of the conservation process, from the preliminary phase of knowledge of the building. Moreover, type, extent and cause of degradation will be identified, including their resolution or at least their decrease according to the criterion of minimum intervention and maximum effectiveness with the lowest cost and the lowest environmental impact using sustainable and compatible products. The guidelines of the open digital platform will be identified through the study and critical analysis of interventions on monuments belonging to Italian historical heritage. The monuments chosen as case studies have been affected by various forms of degradation, in many cases triggered by the presence of rising damp. This latter one has been stopped using an already verified economical and sustainable device that uses charge neutralization technology CNT-Domodry®. The research provides for the initial activity of identification of digital standardization protocol, information cataloguing and metadata in order to achieve the final comparison of interventions and the consequent identification of best practices. The cataloguing rules of the ICCD and the digital platform for risk assessment of heritage of the ICR have been taken as a reference. Future developments of the research project will consist in the acquisition and critical processing of information on relevant number of case studies in order to have scientific evidence to proceed toward a Heritage Digital Guidelines in PPM.

**Paper type** – Academic Research Paper

## 1 Introduction

The new approach of continuum building design has increased the focus on the durability and sustainability of each phase of a building's life cycle (from its design to its dismantlement) and has oriented building's design and planned preventive maintenance (PPM) to the digital world with the aim of extending the architectural heritage life and preserving its memory through the optimization of time and resources required (Hong T. et al., 2020; Jin R. et al., 2019).

The central role of building life cycle management in the environmental, economic and social dynamics is now well known. In particular, the operation and maintenance phases represent 75-80% of the total resources needed during the entire life cycle of a building (Hauashdh A. et al., 2022). For this reason, in order to preserve and safeguard the cultural heritage, it is essential to pay attention to this stage by adopting a preventive approach to conservation to reduce the risk of loss of value and material of the architectural heritage and to optimize time and resources needed for the restoration interventions. It is in this perspective that the

building's design and planned and preventive maintenance (PPM) are oriented towards digital and IT tools (Hong T. et al., 2020; Jin R. et al., 2019).

The development of technology and information systems is increasingly influencing the world of architecture, especially in the design and construction of new buildings. (Hong T. et al., 2020; Llatas C. et al., 2020)

Several studies and scientific works have demonstrated the strong positive impact that technological and IT innovations are bringing in the building design process, but these same studies have shown that the application of information technology tools is limited to specific phases of building life cycle that mainly concern the spaces' design from scratch, plant design and cost analysis (Hong T. et al., 2020; Llatas C. et al., 2020).

However, there are no documented cases of the use of this tools to support the entire building life cycle, while there are few cases related to restoration and planned and preventive maintenance.

Because of the potential linked to the ability to perform predictive analysis and collect a large amount of information, the use of IT tools is extending to all phases of the building's life (Hong T. et al., 2020; Llatas C. et al., 2020). The information and design process' digitization has triggered a change in the methodological approach to the architectural heritage restoration project, enabling the optimization of the time and resources required for the buildings' conservation and preservation (AA.VV., 2021; Accardo G. et al., 2005; Lubelli B. et al., 2018).

## **2 Information technologies tools for architectural design**

Since the construction is a complex activity composed of several multidisciplinary process, the need to optimize the building's construction process to improve its management and performance and to limit the risk of problems that might arise during construction and throