "Megaproject" as keywords. Secondly, it has been applied an inductive process that aimed to include relevant reference and cross-references present in the papers selected in the first part. This stage was the most conservative and inclusive in terms of preservation of both classical and contemporary project management literature.

We identified different research areas related to the issue of the evaluation of the megaprojects from a social perspective, including the role of power, the importance of the infrastructure and social space, the need of people engagement and endorsement.

Megaprojects, indeed, are related to a logic of growth, development, competitiveness and prosperity, and are shaped as public-private institutional arrangements participated by elites and pro-growth coalitions (del Cerro Santamaria, 2019; p. 263). This is one of the reasons why the long-term social outcomes of urban infrastructure development are rarely assessed (ex-ante) or evaluated (ex post), especially in terms of how the respective interests are or will be affected by the multi-scale spatial changes generated by the projects. Megaprojects stimulate and challenge public opinion mobilizing wide citizens' reactions. Given their ability to increasingly attract public attention, they may exert an influence on public participation to collective choices and on political decision making.

These issues are relevant for the evaluation of a project, but unfortunately, they are rarely debated in the managerial literature, even if the issues of power and equality are coherent with the critical management agenda (see for example

Hodgson and Cimcil, 2006) both from a methodological and theoretical point of view.

Our paper wishes to open up a debate related to social issues and how they could be taken into account according to a more managerial discussion.

## **2 Methodology**

In order to propose a comprehensive overview of the existing literature of the social impact of megaprojects it has been performed a review of the existing contributes.

The applied mixed methodology is the result of the combination of a systematic and inductive approach. This specific filtering strategy allows us to combine "the findings of qualitative and quantitative studies within a single systematic review to address the same overlapping or complementary review questions." (Harden A. 2010) and stimulate the debate within a multidisciplinary topic finding new research gaps. Within the models proposed by literature (Pearson et al., 2015) for a reproducible and comparable selecting process (Stern et al., 2020), it has been chosen and adapted the one proposed by Mok et al. (2015).

At first, we used for the systematic approach the Scopus database to select those works that contains in the title and abstract "Social Impact" AND "Megaproject" as keywords (202). The filtering phase limited the research to the articles, books, books chapters, and reviews published in the English language and at final stage of publication. As a result, 164 documents were found.

Secondly, for those papers it has been done an abstract and full text screening, including 44 papers in the final list considered for the analysis.

Thirdly, the full text screening was aimed at the identification of several elements contained in the codebook for content analysis of the study adapted from the widely used model proposed by Laplume et al. (2008).

Therefore, the quantitative variables analyzed are:

- Year, intended as year of publication;
- Author(s), full author(s)' list;
- Article title, title of the article;
- Journal, publication in which the article was published;
- Methodology, namely: qualitative, quantitative, mixed methods;
- Approach, namely: conceptual, case study, discussion, review;

- Data source, list of sources, namely: survey, interview, secondary data, others (non-excluding also a combination of them).
- Concern, focus: local community, internal stakeholders or both;
- Perspective, depending on the project management, managerial practices, sociology or engineering' perspective adopted (non-excluding also a combination of them);
- Geography, country from which the data was collected;

Moreover, the qualitative variables analyzed are:

- Research question(s), Research question(s) explicitly stated in the article;
- Contribution(s), contribution explicitly stated in the article;
- Finding(s), major finding(s) explicitly stated in the article.

Finally, as output of the inductive categorization step, we defined three research areas with the aim of analyzing and discussing them as homogeneous groups for the managerial perspective adopted:

- Infrastructure and social space, in particular with regard to the different phases (study, construction, maintenance and decommissioning) of large infrastructures that have caused positive and negative impacts on local communities.
- People engagement and endorsement, referred to the methodologies (listening, involvement and endorsement) that have been undertaken to limit the negative impacts of the megaproject, as well as their reactions to the methods of involvement adopted.
- The role of power and social issues, aimed at collecting the contributions that relate the hierarchical relationships of exercise of power by listening to the instances of the categories of stakeholders excluded from the listening perimeter or penalized by the negative externalities of the megaproject.

Within each of these three areas, we filtered also papers not coherent with the mega-project literature and managerial practices. The allocation of each paper was done in parallel by two independent authors, to reduce the influence of subjective perception in the allocation to the category. Instances of different allocations were discussed collectively in order to be able to allocate a single shared allocation.

Finally, due to the proximity of the topics, a sub-group of studies pertaining to the topic of energy transition was identified for the category of infrastructure and

social space alone. Given the importance of the pursuit of a socially equitable ecological transition as well, this peculiarity will be emphasized in the discussion section of the results (Esteves et al., 2012; Sankaran et al., 2022).

In the next section descriptive results are proposed and described in accordance to the categories taken into account.

### 3 Results

This section aims to represent the distribution of papers within the selected period. In addition, it is intended to offer descriptive insights useful for the next section, which in turn will discuss the themes and contributions of the three inductive categories.

Firstly, it can be emphasised how the interest regarding the study of social impacts in mega-projects has intensified over time and with a peak in 2021 (8 papers).

Secondly, the distribution of contributions in terms of journals is highly differentiated, involving those within project management areas, such as the *International Journal of Project Management* (6) or the *Project Management Journal* (5), as well as management journal or policymaking. Thirdly, it can be observed that their distribution is not uniform either by methodology adopted or by approach (excluding the 5 reviews). With reference to the methodology adopted, Table 1 shows how qualitative approaches (25) prevail by far over quantitative (8) or mixed methods (6) publications. Similarly, in terms of approach, there is a greater prevalence of case studies (34) than of discussion (3) and conceptual papers (2). A first piece of descriptive evidence can therefore be pointed out: the studies that have dealt with the topic of social impact have predominantly taken a qualitative approach geared towards the presentation of a (multiple-)case study (50%).

Table 1 – Distribution of the number of papers by methodology and approach applied.

<b>Methodology / Approach</b>	<i>Case study</i>	<i>Discussion</i>	<i>Conceptual</i>	Total by rows
<i>Mixed methods</i>	4		2	6
<i>Qualitative</i>	22	3		25
<i>Quantitative</i>	8			8
Total by columns	34	3	2	39

Tables 2, on the other hand, analyses the distribution of studies considering data source and concern. In terms of data source, the extensive use of secondary data (16) in the analyses can be emphasised, as well as the combined use of several sources to ensure a better representation of the observed phenomena. In addition, it can be pointed out that there are more and more studies that combine an interest in both internal and external stakeholders; this evidence emphasizes the holistic perspective required for the proper involvement and endorsement of different stakeholder categories (McLeod, 2023).

Table 2 – Distribution of the number of papers by data source and concern.

<b>Data source / Concern</b>	<i>Both</i>	<i>Internal stakeholders</i>	<i>Local community</i>	Total by rows
<i>Interview</i>	5	1	3	9
<i>Interview, secondary data</i>	1			1
<i>Interview, survey</i>		1		1
<i>Survey</i>	2	1	4	7
<i>Survey, secondary data</i>			2	2
<i>Secondary data</i>	7	1	8	16
<i>Others</i>	4	1	3	8
Total by columns	19	5	20	44

Accordingly with the proposed Table 3, we also deepened distribution of the number of papers by deductive group and concern. In particular, it can be noted that much of the analysis of impacts on local communities in mega-projects has been contextualised in infrastructure impact analysis (20), of which 7 referred to the peculiar focus of energy transition.

Table 3 – Distribution of the number of papers by deductive group and concern

<b>Deductive group / Concern</b>	<i>Both</i>	<i>Internal stakeholders</i>	<i>Local community</i>	Total by rows
<i>Infrastructure and social space</i>	8	2	10	20
<i>People engagement and endorsement</i>	8	3	4	15
<i>The role of power and social issues</i>	3	-	6	9
Total by columns	19	5	20	44

Referring to the distribution of the selected analysis perspectives, it is highlighted that frequently the analysis contributed to the project management literature (8), as well as to the conjoint combination of project management and managerial practices in a broader sense (13).

In this section we have presented the distributions of the papers with respect to the most significative categories of analysis. In the next section the detail of each of the three inductive categories will be discussed.

## **4 Discussion**

As mentioned in the methodology our first result was to identify three different research areas related to the issue of the evaluation of the megaprojects from a social perspective: 1) The role of power and social issues; 2) Infrastructure and social space; 3) People engagement and endorsement. In this section we will discuss such areas identifying possible inspirational new trends and research gaps in coherence with a managerial perspective.

### ***4.1 The role of power and social issues***

Regarding this issue, first of all it is important to underline the journals where papers appeared. There is, in fact, a great variety in terms of scientific research areas, moving from Political science, Economics and Management. From our perspective it is very interesting that even in the managerial community, some scholars (Lee et al. 2017; Badi et al. 2020) are facing social and power issues.

Not surprisingly adopting different lens means sometimes also to change the object of study. For example, Hossain & Fuller (2021; p. 294) looked at mega projects as characterized by political lobbying, privatization and institutional fragmentation which can result in the marginalization of vulnerable communities as well as concerns regarding the transparency and accountability of the decision-making process ( In this sense scholars are interested in understanding which are the power relationships among the different actors involved in the mega-project and how they use their forces in order to get their goals. So they want to underline the unequal power distribution among the projects stakeholders.

On one hand, mega-project sponsors have all the interest in presenting the positive relevance of the project itself, giving a partial picture of the situation, underlying the short-term effects (especially the positive economic effects) and undermining the less visible long term social impacts. This uneven power

distribution could imply a strong conflict between different players (in particular the project sponsor organizations, both private and public, and the local community). A clear example of this kind of behaviour is discussed by Hossain and Fuller (2021) who identified four variables that influence this relationship (and this conflict): choice/alternatives, transparency or access to information, integration of local knowledge and power sharing. According to their study, in the official documents there are different choices in order to underline the positive effects of the mega-project, hiding the potential negative social consequences. The language adopted is always positive and offers only one-sided perspective: there is no space for an alternative choice.

Another example in this area is represented by Atkinson (2020), who reflects on hydropower projects, suggesting that the relationship between electricity provision and poverty reduction in rural areas is unclear; further, the benefit of mega-scale energy projects is limited to increases in energy export, with direct benefits being seen primarily by officials and elites.

From a more managerial perspective, it is possible to define very different research issues. At a network level, Rajput et al. (2022) investigates the risk coming from fragile and political regimes, studying how political, social safety and legal risks affect the project performance of a mega-project. Lee et al. (2017) propose a very interesting study reflecting on social conflicts, underlying how external stakeholders, such as NGOs or local residents, have become more critical factors. Looking at the conflict adopting this lens, they find five types of conflict scenarios and suggested different strategies to manage conflicts solutions. Badi et al. (2020) reflect on amore individual level, identifying the role of social power in defining strategic project innovation implemented by the project manager.

This stream of research also include the Politics Effects of Resistance against Mega-Projects (Silva et al., 2018; Wang and Wu, 2019). It is really interesting to reflect on (Silva et al., 2018; p. 28) how social movement actors with various interests and power resources try to influence mega-development projects, trying to denounce how mega projects could negative influence the phenomenon of marginalisation (Wang and Wu, 2019).

Adopting a social power perspective within different research fields reflects the complexity of this issue: in order to define the concept of evaluation in mega-projects in a managerial perspective, we need to enlarge our typical pathways, looking at different disciplines and journals.

## **4.2 Infrastructure and social space**

Another interesting research area could be represented by the effects of mega-projects in urban infrastructure development. According to Lee et al. (2020; p.2) the long-term social outcomes of urban infrastructure development are rarely assessed (ex-ante) or evaluated (ex post), especially in terms of how the respective interests are or will be affected by the multi-scale spatial changes generated by the projects.

For example, Perez-Sindin (2021) reflect on how labour needs change during a mega project development, leading to a situation of potential social and demographic change to local communities. So, he adopted innovative indicators related to crime or social tensions, to evaluate the social impact of the mega-project. Korytářová and Hromádka (2014) proposes to consider different social dimensions to evaluate a mega-project. Evaluating a transport infrastructure project could imply considering changes in the time consumption, changes in operation costs for vehicles, social costs connected with car accidents and newly impacts on environment.

According to Lee et al (2020) and in coherence with other scholars (Geurs and van Wee, 2004; Vecchio, Porreca and Rivera, 2020) the concept of social space is a key construct in order to evaluate the development of urban infrastructure, both at a macro scale (i.e., change in spatial structure of a city) and a micro scale (i.e., change in physical environment in a local area), showing the need for an integrated and broader approach to urban transport infrastructure development that addresses social consequences of multi-scale spatial changes induced by projects, including those that are unexpected or unintended. What is really useful in order to evaluate a transportation megaproject is the Environmental and Social Impact Assessment (ESIA), that according to Mottee et al. (2020) would improve the assessment and management of the social impacts of megaproject.

## **4.3 People engagement and endorsement**

Mega projects are typically criticised for their significant impact on communities and on society as a whole. It is therefore little surprise that they stimulate and challenge public opinion mobilizing wide citizens' reactions. Given their ability to increasingly attract public attention, they may exert an influence on public participation to collective choices and on political decision making.

The diffusion of social media has of course reinforced such phenomenon. Issues about engagement are crucial with reference to the so called Nimby attitude characterizing the negative social response to unwanted facilities that in recent times unfold especially through social media. Social media have brought about new challenges of widescale information diffusion.

According to Wang et al. (2019), focusing on how information related to megaprojects may circulate and develop, it is possible to put forward a series of socio-economic implications of the diffusion of information model. Government administration should understand what kind of social conflict may be prompted by the project. Government should therefore follow a progressive update which should include not only the casualties and economic impacts of the event, but also subsequent framing of the phenomenon, such as results of project evaluation. Important challenges are originated by the interactions between the megaproject and engaged citizens. Wang et al. (2019) argue that government administration should enhance its online influence through micro-blog operations, communicating with elites, defined as the important groups who are extremely active in the communication and directly promote the emergence of peaks of public concerns, to guide the positive online discourse. More generally, with reference to megaprojects, social media may represent a powerful communication channel to deliver public voice integrating public participation in the real world (Tumasjan et al., 2010).

In addition to issues related to social engagement as such, a number of other contributions (e.g. Aaltonen et al. 2008; Aaltonen & Sivonen, 2009; Davis, 2014; Eskerod, and Huemann, 2013) have dealt (broadly speaking) with stakeholder salience, considering people engagement as a potential stakeholder. The main reference here is to stakeholder salience framework put forward by Mitchell, Agle, and Wood (1997). Stakeholder salience is therefore “the degree to which managers give priority to competing stakeholder claims in their decision making process” i.e. how much and which type of attention stakeholders receive from management. The consideration of people engagement and endorsement is here observed in the light of stakeholder management.

## **5 Conclusion and research agenda**

Far from being an exhaustive literature review, this paper has explored for insights and research areas in the managerial domain. Starting from a simple

keyword research, we found three interesting areas to develop from a managerial perspective. A first one is related to the issue of power and equality that looks coherent with the critical management agenda (see for example Hodgson and Cimcil, 2006) both from a methodological and theoretical point of view. A second one is related to the concept of social space as a construct to adopt in order to enlarge the alternatives in the evaluation process. Finally, the third one was connected with the role of technology and social media, and broadly speaking with considering people management in the light of a stakeholders approach.

The aim of the authors is that these preliminary findings can inspire further and deeper research on these topics, looking for an integrated approach to include all of them into a cohesive framework for managing the social pillar in megaprojects management.

Further research agenda will include a systematic literature review on the topic and, following, a set of questionnaires to be submitted to a large set of megaprojects' stakeholders in order to validate the findings.

This paper is a first attempt to open up a discussion on a variety of issues (such as new frameworks that emphasise the social pillar in sustainable project management, the marginalized role of local communities in a context of increasing capitals and political concentration, the development of a common and comparable set of indicators that may help the understanding of the value distribution among (local) communities) that are still marginalized in the mega-project literature.

## Driving Smart Urban Innovation

---

Mauro Romanelli

University of Naples Parthenope  
Department of Business and Economics  
Via G. Parisi, 13 80132 Napoli

### Abstract

Cities of tomorrow are planning smart urban future, using information and communication technologies to support smart urban innovation by fostering collaborative processes in order to drive sustainable urban growth and improve the quality of life. Cities are becoming smart innovative communities, adopting a smart city framework to urban planning and development. A smart city helps to shape the city of the future as an engine of urban innovation. Sustainable urban future relies on smart cities and communities that support urban innovation for good life, promoting collaborative and multi-actor innovation, following a human-centred approach to smart urban development. As organisational and collaborative spaces, cities are rethinking the urban planning for sustainable future, promoting a smart city vision and developing a smart community. As smart innovative communities, cities are driving smart urban innovation, rethinking the urban future, and planning a smart city view in order to support sustainable growth and construct a wealthy urban future.

**Keywords** – Urban innovation, Smart cities, Smart communities

**Paper type** – Academic Research Paper

### 1 Introduction

As smart communities, cities of the future employ technologies to drive urban innovation and support sustainable growth, improving the quality of life within urban ecosystems and communities (Nam and Pardo, 2011a; Eger, 2005; Martinez, Mikkelsen and Phillips, 2021; Paskaleva, 2011). Cities are constructing a wealthy future, developing a smart city vision and supporting smart community development for collaborative and multi-actor innovation (Sørensen and Törfig, 2018; Fernandez-Anez, Fernández-Guell and Giffinger, 2018). Smart innovative cities enable urban communities to achieve competitiveness and sustainable urban development (Paskaleva, 2011).

City development should be intentional (Knight, 1995). Cities are rethinking the urban planning, by adopting a smart city vision to urban development, leading to “cities becoming cities”, and following bottom-up processes and fostering community-led initiatives (Komninos, Kakderi, Panori and Tsarchopoulos, 2019). Smart cities extensively make use of information and communication technology to improve the quality of living to its citizens (Yigitcanlar, 2017). Sustainable urban development relies on cities that are selecting a «proactive strategy to develop sustainability» (Roseland, 1992, p. 9), and drive future cities to support community engagement, innovation, cultural diversity, and technological advancements in order to ensure the wellbeing of citizens and achieve urban sustainability (Khan and Zaman, 2018). As smart communities, cities support innovation for improving local competitiveness and high quality of life, tracking a pathway for sustainable urban future and communities (Appio, Lima and Paroutis, 2019; Ahvenniemi, Huovila, Pinto-Seppä and Airaksinen, 2017; Nilssen, 2019).

Cities are shaping sustainable urban futures by using the potential offered by information technology to drive social and community innovation (Yigitcanlar, 2021; Ahvenniemi, Huovila, Pinto-Seppä and Airaksinen, 2017; Yigitcanlar and Kamruzzaman, 2018). Intelligent and innovative cities open up to knowledge-led and technology-driven social innovation and development, driving urban innovation by promoting collaborative and multi-actor processes, involving civil society, research, private/public organisations, and advancing technological and social innovation (Zhang and Wang, 2022; Sørensen and Törfing, 2018; Komninos, 2015; Meijer and Thaens, 2018). City is a net action and collaborative space for innovation and knowledge creation where private/public organisations are involved (Czarniawska, 2002; Nijkamp and Perrels, 1994; Yigitcanlar and Bulu, 2016). Smart city vision shapes the city as a collaborative framework (Komninos, 2015). Innovative cities support collaboration, strengthening the potential emerging from socio-economic and technical systems (Marceau, 2008) within smart innovative urban communities (Caragliu and Del Bo, 2019) and smart urban ecosystems for innovation (Zygiaris, 2013; Palumbo et al., 2021). Smart cities contribute to improving urban competitiveness, quality of life and innovation in long-term horizon (Appio, Lima and Paroutis, 2019; Paskaleva, 2011). The smart city is considered as the hub for global smart society (Joss et al., 2019). Cities select smart, sustainability-oriented social and human-centred innovation focusing on citizen engagement (Tura and Ojanen, 2022), and driving sustainable-inclusive growth, and empowering the citizen to proactively support services co-

production and innovation (Martin, Evans and Karvonen, 2018). Cities of the future design smart human-driven urban communities in order to improve the quality of life (Lazariou and Roscia, 2012). As social incubators of change and innovation for sustainability (Newman and Jennings, 2008), cities are becoming smart communities by adopting a smart city strategy, driving urban change and becoming loci and arenas of social innovation (Shearmur, 2012; Zhang and Wu, 2019; Costales, 2022). Smart cities enable open innovative and collaboration-led communities (Lindskog, 2004; Eger, 2005).

While there are many studies that focus on smart city visions and approaches as a means to drive sustainable urban development, few studies investigate the role of smart city planning and vision as a driver of urban innovation. The research question refers to how cities are rethinking the urban future, designing smart communities as engines of urban innovation. Cities are planning the future of urban development by selecting a smart vision to urban growth and innovation. Three case studies are analysed and presented. Some European cities (Paris, Wien, Florence) are rethinking about the urban future by adopting a smart vision planning in order to shape smart-driven, innovation-led and human-centred, and intelligent communities. Cities adopt a smart vision in order to drive the city of the future, making smart, sustainable and innovative urban communities.

The aim of this study is to elucidate how cities are driving smart urban innovation, rethinking the urban future, and planning a smart city view in order to drive cities as a smart innovative community. Future cities develop a smart city and community vision in order to drive collaboration for sustainable innovation. The paper is structured as follows. After introduction and methodological section, in the third paragraph the theoretical framework on rethinking the future of cities as smart innovative urban communities is elucidated. In the fourth paragraph, the issues emerging from the analysis of three case studies with regards to smart city planning adopted in Paris, Wien and Florence are analysed and presented. Finally, discussion and conclusions are outlined.

## **2 Methodology**

The study employed a qualitative, descriptive and exploratory methodology to analyse how cities are rethinking their future development, by promoting urban innovation to shape smart urban communities. While cities are planning to

transform urban environments into smart cities as an urban policy priority, they are rediscovering the smart city as an opportunity to drive social innovation, shaping smart innovative urban communities. In Europe cities are rethinking about the urban planning and adopting smart city strategies to improve urban quality of life and achieve urban sustainability, promoting multi-actor and stakeholder involvement (Yigitcanlar and Teriman, 2015; Yigitcanlar *et al.*, 2019). As engines of urban innovation and socially inclusive growth, some European cities are rethinking the urban future, adopting a smart city vision and framework to urban innovation and growth, revitalising the city as a community, employing technology as an enabler of urban, social and collaborative innovation, and shaping collaborative urban spaces as drivers of value creation and prosperity in the long-term. The study focuses on three case studies, Paris, Florence and Wien, which refer to cities that are rethinking their urban future and redesigning the urban development planning by adopting a smart city strategy in order to promote the city as innovative, sustainable and inclusive community. These illustrative cases are used to explore a phenomenon that is still in progress, happening and emerging in contemporary times. The smart city frameworks reported illustrate the attempt to shape a smart inclusive city as an innovative community. Following Yin's (2009) guidelines, this methodology aimed to provide a comprehensive understanding of the phenomenon at hand without the rigidity of a predefined structure for observations and analysis. The study follows a multiple case study methodology. A case study refers to an empirical inquiry to investigate a contemporary phenomenon, whereas the boundaries between the phenomenon and the context are not clearly evident (Yin, 2009). The research methods involved case selection and data collection from policy documents. In particular, smart city strategy framework (*Paris Smart and Sustainable Looking ahead to 2020 and beyond*, *Firenze Smart City Plan* and *Wien Smart City Strategy Framework*) adopted by the municipalities of Paris, Florence and Wien as policy documents are considered information sources to collect and analyse data and information, and to investigate how some European cities are rethinking and planning their urban future development coherently with a smart city view by designing a smart and inclusive community as an engine of urban innovation and social growth. A descriptive case study research was employed for the qualitative analysis of the smart city strategy adopted by municipalities to make the city as smart city and community. Investigating strategic choices regarding smart city strategy design helps to understand the pathway cities are following in building

their urban future (Angelidou, 2014; Angelidou, 2017; Mora and Bolici, 2017; Sancino and Hudson, 2020).

### **3 The future of cities as smart innovative communities**

As organisational space (Knox, 2010), the city is «a space or 'assemblage' which brings together various actors to pursue their own objectives» (Zhang and Wu, 2019, p. 151), becoming an arena of innovation (Zhang and Wu, 2019). As smart cities and communities, cities are driving inclusive and healthy growth, developing innovation by fostering multi-level and multi-actor collaborative processes (European Commission, 2017; European Commission, 2012), and shaping sustainable, resilient and inclusive urban communities able to ensure good quality of life coherently with the *UN 2030 Agenda for Sustainable Development* and the *New Urban Agenda*.

Cities are rethinking smart urban planning by focusing on citizen engagement and supporting sustainability-oriented, social and human-centred innovation (Tura and Ojanen, 2022). Developing a smart city vision leads to urban innovation (Nam and Pardo, 2011a) and supports community development (Allwinckle and Cruiskshank, 2011), shaping smart communities for citizen satisfaction and well-being (Silva, Khan and Han, 2018), and improving urban environment, economy, living, mobility governance and education (Giffinger *et al.*, 2007). Sustainable urban development relies on cities that adopt a smart city vision and contribute to public value creation and innovation (Pardo, Gil-Garcia, Gascó-Hernández, Cook and Choi, 2021; Paskaleva, 2011; Nam and Pardo, 2011a). According to Gil-Garcia, Pardo and Nam (2016) «a smart city should be seen as a continuum in which local government officials, citizens, and other stakeholders could think about the initiatives that attempt to make the city a better place to live» (p. 5). A «smart city is *"a community that systematically promotes the overall wellbeing for all of its members, and flexible enough to proactively and sustainably become an increasingly better place to live, work and play"*» (Lara *et al.*, 2016, p. 9). Yigitcanlar *et al.* (2019) state that «what needed is to make the city itself 'smart' – that includes its people, in other words smart community» (p. 8). A city is going smart by shaping a smart community in order to drive urban innovation to achieve sustainable and inclusive growth (Nam and Pardo, 2011a; Paskaleva, 2011).

Cities support open innovation, using digital technology to improve quality of life and achieve long-term sustainability, focusing on people and human capital

(Paskaleva, 2011; Hollands, 2008), shaping innovation-led and sustainable cities as well as inclusive and people-centred communities (Nam and Pardo, 2011b; Chang *et al.*, 2022).

Urban innovation relates to innovative practices that improve the urban environment. Urban innovation refers to a sociotechnical innovation that involves the use of new technologies and also changes in routines, collaborations, and roles of actors in the public domain. Urban innovation is conceived as «the intentional and proactive process that involves the generation and practical adoption of new and creative ideas, which aim to produce a qualitative change in an urban context» (Meijer and Thaens, 2018, p. 366). The city acts for driving smart innovations (Joss *et al.*, 2019). «A smart city is ICT-enabled public sector innovation made in urban settings» (Nam and Pardo, 2011, p. 186). Urban innovation relies on smart cities that develop information ecosystems to address economic, social and environmental needs, valuing identity and community development (Han and Hawken, 2018). Smart cities are the symbol of technology-driven urban innovation (Mora, Deakin, Reid and Angelidou, 2019). Cities adopt a human-centric view in shaping the smart city as a platform for technological and social innovation (Costales, 2022). A smart city helps to shape the city of the future as an engine of social innovation (Anttiroiko, Valkama and Bailey, 2014). Sustainable urban growth relies on smart future-oriented and open innovation-driven cities and communities that employ human, technological, social and institutional capabilities (Angelidou, 2015; Paskaleva, 2011; Nam and Pardo, 2011a). Smart cities develop innovative and sustainable solutions for wealthy urban growth and prosperity (Bătăgan, 2011).

Cities drive urban innovation by promoting smartness as the ability to attract and mobilize human capital in collaboration with urban actors and stakeholders by using information and communication technologies (Meijer and Bolívar, 2016). As *loci* of smart innovation and innovative milieus, and smart communities (Shearmur, 2012; Nam and Pardo, 2011a), cities contribute to democratic, open and socially inclusive innovation, fostering human-centred and collaborative decision-making processes within community development (Andreani *et al.*, 2019; Lindskog, 2004; Eger, 2005; Bătăgan, 2011), bringing together a range of stakeholders (private, public, no profit sectors, citizens) in interactive arenas to develop new solutions and innovative approaches to urban problems (Hartley, Sørensen and Törffing, 2013), and fostering community and collaborative spaces (Skelcher, Mathur and Smith, 2005).

Smart urban innovation relies on smart communities that support stakeholder collaboration and cooperative processes to improve the urban wellbeing (Nilssen, 2019; Paskaleva and Cooper, 2018), opening to multi-actor cooperation to transform the urban community in significant ways and support community development (Lindskog, 2004; Eger, 2005; Stratigeia, 2012). Driving a smart city vision shapes urban innovation views to community development (Nam and Pardo, 2011b), and helps cities to drive urban collaborative innovation (Meijer and Thaens, 2018), enabling the city as a smart innovative community (Paskaleva, 2011) where citizens promote innovations (Kummitha and Crutzen, 2017).

#### **4 Rethinking and planning smart innovative cities**

Cities are planning their future urban development by selecting a smart vision to urban growth and innovation. Rethinking smart innovative cities relies on driving smart city planning and implementation in order to shape cities as smart-driven, innovation-led and human-centred communities. In this study three case studies are analysed and presented. Some European cities are rethinking about the urban future by adopting a smart vision planning in order to support innovation and drive sustainable urban development, shaping innovative and intelligent communities. This analysis elucidates that cities are designing the urban planning, rethinking about the future of urban communities, adopting a smart vision in order to shape the city of the future as sustainable and innovative community by strengthening a collaborative framework, designing urban collaborative spaces that enable various stakeholders to contribute to innovation processes to improve the quality of life of citizens within urban communities.

In the smart city framework *Paris Smart and Sustainable. Looking ahead to 2020 and beyond* the smart and sustainable city is using the potential of information technology to support urban innovation and contribute to improving the quality of life within urban communities. Smartness is a means to drive the city towards a sustainable future and quality of life improvement. The smart city is an open platform and resolutely future driven that supports the experimentation and the development of new innovative services and solutions that improve the quality of life and the wealth of urban environments and spaces. Developing the city of the future means to bring together social, technological and organisational dimensions, relying on a smart and sustainable city shaped on three pillars: the *connected city* (the tool) relies on continually integrating technological advances;

the *open city* (the method) relies on stimulating citizen participation and collaborative projects, and driving innovation by exchanging, sharing and co-creating with researchers, scientist and academics, by transforming public administration, simplifying processes; the *sustainable city* is a place where technology serves people, improving their inclusion in city life by allowing them to be involved in creating public services and policy decision-making processes. Smart innovative cities include people in the city life, bridging the gap between new public services and policymaking, and focusing on cities as effective agents of social change and innovation.

In the *Smart city Wien Framework Strategy* looking at the 2050 the smart city vision develops to enable actions that enhance some key concepts: quality of living, sustainability, prosperity, opportunities for education and workplaces. The role of information technology is to contribute to simplifying the urban life, enabling people to continue professional education boundary less. Shaping smart cities supports urban change processes. Driving smart urban innovation helps the urban future and contributes to social integration and inclusion of citizens within urban communities and supports civic participation (not let anybody down and let people have access to the same degree of participation). Smart innovative cities have to ensure top-level quality of living and focus on social participation and inclusion, safety and security, leisure quality and culture, and support both social openness and cultural diversity, strengthening high degree of social participation to enable urban development and support inclusive and sustainable growth.

In the *Firenze Smart City Plan* cities are living organisms made up of people within the process of urban transformation, leading to intelligent urban communities. Smart urban innovation relies on citizens who are able to play a proactive role in identifying some pathways for urban development and quality of life improvement. In particular, planning a smart urban vision supports the city as an engine of innovation and a community of people able to produce meanings and culture, and to enhance human and civil progress. Promoting smartness relies on using technology in order to make cities more innovative, sustainable and intelligent communities capable to drive innovation, reinforcing social relationships. A smart city refers to a city that is changing and constructing new social, urban, and economic responses to environmental and historical pressures. The smart city plan is an open space for debate, confrontation, exchange of information and knowledge among all urban stakeholders which are interested in

contributing to urban, social and economic development. A smart city master plan helps the city to drive continuous urban sustainable innovation, improve the quality of life within community and relies on distributed and collective leadership and vision. Smart urban innovation relies on promoting collaboration among all the involved stakeholders (public administration, research centres, cultural institutions, businesses, associations, groups, citizens) along the urban value chain. A smart city strategy relies on promoting open innovation by involving the stakeholders and embracing the four *Is*: *integration* of all possible aspects in charge of a municipality's competences and background; *innovation* as the development of innovative services and solutions through digital and interactive information technology; *involvement* as a means to enable stakeholders to identify, plan, share, and implement strategic, long-term vision and goals; and the *information* relies on the use of information and communication technology as a way to reinforce and consolidate the relationships between municipality and citizens, by monitoring the implementation of urban smart strategy.

## **5 Discussion and conclusions**

Cities of tomorrow are planning their future as well as smart innovative urban communities, and contribute to promoting high quality of life, and achieving urban sustainability, making urban collaborative open spaces, arenas and *loci* of innovation and engines of social inclusion. Smart cities and communities contribute to urban innovation and drive sustainable growth and urban development for better quality of life, driving cities as smart and inclusive communities. As engines of urban innovation and smart communities, cities, therefore, develop the potential offered by digital technologies, moving from a technology-enabled to a community-oriented and human-centric approach, putting the people first, focusing on human and social capital, and community, shaping urban collaborative spaces to drive continuous social and economic innovation, strengthening participation and stakeholders' involvement as a key driver for supporting the city as a collaborative, inclusive and innovation-led community.

Paris sustainable city vision stresses the connected city as a tool, the open city as method and sustainable city as a goal. Wien smart vision relies on use of technology as a means to enhance co-participation, co-decision-making and inclusion as strategic view to urban sustainable development. Florence's smart

city planning focuses on searching for bringing together integration, innovation, involvement, and information. Technology enables citizen and community participation and engagement for continuous innovation for urban sustainability. As engines of innovation, cities are tracking a pathway for future sustainable urban innovation. Smart cities strengthen community participation to drive sustainable innovation. Socially inclusive and technology-led innovative urban communities adopt a human-centred and participative-oriented view to urban growth dealing with technology to make the city as a better place for value creation and social innovation. Cities of the future drive sustainable innovation, understanding the potential of information technology to adopt a human-centered smart-oriented vision to develop the city as socially inclusive, innovation-driven and knowledge-oriented community.

### Abstract

The knowledge-based theory considers that knowledge is the most important resource of an organization, while knowledge management is increasingly more considered a way of ensuring competitive advantage, an effective tool for valorising resources, helping manage change and being more resilient, and determining enhanced performance for organizations. All these aspects are also relevant for effective museum activity. Thus, through three focus groups, the paper sheds a light on challenges and practices that are shaping the environment in which continuity of efforts and sharing of knowledge is ensured amongst museum professionals in Romania. The findings are useful for museum managers to better organize knowledge flows and manage knowledge effectively, while for various museum professionals, they help understand knowledge gaps, the various sources of knowledge available as well as the specific dynamics in the field.

## 1 Introduction

Museums are information utilities, knowledge-based and learning-driven, and community-oriented organizations that contribute to value creation (Bagdadli, 2007; Freedman, 2000; Hein, 1998; MacDonald and Alford 2001), making available and sharing their knowledge with audiences within a cultural ecosystem (Borin and Donato, 2015). Museums are successful organizations by managing effectively knowledge (Freedman, 2000). Knowledge is a critical organizational resource for competitive advantages (Davenport and Prusak, 1998). Knowledge is a core resource for successful museums that create social value within communities. It is the commodity that museums offer. Knowledge is constructed individually and socially through interaction between participants and staff coherently with a constructivist view (Hein, 1998). As knowledge enablers and storehouses of knowledge, museums integrate knowledge, content acquisition and organization to develop application in academic research, exhibition and education for users (Hsu, Ke and Yang, 2006). While museums could be also considered as are knowledge municipalities (Freedman, 2000) and shape knowledge (Greenhill, 1992), legitimizing information and knowledge management (MacDonald and Alford, 1991), there are still few studies that focus on the relationship between knowledge management and transfer within the museum. Knowledge transfer contributes to competitive advantages. Successful organizations are able to drive and manage effective knowledge transfer. Effective organizations transferring knowledge internally are more successful than those lack knowledge management and transfer. Knowledge transfer has been defined as the process through which one unit is affected by the experience of another one within organizations (Argote and Ingram, 2000). Social capital and networks play a critical role in supporting knowledge transfer. Managing efficiently knowledge transfer relies on organizations managing and building social capital proactively (Inkpen and Tsang, 2005). According to Wang and Noe (2010) knowledge transfer relates to the «movement of knowledge between different units, divisions, or organizations», and «involves both the sharing of knowledge

by the knowledge source and the acquisition and application of knowledge by the recipient» while «knowledge sharing refers to the provision of task information and know-how to help others and to collaborate with others to solve problems, develop new ideas» (p. 117).

This paper is focused on knowledge transfer within the museum world as it seeks to explore various methods and practices employed in the process; it also goes beyond the conventional framework that primarily links knowledge transfer to a process that involves the transmission of knowledge from specialists, researchers and curators towards different external audiences, mainly the visitors (Cranmer, 2016; Navarrete, 2020) and addresses a variety of process taking place under the

In doing so, the first part of the paper is focused on the field literature regarding museums as knowledge organizations detailing the various type of knowledge produced by museums and the management process of knowledge sharing. Drawing upon prior research (Zbucea and Leon, 2015; Bira and Zbucea, 2019), the subsequent section presents findings from a qualitative study (comprising 3 focus groups) that aimed to investigate the methods currently employed by museum professionals to facilitate communication and the sharing of skills, experiences, and data. A secondary avenue of research aimed also to identify the main patterns and/or means that are employed when keeping in touch not only with activities and events organized by their peers, but when it comes to actually build upon previous experiences and results. Thus, our study sheds a light on challenges and practices that are shaping the environment in which continuity of efforts and sharing of resources are ensured amongst museum professionals in Romania.

## **2 Knowledge management in museums. A brief literature review**

The relevance of knowledge assets as fundamental strategic factors of business success has been widely recognized in today's competitive scenario (Barney, 1991; Drucker, 1993; Grant, 1991). More and more organizations accredit their competitiveness essentially to their knowledge assets and consider knowledge as the differentiating competitive lever in the knowledge economy (Nonaka and Takeuchi, 1995). In such a prospect, the suitable development and deployment of an organization's knowledge assets have become a strategic decision for its success.

Museums are knowledge organizations, therefore knowledge management could be vital for reaching their missions, providing a way of ensuring competitive advantage, an effective tool for valorizing internal and external dynamics, helping museums cope with change and being more resilient, and determining enhanced performance. All these aspects could be considered for effective museum activity, focusing both on the inner processes and the public activity of museums; knowledge management is relevant for all activities and subsystems associated with museums (Huber, 2003). To be effective, museums should strive to become “knowledge-centric organizations”, meaning to be proficient in using collective knowledge to achieve their missions and to view knowledge as a main asset (Vakharia, 2017).

### ***2.1 Typology of museum knowledge***

Knowledge management literature considers several classifications of knowledge. Depending on its nature, knowledge can be explicit or tacit. Explicit knowledge is codified in words, numbers, and symbols, and can be stored, analyzed, used, and easily transferred. Tacit knowledge is implicit, consisting of thoughts, experiences, capabilities, and even the intuition of the employees. It is diffuse in museums, and uncoded, sometimes even unperceived. Both tacit and explicit knowledge could be important museum assets, therefore, they have to be properly managed and activated to work for the benefit of the museum’s heritage and its beneficiaries. Nonaka (1994) proposed the SECI model to convert tacit knowledge in organizations through socialization, externalization, combination, and internalization of knowledge into explicit knowledge. Most of the knowledge in organizations, including museums, is tacit. To be valorized, knowledge management processes involving discussions, training, even socialization, and enhancing organizational culture, should be designed and implemented in museums.

Depending on its source, knowledge can be internal or external. Organizations tend to concentrate on internal organizational knowledge, being easier to identify, analyze and use. Still, proper knowledge management strategies are needed to handle both internal and external knowledge. The latter might be a relevant resource for museums, extending their knowledge base and leading to diversification of offers and enhanced benefits for museum visitors and communities.

Another classification of knowledge is related to its transferability readiness. Knowledge could be codified or uncoded. The first one is easier to handle, therefore, knowledge management strategies should aim to codify as much relevant knowledge as possible. Knowledge could be also theoretical or applied. Especially museums have a strong capital of theoretical knowledge, the specialty one related to its heritage and domain of investigation. Also, knowledge in museums could be administrative in nature, related to administrative and legal processes associated with museums' activities.

The last classification we mention is concerned with how knowledge is processed by humans. The theory of knowledge fields developed by Bratianu (Bratianu and Bejinaru, 2019) divides knowledge into three categories: rational, emotional, and spiritual. Rational knowledge is explicit and objective, the result of human reasoning. An important part of the rational knowledge in museums is related to the scientific knowledge related to the museum's collections and domains. Emotional knowledge is associated with feelings and emotions. As a form of tacit knowledge, it is difficult to identify and understand, although it contributes to decision-making and stimulates cognition. It also contributes to organizational culture, being an important influencer inside museums, from a practical perspective. Spiritual knowledge is also tacit, related to values, and concerns related to the meaning of life. It provides a sense for organizations and individuals, framing it in a meaningful vision. It might also be connected with organizational culture, organizational learning, knowledge creation, and sharing (Rocha and Pinheiro, 2019, 2021).

## ***2.2 Knowledge management processes within museums***

Although knowledge is essential for museums' activities and "museums are shaping knowledge" (Greenhil, 1992), knowledge management is lesser investigated in museums focusing mainly on very specific aspects. Nevertheless, some studies offer a more comprehensive view. Such an investigation aimed to identify knowledge management orientation, its enablers, and its relationship with the organizational performance in museums across the US (Vakharia, 2022; Vakharia and Poole, 2023). It reveals that museums' performance and their ability to create public value are hindered by how they create, manage, and share knowledge. Thepthea and Mitsufuji (2016) surveyed two national science museums in Thailand and show that knowledge management processes,

especially knowledge acquisition, and dissemination, enhance organizational learning. This study also reveals different perspectives of managers compared with other staff members. Managers tend to perceive knowledge management processes at higher levels. Differences in perceptions between managers and other employees have been identified also by Zbucnea and Leon (2015), with managers having more complex views on knowledge management processes.

Perera and Chandra (2011) point out that knowledge management has long-term significance for museums, helping museums serve their communities and acting as educational forums. The main benefits of knowledge management for museums that were identified are enhanced quality for the museum offer, surpassing visitors' expectations, upgrade museum communities/audience development, and employee development.

Some studies on arts, cultural, and crafts organizations point out a lack of focus concerning the transfer of know-how and skills (Manfredi Latilla et al., 2019), suggesting a low awareness of tacit knowledge in such organizations. Still, knowledge sharing, including formal aspects associated with this process seems to be of high concern in cultural organizations (Zbucnea and Leon, 2015). Also, some knowledge transfer has been documented between higher education organizations and the cultural industry (Cruz et al.2019). Stakeholders and common interests play an important role, in the framework of unstimulating and weak policies in the field. Being part of a network, either social or formal, to share knowledge and increase access to resources is positively approached by museums (Bira and Zbucnea, 2019).

Of wider concern seems to be knowledge sharing for better designing exhibitions and museum offers. Moussouri (2012) points out how knowledge management makes exhibition development more effective, ensuring a user-centered perspective, and valorizing communities of practice. He stresses that sharing of knowledge and learning in museums are social phenomena, involving all types of knowledge. Long-distance collaboration should be successfully mediated by online tools.

We also observe that knowledge management in museums is tightly related to technology and digitalization (Ignjatovic, 2004; Hsu, Ke, and Yang, 2006; Srinivasan *et al.*, 2009; Datunashvili *et al.*, 2018; Romanelli, 2020). Technology facilitates access to museum heritage and its online valorization (Häyrinen, 2012). To properly manage these activities, be updated with the new technologies, and positively react to their new challenges, there is a continuous need of improving

the technical skills of its employees (Hess et al., 2019). Also, even medium-sized museums are aware of the importance of information infrastructure, of processes associated with knowledge sharing, to connectivity, that they set up a routinized formal information exchange (Huvila, 2013).

Information systems are vital for museums from many perspectives, the most important one is related to collection management. But museums are increasingly aware that their information management system should serve more, and the organization overall, contribute actively to achieving its mission. For proper systems, integrated with wider knowledge management strategies, museums should consider also the needs of various stakeholders for successful knowledge transfer and cooperation (Kavakli and Bakogianni, 2003; Neves et al., 2021). Not only knowledge sharing, transfer, and valorization are enhanced through proper systems, but other backstage activities, vital for heritage, could be supported by effective knowledge management – as in the case of conservation (Moraitou and Kavakli, 2018). Various studies also stress the importance of adapting/choosing the right software and approach, to satisfy the specific needs of heritage management (Hervy *et al.*, 2013, 2017; Neves et al., 2021).

Digitalization and new technologies facilitate several of the processes associated with knowledge management: acquisition, storage, sharing, and utilization. Knowledge management processes are useful tools contributing to designing effective knowledge management strategies. They are usually classified into acquisition and creation of knowledge, storage, and protection of knowledge, sharing of knowledge, and utilization of knowledge.

Knowledge acquisition and development influence the quality and the outcomes of museums' activities. Knowledge can be created or can be harvested both from internal or external resources, through sharing. Within the museum world, knowledge utilization and transfer are mostly approached in the classical framework of this cultural institution, which considers the transfer from specialists, researchers, and curators towards different external audiences, mainly visitors (Cranmer, 2016; Navarrete, 2020).

### **3 Managing and transferring knowledge with the Romanian museums**

#### ***3.1 Methodology***

Building on previous research (Zbucea and Leon, 2015; Bira and Zbucea, 2019) the current paper aims to further explore the mechanisms currently in use when ensuring the communication and transfer of skills, experiences, and data amongst museum professionals. The current research aims also to identify the main patterns and/or means that are employed when keeping in touch not only with activities and events organized by their peers but when it comes to actually building upon previous experiences and results.

Qualitative investigation is appropriate considering these objectives.

The focus groups are organized around three distinct categories of people working in museums. The groups are therefore composed of representatives of museum management (group 1), museum educators or assimilated personnel (group 2), and other museum professionals (group 3). The research results are organized around two main themes, namely: how the availability of knowledge is constructed and perceived by those involved in museum educational activities and how is the knowledge transfer formally organized, implemented, and monitored.

#### ***3.2 Findings and discussions***

##### ***3.2.1 Sample***

The current research was organized in April, on a convenience sample of 17 respondents, organized in three groups: the first group, N=7 consisted of people with management attributions (general managers or department managers); the second group comprised museum educators (N=5), meanwhile the third was composed by people with roles as researchers, curators, specialists and / or support activity (e.g. communication and associated domains). As work experience, including the length of activity within the domain and job roles, is significant in how individuals perceive their involvement in knowledge sharing and acquisition, participants to this study form two equal groups around the following categories: mid-career professionals (over 15 years of experience, N=4) and professionals having a consistent experience (5-10 years, N= 4). A small

number of participants were in the early stages of their career within the field (under 2 years of experience, N=3 and 2-5 years of experience, N=2), while only one participant was nearing the end of their career. This being said, it is also important to keep in mind that participants in these focus groups had various background, both in terms of academic training and previous work experience, prior to museum activity. Equally important for the process of knowledge management is the number of employees; in this study, most participants belonged to small museums, between 10 and 50 employees (N=7), meanwhile those hired in organisations over 100 employees were 5. Only 3 employees belonged in medium size museums, with a number of employees between 50 and 100 employees.

### *3.2.2 Findings*

The themes that emerged during focus groups gravitated towards two main issues (1) defining relevant knowledge (alongside its sources, production and acquiring mechanisms) and (2) knowledge transfer (amongst colleagues within museum but also transfer towards outside – visitors, children -during education program- and partners).

When discussing about what is knowledge from the viewpoint of the current activities in a museum, one of the main differences occurred along the lines that separated groups according to their activity type (management, education, research & specialized support activities – e.g. communication, restauration). As expected, each group had similar definitions and shared several common views in accordance to their main activity. Managers often view networking skills and the ability to take an interdisciplinary approach to managing a museum as crucial competencies. As one participant to the focus group said: "it is important what you find out from people next to you, is important to talk to people over a coffee or a drink, to find out useful information to your future career" (S4, ≥15 years in the domain) or, as another participant expressed: "to communicate (...) to interact, to adapt to those we are work together with" (S2, 5-10 years in the domain).

During the focus group, participants identified that having knowledge and expertise in management was crucial for success. This included understanding the procedures and processes within an organization, as well as the legal requirements when working with museum objects and the public. Both experienced managers and those who were new to working in museums

acknowledged the importance of being acquainted with formal rules and legal regulations, albeit from different perspectives and with different aims. However, one participant also pointed out the inconvenient of relying too heavily on procedures as they can hinder communication instead of facilitating a smooth exchange of information. Peer learning was also mentioned in relation to knowledge about communication protocols and procedures; thus, formal study or trainings on procedures and formal regulations slid towards a more informal activity of sharing knowledge. Navigating the internal flow of communication and interacting with support departments (such as accountability) was mentioned within the context of information management, procedures and protocols. A challenge especially to those in their early career stage, an efficient communication by the rules is also dubbed essential for people in their mid-career.

Participants also emphasized the importance of having a deep understanding of the museum domain (such as history, arts, natural history etc.) within the broader context of a public institution interacting with various stakeholders. This view was shared by all respondents, although those working as museologists mentioned it more frequently. Knowing the "theory by the book" is deemed essential for professionals regardless of their specific field of activity (research activity, curating an exhibition, communicating about programs and activities etc.). As one participant expressed the need to acquire expertise in the domain: "understanding the domain is the minimum required and more knowledge is always helpful; however, since it is impossible to know everything all at once, from the beginning, one must have the capacity to research and learn (...)".

It was also noted that constantly updating one's knowledge is paramount for a museum activity. Understanding knowledge as a set of information that should be constantly enlarged and updated, alongside with the need to improve skills and know-how was addressed by most of participants. In all groups, participants mentioned the importance of gaining theoretical and practical information in the context of formal learning, on the background of limited funding available for training and lifelong learning activities for museums specialists in Romania. If managers considered the topic from the viewpoint of enabling an organisation to move forward and respond to stakeholders' expectations, other museum specialists referred to formal learning as opportunity to exchange, build a network and getting to know people facing similar challenges / difficulties.

A good English command is implicitly assumed by participants when discussing the various information sources (e.g. publications in English) they used to keep track of museum novelties and innovations. It is basically a sine qua non precondition to access the most recent information related to museums. Largely acknowledged and discussed by museum educators, knowledge access via English is, definitely a barrier when it comes to knowledge sharing since, in Romania, BA programs usually include one or two semesters of studying a foreign language, and therefore museum professionals in domains such as history, art history, natural history, ethnography heavily rely on previous knowledge from high school or on independently acquired knowledge.

#### **4 Conclusions**

Vårheim and Skare (2022) show that museum-related investigations are limited in the mainstream academic literature, and case studies are predominant, while most of the research is focused on museums' beneficiaries and communities. The investigation confirmed the low interest in knowledge management in the museum sector both considering the academic investigations, and the practice within museums. It also proved a more consistent interest in practical aspects, compared to providing a conceptual framework in the field. Most of the academic attention has been focused on information systems within museums, digitalization, and the impact of new technologies on museum knowledge and activities.

In the specific case of the Romanian museums, the study suggests that specialized knowledge (whether it is in the general domain of the museum – e.g. history, arts etc., in specific domains of activity e.g. social media communication) is still considered among the most important type of knowledge. Another important set of knowledge relays also on specialized know-how, but it regards stakeholder interaction and communication, namely the visitors (or participants to educational programs).

The findings are helpful for museum managers to better organize knowledge flows and manage knowledge effectively, while for various museum professionals, they help understand knowledge gaps, the various sources of knowledge available as well as the specific dynamics in the field.

### **Abstract**

The paper aims to analyze academic literature in the field of digital transformation and business model innovation, with particular reference to the tourism sector, in order to identify challenges, opportunities, and policy directions for stakeholders in the industry to be able to face the challenges of the current socio-economic scenario and gain a

sustainable and lasting competitive advantage, as well as to activate development dynamics in the territory. In the digital era, the competitiveness of organizations depends on their ability to adapt and innovate business models to market trends and changing stakeholder needs. These innovations cannot neglect digital dimensions, which have become even more essential after the pandemic situation. However, innovation is not an easy process and presents many risks and barriers, particularly in the tourism sector, which is considered a labor-intensive production sector where the competitive advantage depends on the differentiation of the tourism product and the humanization of the experiences offered. As a result, tourism is often hesitant to embrace digital transformation, fearing it will lead to standardization and loss of appeal to the end customer. Despite the growing relevance of this topic, especially in the wake of the Covid-19 pandemic, there has been little exploration of ways to support tourism and cultural organizations in embracing digital innovation journeys. This paper, thus, identifies challenges, opportunities, risks, and needs for tourism organisations involved in digital transformation and business model innovation processes, and propose policy recommendations and future research directions to support their transformation of those tourism organizations.

## 1 Introduction

The process of Digital Transformation (DT) is crucial to track, because the most relevant socio-economic and labour-market arising impacts are innovating the business models, through the transformation of work, processes, services, products, as well as the paradigm of the whole economy (Muro et al., 2017). At the centre of this impact, there is digital technology (e.g. Big Data, Analytics, Artificial Intelligence, etc.) that contribute to the improvement of workers' abilities and companies' effectiveness. The integration of emergent technology in the company's routines alongside the employees instead of in their place should contribute to the increase of knowledge creation and management dynamics. This, allowing workers to dedicate more time to added value processes rather than consuming and alienating ones. It follows that technology is, even more, resulting as a driving force of today's competitive landscape. Therefore, DT, Business Model Innovation (BMI), and the processes to implement technology in the right way to produce innovation are current almost mandatory topics for organizations' competitiveness and survival.

In this regard, in this chapter, desk research in the fields of DT, and BMI has been carried out to identify challenges, opportunities and organizations' risks and needs, with a particular emphasis on tourism organizations.

The chapter is structured as follows. The second paragraph analyzes the DT concept, paying attention to the state of the art, definition, critical process' stages, challenges, and the situation in tourism. Then, the third paragraph focuses on BMI. The research concludes with discussions about how to support and foster DT and BMI in tourism organisations.

## **2 Digital Transformation in Tourism**

Digital transformation (DT) is a buzzword that has been around for several years, and it is gaining momentum as companies strive to stay relevant in the digital age. According to Capgemini, DT is defined as "the use of technology to radically improve performance or reach of enterprises" (2011, p. 5). Digital tools and innovations, such as smart devices, mobile apps, analytics, social media, and more, are tested and employed by a growing number of enterprises interested in improving efficiency in customer relationships, internal processes, and growth strategies (Westerman et al., 2014).

The impact of DT can be seen in almost every sector of society, affecting economies, improving processes, and fostering networking opportunities between different actors (Schallmo et al., 2017).

From the 2000s, the fast development of smartphones, digital devices, and social media platforms radically changed the ways of interaction between customers and companies. Customers used to spend more time online, and they are connected on a multi-channel base, producing and sending data through the interaction with the web. Their needs and habits are changing, as well as the ways and speed of exploiting goods. Companies have been encouraged to develop and test new approaches and methods to communicate with consumers on an individual basis and often in real-time, as well as to gather data to understand their desires and behaviors. Digital innovations like chatbots, AI, analytics and more, have been introduced to contribute to the above-mentioned purposes.

As a consequence, the digital presence of companies actionable through internal DT journeys and digitization of products and processes is becoming mandatory for organizations aiming at staying relevant and keeping the pace of change in the current business scenario. The customers' expectations have

radically changed as well. The fast development of digital technologies and solutions raises the efficiency standards, increases the speed of market dynamics, and decreases the product lifecycle (Schiuma, 2012). Moreover, consumers are evolving into prosumers not more interested only in the buying process. They look for experiences and want to get a central position in the process, so they aim at getting engaged in co-creation processes of products, services, and experiences.

Therefore, innovation rapidly and easily becomes quite common and replaced by new emergent innovative digital solutions based on technological advancements and that meet even better the customers' needs. It follows that organizations operating in such mutable and unpredictable digital ecosystems have to become resilient, proactive and able to evolve in the same way the competitive landscape does. To do so, it is relevant to consider that the broader goal of DT is not to digitize the company. It is more related to the generation of growth (Suh et al., 2018).

In conclusion, DT is not just about implementing new technologies; it is a process that involves the entire organization, requiring skills, competencies, and a shared vision.

In the tourism industry, DT offers numerous opportunities for growth, increased efficiency and productivity, competitive advantage, and innovation. Specifically, DT can lead to the development of innovative tourism offers, destination management, the customization of products and services, the creation of new tourism packages, and the provision of policy guidelines for local tourism ecosystems (Dredge et al., 2018, p. 6).

Compared to other sectors, the tourism industry presents a fragmented offer, and its sub-sectors are inherently labor-intensive, characterized by humanization and direct client contact. As a result, the industry is often reluctant to innovation and digitalization (Meyer and Mayer, 2015). Additionally, sub-sectors within the tourism industry vary in terms of resources, access to finance, skills, culture, and other factors. Therefore, achieving DT in tourism organizations can be a complex and challenging process.

To ensure an effective DT process in tourism organizations, a holistic vision that involves the entire sector is necessary. Three key phases can be identified regarding the transformation of the sector based on the evolution of technologies (Xiang and Fesenmaier, 2017). The first phase involved the diffusion of the Internet from 1990 to 2000. During this phase, technologies were used as

supporting tools for the incremental improvement of internal operations. The digitization of tourism offers began with the creation of websites to replace traditional paper-based catalogues. At the same time, reservation and distribution systems became web-based, making online transactions easy and facilitating the growth of the industry.

The second phase saw the consolidation of digital business ecosystems between 2000 and 2010. With the help of technologies, travelers became more informed and aware of their needs. Virtual marketplaces proliferated to allow customers to become the protagonists of their travel and influencers for future travelers. OTA replaced traditional agencies, and innovative startups like Airbnb and TripAdvisor entered the market in a disruptive manner.

The last and current phase, which began in 2010, coincides with the development and spread of cloud computing, Virtual Reality (VR), GPS, wearable technologies, and other technologies that allow a real-time integration between digital and physical worlds. The combination of traditional tourism offers with web and social media platforms offers relevant opportunities to develop new products and services, innovate, create new business models, and guarantee growth and sustainable advantages to resilient and proactive organizations that are aware of market change and ready to adapt their business.

The emergence of DT in tourism has led to the need for new ways of planning and configuring destinations. This includes the development of new business models, value chains, and ecosystems, as well as evolved and new roles for customers, producers, and tourism organizations in general. In addition, the interconnection between physical and digital worlds has allowed for the reimagining and customization of visitor experiences, which is particularly relevant for second-rate destinations that are victims of the fragmentation of the sector.

This requires a holistic vision that contemplates and engages the entire sector to ensure an effective DT process in tourism organizations. The success of digitalization in the tourism sector ultimately depends on the capacity of the sector to share, learn, and collaborate.

In conclusion, the evolution of technologies has resulted in a transformation of the tourism sector, offering significant opportunities for growth, innovation, and competitiveness. However, it also requires organizations to be resilient, proactive, and adaptable to market changes. Those who have proven to be aware of the context and visionary have entered the market in a disruptive way, while those

who have ignored this reconfiguration have been replaced or pressured to reconfigure their businesses. In definitive, an effective and targeted DT require “a collaborative network and learning environment be established so that SMEs can be inspired by technology-savvy businesses both in and outside tourism and can learn and collaborate together” (Dredge et al., 2018, p.10). Moreover, technologies and digital innovation even though they can be new, they rarely impact radically on a market or ecosystem. What has the potential to be radical and disruptive is the way by which they are exploited. So, the logic behind technologies and the business model deriving from their usage and application. Hence, the concept of BMI.

### **3 Business Model Innovation in Tourism**

In an increasingly digital world, BMI is crucial for companies that wish to remain competitive. The rise of digital technologies has enabled new business models to emerge at an unprecedented pace, creating opportunities for companies that can adapt quickly and innovate. For instance, digital platforms like Uber and Airbnb have disrupted traditional industries by creating new business models that utilize technology to create new markets and services.

However, implementing BMI can be complex and challenging, requiring a deep understanding of strategic goals, the competitive landscape, and customer behavior. The process entails analyzing existing business models, identifying areas for improvement, and developing and testing new ones.

There are several drivers of BMI, including technology, customer behavior, and competition. Technology is a significant driver of BMI since it enables new products, services, and processes that can transform the way organizations operate. Customer behavior is another essential driver of BMI since customers increasingly demand more personalized and convenient services, forcing companies to adapt their business models to meet these changing needs. Additionally, competition is also a driver of BMI since new players entering the market can disrupt traditional industries, necessitating changes in business models to remain competitive.

In the tourism industry, BMI has become increasingly important due to the impact of DT on the sector. Considering the study by Linton and Öberg (2020), who focus on digitalization and destination location as relevant contextual factors, they define typologies of business models in tourism organizations,

developing a framework distinguishing four types of tourism business models (Figure 4). The first typology is defined as 'Bricks and Mortar,' which calls to mind the features of the traditional and homonymous tourism business model (Livi, 2009). That is the case of those organizations established in an attractive destination representing, for tourists, the reason for the travel. The proximity to attractions or dedicated facilities is the base of the business model. Services and activities provided are the traditional ones, as the accommodation, incoming, and those related to the management of tourists' experience. Therefore, digital capabilities are not required.

Instead, in areas where tourists usually are not attracted, organizations with medium digital capabilities may develop based on a 'Create-a-destination' business model. This kind of organization develops the business in high-potential areas that are still out of the usual tourists' itineraries. Therefore, the attractiveness depends on the ability of the organization to communicate value propositions and offers, as well as the capacity to provide unique experiences that become the primary reason for travel. It may be the case of those hotels that offer unique experiences, like ice hotels, tree houses, and so on.

The third typology of business model is related to those organizations that are not located in tourist areas but may be involved in tourism activities due to the high digital capabilities they possess. The 'Intermediary' business model includes P2P and digital activities. Therefore, organizations act as digital platforms fostering interconnections between travelers and destinations. Typical examples of this typology of companies are booking platforms like Booking.com, TripAdvisor, and so on. Moreover, with the arising of the Sharing Economy business dynamics, have been changed to the advantage of co-creation and tourism engagement (Schor, 2019). As a consequence, new platforms have emerged to connect customers and service providers to co-create experiences and tourism offers.

The last business model is that of 'Digitalized destinations,' namely destinations characterized by organizations with high digital capabilities that are interconnected in a digital ecosystem. These organizations offer advanced tourism experiences that are often integrated with advanced technologies such as big data, analytics, IoT, smart devices, and so on, distinguishing the concept of smart tourism (Gretzel et al., 2015). The critical activities are related to the collection, analysis, and representation of data. These activities allow increasing the understanding of customers' needs and habits, to adapt the offer with even

more customized products and services, as well as to guide management decisions. At the same time, core activities are related to the provision of innovative experiences that should act as attractors and differentiating factors (Chesbrough, 2007).

Once assumed the possible tourism business models, it becomes relevant to consider the business goal that in tourism, as in the other sectors, is related to the value generation achievable through the improvement of performance, the understanding of the competitive landscape, and the development of products and services even more attractive.

BMI should be pursued with different paths for each identified typology of business model, but it is recommended not to neglect DT. Digital capabilities can contribute to the development of new concepts of destinations, impacting more than just attractiveness. Therefore, business models based on digital capabilities should be considered one of the main goals for tourism organizations.

In conclusion, BMI is crucial for tourism organizations to remain competitive in a constantly changing landscape. Digitalization and destination location are two contextual factors that determine the typology of business models that can be adopted. By considering the value drivers of novelty, efficiency, complementarity, and lock-in, tourism organizations can identify the path towards successful BMI. The integration of DT is essential to achieving a good positioning in the market and satisfying the changing demands of tourists in the Digital Era and the age of Smart Tourism.

#### **4 Challenges for Tourism Organisations**

The capacity to innovate represents one of the most relevant factors determining the development of a productive sector. Looking at a global scenario where the demand is evolving, the tourism flows are changing, the average age is growing as well as the income, and the sustainability's challenges are becoming even more pressing, new technologies and new digital innovation in general, are modifying the supply chain heavily (Fereidouni and Kawa, 2019). Data about technology and digital innovation implementation in tourism companies are encouraging due to the growing number of organisations who have implemented ERP (Enterprise Resource Planning) and CRM (Customer Relationship Management) systems. These data record a growth of 18% and 11% respectively, in the Italian tourism sector (Dredge et al., 2018). However, at the same time,

digital innovation is interesting companies, mostly in terms of digitalisation and digitisation rather than DT. Indeed, coining the term provided by Westerman et al. (2014), few are the 'digital master' tourism organisations.

However, innovation in tourism includes aspects that go beyond the mere concept of technology innovation, namely the ability to develop or innovate a business model to exploit new technologies and to adapt the business to the emerging trends (e.g. sustainability, co-creation, prosumerization, etc.), as well as the attitude to manage and develop new innovative solutions to keep the pace of change (Gimpel and Westerman, 2012). Therefore, DT and BMI are vital challenges to look forward.

However, what is the real scenario of the tourism sector? Furthermore, why, how, and with which results, tourism organisations approach to DT and BMI?

Considering the study by Dredge et al. (2018) that examines the challenges and opportunities of digital innovation in tourism, the reasons leading organisations to approach to DT may be grouped into five categories.

The most relevant are those related to the search for improvement of the web presence and the growth opportunities. Then, other reasons are those related to the potential of digital innovation to exploit future opportunities and to find new solutions to face the seasonality as one of the critical challenges for tourism businesses. Then, the will of improving networks.

These reasons highlight the optimistic perception of digital innovation. Organisations seem to consider DT as a powerful solution enabling growth and performance improvement, in terms of cost reduction and satisfaction of the demand. Moreover, the willingness of improving networks reflects the importance that organisations pay to relationships, supply chains, and the establishment of a dialogue with the ecosystem's actors and customers.

Furthermore, organisations approaching DT and more in general Digital Innovation believe that investments on technologies will return in terms of the following typologies of benefits: Customer acquisition; improve online brand visibility; expand international reach; improve service quality; increase visitor satisfaction (Dredge et al., 2018).

In this regard, it is possible to state that DT enables BMI and the generation of new business models. Moreover, the careful implementation of digital innovation may improve the quality and accessibility of new products, services, and experiences.

In the specific, successful implementation of digital innovation in tourism may occur in examples of the resolution of problems like crowding or social distancing, especially during the Covid-19 pandemic. Mobile apps equipped with GPS or live assistance may suggest new, unusual and less beaten tourist paths. These solutions may also result in strategies to value rural areas, to generate new tourist destinations and/or to safeguard the cultural heritage (UNWTO, 2020).

Another relevant aspect coming out of Dredge et al. (2018) is the distinct organisations' attitude to digital innovation based on the internal levels of digitalisation. Organisations with a low level of digitalisation are only interested in improving internal processes and productivity. On the contrary, organisations with an adequate level of digitalisation, and so, those who have already experimented digital innovations implementation are aware of the resulting potential and impact. Therefore, they are interested in increasing the level of trying to pursue BMI to find new opportunities and generate innovative solutions.

It follows that a sort of roadmaps towards the complete digitalisation is pursued. However, a lack in terms of awareness of DT and innovation potential emerge as well. From the analysis emerged that the same awareness is an aspect that is developed ongoing. In fact, from the second step, organisations seem to be more open to understanding the potential of BMI, and they aim more frequently to extend and scale the business to a global level.

In this regard, it appears that the DT is more like a journey that requires a structured and gradual roadmap rather than an instant implementation. However, this is not an easy process, and it hides various risks, difficulties and barriers. The first of which is the lack of plenty of awareness of DT potential. It is indeed gained during the process exploitation. This, however, denotes a barrier deterring organisations, SMEs in particular, to program such investments.

In the following, a focus on the relevant barriers to digital innovation is proposed.

Freidouni et al. (2019) in their research, identify three main categories of gaps, linked to technology, productivity and regulatory.

The impact of digital innovation and technology advancement is acknowledged (Hinings et al., 2018; Schiuma, 2012). Latest inventions and the fast technological progress of the past years contributed to improve performance, reduce costs and waste, enhance communication, as well as the management. However, if technological progress has a positive impact on the market side, for companies, it may become a high barrier. Quality standards become higher; competitiveness is

rigid. Therefore, digital technologies became a dependency, a discriminating factor without which is even more challenging to compete. The required large investments penalise SMEs in particular and accentuate most the digital divide between large and small companies. The same logic is replied in the tourism destinations scenario. There, small and secondary destinations denote more difficulties in keeping the pace of change and implementing required digital solutions.

This divide is moreover accentuated by the ability to manage data and knowledge, that in the current business landscapes, are the factors which are influencing most the productivity (Carlucci et al., 2004; Schiuma, 2012). Tourism digital platforms, for example, have entered disruptively the market thanks to their capacity to manage data and orient decisions to meet the demand better. Therefore, companies, as well as destinations, that will continue keeping a traditional management system ignoring the change in demand, context and processes, will be locked out of the market. The World Economic Forum (2019) in fact, estimates a loss of 940.000 jobs in the hotel industry in the next ten years due to change in consumers behaviours. Travellers prefer apartments and short terms of staying rather than a traditional hotel. Therefore, without the innovation of business models to adapt businesses to the new demand, the whole industry will suffer from a massive crisis. In this regard, the recurring to digital platforms or tools, allowing the analysis of data may support companies in anticipating trends and adjusting the offer before the crisis.

Ascertained the strategic relevance of DT, the difficulties in implementing this process are sometimes accentuated by the regulatory system that does not follow the same pace of technological progress. New services made possible by new emerging technologies are not yet disciplined by the law because they are facing issues never treated before. Therefore, some services are perceived as dangerous, and their development is heavily slowed down.

On the contrary, for relatively new services like the e-commerce whose regulatory has been disciplined, rules appear stricter and challenging to be followed by the SMEs that are so forced to desist in strengthening their turnover.

Another relevant obstacle on which SMEs, in particular, occur and that is strictly related to the lack of awareness of the potential of DT, is the need for training to learn how to exploit and manage a new technology once it has been introduced in the company (Dredge et al., 2018). New technologies require dedicated technical skills and competencies that often SMEs lack. So, training sessions are

necessary to understand how technologies work, but at the same time also to approach the right technology and to divulge it, as well as involve the entire company in the implementation and diffusion process. Therefore, the training should be considered as a deterring barrier for organisations that also lack time and finance to execute this activity.

Especially when a company does not understand the importance and potential of DT, it perceives the expense required as a cost rather than an investment. Then, considering that SMEs, often family-run highly populate the tourism sector, the lack of financial resources joined to the lack of awareness and knowledge on this topic are the biggest stumbling block.

Besides, these obstacles are followed by the 'We have always done in this way' syndrome (Zimmerman, 2019) that affect those companies who believe that their current level of digitalisation is enough. Companies declare that, without any analysis or benchmarking activity.

This is an intangible obstacle that may have a crucial impact on organisations who do not have a clear vision and lack of context analysis. This because the real key challenge for companies is business, and the improvement of productivity, not the mere digitalisation. It follows that DT, in this scenario, is the recommended path to achieve competitive advantage.

Moreover, the rapid pace of change and the fast evolution of digital solution decrease the technologies' lifecycle and make easier their obsolescence undermining the efficacy of the investments. Therefore, understand the right technology for the business and the right level of digitalisation is a delicate challenge that requires qualified support.

## **5 Discussion – Supporting and Fostering Digital Transformation and Business Model Innovation in Tourism**

DT and BMI are essential for organizations competing in this particular business landscape (Berman 2012; Schallmo et al., 2017). These processes favour the enhancement of productivity, performance, as well as the implementation of product, process and business models' innovations that are otherwise impossible to achieve. However, tourism innovation is not an easy process. On the contrary, it entails risks, and it is affected by barriers, difficulties and obstacles mining the exploitation.

From the literature, a lack of knowledge and awareness of the potential of investments in this field has emerged. Besides, costs for change, training and technology implementation proved to be high for most of tourism SMEs. All the more if these costs are linked to the abovementioned lack of awareness.

However, DT is not only about technology (Nonaka and Takeuchi, 2019). The fast development of digital technologies and solutions, raise the efficiency standards, increase the speed of market dynamics, and decrease the product lifecycle (Schiuma, 2012). Moreover, consumers are evolving in prosumers aiming at getting engaged in co-creation processes of products, services, and experiences. Their needs and habits are changing, as well as the ways and speed of exploiting goods. Therefore, innovation rapidly and easily becomes joint and replaced by new emergent innovative solutions. It follows that organizations operating in the digital ecosystem have to become resilient, proactive and able to evolve in the same way the competitive landscape does. Innovation, then, must be recurrent, cyclical. Continuous innovation is required and has to be pursued through a holistic engagement of the whole organization, stakeholders, and customers, rather than just of top management and dedicated facilities. Each actor engaged in innovation must be aware of the organization's vision, goals, and strategies in order to be able to effectively contribute and generate value (Lianto et al., 2018; Nonaka and Takeuchi, 2019).

Moreover, innovation is increasingly digital and data-driven, and frequently organizations have to embark on a digital innovation journey and not without problems.

The fast development of digital technologies contributes to the generation of a high amount of data, information, and knowledge that increase even more the innovation barriers and accelerate the pace of change. To effectively understand and manage technology, codify and exploit generated knowledge, specialized skills and new governance models are required (Joshi et al., 2010). However, even if equipped with high tech infrastructure, and skilled staff, current innovation actors, like R&D labs, or innovation centres, are not able anymore to sustain and enhance the innovation capacity of companies (Capgemini, 2017). These environments are still conceived as separate entities and are not able to guarantee a stakeholders' commitment and a prolific dialogue with the entire organization. Employees, due to a mismatch in terms of digital skills and awareness, are not able to understand the reasons and potential of new technology implementation and shift.

Digital innovation, indeed, is not only about technology innovation. It is more about the innovation of knowledge and cultural attitudes. Therefore, a further challenge in the digital ecosystem is the promotion and definition of conditions, roadmaps and management models for the implementation of digital innovation strategies, to manage digital knowledge and foster continuous innovation (Bharadwaj et al., 2013; Nonaka and Takeuchi, 2019). A mindset, therefore, composed of skills and attitudes necessary for the management of new digital solutions that, in the future, will be even more numerous and frequent, is required. Furthermore, companies used to invest in technologies and processes to generate and develop new digital solutions. For these organizations often concerns do not arise regarding the accompanying of these activities with BMI ones. However, if a new technology were introduced in a new market through two different business model, it leads to completely opposite results. Therefore, it emerges the importance of investments in innovation capacity development in order to manage these technologies and innovate organizations' business models to face context changes and continuously new digital solutions. What is needed is then a digital innovation capacity understood as the attitude to innovate and managing digital innovations.

### Abstract

The paper examines the role of Public Innovation Labs (PILs) in facilitating the adoption of Artificial Intelligence (AI) in Public Administrations (PAs) and promoting the principles of Society 5.0. PILs are viewed as an essential management model that integrates an organizational initiative and management toolbox to support the implementation, adoption, and exploitation of enabling technologies, with a particular focus on AI, to improve sustainable value creation dynamics, social innovation, and the transformation of cities and communities.

Although many organizations have experimented with innovation labs, there is a lack of understanding of their role, governance models, working mechanisms, and adopted tools in the public sector. PILs offer a space for experimentation and collaboration where PAs can gather feedback from citizens to identify and implement solutions that meet their specific needs, facilitating the adoption of AI in PAs.

The paper conducts a case study of a PIL identified as a best practice in supporting PAs in implementing AI-based solutions to improve the urban context and the life quality of communities. The study outlines the management principles of a PIL and provides a roadmap, guidelines, and policy directions to foster the diffusion of PILs among PAs interested in becoming data-driven organizations.

Overall, the research contributes to understanding the critical role of PILs in facilitating the implementation of AI in PAs and fostering the adoption of Society 5.0 principles in the public sector. The study provides insights into the benefits and challenges of implementing AI in PAs and how PILs can support overcoming these challenges and realizing the potential benefits. The paper emphasizes the importance of human-centric and user-driven

approaches and enabling technologies in tailoring the offer of services and products, improving performance, and creating value for people and communities.

## 1 Introduction

In recent years, there has been a growing interest in investigating and identifying management models that follow human-centred and user-driven principles and that exploit enabling technologies to understand the needs of users, people, and communities and accordingly tailor the offer of services and products and improve performance and create value (Santarsiero et al., 2021; Schiuma et al., 2021). This need has become more and more recurrent among Public Administrations (PAs), which often show a reluctance to digital transformation due to a lack of cultural mindset and digital skills, and often incur huge investments to implement transformation processes of cities that, however, turn out to be unsuccessful and do not respond to the real needs of communities (Brunetti et al., 2020; Mittal, 2020). In this perspective, Public Innovation Labs (PILs) can be poised to become a ubiquitous part of the social infrastructure of modern societies. A PIL is configured as an environment of technological experimentation and creative cross-fertilisation that, following human-centric and user-driven approaches, supports organisations in implementing and exploiting enabling technologies facing the real needs of users and communities and fit the application context (Carstensen and Bason, 2012; Lewis and Moultrie, 2005). Despite many organisations experimenting with adopting management initiatives that can be interpreted as innovation labs, the phenomenon is still understudied significantly in the public sector. There is a lack of understanding of their role, working mechanisms, governance models and adopted tools (Memon et al., 2018; Osorio et al., 2019; Schmidt and Brinks, 2017). The paper proposes the PILs as a valuable management model integrating an organisational initiative and a management toolbox to support the implementation, adoption and exploitation of enabling technologies, with a particular focus on the role of Artificial Intelligence (AI) to supporting PAs in improving sustainable value creation dynamics for urban purposes, social innovation and fostering the transformation

of cities and communities according to the principles of society 5.0, based on innovative, human-centric, resilient and sustainable processes. The idea behind PILs is to create a space where PAs can experiment with new technologies and gather feedback from citizens to identify and implement the solutions that best meet their needs. This approach allows PAs to go beyond a one-size-fits-all approach, which can be detrimental for both citizens and PAs, and instead create custom solutions that truly meet the community's specific needs (Wirtz et al., 2019). PILs play a crucial role in facilitating the implementation of AI in PAs by assuming a coordinating role and becoming a tool to support the public sector for urban purposes and social innovation (Shneiderman, 2020). The ability of AI to process large amounts of data and make predictions about future events makes it a powerful tool for PAs, which can be used to improve service delivery, decision making and overall efficiency of the public sector (Bock et al., 2020; Girasa, 2020). However, implementing AI in PAs can be challenging, as it requires a deep understanding of the community's specific needs and the ability to communicate and collaborate with citizens effectively. PILs, by providing a space for experimentation and collaboration, can help bridge this gap and facilitate the implementation of AI in PAs. This paper focuses on exploring the role of PILs in facilitating the adoption of AI in PAs with a specific focus on the role of AI in society 5.0. Society 5.0 is a vision for a future society in which advanced technologies such as AI, big data, and the Internet of Things (IoT) are used to create a more sustainable, resilient and human-centric society. The paper, after a literature review of PILs aimed at understanding their role, working and management mechanisms, will conduct a case study of a PIL identified as a best practice that supports PAs in the implementation of AI-based solutions to foster value creation dynamics, social innovation and to improve the urban context and the life quality of communities. This will make it possible to outline the management principles of a PIL and to define a roadmap, guidelines and policy directions to foster the diffusion of the phenomenon among PAs willing to become data-driven organisations and interested in exploiting technologies to make wiser AI-supported decisions that align with the principles of society 5.0. Furthermore, the case study will provide insight into the benefits and challenges of implementing AI in PAs and how PILs can support overcoming these challenges and realising the potential benefits. Overall, this research will contribute to understanding how PILs can play a crucial role in facilitating the

implementation of AI in PAs and fostering the adoption of society's 5.0 principles in the public sector.

## **2 Theoretical Background**

The widespread adoption of AI has led to the emergence of Society 5.0, a human-centred society that aims to solve social challenges and promote economic growth using AI and other technologies. Society 5.0 focuses on achieving seamless integration between cyberspace and physical space by harnessing AI, big data and the Internet of Things (IoT) to create a more efficient and smarter society. However, the adoption of AI by governments presents a unique set of challenges. Sun and Medaglia (2019) conducted a study on the challenges of implementing AI in the public health sector and identified several key issues, including data quality, lack of technical expertise, privacy concerns and ethical considerations. These challenges are not limited to the healthcare sector and can be observed in different areas of public administration.

The implementation and adoption of AI in the public sector remains limited, despite the potential benefits of AI in public services. The lack of clear policies and regulations, limited technical capacity and limited financial resources hinder the successful implementation of AI in public services, as noted by Misuraca and Van Noordt (2020). Furthermore, the use of AI in the public sector raises several ethical issues, including transparency, fairness and accountability. The use of algorithms in decision-making processes, such as recruitment and public safety, can perpetuate bias and discrimination. Lack of transparency in the development and use of AI models can limit public trust in government decision-making.

The challenges of implementing AI in the public sector require careful consideration and management. Governments must prioritise the development of clear policies and regulations, invest in technical skills and capabilities, and address ethical issues to ensure that the benefits of AI can be fully realised in the public sector.

There are four focus areas in which PAs can engage to play a crucial role in fostering the adoption of AI in Society 5.0. First, there is a need to foster the creation of ecosystems that promote AI innovation, bringing together researchers, policymakers, practitioners and citizens to collaborate on the development of AI-based solutions. Secondly, there is a need to facilitate knowledge sharing among the various stakeholders of Society 5.0 by creating

platforms for the exchange of information and best practices. Thirdly, there is a need to set up test beds for new AI applications and to help create ethical and accountable, transparent and responsible AI systems. Finally, there is a need for approaches that can act as facilitators of public-private partnerships that promote the adoption of AI in Society 5.0, bridging the gap between governments and businesses.

In this context, PILs can play a crucial role in addressing these challenges and taking advantage of these opportunities. PILs are management models that focus on promoting innovation in the public sector. PILs can provide an environment for experimentation and innovation, where new ideas can be tested and refined. They can also provide a platform for collaboration among different stakeholders, including government, industry, and academia.

PILs can help governments develop and implement human-centric AI-based services, ensuring that AI is used to enhance the quality of life for citizens. PILs can also help governments adopt the Government as a Platform approach, by providing a platform for collaboration and knowledge-sharing among different governments. PILs can support governments in making strategic use of public procurement, by facilitating partnerships between governments and industry.

Finally, PILs can play a critical role in safeguarding fundamental rights in AI-based public services and protecting societal infrastructures. Misuraca and Van Noordt (2020) highlight the importance of ensuring trustworthy AI in the public sector, as there are concerns around the potential for AI to perpetuate biases and discrimination, and to violate privacy and other human rights. PILs can act as a testing ground for AI-based public services, allowing for the evaluation of the impact of AI on fundamental rights and societal infrastructures. Additionally, PILs can promote transparency and accountability in AI-based decision-making by ensuring that citizens have access to information about the algorithms used and the data collected.

### **3 What is Public Innovation Lab?**

A Public Innovation Lab (PIL) is a term used to describe a diverse range of organisations that are tasked with promoting innovation and fostering the development of new ideas in the public sector. According to Schuurman and Tönurist (2017), PILs are "change agents" that operate with a high degree of autonomy and are structurally set apart from the rest of the public sector. PILs are

dedicated "safe" spaces where experiments with policy ideas and innovations can take place (Carstensen and Bason, 2012). PILs are experimental in nature and are ongoing structures that use experimental methods to address social and public challenges (Puttick, 2014). PILs vary significantly in their proximity to executive power, with some centrally located within the executive branches of government, while others sit between multiple government agencies and departments or operate as non-governmental organisations contracted to work on policy and public sector innovation. While the term PIL may be indeterminate and often used interchangeably with other terms, such as government innovation labs or social innovation labs, what distinguishes PILs is their use of novel experimental methods. PILs employ different methodological approaches, including user-centred design, new analytical techniques in data science, randomised assignment experiments, and behavioural insights. Therefore, PILs are "ideational institutions" or "experimental R&D lab[s] for solving the social and public problems that vex governments" (Williamson, 2015). PILs are becoming increasingly popular worldwide, with PILs emerging in different contexts, such as the MindLab in Denmark, the Behavioural Insights Team in the United Kingdom, and the Office of Innovation in the United States, among others.

The PILs' distinguishing characteristics described in the management literature, allow to conceive these peculiar labs as innovation management models based on the construction of an innovative space – physical, virtual, hybrid, relational – on the definition of dedicated time for innovation; and on the development of a platform that contemplates tangible and intangible infrastructure dimensions (Schiuma and Santarsiero, 2023). They can drive the organisation in finding the best ways to generate knowledge and digital culture, in introducing technology, digitising operations and implementing digital strategies for continuous and digital innovation.

The management cycle of PILs can be divided into five critical phases (Santarsiero et al., 2021): focusing, engagement and enabling, developing innovative solutions, delivering and application support, and reviewing and consolidating. The first phase, "focusing," involves defining strategic intentions, developing a shared vision, and identifying necessary resources to develop a project plan. The second phase, "engagement and enabling," focuses on activating facilitation mechanisms to engage users and encourage a working atmosphere that reduces hierarchy, provides stimuli to empathize with given challenges, and stimulates creativity and innovation. Additionally, the innovation

lab may act as an innovation intermediary to build communities and partnerships with various stakeholders, according to users' needs and pursued innovation goals. The third phase, "developing innovative solutions," begins once the challenges and objectives have been addressed. During this phase, traditional innovation management stages are followed to transform ideas into solutions or to develop innovative skills and mindset in users. Innovation labs should provide services such as mentoring, coaching, or facilitating sessions with final users to gain feedback and control the risk of failure. Tools, equipment, and technologies for testing and prototyping should be made available under assistance. After the innovation development, the fourth phase, "delivering and application support," is aimed at delivering and/or applying the generated value. In this phase, innovation labs provide consulting or mentoring services, assisting users in activities such as developing time-to-market, go-to-market, or growth hacking strategies, codifying learned knowledge, or improving routines. Additionally, innovation labs may play a strategic role in building bridges between companies and markets. The final phase, "reviewing and consolidating," involves reviewing activities carried out and reflecting on final results. Insights are detected from comparing final results with initial objectives, from which new innovation activities and strategies can be designed and learned.

#### **4 Public Innovation Lab for the adoption of AI in Society 5.0 – Insights from a case study**

##### ***4.1 Methodology***

This study uses a case study analysis approach to examine the Smart Government Innovation Lab (SGIL) in Hong Kong as an example of a Public Innovation Lab (PIL) for Artificial Intelligence (AI) adoption in the public sector (Yin, 2009). The case study methodology allows for an in-depth exploration of the SGIL's role in promoting AI adoption in the public sector, as well as its effectiveness in achieving the goals of Society 5.0.

Data collection methods included secondary data sources such as website materials, government reports, and media coverage (Myers, 2013). The selection of the SGIL as a case study was based on its prominence as a PIL for innovation in the public sector, as well as its focus on AI and related technologies. The SGIL was established in 2016 by the Hong Kong Special Administrative Region Government

with the aim of promoting innovation in the public sector and developing new technologies for public service delivery.

The analysis approach involved an examination of the SGIL's organizational structure, its functions and activities, and its impact on AI adoption in the public sector. The effectiveness of the SGIL's approach was evaluated by considering its alignment with the recommendations from the European Union's AI Watch report, including the provision of human-centric AI-based services, the government as a platform approach, the strategic use of public procurement, and the safeguarding of fundamental rights in AI-based public services.

The Smart Government Innovation Lab in Hong Kong provides a valuable case study for the examination of the potential of Public Innovation Labs for AI adoption in the public sector. However, the case study is limited by the availability of secondary data sources and may not provide a comprehensive picture of the SGIL's activities and impact. Future research could benefit from incorporating primary data collection methods such as semi-structured interviews with stakeholders involved in the SGIL's activities.

#### **4.2 Research Context**

The Smart Government Innovation Lab HK (SGIL) was selected as the case study for this research. SGIL was established in 2016 by the Government of the Hong Kong Special Administrative Region (HKSAR) with the aim of providing a collaborative platform for government departments to test and develop innovative digital solutions. SGIL operates under the Office of the Government Chief Information Officer (OGCIO) and is supervised by a steering committee comprising senior officials from various government departments.

SGIL's activities are guided by its mission to enhance public services through innovation and technology, and to promote the development of a smart city in Hong Kong. The lab focuses on four main areas: artificial intelligence, smart mobility, digital government, and Internet of Things (IoT). SGIL aims to promote the adoption of innovative technologies by facilitating collaboration between government departments and industry partners.

SGIL has initiated several projects that leverage AI technologies to improve public services in Hong Kong. One such project is the Chatbot Framework, which was developed in collaboration with Microsoft Hong Kong. The framework enables government departments to easily create and deploy chatbots to

enhance their service delivery. Chatbots have been deployed in various departments, such as the Immigration Department and the Customs and Excise Department, to provide round-the-clock assistance to the public.

Another project is the Smart Traffic Management System, which utilizes AI to improve traffic flow and reduce congestion in the city. The system is able to predict traffic volume and adjust traffic signals accordingly, thereby reducing waiting times and improving the overall efficiency of the road network.

SGIL has also developed the Anti-Mosquito Robot, an AI-powered robot that can detect and eliminate mosquito breeding sites in public areas. The robot has been deployed in various locations across Hong Kong, including parks and housing estates, to help combat mosquito-borne diseases.

#### **4.3 Research Results**

The Smart Government Innovation Lab (SGIL) is structured around the five phases of the Public Innovation Labs (PIL) management model. In the first phase, the focus phase, the SGIL identifies priority areas for innovation and challenges to be addressed through collaboration with public sector stakeholders such as government departments, non-governmental organisations and universities.

In the second phase, the engagement and enablement phase, the SGIL encourages collaboration among stakeholders and provides support to enable innovation by organising events such as workshops and seminars, and providing a platform to share ideas and experiences.

In the third phase, the development phase, the SGIL supports the development of innovative solutions by providing resources such as funding, expertise and access to data. The lab also works with stakeholders to design and test prototype solutions, ensuring that they meet the needs of end users.

In the fourth phase, the delivery and application support phase, SGIL helps to implement and scale the solutions developed in the lab. This involves working with stakeholders to ensure that the solutions are integrated into existing systems and processes, and providing ongoing support to ensure that they work properly.

In the fifth and final phase, the review and consolidation phase, the SGIL assesses the impact of the solutions and identifies opportunities for further improvements. This involves collecting feedback from stakeholders and conducting reviews to assess the effectiveness of the solutions in solving the identified challenges.

The SGIL team consists of experts from various fields, including information technology, engineering, and business management, who work together to develop innovative solutions to public sector challenges. The lab also partners with academic institutions and private companies to access the latest technologies and expertise. This collaborative approach enables SGIL to access a wide range of knowledge and resources to develop effective solutions.

The adoption of AI in public services has resulted in several benefits for the government and citizens. For example, the AI Chatbot Service has reduced the need for human customer support, resulting in cost savings and faster response times. The STMS has improved traffic management, resulting in reduced congestion and improved safety on the roads. The use of AI in public services has also created value for citizens by providing more convenient and accessible services.

Moreover, the use of AI has enabled government departments to reduce costs and increase efficiency in their service delivery. Chatbots, for instance, have enabled departments to handle a larger volume of inquiries without the need for additional staff. The adoption of AI has also enabled the government to provide more personalized and effective services to the public. Chatbots are able to provide customized responses to user inquiries, based on their specific needs and preferences. Lastly, the adoption of AI has created value for society by improving public health, reducing traffic congestion, and promoting the development of a smart city.

In conclusion, the Smart Government Innovation Lab in Hong Kong has successfully demonstrated the potential of public innovation labs in promoting the adoption of AI in government operations. By adopting a human-centric approach and partnering with academic institutions and private companies, SGIL has successfully developed innovative solutions to public sector challenges. The adoption of AI in public services has resulted in several benefits, including cost savings, increased efficiency, and improved service quality. However, the use of AI in public services also poses challenges, such as the need to ensure transparency, accountability, and fairness in decision-making. Therefore, it is essential to continue evaluating and improving the use of AI in public services to ensure that it is used responsibly and effectively for the benefit of society.

## 4 Conclusions

The adoption of AI in Society 5.0 requires a solid innovation strategy, and PILs have emerged as a promising approach to achieving this goal. PILs have the potential to foster innovation in the public sector, and their collaborative spaces provide an opportunity for public, private, and community stakeholders to co-create innovative solutions to societal problems. By leveraging the framework presented in this paper, PILs can effectively support the adoption of AI in Society 5.0 by implementing key strategies and best practices for successful implementation.

The case study of the Smart Government Innovation Lab in Hong Kong has demonstrated the benefits of using PILs in promoting innovation in the public sector through AI. The lab has successfully adopted AI to enhance the efficiency and effectiveness of public services, creating value for the society. However, the limitations of the case study should be noted, and further research is needed to explore the potential of PILs in different contexts.

The implications of our findings suggest that PILs can be a valuable tool for promoting the adoption of AI in Society 5.0. PILs provide a collaborative space that encourages experimentation and learning, and their evidence-based insights can inform policy-making processes.

This research suggests several areas for future research in this field. Firstly, it is necessary to further explore the role of PILs in promoting the adoption of AI in the public sector, and to investigate how PILs can effectively manage the adoption process. Secondly, it is important to examine the ethical and social implications of AI adoption in the public sector, and to develop policies and frameworks that ensure the responsible and equitable use of AI. Finally, it is necessary to explore the potential of AI in promoting citizen participation and engagement in the public sector decision-making process.

The results of this research can be used to inform and develop policies and programs aimed at promoting AI adoption in the public sector. In particular, the effective management practices of Smart LAB can serve as a model for other PILs looking to adopt AI in their operations. Additionally, the successful projects developed by Smart LAB can be used to demonstrate the value of AI adoption in the public sector to policymakers and the public. Ultimately, the adoption of AI in the public sector has the potential to transform the way governments operate, and to create more effective and efficient public services that better serve citizens.

Enrico Sicignano

Department of Civil Engineering  
University of Salerno  
Via Giovanni Paolo II, 132 - 84084 Fisciano (SA)

### Abstract

The European Agenda for Sustainable Development has set a target of 2030 to achieve 17 Sustainable Development Goals (SDGs) which are: 1: Eradicate poverty; 2: Eradicate hunger; 3: Health and wellbeing; 4: Quality education; 5: Gender equality; 6: Clean water and sanitation; 7: Clean and affordable energy; 8: Decent work and economic growth; 9: Business, innovation and infrastructure; 10: Reducing inequalities; 11: Sustainable cities and communities; 12: Responsible consumption and production; 13: Combating climate change; 14: Life under water; 15: Life on Earth; 16: Peace, justice and sound institutions; 17: Partnership for the goals (1/2 - 2/2) and 169 associated sub-goals. This contribution makes a reflection aimed at extending the concept and meaning of sustainability, to speak and bring into play - clearly and explicitly - other mental categories and values such as the human dimension of domestic and urban space, mathematical perfection, roots and historical memory as well as aesthetic quality. Citing some of Italo Calvino's *The Invisible Cities* therefore seemed appropriate and pertinent. To emphasise the importance of the role of memory and roots, reference is made to classical mythology to examine two emblematic figures: Ulysses and Aeneas.

**Keywords** – Sustainability, Memory, Roots, Aesthetics

**Paper type** – Academic Research Paper

### 1 Introduction

The 17 Sustainable Development Goals or Goals of the European Union to 2030 are a necessary but not sufficient condition. This contribution makes a reflection on extending the concept and meaning of sustainability to talk about and bring into play – clearly and explicitly – other mental categories and values such as the human dimension in both domestic and urban spaces, mathematical perfection, roots and historical memory, as well as the aesthetic quality that can be glimpsed again in some recent interventions both at a national and international level. It is

complexity that governs today's building process in all its phases, from the initial design to execution, testing, management and maintenance. The approach can only be multidisciplinary and transversal. The problems of architecture must be solved in a broader scenario that is no longer only strictly disciplinary.

## 2 Sustainability

From a political, social and economic point of view in the supranational dimension of the Member States, the European Agenda for Sustainable Development has set the achievement of 17 Sustainable Development Goals (SDGs) to 2030, which, as is well known, are: 1: Overcoming poverty; 2: Overcoming hunger; 3: Health and wellbeing; 4: Quality education; 5: Gender equality; 6: Clean water and sanitation; 7: Clean and accessible energy; 8: Decent work and economic growth; 9: Business, innovation and infrastructure; 10: Reducing inequalities; 11: Sustainable cities and communities; 12: Responsible consumption and production; 13: Combating climate change; 14: Life under water; 15: Life on Earth; 16: Peace, justice and sound institutions; 17: Partnership for the Goals (1/2 - 2/2) and 169 associated sub-goals that take into account different dimensions in a balanced manner. Each objective is then broken down into state of the art, programme implementation methods, actors involved, time and costs, expected results and objectives achieved, and verification and feedback. In particular, "Point 11 Sustainable Cities and Communities", the one that concerns us most closely, is divided into 10 Goals. Development is Sustainable when it is the intersection of four areas of sustainability: economic, social, environmental and institutional. This is a necessary but not sufficient condition.

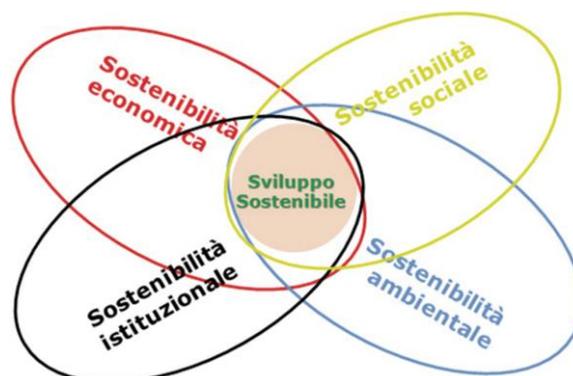

Fig. 1 - Sustainable Development

To be sufficient, at least three other values (but there are others) must come into play: aesthetic quality, the human dimension, roots and memory. Aesthetic quality is in turn attainable through two paths: beauty and exactitude, mathematical perfection. We also know that at very high levels, the two categories, the artistic and the scientific, touch each other, equate, sometimes they can be the same thing. Artifice and nature have always been two realities that are only apparently distant and separate, but in reality, they are inseparable; with artifice, art has always followed nature by imitating its laws, but also building its own autonomy. Thus, man's works are defined as works of art and works of genius if they have an aesthetic quality of beauty and mathematical perfection, even if achieved with special techniques.

### 3 Mathematical perfection

The golden number, identified by the Greek letter  $\phi$  (pne) and whose approximate value is 1.6180, is first mentioned by Euclid (4th-3rd century B.C.) in Book VI of the Elements. The golden number is found throughout the architecture of Greek temples, in the works of Leon Battista Alberti, Luca Pacioli (1509 De Divina Proportione), Piero della Francesca, Leonardo, and Albrecht Durer. The golden number is associated with the Fibonacci Series. The Golden Ratio and the Golden Number are held in high regard by Wolfgang Amadeus Mozart, just as it is present in the helical structure of DNA. For example, the nautilus is the natural manifestation of the golden spiral that underlies the architectural composition, both in plan and elevation, of the Parthenon, the most perfect building of all time. Similarly, Giuseppe Terragni re-proposes the golden spiral in the architectural version of the Divine Comedy, the Danteum, a work only designed. In the representation of Inferno, the circles follow one another according to the golden spiral, descending in landings that each have a column in the centre.

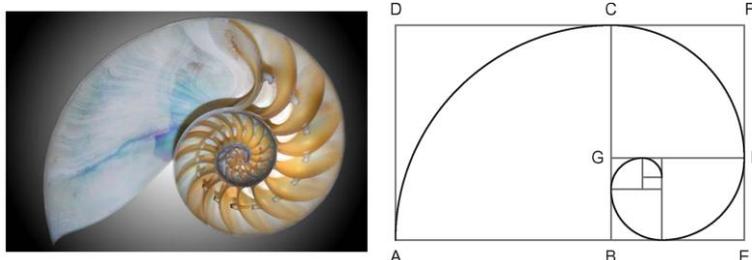

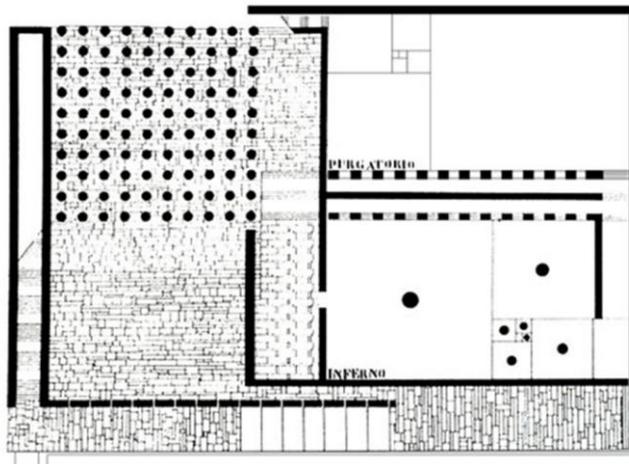

Fig. 2 – The Nautilus and the golden spiral

*Fig. 3 – The Parthenon (447-432 BC)*

*Fig. 4 – Danteum by Giuseppe Terragni (1938)*

The geometric construction is present in the work of Leon Battista Alberti who speaks of *concinnitas* which means refinement, elegance and, in the Renaissance, harmony. In the Malatesta Temple in Rimini, Leon Battista Alberti secretly and never mentioning the type of proportion uses the golden section as a recurring and permanent rule that dominates all his works and constructions. The classical inheritance lives again, in a changed guise and masterfully metabolised, in the thought and work of Le Corbusier, who sinks and finds all his poetics by excavating into the Hellenic world in search of an order and harmony that is always implied, subtended but present in all his works, both in architecture and painting, which can be found in the regulating traces of his Purist works. The Ville Savoye, the Maison a Garches, the Maison La Roche and the Villa Stein above all

are the physical, three-dimensional explication and embodiment of composition according to proportions, harmonic squares and rectangles and according to the golden section.

#### **4 The human dimension**

The other value is the human dimension of the space as it once was in the ancient Greek polis, both in the domestic space and in the urban space, in the public works, the agora, the temple, the acropolis, the theatre all interconnected and related to each other. To cite just one example, the space of the Forum of Pompeii with the Temple of Jupiter, the Basilica, the building of Eumachia has a human dimension, which the young Le Corbusier measures with his own steps and sketches to treasure his knowledge of the classical world and thus his own poetics. The domestic space of the House of the Vettii, elegant and stately is the same. Beyond the Greek and Roman worlds, even the medieval city, especially the Italian one, always follows the morphology of places, its narrow streets, alleys, glimpses, and its square with its church is on a human scale. The Italian piazza is the living room of the town and the city, where everyone loves to gather, to meet and there to have those 'non-economic' moments (as the French sociologist Emile Durkheim would say) that are so useful to the life of a person and a society. This is true not only for St Mark's Square in Venice, Piazza del Campo in Siena, Piazza Navona or St Peter's in Rome, but also and above all for all the anonymous squares in thousands of towns, villages, historic centres and minor fabrics that are the 'crystallised memory' of those places.

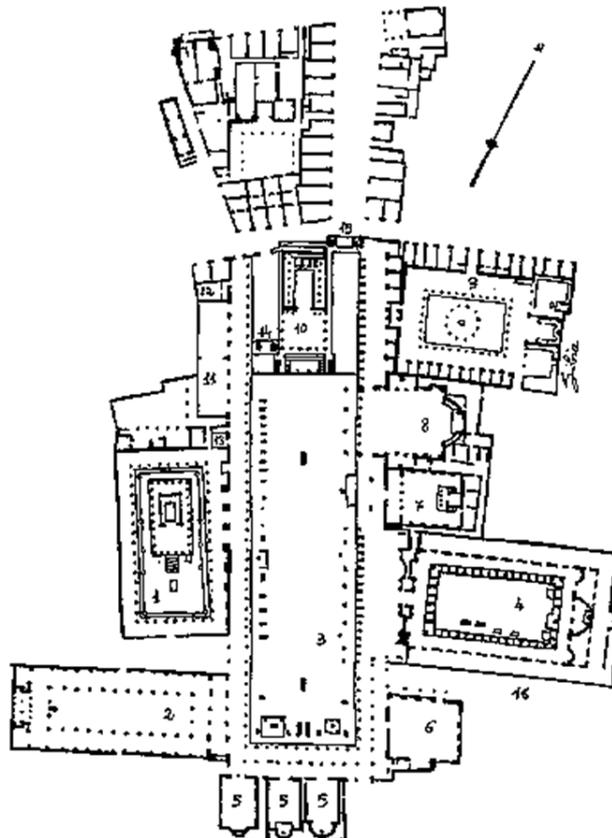

Fig. 5 - Forum of Pompeii

## 5 Roots and memory

Urban space on a human scale was perpetuated in towns and villages for centuries throughout the Middle Ages, the age of the Communes, and the Renaissance. The Italian situation is then unique. Historical memory is enriched with new values, grows, modifies itself without ever forgetting the root. The Roman amphitheatre of Lucca is the maximum in this sense, with the settlements and stratifications that have taken place over the centuries but respecting the Roman layout of the amphitheatre, its geometry in plan, its ellipsoid shape. For climatic reasons (we have no deserts, no unexplored Amazonian forests, etc.) the Italian situation also witnesses the anthropisation of the landscape. While the city designed on the drawing board is not a city born and developed spontaneously; it is dropped from above with precise forms where axes and paths predominate. This is the case of Palmanova, but also of the utopian cities of Owen and Fourier,

the city of Chaux or Brasilia, the new capital of Brazil by Lucio Costa, Oscar Niemeyer, Rino Levi, Roberto Burle Marx, where everything is designed in a monumental manner and on a large urban scale.

*Fig. 6 - The town of Palmanova (1593)*

Chandigarh, the capital of the Indian state of Punjab, is no less impressive with important works and institutional sites such as the Parliament, the Capitol, the seat of the High Court of Justice, the Secretariat, the Art School, the Nautical Club, all designed by Le Corbusier. Large spaces and different road networks, public, private, squares, water tanks characterise the complex, but where what is missing is precisely and above all the human dimension. A built utopia and mega-structure is The Unité d'Habitation in Marseille designed by the same Swiss-French Master, conceived as a small self-sufficient city, suspended on pilotis, with all services, a kindergarten on the roof, etc. Nowadays, it is fashionable and chic to live there but as soon as it was finished it remained empty for three years because nobody wanted to go and live there.

*Fig. 7 - The Unité d'Habitation in Marseille by Le Corbusier (1952)*

It has the same number of inhabitants as a medieval village. In some contemporary cities and metropolises, the memory has been completely erased because the infrastructure, the motorway networks, have taken over and obeyed only the iron laws of efficiency and safety. In *The Invisible Cities*, Italo Calvino, with regard to the relationship between the city and desires, describes Zenobia as follows: " Having said this, it is pointless to establish whether Zenobia is to be classified among the happy cities or among the unhappy ones. It is not into these two species that it makes sense to divide the city, but into two others: those that continue, through the years and mutations, to give their shape to desires and those in which desires either succeed in erasing the city or are erased from it'. Having lost the relationship with memory, or the relationship it never had with memory, the contemporary city has become a city of fear due to the coexistence of millions of people, the loss of quality of life and deteriorating relationships, social conflict, unease, marginalisation. Crime and violence proliferate. This explains Stanley Kubrick's 1971 film 'A Clockwork Orange', the sad and painful outcome of a sick society that has lost values. Anthropological and social degeneration also takes shape in the degraded urban suburbs where, in some of them, memory, urban and architectural aesthetic quality, and the dignity of people and places have never existed. Among the many places that can be mentioned, certainly and by way of example, it is worth mentioning the Vele of Scampia in Naples, a degraded suburb where the failure of the utopia of Naples, of its alleys and social solidarity was consummated, transformed, abandoned to

itself and to its fate, into a hallucinating and gruesome nightmare masterfully witnessed by the film Gomorra. Cities can also be impossible or unlivable. Diego Lama has ironically drawn 'Città di china', a set of extraordinary sketches of how the city should not be (windy city, city of the splitter, city with archaeological constraints, etc.) exasperating the negative and worst sides of a city and its citizens. It is our duty as educators, teachers, critics, and professionals to say yes to energy efficiency, renewable sources, NZEB, and near-zero consumption buildings, but what should never be lacking, in a discourse of broader sustainability, is the quality of architecture, in which the words and concepts of aesthetics, mathematical perfection, exactitude, beauty, roots, memory, and creativity converge. The new law of the Campania Region, no. 19/2019, for the first time incentivises and advocates the quality of architecture in public and private works to once again affirm the centrality of the project in the processes of recovery, reuse, redevelopment, restoration and new one. Quality can again be glimpsed in a number of recent interventions both nationally and internationally where it is now complexity that governs the building process in all its phases, from initial design to execution, testing, management and maintenance. Moreover, the approach cannot but be multidisciplinary and transversal to several fields, as in the intriguing and beautiful recent project of the 'Bosco Verticale' in Milan by Stefano Boeri, where energy, technical physics, and botany issues are well combined with architecture, structural engineering, and technological systems, also achieving an objective new aesthetic quality in building and urban design.

*Fig. 8 – Bosco vertical by Stefano Boeri (2009-2014)*

The project must be universal, designed for everyone and for a multi-ethnic society, open, dynamic, in progress. The problems of architecture must be solved in a broader scenario that is not only strictly disciplinary. The architectural project must strive to satisfy all the 17 Goals/Goals of Sustainable Development of the 2030 Agenda, without ever forgetting beauty, aesthetic qualities, roots, memory, the human dimension of which the historic Italian city remains an absolute model for all that it has contained among its stones for centuries. Once again Italo Calvino returns when he describes Zaira in 'The Invisible Cities': "Of this wave flowing back from memories, the city soaks up like a sponge and expands. A description of Zaira as it is today should contain all of Zaira's past. But the city does not say its past, it contains it like the lines of a hand, written in the corners of the streets, in the grills of the windows, in the handrails of the stairways, in the antennas of the lightning conductors, in the poles of the flags, each segment striped in turn with scratches, serrations, notches, twists."

## **6 Conclusions**

The black box of ancient Mediterranean civilisations and Western thought is mythology and myth telling. In it, I have always identified two existential archetypes, two protagonists, two behavioural models that we can thus relate to the above reflections. On the one hand, Ulysses who travels the sea for ten years; he fights against bullies; he overcomes all kinds of pitfalls; he resists the song of the Sirens; he falls in love with the beautiful and seductive Calypso; he witnesses the transformation of his companions into pigs by the Sorceress Circe; he blinds Polyphemus. The Odyssey is man's journey within himself and is not completed until these complex human experiences are concluded. Outside of myth and in normal, 'human' discourse, the relevant geographical distances could have been bridged in quite different times. This is not the case. In the myth, however, the journey lasts ten, long years. The return to his Ithaca is difficult and complex: the recognition only by the faithful dog Argos, the arcane question to Penelope linked to a marital secret to prove to her that it is indeed him, although tired and aged, the revenge and the killing one by one of the Proci who, taking advantage of his absence, took possession of his house, devastated and violated it; they undermined his wife Penelope, etc., In Homer, all this story begins and ends with him. It is only Dante who in the Divine Comedy (26th Canto of the Inferno) where sets Dante on a journey as far as the Pillars of Hercules (the present Strait of

Gibraltar), eager to go into the world of the unknown, and who reminds his sceptical and reluctant companions, calling them to follow him again "Consider your seed: you were not made to live like brutes but to follow virtue and knowledge". The Homeric Ulysses ends his journey and his life in Ithaca. And everything ends with him. On the other hand, we have another existential and behavioural archetype from classical mythology: Aeneas and we go straight to an extraordinary representation of him. In the sculptural group, a masterpiece by Gian Lorenzo Bernini, preserved in the Galleria Borghese in Rome; he carries his elderly father Anchises on his shoulders, who in turn holds the urn with the ashes of his ancestors (the Penates) and his young son Ascanius. He is fleeing from the flames, destruction and death of Troy in a complex and dangerous journey that leads him to the end and ends with the foundation of Rome as he is foretold by the Cumaean Sibyl in the cavern of the Sibyl at Cumae. This sculptural group simultaneously represents the past, the present and the future. It is the root that perpetuates itself and goes forward. It is a warning. And it is exactly what we should all do and never forget.

## Abstract

Although companies frequently make great efforts to encourage workers to share knowledge and voice concerns, many workers intentionally choose to conceal their knowledge rather than share it. This ‘an intentional attempt by an individual to withhold or conceal knowledge that another person has requested’ is called knowledge hiding. This review systematically reviews, categorises, and synthesises the current body of literature regarding knowledge hiding. The current literature is categorised based on methods, theories, research context, and geographical distribution. Secondly, the antecedents and outcomes of a KH across the different levels of analysis are mapped using an inductive approach. This thematic map offers a visual guide to KH, placing antecedents and outcomes at different levels of analysis and suggesting where future research in KH might be headed.

**Keywords** – knowledge hiding, knowledge withholding, literature review

**Paper type** – Academic Research Paper

## 1 Introduction

Knowledge is a core resource for organisations to gain and keep a competitive advantage (Barney, 1991; Grant, 1996). Studies in the past demonstrated that businesses with effective knowledge management could grow more quickly and are more competitive than others (Wang and Noe, 2010). Therefore,

organisations must encourage employees to share knowledge to get the best performance from their knowledge resources.

Although companies frequently make great efforts to encourage workers to share knowledge and voice concerns, many workers intentionally choose to hide their knowledge rather than share it (Prouska and Kapsali, 2021). In a survey conducted in the USA, 76% of participants acknowledged they had at one point hidden knowledge (Connelly et al., 2012). In a survey from China, 46% of participants said they had hidden knowledge that another person had requested in professional settings (Peng 2013). This ‘an intentional attempt by an individual to withhold or conceal knowledge that has been requested by another person’ (Connelly et al., 2012, p. 65) is called knowledge hiding (hereafter: KH).

Due to the significance of the subject, there has been a sudden increase of articles on KH in recent years (e.g. Khan et al., 2021; Zhang et al., 2021; Batistič and Poell, 2022; Hao et al., 2022; Guo et al., 2022; Donate et al., 2022; Sofyan et al., 2022). Recent empirical studies confirmed the negative effects of knowledge hiding on individual and organisational outcomes. For instance, diminished creativity (Feng et al., 2022; Chatterjee et al., 2022; El-Kassar et al., 2022), project and task performance (Zhang et al., 2022; Moin et al., 2022; Singh, 2019), innovative behaviour (Chen et al., 2022; Donate et al., 2019) and interpersonal deviance (Arain et al., 2022; Singh, 2019) are some of the problems caused by KH. KH may also have positive intentions or outcomes to protect the other party's feelings, maintain confidentiality, or advance the interests of a third party (Connelly et al., 2012). Existing studies have also begun to investigate situational and interpersonal antecedents of knowledge hiding, such as leader-member exchange (He et al., 2020; Zhao et al., 2019), moral disengagement (Khan et al., 2021), abusive supervision (Hao et al., 2022; Agarwal et al., 2022; Offergelt and Venz 2022; Wang et al., 2021), personality (Soral et al., 2022; Han et al., 2021) and job security (Nguyen et al., 2022; Shoss et al., 2022; Chhabra and Pandey, 2022).

We acknowledge three previous systematic literature reviews have been conducted (Siachou et al., 2021; Anand et al., 2021; Di Vaio et al., 2021). Although these systematic reviews examined KH, substantial research has accumulated in the last two years. At least 200 peer-reviewed articles have been published in only the business and management areas since the last reviews on this topic. This review is different from the review of Siachou et al. (2021) in its search scope: we used Web of Science and Scopus as databases instead of EBSCO and Science Direct; we have included other journals with 2 stars according to the Association

of Business Schools' Academic Journal Quality Guide 2021 and included additional search terms such as "knowledge detention" and "knowledge concealment" instead of general keywords "employee competitive behaviour" or 'counterproductive work behaviour". This work is also distinct from the review of Anand et al. (2021) with its inclusion of an additional database, WebofScience. This study is different from Di Vaio et al. (2021) review primarily because we extended search terms from knowledge hiding to knowledge hoarding, knowledge withholding, knowledge detention and other related terms. We have only considered articles exclusively focusing on KH instead of a general focus on knowledge sharing and knowledge management systems. Even though all these three previous systematic reviews have identified antecedents and outcomes of KH, no systematic review has offered a thematic analysis of KH antecedents and outcomes. The current review also includes additional analysis of context (the research setting), data analysis technique, and thematic evolution of KH research that other authors haven't offered.

Against this background, the aims of our review are threefold. First, we will categorise the current literature based on methods, theories, research context and geographical distribution. Secondly, we aim to map and evaluate antecedents and outcomes of a KH across the different levels of analysis using an inductive approach. Finally, we want to support and advance the theory development of KH. To this end, we systematically reviewed and categorised papers focusing on antecedents and outcomes of KH published between 2012 and 2022 in databases selected according to clearly specified criteria. Thus, our study offers a thematic map that provides a visual guide to KH, placing antecedents and outcomes at different levels of analysis. Based on these aims, we try to answer these research questions:

*(RQ1) What methods have been applied in the research?*

*(RQ2) What theories have been used in the research?*

*(RQ3) What are the antecedents and outcomes of KH at different levels of analysis?*

We begin this article by defining knowledge hiding and distinguishing it from other constructs such as knowledge hoarding, knowledge withholding and knowledge sharing. Then we summarise the method used in selecting and reviewing the literature and detail our search strategy, analysis, and evaluation of the studies reviewed. Following that, we present our findings of the SLR of the papers reviewed. After this, we discuss future directions for theory development,

methodology and content areas. We conclude by considering the limitations of our review and highlighting the paper's contributions to future research on KH.

## **2 Methodology**

Following our study purpose, we adopt a systematic literature review method. In order to gather relevant papers for a particular topic and to avoid bias, this systematic review follows a set of predetermined procedures as outlined by Tranfield, Denyer, and Smart (2003) and Kraus, Breier, and Dasí-Rodríguez (2020). This ensures that the review is reliable, comprehensive, and rigorous (Rousseau, Manning and Denyer, 2008). The procedure consisted of three steps: (1) planning the review, (2) carrying out the review, and (3) reporting the review.

### ***2.1 Planning the Review***

The study's criteria for selection were outlined in a protocol for the literature review. Scopus of Elsevier was used to build a database with relevant articles about KH in business and management studies. Compared to WoS, Scopus presently has more extensive coverage of the academic literature. The most recent Scopus fact sheet<sup>1</sup> from 2022 indicates that the database currently includes more than 25,800 active peer-reviewed journals, over 84 million records, and 1.8 billion cited references (dating back to 1970) in different fields. A thorough overview of the Scopus database may be found in a recent paper by Thelwall and Sud (2022).

Next, the authors found 634 articles from the Scopus database based on the abstract, title, and keywords. In the second step, the authors narrowed the results to only the business and management research areas. It yielded 369 papers published in Scopus databases. In step three, the authors only included articles published in scholarly journals to focus on reviewed research. As a result, 341 publications were identified in Scopus. In step four, articles published in languages other than English have been removed, leaving 339 papers. In step five, only articles published in peer-reviewed journals and graded 2, 3, and 4 stars in the Association of Business Schools' Academic Journal Quality Guide 2021 were selected for further examination. Thus, the dataset was reduced to 202 articles. In step six, the authors screened the titles, keywords, and abstracts of all remaining

<sup>1</sup> [https://www.elsevier.com/\\_data/assets/pdf\\_file/0017/114533/Scopus-fact-sheet-2022\\_WEB.pdf](https://www.elsevier.com/_data/assets/pdf_file/0017/114533/Scopus-fact-sheet-2022_WEB.pdf)

papers and excluded those that did not deal with KH or related terms despite prior filtering. As a result, after the screening process, the sample consists of 189 articles from 47 different journals. Table 1 displays the search and selection processes performed in December 2022.

Table 1. Search and selection

<b>Steps</b>	<b>Scopus</b>	<b>Web of Science</b>
Step 1. Identify relevant studies	n=643	n=476
Step 2. Include the articles in the subject areas Business and Management	n=373	n=284
Step 3. Include the studies that were articles or reviews or early access	n=345	n=271
Step 4. Include the articles in the English language	n=343	n=271
Step 5. Include the articles published in ABS journals ranked 2 or higher	n=204	n=175
Step 6. Remove duplicates	n=209	
Step 7. Exclude the studies based on titles, keywords, and abstracts	n=189	

## **2.2. Conducting the Review**

More thorough explanations of the methods used to locate relevant articles are provided in this section. The search string consisted of the keyword "knowledge hiding". We also searched for other articles where keywords such as "knowledge withholding", "knowledge hoarding", or "counterproductive knowledge behaviour" were used, as we wanted our initial sample to be as complete as possible. Despite using different terms, these articles might be about KH. The complete list of the keywords is adopted from previous systematic reviews by Anand et al. (2021) and Siachou *et al.* (2021).

Table 2. Search syntax in KH

Search terms
<i>TITLE-ABS-KEY ( "Knowledge Hiding" OR "Hiding Knowledge" OR "Knowledge Hoarding" OR "Knowledge Withholding" OR "Knowledge Detention" OR "Knowledge Concealment" OR "Non-sharing Knowledge" OR "Knowledge Sharing Barrier" OR "Knowledge Sharing Resistance" OR "Knowledge Sharing Disengagement" OR "Knowledge Sharing Obstruction" OR "Knowledge Sharing Hostility" OR "Knowledge Sharing Blockage" OR "counterproductive knowledge behav*"</i>

Table 3 provides a descriptive summary of the articles included in the present study. The articles involved were produced by 431 authors of which 55 articles were published by a single author, and 140 articles were published as part of a co-authorship.

Table 3. Summary of articles resulting from the searches.

Description	Results
Documents	189
Sources (journals)	47
Author's keywords	933
Period	2002–2022
Average citations per document	44.5
Authors	649
Authors of single-authored documents	16
Authors of multi-authored documents	633
Authors per document	3.43

### 2.3 Methods

First, a descriptive analysis of the database was performed to answer the research questions. In this analysis, each paper was categorised according to its year of publication, authors, journal (ABS ranking is 2 or higher than 2), number of citations, and country of origin, which was determined to be the country of the first author's place of employment. Next, we examined the selected papers to determine the main themes.

### 3 Results

This section shows (1) the chronological progression of the number of articles published as well as the number of citations and an overview of top-cited articles; (2) publication outlets, and (3) research methods.

#### 3.1 Analysis of findings by the number of articles.

Figure 1 shows the number of articles published and the number of citations by year. The average year of publication is 2020. There is a growing trend in terms of the volume of publications. Only in the last decade has there been an increase in interest in the area of KH in business and management studies. Since 2012, the topic has gained more attention and 85% (160 out of 189) of all articles studied in the current work were published within the last four years.

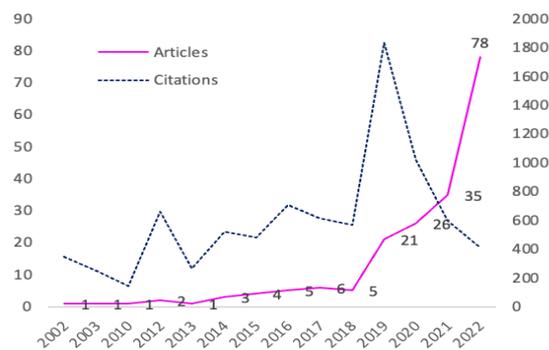

Figure 1. The number of articles published and the number of citations of published papers by year.

The publications included in this study received an average of 44.5 citations out of a total of 8405. Looking more closely, it can be observed that 18 articles (10%) had no citations, 46 articles (24%) had one to five citations, and 54 articles (29%) have been cited 50 or more.

Table 4 demonstrates the top 10 publications with the highest number of citations. 8 articles were published after 2012.

Table 4. Top publications in the KH in business and management studies

Article	Number of citations (WoS Core, if it's not available, then Scopus)
<b>Connelly C.E., Zweig D.</b> , Webster J., Trougakos J.P. (2012)	596
<b>Černe M.</b> , Nerstad C.G.L., <b>Dysvik A.</b> , <b>Škerlavaj M.</b> (2014)	414
<b>Husted K., Michailova S.</b> (2002)	345
Peng H. (2013)	265
<b>Connelly C.E., Zweig D.</b> (2015)	255
<b>Michailova S., Husted K.</b> (2003)	249
Serenko A., Bontis N. (2016)	246
Zhao H., Qingxia, He P., Sheard G., Wan P. (2016)	185
<b>Cerne, M;</b> Hernaus, T; <b>Dysvik, A;</b> <b>Škerlavaj, M</b> (2017)	179
Singh S.K. (2019)	163

The authors also organised the retrieved articles based on the first author's country (Table 5). As we can see, most of the articles are produced in China (63 articles), and authors from India (14 articles), Canada (14 articles) and Pakistan (13 articles) are the next most active researchers in the field.

Table 5. List of countries with the largest number of articles.

Country	No. articles	% of articles
China	63	33,33%
India	14	7,41%
Canada	14	7,41%
Pakistan	13	6,88%
United Arab Emirates	7	3,70%
Australia	7	3,70%
USA	6	3,17%
France	6	3,17%
United Kingdom	4	2,12%
Turkey	4	2,12%

### **3.2 Publication outlets**

As shown in Table 6, most of the articles were published in the Journal of Knowledge Management, accounting for 33% of the studies reviewed (see Table 5). Publications on KH in business and management appear to concentrate in a relatively small number of outlets, with the 3 journals comprising the number of articles making up over 53% of our sample.

Table 6. Journals with the largest number of articles related to studies of KH in the business and management area.

<b>Journals</b>	<b>No. of papers</b>	<b>%</b>	<b>ABS ranking</b>
Journal of Knowledge Management	62	32,80%	2
Journal of Business Research	30	15,87%	3
Journal of Organizational Behavior	9	4,76%	4
Management Decision	7	3,70%	2
European Journal of Work and Organizational Psychology	6	3,17%	3
Journal of Business Ethics	6	3,17%	3
International Journal of Contemporary Hospitality Management	5	2,65%	3
Journal of Managerial Psychology	4	2,12%	3
International Journal of Conflict Management	4	2,12%	2
International Journal of Hospitality Management	4	2,12%	3

### **3.3 Research methods used in the studies.**

Most (93%) of the remaining 189 articles present empirical work, and 7% feature conceptual/review papers. As illustrated in Table 7, the empirical research builds on qualitative methods in 11% of the cases and on quantitative methods in 89% of the cases. Some 3% of the articles utilise a mixed-method approach.

Table 7. Research methods used by studies (N = 189).

<b>Research methods</b>	<b>No. of papers</b>	<b>% of No.</b>
Qualitative	20	10,58%
Interviews	10	5,29%
Case-study	7	3,70%
Critical incident	2	1,06%
Mixed (interviews, observations)	1	0,53%
Quantitative	151	79,89%
Survey, questionnaire	142	75,13%
Experiment	1	0,53%
Diary	3	1,59%
Experiment and survey	4	2,12%
Expert opinion	1	0,53%
Mixed	5	2,65%
Interviews and surveys	2	1,06%
Case studies (interviews) and surveys	1	0,53%
Interview and focus groups	1	0,53%
Survey and quasi-experiment:	1	0,53%
Others	13	6,88%
Conceptual/SI review articles	4	2,12%
Systematic review/bibliometric analysis/meta-analysis	9	4,76%
Total	189	100%

#### 4 Thematic mapping of KH studies

KH in the workplace is influenced by various factors related to leadership, job characteristics, social resources, and the workplace environment.

- **Leadership factors.** Leadership style and leader-member relationship directly affect knowledge hiding in the workplace. Leaders who adopt a directive or controlling leadership style are more likely to induce knowledge hiding in their subordinates, and employees who have a weak relationship with their leaders may not trust them with confidential information (Feng et al., 2022; Koay and Lim, 2022; Agarwal et al., 2022; Scuotto et al., 2022; Oubrich et al., 2022).
- **Job characteristics.** Job autonomy, job overqualification, and job territoriality are job-related factors directly affecting knowledge hiding in the workplace. Employees with a high degree of job autonomy, are overqualified for their jobs or are territorial about their job responsibilities may hide knowledge from others (Singh 2019; Ma and Zhang, 2022; Shafique et al., 2022).
- **Social factors.** Social resources and job insecurity are social factors that directly affect knowledge hiding in the workplace. Employees with access to social resources, such as a supportive network of colleagues, are likelier to share knowledge than those without. Conversely, employees who feel insecure in their jobs may be less likely to share knowledge (Kmieciak 2023; Shoss et al., 2022; Wang et al., 2022)
- **Workplace environment.** Conflicts in the workplace, work ostracism, workplace bullying, negative workplace gossiping, competitive climate, organisational politics, and organisational justice are environmental factors that directly affect knowledge hiding in the workplace. Employees who experience workplace conflict or bullying may feel that sharing knowledge could put them in a vulnerable position. Similarly, employees who perceive a highly competitive or political work environment may be more likely to hide knowledge. Finally, employees who feel their organisation is unfair or just may be less motivated to share knowledge with others (Bhatti et al., 2023; Khan et al., 2023; Yao et al., 2020; De Clercq et al., 2022; Kaur and Kang, 2022).

### **Abstract**

Nowadays, we are facing a world in social and economic compulsion. Different kinds of crises and shocks in the economic and social systems crashed in our reality. This is creating a chaos and uncertainty environment among leaders, entrepreneurs and organizations. It is precisely in this moment of uncertainty that an innovator and resilient leader can identify new opportunities to integrate emotions around an organization. These innovators and leaders are struggling with this issue and sought ways of working and continue daily activities. In essence, these leaders are adding resilience into the organizational culture using two sides: rational and emotional sides of innovation. For that reason, understanding resilience and innovation as a symbiosis is a guide for modern organization. This relationship is a priority for many organizations, actors and governments in the current scenario of changing. Under this context, having an index that measures dynamics and main practices (rational and emotional sides) around a culture of innovation allows us to know and recognize how does our organization resilience react front a major economic impact. In the case of the study, the application of the instrument was carried out during the months of September to December 2022 to 177 managers and/or founders of small and medium-sized companies in the state of Guanajuato, México. We use a Partial Least Square Equation Model (PLS-SEM) methodology to prove validity into relationships and sample size. We draw on our findings detecting that managers mostly are focused on the rational side of innovation (resources, processes and successes) and less on the emotional side (values, behaviours and work environment). This finding provides an opportunity to improve this emotional side of innovation, because this is a core element to enhance

resilience in organization. We recommend further development and evaluation of future approaches about leadership, innovation and resilience.

**Keywords** - innovation, resilience, emotional, SMEs, management.

**Paper type** – Practical Paper

## **1 Introduction**

Innovation is a key element for survival and for developing a competitive advantage from over competitors (Arenhardt et al., 2018). COVID-19 pandemic showed us how the capacity of adaptation of a company to innovate made a difference in survival and future relationships with customers and other actors in the ecosystem. We believe that during a crisis (real or perceived) innovation's culture of a company activate two sides during adaptation process, integrating emotional and rational sides.

For that reason, having an analysis of the dynamics and practices about innovation during a crisis would develop a future index that measure of innovation in this integrality of emotional and rational sides and how affect resilience in an organizational environment. This allows us to know and recognize different effects on resilience strategies depending on innovation.

The objective of this research is to analyse how dimensions of the innovation culture of a company integrates an index with two sides: emotional and rational. And how this is a key element to improve resilience inside organization. To do that, we use a sample of SMEs in the state of Guanajuato where we evaluate six dimensions. There is a database of 177 companies in the region of the state of Guanajuato. The interview phase was carried out during the months of September to December 2022, by various means, both digital and face-to-face, although due to health issues, the first was chosen as the most used option.

## **2 State of the art or literature review**

### ***2.1 Innovation is changing.***

Innovation is a fundamental process for the development of a dynamic economy. There are several ways to define it, but if we look in the contextual origin, we can observe how this concept have evolved during time. Since ancient

Greek philosophy where innovate were related with terms of imitation and invention until our days where era of technology, consumerism, and industrialization have established a relationship with innovation.

However when innovation is mentioned as a concept in the literature, it inevitably invites us to frame it from the paradigm of economic development, in which Schumpeter (1934) through his work provided a frame of reference in the first decade of the 20th century. For the author vision, during production processes occurs an interaction where *tangible* and *intangible* forces interacted in new economic cycles, creating, destroying, and recreating products, services, and markets. This argument it might be assumed that innovation process it is just an economic stage, and nothing related with a human emotion, this mindset of a rational view (Weber et al., 1947) of innovation gives us such assumptions related to a rational, machine-like view, *where any emotional experience of innovation is minimized for managers and leaders who only deploy rational strategies for a company's profits.*

Our pragmatic approach toward innovation process recognises that exists an *integrality between rational and emotional actions* where leaders and managers reflect emotions and rational decisions in a company. In a complex, turbulent and uncertain business environment as we are living, integrate emotions in innovation process creates an opportunity to focus research on resilience for managers or leaders.

For that reason, we used an adaptation of the Rao and Weintraub Model (2013) for an analysis of the culture of innovation through the vision of the general managers and/or founders adding these emotional and rational elements, creating an *index of integrality*. This index provides invaluable assets to decision makers for the promotion of elements towards a culture of a dynamic concept of innovation (Edwards-Schachter, 2018). *Integrality Innovation Index* includes *rational and emotional* approaches to develop a mindset of innovation where emotions play an important role in an uncertainty environment for organizations and leaders who are seeking resilience among teams' company.

In our current context of industrial and technological change something is happening with innovation and production relationship. Schumpeter (1934) anticipated this when he mentioned that when occurs an increase in production depends directly on the relationship of the productive factors and the rates between technology and the value exchange of the socio-cultural environment of the time. This means that when elements related with intangible fields

(knowledge) tangible (raw materials) and value of cultural context determines combinations and therefore the effect of innovation in society and companies.

The foregoing is related to what was mentioned by several authors who points out the importance of resilience, emotions and innovation relationship in our current cultural context (Dyer et al., 2008; Valor et al., 2022). For example, Martin (2016) points out the importance of sustainability in this second half of the 21st century and how this paradigm will determine the type of innovation in which it will be invested, perhaps giving birth to dark ways of innovation, this being the real challenge of managing innovation in the 21st century in environments of uncertainty and accelerated change.

This process of contextualizing how innovation is changing allow us, from this work, to address a relationship between the work of Schumpeter (1934) and what the Global Entrepreneurship Monitor (Global Entrepreneurship Research Association, 2017) mentions about economies at a global level. This report establishes the connections between innovation, entrepreneurship and quality of life in various countries. Its recommendations recognize the need to integrate innovation not just from a rational stand but as an 'social glue' into the business and social agendas of large, small and medium-sized companies and social environments to promote revitalized emotional environments. The challenge is to facilitate the conjunction of these ecosystems and coordinate various levels of government, the educational sector and the private sector.

As mentioned, innovation is a lever for the economy and for new economic cycles. Without it, entropy would generate less benefit for all actors and the generation and accumulation of wealth would stop (Suárez, 2004). For various authors and tools, the measurement of innovation allows contributing not only with an expansion of the concept from pragmatic fields, but also allows attending to the context in question. For example, according to the Oslo Manual (OECD/Eurostat et al., 2005), innovation can be presented in various forms and tangible products, but also in the development of customer service campaigns, such as through marketing. In summary, innovation can have various forms (Edwards-Schachter, 2018; Kogabayev & Maziliauskas, 2017; Martin, 2016), however, it is possible to classify it according to its attributes:

1. Depending on its nature: Product, process and business.
2. Depending on the form: Technological and organizational.
3. Depending on the geographical impact: Company, local or international market.

4. Depending on the impact on the market: Incremental, semi-incremental, radical.
5. Depending on the objective: Occasional and intentional.
6. Depending on the internal culture of the company: Focused (areas or departments) and systemic (organization).
7. Depending on the use of systems, tools or methods: Empirical, experimental, methodological or systematic.

Although there is work in the literature to define innovation, there is an area of opportunity to investigate how of innovation is moving and its new characteristics and realities as resilience and emotions. That is to say: *How emotions affect innovative capacity? What determines an environment of innovation in a turbulent world? What characteristics of innovation are linked with resilience?*

Crisis not only give us opportunity to create new practices, businesses and dynamics but to re-create concepts as innovation. COVID-19 pandemic was a great teacher for that, left us with something and it was the debate around the generation of new ecosystems of economic growth and how to relate it to the systematic search for innovation (Donthu & Gustafsson, 2020). The economies that aspire to become leaders in this new paradigm must decide for a high investment in resilient human capital with high capacities for innovation and entrepreneurship. Crises would shake the world in short term (World Economic Forum, 2023), but those who stand out are those who take the stage as an opportunity to create new niches and markets. The challenge of the new economy is creating organizations based on collaboration, innovation and resilience as core of production process. *Innovation that generates value is changing and now is emerging an ethical and emotional approaches where their performance outcome is not only in financial fields* (Bakhshi et al., 2017). In this paradigm, if a company, especially a small or medium-sized, commits to strengthening a culture of innovation and incorporates an emotional side of it.

Innovation therefore is not just a consequence; it is a key element in the birth of a successful organization. It is directly associated with the acceptance of products or services in the market and generates better returns in companies that visualize and execute it in the various areas.

## **2.2 Emotional and Rational Sides of Innovation: Resilience.**

Imaging an integration where productive factors, socio-cultural environment and technology (Schumpeter, 1934) give us natural tensions where resilience plays a crucial role in innovation process. Complex, turbulent and uncertain business environment creates scenarios for a resilience management perspective, which according with research enhance organizational innovation (Richtnér & Södergren, 2008). Resilience is viewed as the return of an equilibrium state of our environment (De Noronha & Pinto, 2016) and become one of the key competences for future (World Economic Forum, 2020), for that reason a relationship between innovation and resilience allows to any organization to create and develop a capacity to *absorb these shocks* without losing *innovation mindset* and even creating a new one (equilibrium). Resilience with an innovation culture allow to recognize how these different levels of re-covering, re-shaping and re-orientation of economic and social systems are integrated in the organization (in a rational and/or emotional side).

From a managerial point of view, *managers and staff need to develop a capacity of resilience in order to generate creative scenarios for organization, in this process they need to put focus on soft skills in addition to other resources* (Richtnér & Löfsten, 2014). This is a real challenge, because managers need to use both sides of innovation (rational and emotional) with expertise to cope turbulence situations and boost creativity among people.

Company culture is the software of its social technology, making a technological analogy. It belongs to the dynamics, behaviors and internal rituals that allow the generation of new connections between people or areas or, where appropriate, hinder the development of projects.

The management in terms of innovation allows the company to evolve or disappear according to the challenges that each context provides. And in the literature, although there are studies on innovation and organizational performance (Alvarez-Torres et al., 2019; Bach et al., 2019), there is no single formula for a certain culture can achieve success.

An innovation management process that *uses emotional and rational sides should be mainly oriented towards comprehensiveness with the vision of the company*, its workers and its processes, and must consider both the skills and emotions of the human talent that integrates the workforce, market and the purpose of the organization and how its main actors and technology add to that

great creative force that emanates from the organization creating a resilient environment. *The integrality of these elements should be a central point of a creation of a culture of innovation with a resilience perspective since it refers to the fact that should be aligned and configured to obtain the greatest potential of the organization in accordance with its values and resources.* It is not just innovating for the taste of innovating, but the meaning and ethical significance of contributions to the market.

Although the culture of the organization is a fundamental axis to promote or hinder innovation projects and advances. As research showed us, there are norms, beliefs or values, both individual and organizational, that allow sheltering or limiting efforts in innovation and creativity (Zhou et al., 2019). A culture of innovation provides practices, narratives and environments willing to generate connections between senior management staff and operational staff, stimulating risks and therefore the right ground for a possible entrepreneurial management (Alvarez-Torres et al., 2019).

Those organizations with a prioritization of discipline, authority and individual work lack the structures to become an innovative organization. Rigidity limits creativity and autonomy, that is, it corrupts integrity. The creative digital new business setup seems to require other types of structures (Lyytinen et al., 2016) and if these are not adopted in the medium term, it would seem to put the survival of traditional organizations in the market at risk. Change in this sense is not easy, since it requires horizontal, improving emotional sides of innovation and open-active communication.

### ***2.3 Innovation and Resilience relationship: Leadership is the key.***

COVID-19 pandemic showed us new limits about technological and human adaptation to new conditions, in an uncertainty world as we lived, we are not very resilient to error or failure. This scenario gives us serious organizational conditions to push innovation, leadership and soft skills of personnel. Be resilient could be defined as capacity to remain stable or back to a form of stability when it is perturbed. It is a limited capacity but also an invisible asset. This is curious, because this means the core of resilience in organizations are people and its daily dynamics among work and co-workers. Most companies trade resilience for innovation after pandemic. The main reason is: "nothing is stable as it seems". This is controversial and even dramatic, especially when leaders and managers

should appear with a solid business or operation plan for next quarter. And give us one of the main actors of innovation-resilience relationship: Leadership. Little is mentioned in literature, but when it is done is highly mentioned in contexts of rapid change as digital environments (Belair-Gagnon & Steinke, 2020). This could mean a future research question focusing *how leadership is developed with resilience in highly demand environments as full-digital?* In that sense, it is necessary to address any relationship between innovation and resilience from top management, since as the person responsible for the strategy, the organization's approach, the use of resources and the reinforcement of practices, it is the one that allows defining the dynamics and values around error, innovation and creativity. If top management does not play with these principles, it is very difficult for innovation with any paradigm or guide to be a priority.

The challenge of innovation is to make all leaders, managers and middle managers be facilitators and promoters of innovation in the organization's environment, however, people must be able to take risks supported by senior management and in the same not trade full resilience capacity by innovation capacity (Volberda et al., 2013). But the weight of innovation does not only lie in the leaders, but the true gene is also found in the people, who, although supported by a good structure, access to resources, can make a difference. However, it is more complex to have the infrastructure but not the people trained for this purpose. Measuring how people innovate in a context is a fundamental element to understand a culture of innovation. Some organizations have chosen to reward innovation efforts individually, others collectively. Valuation is not always economic, but it is one of the elements that was measured in the model of this research (Rao & Weintraub, 2013).

#### **2.4 Rational Side for Innovation and Resilience.**

Managing an innovative organization is either a chaos or a virtue for any modern organization. Since the challenge requires a structure that facilitates change, rewards mistake and facilitates both individual and collective creativity (Robinson & Aronica, 2016). A flat structure with few levels of hierarchy tends to favor innovation, while a pyramid-like structure limit it. Some organizations choose to centralize activities in a department designated for this purpose and although it could work in some contexts, in the reality of our country it can generate more steps, obstacles or excessive bureaucracy (Domínguez, 2010;

OECD, 2009). This is a traditional view of innovation, as we described as *rational side*. Structure, resources, hardware and software are vital to visualize working in projects or to take responsibility in innovation area. In this *side* most managers visualize strategies to maintain control and efficiency. For example, a good strategy of automation will increase efficiency in a motor company, but it is probable to reduce transparency of operations and eliminates any human motivation to express emotions. Innovations in rational side could be like a control inventory management to improve resources as time or raw material, but they make it difficult for a company to adapt new conditions in a crisis. In this mindset of innovation, resilience could be adapted as a system, of course with limitations.

### **2.5 Emotional Side for innovation and Resilience.**

Resilience influences potential for leaders and managers to future innovation and how deal with failures and errors during innovative process (Moenkemeyer et al., 2012). This behaviour is key to push an *emotional side* of innovation inside organizations. *How people deal with stressful events? How people react to failure or errors? Is the organizational culture resilient when an error or a crisis happened?* Resilience is a lever for innovative culture and keeps functioning and acquiring experience dealing with crisis and variables about uncertainty. However, very few organizations have a formal element about innovation and resilience management. In the Mexican case, Small Medium Enterprises (SME) companies and educational institutions have overcome a couple of years of chaos in terms of performance and talent retention (Schmelkes, 2020). Especially a crisis in the acquisition, retention and motivation of talent, a crucial element when we talk about *soft skills*. In that sense, to promote the innovation process within an organization is real challenge, because innovation is transforming ideas into value and knowledge, resilience is keeping order, so balance needs entails talent and a suitable environment where evaluating, organizing, experimenting, investing and developing is a constant dynamic. Embracing the power of an emotional side of innovation and its practices.

Establishing a methodology to measure whether the culture of innovation is conducive to certain processes or interventions is an essential issue for the ecosystem and companies. Including an emotional side could give us information about some elements for resilience. Although its measurement is difficult due to

the multiplicity of factors, we adapted Rao and Weintraub (2013) model, where it is possible to have a measurement of the various basic components of an organization's culture of innovation. According with this, we develop *Innovation Integrality Index*, which is the result of measuring innovation in six dimensions, three for a rational side and three for an emotional one. The index allows defining possible actions to specify a culture of innovation in a company.

### 3 Methodology

To carry out the study, managers of 177 SME companies in the state of Guanajuato from various sectors were interviewed. For this, the cultural adaptation of the instrument developed by Rao and Weintraub (2013) was carried out with 54 closed items evaluated by a Likert scale with 5 response possibilities. The information was analysed considering 6 dimensions. The proposed model allows evaluating the key areas of the organization: *The rational area of the business and the emotional*. To carry out the study, the General Manager of the Company or Founder was interviewed by face-to-face and/or digital means. To carry out the statistical verification and validation process, the partial least squares structural equation system (SEM-PLS) was used (Hair et al., 2010; Iacobucci, 2010) its relevance in the use of small samples. The research model has six reflective dimensions (see Figure 1) (Becker et al., 2012). The dimensions make it possible to portray the phenomenon of innovation dynamics in the SMEs surveyed and allow the results to be discussed considering the implications for the post-Covid economic recovery.

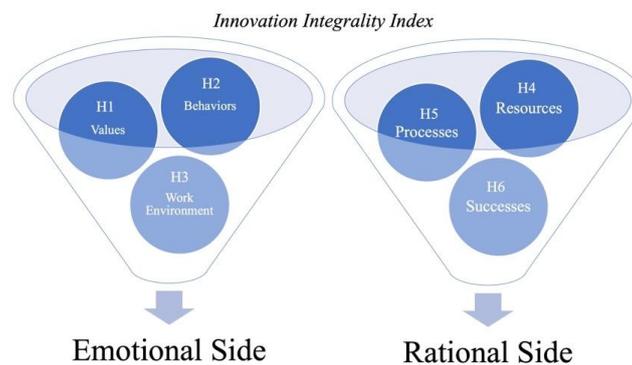

Figure 1. Theoretical model adapted for research. Adapted from Rao & Weintraub, 2013.

The six dimensions evaluated consider the following elements of the Rao & Weintraub Model (2013):

Table 1. Dimensions and Sides of the model.

<b>Emotional Side of Innovation</b>	<b>Rational Side of Innovation</b>
1. Values.	4. Resources.
2. Behaviours.	5. Processes.
3. Work environment	6. Successes.

From the above, six hypotheses were derived about the dimensions of the Model:

*Hypothesis 1. The Values dimension is positively and significantly reflected in the Innovation Integrality Index.*

*Hypothesis 2. The Behaviors dimension is positively and significantly reflected in the Innovation Integrality Index.*

*Hypothesis 3. The Work Environment dimension is positively and significantly reflected in the Innovation Integrality Index.*

*Hypothesis 4. The Resources dimension is positively and significantly reflected in the Innovation Integrality Index.*

*Hypothesis 5. The dimension of Processes is positively and significantly reflected in the Innovation Integrality Index.*

*Hypothesis 6. The Success dimension is positively and significantly reflected in the Innovation Integrality Index.*

To apply the PLS-SEM methodology, it is necessary to design the Type I reflective model (Becker et al., 2012) in the SmartPLS® version 3.3.3 software (Ringle et al., 2015) for the 177 observations. For evaluating this type of models, it is necessary to analyze the load of the indicators. Loads greater than 0.700 indicate that the construct explains at least 50% of the variance of the indicator, which is why the indicators lower than this parameter were removed. In this case, the eliminated items correspond to item 2 of the Values Dimension (0.403), item 3 (0.175), item 5 (0.664) and item 9 (0.669). Being the dimension that more items were removed from the index. Item 24 of the Work Climate Dimension (0.612), item 25 (0.179) and item 26 (0.557). Item 54 of the Success Dimension (0.557). Item 41 of the Processes Dimension (0.643) and 43 (0.647). Similarly, item 14 of the Behaviours Dimension (0.673).

The next step in the validation of the model is to analyze the reliability of internal consistency for the use of SEM-PLS, it is determined through the composite reliability, which determines that for exploratory studies the margins of 0.600 to 0.700 are acceptable, parameters between 0.700 and 0.950 are considered satisfactory and excellent and those greater than 0.950 are problematic. The dimensions obtained scores greater than 0.850 and less than 0.950 (see table 2).

Table 2. Innovation Integrality Index reflective model measurement settings.

<i>Dimensions</i>		<i>Composite reliability</i>	<i>AVE</i>
<i>Innovation Integrality Index</i>	Values (V)	0.876	0.586
	Behaviours (C)	0.936	0.619
	Work Environment (CL)	0.903	0.608
	Resources (R)	0.925	0.577
	Processes (P)	0.921	0.595
	Successes (E)	0.934	0.638

Source: Own elaboration based on the information obtained by SmartPLS®

The next thing in the validation process is to analyze the Convergent Validity, which is determined by the Average Variance Extracted (AVE). This indicator is calculated by the mean of the square of the loads of all the indicators associated with that construct (Sarstedt, Ringle, Smith, et al., 2014). An acceptable AVE corresponds to 0.500 or greater (see table 2), which is fulfilled in the proposed Model. After the previous tests of the model, it is necessary to determine the Discriminant Validity. This determines how different a construct is from others in the model. The most conservative way to do it is through the Fornell-Larcker criterion (Hair et al., 2014) (see Table 3).

Table 3. Fornell-Larcker criterion.

	<i>V</i>	<i>C</i>	<i>CL</i>	<i>R</i>	<i>P</i>	<i>E</i>
<i>V</i>	<b>0.766</b>					
<i>C</i>	0.651	<b>0.805</b>				
<i>CL</i>	0.647	0.736	<b>0.780</b>			
<i>R</i>	0.713	0.726	0.765	<b>0.760</b>		

<b>P</b>	0.669	0.638	0.733	0.854	<b>0.788</b>
<b>E</b>	0.643	0.658	0.664	0.850	<b>0.799</b>

Source: Own elaboration from the information obtained

The next step is the evaluation of the structural model. For this, the following are evaluated: a) determination coefficient (R<sup>2</sup>), b) cross-validation redundancy (Q<sup>2</sup>) and c) path coefficients (Sarstedt, Ringle, Smith, et al., 2014) (see table 4).

Table 4. R<sup>2</sup>, adjusted R<sup>2</sup> and Q<sup>2</sup> of the structural model.

	<b>R<sup>2</sup></b>	<b>R<sup>2</sup> Adjusted</b>	<b>Q<sup>2</sup></b>
<b>V</b>	0.624	0.622	0.355
<b>C</b>	0.709	0.708	0.454
<b>CL</b>	0.733	0.732	0.431
<b>R</b>	0.889	0.889	0.503
<b>P</b>	0.792	0.790	0.485
<b>E</b>	0.793	0.792	0.494

Source: Own elaboration based on the information obtained by SmartPLS®.

The R<sup>2</sup> indicator is a measure that allows us to predict the results of the model. Values between 0.660 and 0.330 indicate a moderate explanatory value of the model. All six dimensions possess this characteristic. Another way to evaluate the predictive relevance of the model as a measure of precision is Q<sup>2</sup>, as measured values greater than 0 indicate an acceptable predictive value (Hair et al., 2014; Sarstedt, Ringle, Henseler, et al., 2014).

Table 5. Hypotheses, path coefficients, t value and significance of the structural model.

<i>Relationships and Hypotheses</i>	<i>Sides of Model</i>	<i>Coefficient Path</i>	<i>Values t</i>
<i>Hip. 1.</i>		0.790	*** 20.926
<i>Hip. 2.</i>	Emotional Side	0.842	*** 27.972
<i>Hip. 3.</i>		0.856	*** 39.690
<b>Hip. 4.</b>		<b>0.943</b>	*** 115.718
<b>Hip. 5.</b>	Rational Side	<b>0.890</b>	*** 48.322

\*\*\* p < 0.001. Source: Own elaboration based on the information obtained by SmartPLS®.

Bootstrapping was carried out with 5,000 subsamples (Sarstedt, Ringle, Smith, et al., 2014) obtaining six relationships between the variables (see table 5). Through the results, it can be observed that the index is reflected in a *positive and significant* way with a higher coefficient for the dimensions of *Resources* (0.943), *Processes* (0.890) and *Successes* (0.890), the *Rational Side* of Innovation.

#### 4 Discussion of Results

Six hypotheses and validity of model were accepted, next step of results analysis is frequency data. In that issue, results indicate that more than 50% of the companies surveyed represent micro-small companies that have between 10 and 50 workers.

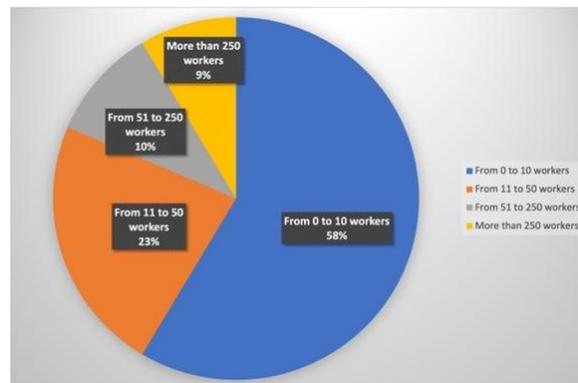

Figure 2. Percentage of sample of companies interviewed by number of workers. Source: Own elaboration with Google tools.

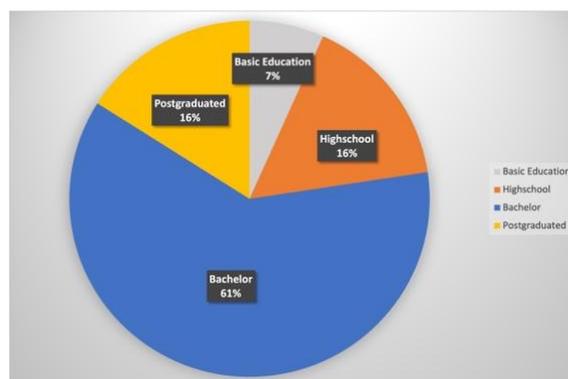

Figure 3. Percentage of sample of people interviewed by schooling. Source: Own elaboration with Google tools.

In terms of schooling, 61.4% of the managers indicated having a bachelor's degree, which may indicate an educational capacity when they're applying a managerial skills in the state of Guanajuato (Jiménez et al., 2015), a phenomenon that would be worth considering in the future research. In what corresponds to the preparation in innovation issues, the group has two very marked tendencies. 50.3% indicated having previous training and 49.7% mentioned not having it.

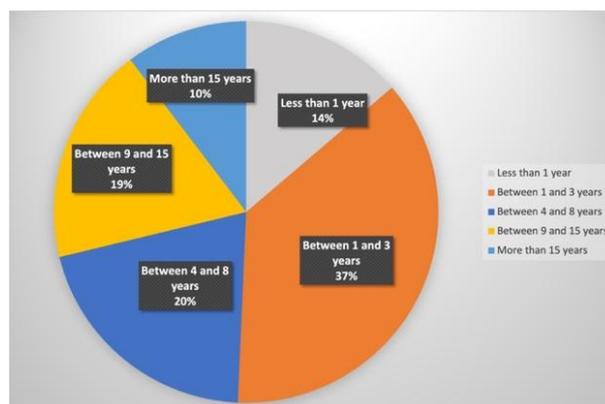

Figure 4. Percentage of sample of people by seniority in the company. Source: Own elaboration with Google tools.

Seniority in a company symbolizes stability but could also minimize the orientation to innovation, especially if there is no Career Plan, in the case of the sample more than 50% of the sample indicates having between 1 to 8 years. The descriptive analyses allow us to portray a panorama of SMEs in the state of Guanajuato, in which the majority (48.7%) are young companies. This allows us to infer that the innovation processes that are portrayed in the analysis are mostly reflected by this type of company, in which the *Resources dimension (0.943)* is a very valuable area for the creation and development of an innovation culture, meaning that a rational view of innovation is hardly in the core of strategy.

In the case of the values dimension and emotional side, the *items related to exploration, creativity and experimentation* reflected a higher factorial load and the *items related to tolerance to failure and error* were eliminated as they did not have the necessary factorial load to form part of the dimension. This is an important finding in the research. It seems that creativity and experimentation are dynamics that can exist well on paper but not in practice, since experimenting or creating implies errors or failures. This element is crucial, because they're antecedents for an resilient environment (De Noronha & Pinto, 2016).

According to the results in the work environment dimension, the items related to autonomy, taking responsibility or an orientation towards more flexible norms or structures were the ones that did not have the factorial load necessary to be reflected in the index. However, the language of innovation and teamwork stood out in this dimension (See Figure 5).

## 5 Conclusions

According to Rao and Weintraub (2013) when it comes to promoting innovation in organizations, in general it is essential that managers and directors pay special attention to the six dimensions, however, *resources, processes and successes stand out because they form the more rational side of innovation and is somehow easier to measure*. In the sample of SME companies surveyed, it reflects these dimensions. What corresponds to a more emotional approach to innovation that corresponds to values, behaviours and work environment, intimately related to people, does not seem to be reflected in the same way in the orientation of managerial decisions.

During process some managers reported the main importance of soft skills during a crisis moment, especially during COVID-19 pandemic (values, work environment and relationships) and how these skills provide a secure and resilient scenario for better communication and self-awareness of what's going on around company. Managers appeared to build innovation strategy from automatic reactions "to manage" innovation as only focusing resources and results. The challenge for them is including emotional situations and taking responsibility to communicate with emotional and resilient competence. This kind of leadership has a potential, but it needs strengthening cognitive, behavioural and contextual capacities around a resilience organization perspective (Nzinga et al., 2021).

The lack of an emotional side could be analysed as a negative point, but also as an area of opportunity to improve the management of talent and human resources to promote innovation from a more emotional aspect, which involves the promotion of values and behaviors that cover the key processes of

innovation. The human is the key in this post-covid era, however, in a complex environment it also seems the most difficult to address. However, these dimensions are the ones that could shape a new culture of innovation and create present and future competitive advantages.

Although the results allow dimensioning a reflection towards a culture of innovation of the companies surveyed, the risk of developing a single block, such as the rational one, is a weakness in the medium and long term for the companies of the region, especially for a learning towards the automation and digitization of administrative and production processes. Well, an orientation towards innovation from people could attract better talent to the organization.

The analysis of SMEs allows identifying areas of training, qualification and education for the managers of this type of company in emotional sides of innovation (See Figure 6). This means plans to structure continuing education programs inside company teams to shore up the weak points of a culture of innovation oriented by resilience.

### Abstract

In recent years several routes have been entered to face the existing discrimination in the access to credit between male and female. In this framework, the initiatives undertaken by the United Nations and the national governments have shown growing attention in order to alleviate the gender gap in various economic sectors. Among those, the non-performing loan one, given the recent economic and pandemic crises, is registering a fast increase. The objective of this work is to examine if and how gender is considered among the evaluation criteria of non-performing loans (NPLs) portfolios.

An inductive content analysis has been carried out on 30 documents relating to NPLs. Specifically, the sample is made up of official publications and reports published on the websites of European and National Institutions, supervisory authorities, main banks groups, specialized sectorial consultancies and leading servicers.

The analysis of the documents shows that, at present, gender is not particularly taken into consideration when banks and servicers illustrate their NPLs portfolio. On the contrary, it is possible to find classifications based on other variables (e.g. geographical position, business sector or presence of guarantees). Therefore, it is possible to conclude that gender – so far - does not appear to be an element that is considered when discussing the management of NPLs.

This work is the first part of broader empirical research intended to open a debate about the relevance of the gender factor in the management of NPLs. In fact, while the gender variable seems to be taken into account as an element for granting credit, it is not considered for its management.

**Keywords** – Female-run business, Asset quality management, credit crunch, gender diversity, non-performing exposure

**Nature of proposed paper** - Academic Research Paper

## 1 Introduction

Access to credit and financing is a topic of great interest in studies on female entrepreneurship, which have shown significant differences between male and female businesses, seeing the second category as more disadvantaged than the first (Paoloni, 2011).

However, the attention paid by the International and National institutions to female entrepreneurship and gender equality is gradually reversing this trend in almost all economic sectors. Through an in-depth analysis of the content of several cases and official documents recovered online, this work aims to understand if the secondary financial market is aligned with this gender growth model. The research question (RQ) examined is: *"Does gender somehow enter into the management of a bank's credits portfolio, and in particular into the management of non-performing loans (NPLs)?"*. According to the European Central Bank, "groups of loans created to estimate allowances on a collective basis should be sufficiently granular to ensure that grouped exposures have shared credit risk characteristics so that banks can reasonably assess changes in credit risk and their impact on the estimate of allowances" (European Central Bank, 2017). From the analysis literature, women's enterprises have some peculiar characteristics that allow homogeneous classes to be determined since some studies demonstrate their higher credit quality (Paoloni, 2011; Mustapha, 2016; Cesaroni and Stentuti, 2015).

The stock of NPLs, in the last twenty years, due to the successive financial crises and the recent pandemic, has considerably increased to bring out the need for specialized operators (Paoloni *et al.*, 2020). But which characteristics does the market have? What criteria do banks and sector operators adopt to evaluate NPLs' portfolios? For example, is gender used as a criterion? If yes, by whom was

it initially suggested or regulated, and what benefits does it present? If not, what are the reasons, and what are the reasons for its inclusion?

To answer these questions, the authors first proceeded with an analysis of the literature on the origin of NPLs, both from a business and legal point of view, as well as the possible correlation between female entrepreneurship and creditworthiness (Section 2). Subsequently, the authors proceeded with the content analysis of selected documents to identify which are the segmentation criteria used (Section 3). From the analysis (Section 4), it emerged that this sector is still fragmented and far from complete harmonization. Supranational Institutions have carried out the greatest sectorial assessment production, however, with scant attention to a specific identification of portfolio classification criteria. When these criteria are present, they mainly refer to general classifications, such as geographical position, business sector or presence of guarantees. The results lead authors to conclude, in Section 5, that the gender variable is neglected by the main actors of the sector, completely in contrast with the evolution of the literature or, in any case, with respect to other similar or/and collateral sector trends, which have recognized female-run businesses as having greater solvency and, therefore, a better ability to repay debt in any cases of insolvency.

## **2 Literature Review**

### ***2.1 The origin of Non-Performing Loans***

Non-performing exposures (NPEs) are an umbrella term for various defaulter debtors. In the past ten years, the legal system has identified specific criteria that distinguish NPEs from other types of defaulter loans, such as the likelihood of recovering the debt (Capriglione, 2019). Studies in this area have focused on examining the circumstances where the potential loss is beyond the normal range, necessitating an evaluation of the magnitude of the debt and its distinguishing features.

Specifically, when talking about NPEs, it is possible to identify three categories which are distinguished according to the different probability of recovering the credit at maturity (EBA, 2014):

- The expired and/or exceeding exposures (Past Due), that have exceeded the lending limits by more than 90 days;

- The Unlikely-To-Pay (UTP), that are exposures for which the bank considers it unlikely that the debtor will fulfil his contractual obligations without resorting to actions such as the enforcement of guarantees;
- Non-Performing Loans (NPLs), which are exposures towards subjects in a state of insolvency or similar situations.
- From a business perspective, non-performing loans are specifically generated by a company's inability to meet its financing needs conveniently, timely and satisfactorily, an element necessary for an enterprise to be profitable (Zanda, 2015; Paoloni and Paoloni, 2021). The reasons that can produce this situation are:
  - Severe financial imbalances, in that firms cannot find the appropriate financing sources to meet obligations;
  - Economic imbalances, in that firms run businesses that do not generate enough revenue. Therefore, this permanent situation has a negative effect on the company's equity.

From a legal point of view, the definition of NPLs has undergone several changes, made necessary by the contingent situations that led to the explosion of the problem around 2012-2013, following and reflecting the financial crisis of 2008 (Capriglione, 2019). As seen before, NPLs are exposures to entities in the insolvency or substantially similar situations. The state of insolvency is manifested by defaults or other external facts, which show that the debtor can no longer meet its obligations regularly. Therefore, an NPL arises from a continuous and ongoing contractual default of a party towards its creditors.

For obvious reasons, the topic of NPLs has always been linked to the banking sector, as companies whose business, in part, is based on lending resources to other companies (Cucinelli, 2015; Paoloni *et al.*, 2020).

Following tightening regulations after the 2008 economic crisis, banks implemented several policies to reduce the NPL phenomenon. While on the one hand, specialised NPL management businesses have sprung up, on the other hand, banks have also started to decrease and weigh their investment choices. This has led to a credit contraction but, even more generally, to a greater focus by banks on whom they lend money (Cucinelli, 2015).

Previous literature on NPLs has tried to understand the variables that affect NPLs' waves (Khairi *et al.*, 2021).

Several studies linked NPLs to macroeconomic variables (such as GDP growth, unemployment, and inflation) (Kauko, 2012; Louzis *et al.*, 2012, Beck *et al.*, 2015).

In addition, the uncertainty in economic policies has also been identified as a factor affecting credit risk since changes to economic policies can lead to the misallocation of banks' credit resources or deterioration of borrower firms' operations (Chi and Li, 2017). Kauko (2012) researched the connection between the current account and the development of NPLs during the recent financial crisis, showing that macroeconomic factors, rather than banking sector solvency and liquidity, are the main drivers. All these studies have as their main idea that the NPL phenomenon depends on variables exogenous to the banks' control.

However, some other studies have identified bank-related variables (such as bad management) as the main factors that affect NPLs (Anastasiou *et al.*, 2019). In addition, other studies have identified the banks' governance composition as a factor that could limit the presence of NPLs (Lafuente *et al.*, 2019). For example, a study (Tarchouna *et al.*, 2017) identified that, before the 2008 crisis, big and medium banks were more likely to fail in that directors had more liquidity to invest and put banks over an adequate level of risk. This did not happen in small banks with no available resources to invest. Therefore, these studies focused on a second category of variables, specifically banked-related factors.

Among the most critical aspects of banking variables is the proper management of credits. This aspect consists of correctly selecting and evaluating credits to be disbursed and knowing how to manage NPLs when they are generated. In this sense, a third category of factors influences the creation of NPLs, namely the characteristics of the companies to which credit is given is identifiable. However, this category (which can be defined as microeconomic factors) has been developed by existing literature directly concerning credit quality (e.g. Ashbaugh-Skaife *et al.*, 2006) rather than NPLs.

Therefore, it is interesting to analyse whether firm-specific characteristics are directly related to the presence of NPLs.

## **2.2 Female entrepreneurship and creditworthiness: is there a link?**

Business studies have identified many criteria for analysing companies: based on sector, size and geographical location. A feature that has been finding ample space for analysis in entrepreneurship studies lately concerns gender (Ramadami, 2015; Dal Mas and Paoloni, 2016). In the last 30 years, female entrepreneurship is a growing phenomenon, also thanks to various measures that attempt to close the existing gender gap also at the entrepreneurial level (Paoloni, 2011). However,

the path of a woman entrepreneur is often characterised by several difficulties, such as acquiring funding, balancing work and family, and obtaining the necessary education (Paoloni, 2011; Mustapha, 2016; Cesaroni and Stentuti, 2015).

As mentioned, access to credit and financing could be difficult for female entrepreneurs (Moro *et al.*, 2017) and, nowadays, it has become a topic of great interest in studies on female entrepreneurship, showing significant differences between male and female businesses (Paoloni, 2011; Cesaroni and Stentuti, 2015).

In particular, female entrepreneurs start their businesses with lower initial capital and even in subsequent phases, they mainly resort to personal, family and friendly resources rather than bank loans (Cesaroni and Stentuti, 2015; Paoloni, 2021). Despite numerous studies, the causes of these differences have yet to be clearly and definitively identified and are attributed to factors such as the structure of businesses, the decision-making processes of banks and the behaviours of female entrepreneurs. Looking at the business structure, Cesaroni and Sentuti (2016) found that female-run firms tend to be smaller and younger than their male-run counterparts, which usually require less capital. Considering female behaviours, Rita *et al.* (2018) have observed that gender stereotypes lead to differences in male and female behaviour, with males being more inclined to take risks and be aggressive, while females tend to be more empathetic and prefer stability. Heilman (2001) has shown that these personal traits manifest in how they manage businesses, as women are more averse to risk. As for the causes related to bank choices, it is not a discriminatory attitude *per se*, but rather a mistrust of the female firms because they are small and generally have fewer guarantees (Cesaroni and Stentuti, 2015).

However, the situation is changing. Thanks to the attention paid to female entrepreneurship by the UN in its 2030 Agenda, governments are now trying to support these realities, which are seen as one of the ways to achieve gender equality. For this reason, even the investments foreseen in the National Recovery and Resilience Plan (NRRP) pay attention to this theme. Mission 5 plays a fundamental role in pursuing the other objectives, transversal to the entire NRRP, concerning supporting female empowerment and promoting women's economic independence.

But how does this growing support of institutions for female entrepreneurship translate? Banks are adapting to this demand from institutions and increasingly

organise initiatives to support female entrepreneurship<sup>1</sup>. This gives rise to an issue related to the credit quality of women's enterprises.

From the literature review, it emerges that there is not a clear correlation between the gender of the entrepreneur and the quality of credit.

Several studies argued that females are less likely to default on their loan payments compared to male borrowers (Cheston and Kuhn, 2002; D'Espallier *et al.*, 2009). In addition, women-run businesses are less likely to go into default, being less risky (De Andrés *et al.*, 2021). Other reasons for women to have less probability of default are related to the fact that they are more inclined not to take risks and not to misappropriate resources provided by third parties in order to combat the stigma that exists in the comparison of women's credit (Garikipati, 2008).

However, other studies have found no particular correlation between credit quality and gender. In particular, several studies found a non-significant relationship between the gender of the borrower and the probability of not repaying the credit (Anthony and Horne, 2003, Godquin, 2004, Adusei and Appiah, 2011).

Nevertheless, the evidence on this point needs to be more conclusive, even though part of literature suggests that credits given to female enterprises perform better than those given to male enterprises. Therefore, it is interesting to see if this aspect is ever considered when talking about NPLs.

### **3 Research design**

#### **3.1 Historical and regulatory contextualization of the European and Italian NPL market**

As mentioned, the phenomenon of NPLs has attracted the attention of the economic system since the financial crisis of 2007, when due to the worsening of the real economy, the solvency of debtors decreased, resulting in the accumulation of NPLs and the progressive deterioration of bank balance sheets. This liquidity crisis has triggered a vicious circle characterized by the increase in credit risk, legal and administrative cost of the loan, the decrease in interest income and related profits, as well as the request by supervision for a growing

---

<sup>1</sup> Without going into detail, support for women's enterprises has been given by all the major Italian banks (e.g. Intesa San Paolo, Unicredit, Banco BPM, Banca Ifis, etc.), which currently have several specific financing activities in place.

prudential amount of capital. Institutions and supervisory authorities initially intervened by injecting public resources into the system to restore the credit institutions' ability to raise funds. They operated by subscribing to capital increases and/or providing government guarantees on the liabilities issued.

This determined an acceleration of the regulatory adoption process in order to harmonize the European regulatory context of the classification and management of NPLs, still fragmented among the various Member States, within the attempt to create an homogeneous secondary market capable of supporting the real economy, dealing with the endemic deficiencies of the system.

Within this context, the European Banking Authority, in July 2014 published the document "Final draft Implementing Technical Standards (ITS) on Supervisory reporting on forbearance and non-performing exposure under article 99(4) of Regulation (EU) No 575/2013", adopted by the European Commission with EU Regulation no. 227/2015 on 9 January 2015, which amended the EU Implementing Regulation no. 680/2014 (implemented at the Italian national level with the seventh update of 20 January 2015 of circular no. 272 of 30 July 2008 by the Bank of Italy). This regulation aimed at introducing a harmonization of the definition of NPLs, still in force today, as well as the different methods of assessing and reporting loans.

In light of the effects of the financial crisis and after the emergency period, the European Commission has adopted the so-called *macro-prudential supervisory* approach by defining in the "Communication on the banking sector" more stringent criteria for the granting and use of public money to rescue the banking system to encourage greater involvement of resources directly by private individuals and bank stakeholders. Moreover, it assigns a central role to diminishing the stock and mitigating future accumulation of NPLs.

Furthermore, since 2017, the European Central Bank has drawn up the "Guidelines for banks on non-performing loans" and subsequent annual "Addendum" updates, which, without replacing supranational or national standardization, provide a common framework for credit institutions and best practices on the subject management of NPLs, clarifying the supervisory expectations on prudential provisions. Furthermore, since March 2017, national credit institutes have been called to highlight their commitments to dispose of non-performing assets in the short and medium term.

The EU Council and the European Commission also intervened in 2017 with the same aims, respectively approving an "Action plan to reduce the onset of non-

performing loans in the banking sector” and a “Package of measures for a more speed of NPLs in the banking sector”, calling for greater banking supervision, further development of secondary markets and the restructuring of banking sector. As a result, EU Regulation 630/2019 was adopted in April 2019, amending the s.c. Capital Requirements Regulation, CRR 575/2013, by establishing a prudential limit on the accumulation of NPLs by banks, integrated with supervisory expectations on the matter, the Calendar Provisioning.

Subsequently, to ascertain the effects of Covid, the EBA adopted the document “Guidelines on legislative and non-legislative moratoriums on loan payments applied in the light of the Covid-19 crisis”, allowing credit institutions to freeze own credit exposures and postpone the identification of non-performing assets. Subsequently, the European Parliament and the Council adopted Regulation (EU) 2017/2402, amended by Regulation (EU) 2021/557, which establishes a general framework for securitizations to support the recovery from COVID.

Regarding instead the Italian context, it is helpful to note how the financial crisis manifested itself more slowly and less severely than in the other northern European markets, due to the lower presence on the balance sheets of national banks of securities linked to the US real estate market. However, the structure of the domestic market based on a more traditional business model and a more stable supervisory and collection system, was not enough to counter the effects of the 2008 and 2013 recessions. The reason lies in the typical composition of the productive national system, made up mainly of Small and Medium Enterprises, in whose activities it is concentrated most of the credit disbursed by the banking system.

This delay in the national effects, compared to the European counterparts, has ended up limiting the capacity for intervention of the national government, since in the meantime, the approach of the European Commission, first with the Communication of 2013 and, then, with the adoption of the Directive 2014/59/EU, the Bank Recovery and Resolution Directive (BRRD), had already been changed and became more stringent. Therefore, having set aside the possibility of using alternative bailout instruments or of being able to establish a national bad bank, the government in 2016 opted to speed up the bankruptcy procedures related to NPLs and to establish the “Guarantee on the securitization of bad debts” (GACS) (decree-law 14 February 2016, n.18). This instrument, in compliance with state aid regulations, is based on the granting of a public guarantee on the senior tranches of securities, relating to NPLs. In addition, since 2016, a pool of banks and

institutional investors have set up specific private investment funds aimed at investing in the recapitalization of some banks and the purchase of the related NPLs at a price higher than the market average.

The national context is characterized by the presence of a significant pricing gap between supply and demand for NPLs and, therefore, between the price at which investors are willing to acquire NPLs on the secondary market and the book value of non-performing assets required by banks. This gap originates in the different techniques of recording credits and related costs adopted by banks and investors with negative effects on the lengthening of the recovery times of the assets; aggravated by the cumbersome nature of the functioning of judicial and civil proceedings. As a result, Italy has a higher average permanence of NPLs in the balance sheets of credit institutions compared to other European countries and an extinction rate among the lowest in Europe.

For this reason, credit institutions are progressively adopting business models capable of combining: in-house recovery management (with high fixed costs); outsourcing to intermediaries specialized in the recovery, servicers (higher verification costs but better performances and generation of liquidity by the bank); sales on the market which, however, as anticipated, envisage a lower recovery capacity.

From a regulatory point of view, the national legislation on NPLs is based on art. 58 of the Consolidated Banking Act, legislative decree n. 385/1993 and on the law on credit securitization n. 130/1999. Recently, with the Legislative Decree no. 34/2019, Legislative Decree no. 50/2017 and the 2019 Budget Law the Government introduced simplification measures on the transactions of non-performing loans, as well the definition of possible new forms of financing of SMEs by the SPVs. Furthermore, the Bank of Italy, as supervisory authority, has been publishing and updating its guidelines on the sector since 2018, requiring credit institutions to adopt more rigorous approaches and strategies to optimize the management of NPLs and prevent future accumulation.

Also in Italy, the impact of Covid has further aggravated the deterioration rate of loans, lengthening the times of legal proceedings and the period of permanence of NPLs in the balance sheets. In this regard, the national Government had imagined the definition of the GLAM (Guaranteed Loans Active Management) platform, structured by AMCO, the Ministry's Asset Management Company, based on the transfer to specialized operators of a part of the vast portfolio of NPLs, which in Italy has reached 300 billion.

However, as the picture is still uncertain, it can be positive to investigate the introduction of new criteria for a better assessment of creditworthiness that can be applied within the evaluation of non-performing status. For this reason, the present work intends to analyze the use of the gender parameter, understand whether it is used in the NPL portfolio evaluation phase. Given that, as anticipated, women's credit presents a lower risk of default and greater reliability even in the event of deterioration, it would seem to have all the connotations to be included among the actual evaluation principles.

### **3.2 Methodology**

The present analysis consists of a inductive content analysis of documents found online that deal with the topic of NPLs (Elo and Kyngäs, 2008). Specifically, content analysis is a process for analyzing written, spoken, or visual content to identify patterns, trends, and themes within the content. It relies on the systematic coding of textual information into categories and the tabulating of the frequency of each coded category (Krippendorff, 2018). This analysis can be considered inductive, as the categories used to classify NPLs were formed after reading the documents, abstracting from the particular to the general (Elo and Kyngäs, 2008).

The documents were found online and classified according to the issuer.

- International institutions;
- International supervisory authorities;
- National institutions;
- National supervisory authorities;
- Banking groups/servicers;
- Others

The search for information was conducted mainly online using the two main search engines: Google and Yahoo. The use of these two engines is justified by the fact that there is authoritative literature (Hewson *et al.*, 2003), which considers observation studies conducted online, as satisfying the criteria of reliability and validity necessary for the robustness of a research method.

After the search, 30 main documents were included in the analysis sample. These documents include laws, reports and commentary on NPLs.

For each document, the content was examined (Elo and Kyngäs, 2008), focusing on the segmentation methodologies of NPL portfolios to understand whether

gender was an element taken into account by the actors dealing with this issue. Therefore, firstly, it was verified whether the topic of segmentation of NPLs was addressed in the document. If it was dealt with, the various criteria identified were analysed, with a particular focus on gender.

The output of this analysis concerns tables and figures typical of descriptive statistics.

#### 4 Findings and discussion

In this paragraph, findings of the content analysis are illustrated and discussed. Before going into the details of the analysis, a preliminary result is shown related to sample composition is presented in table 1.

Table 1. Sample description

Type of organization	N° of documents
International institutions;	10
International supervisory authorities;	5
National institutions;	3
National supervisory authorities;	4
Banking groups/servicers;	2
Others	6
<b>Total</b>	<b>30</b>

Source: Authors' elaboration

This table shows that much of the documentation (15 out of 30) on NPLs comes from international actors (institutions or supervisory authorities). This is because the topic is relevant at the European level, as Europe has a banking union. Interesting how other actors (consulting firms mostly) are strongly active on the topic (6 documents out of 30).

Going into the selected documents, it can be seen that 19 out of 30 have a focus on segmentation issues. Table 2 shows the above-mentioned classification by the type of organizations that issue the document.

Table 2. Documents with and without references to NPLs segmentation

Type of organization	References to segmentation criteria	No references to segmentation criteria
International institutions;	6	4
International supervisory authorities;	3	2
National institutions;	0	3
National supervisory authorities;	4	0
Banking groups/servicers;	1	1
Others	5	1
<b>Total</b>	<b>19</b>	<b>11</b>

Source: Authors' elaboration

Many of the documents relating to these aspects derive from supervisory authorities (7 out of 19) or from others, mainly consulting firms (5 out of 19).

From the analysis carried out, it is possible to identify macro-classes of elements: the type of loan, borrower characteristics and collateral characteristics. Table 3 illustrates how many documents, among the 19 that refers to segmentation criteria, take into account each category.

In the loan type, it is possible to find both classifications based on maturity of the loans and classifications based on destination (typical of IFRS9). These types of classifications have a particular impact on the methods of accounting in the financial statements. In addition, the main segmentation about the loan type is related to the presence or the absence of security.

Table 3. NPLs macro-categories of classification

Type of organization	Loan Type	Borrower characteristics	Collateral characteristics
International institutions;	6	2	1
International supervisory authorities;	2	3	1
National institutions;	0	0	0
National supervisory authorities;	3	4	0
Banking groups/servicers;	1	0	0
Others	4	4	2
<b>Total</b>	<b>16</b>	<b>13</b>	<b>4</b>

Source: Authors' elaboration

With regard to borrower characteristics, the analysis of the documentation shows a more alternative choice. Several documents (13 out of 19), refer to the

possibility of segmenting portfolios according to geographical origin or activity. Next, reference is made to company size, which also appears in the literature (e.g. Lubis *et al.*, 2015) to be a discriminating element of creditworthiness.

Other elements regarding the borrower are the nature of the borrower and distinguishing between corporate and individual entrepreneur/person. Among the criteria of this type, were mentioned age but also gender (1 document of the National authorities).

Finally, it is possible to focus on a particular category of claims, namely those backed by collateral. In particular, it is possible to subdivide these credits on the basis of the nature of the guarantee provided. A first macro-subdivision is made based on whether or not a public guarantee is held. For example, in Italy, there has been the GACS<sup>1</sup> scheme. Other subdivisions relate specifically to the type of collateral, whether real or personal. Collateral, normally preferred by the market, is in turn segmented according to the type of underlying property or the location of the property.

## 5 Conclusions

When NPLs are making a comeback, and markets are questioning the best ways to manage them, this paper enters this debate by addressing the issue of gender. As several studies have shown (Paoloni, 2011; Mustapha, 2016; Cesaroni and Stentuti, 2015), female-run businesses have specific characteristics. Since the efficient management of NPLs portfolios also derives from the ability of accurate segmentation, this study aims to understand whether gender could be a variable of interest.

Therefore, to answer the RQ: "Does gender somehow enter into the management of a bank's credits portfolio, and in particular into the management of non-performing loans (NPLs)?", an inductive content analysis (Elo and Kyngäs, 2008) was carried out on a sample of 30 documents from different organizations (authorities, institutions, banks, servicers, consultancies etc.).

The results of the content analysis show that, apart from a single document, gender is hardly ever taken into account as a criterion to segment portfolios.

---

<sup>1</sup> GACS, which stands for *Garanzia Cartolarizzazione delle Sofferenze*, is the most impactful Italian measure supporting securitizations. It was initially approved by the European Commission, under the EU State aid rules, in February 2016 and extended in September 2017, August 2018, and March 2019.

Although the market plays a fundamental role in freeing banking institutions from accumulating liabilities to make them better concentrate on providing credit, the organizations carry out their activity in a context of a supranational and national regulation that limits itself to define criteria and principles only on a general basis. Market operators refine the portfolio evaluation criteria by following a "self-assessment" approach, based on the evolution of their know-how and expertise acquired while managing portfolio transactions, without facilitating market transparency and efficiency. Along these lines, the classifications found in the documents are often broad (presence or absence of collateral, geographical location, business sector). However, more detailed categories could be pushed at the level of institutions and authorities as they align with new market needs (e.g. the numerous funding and support initiatives for female entrepreneurship in recent years).

This article has both practical and theoretical implications. From a theoretical point of view, it introduces the issue of gender in the segmentation criteria of NPLs' portfolios, opening a new strand of gender studies in this specific and technical topic. From a practical point of view, it could suggest authorities and institutions formulate more detailed criteria that follow today's market trends (e.g. the increase in supports for female entrepreneurs).

This work has limitations concerning the selected sample, as the documents only represent what was found online discussing NPLs. A broadening of the sample would allow the results to be expanded. In addition, future studies may concern the analysis of packages of NPLs from a gender perspective to observe the application of this criterion to segmentation

### **Abstract**

The requirements of building sustainability and the use of information technologies have led to the new vision of continuum building design that considers each stage of a building's life cycle, including the recovery and up-cycling of materials and building components according to the circular economy models. Continuum building design promotes planned preventive maintenance (PPM) and moves away from the current emergency acting on assets compromised by serious pathologies. It allows the optimisation of time and resources and the durability of interventions through sustainable and effective practices. The paper presents the preliminary results of a research activity aimed at identifying and validating guidelines for architectural heritage conservation through the development of an open knowledge platform to dissemination of the best practices currently available. The main goals are promoting preventive and planned maintenance as the main strategy of conservation of the building heritage and overcoming the fragmentation and scarcity of reliable information of scientific and technical literature for diagnostics, interventions and durability monitoring. The guidelines will cover all stages
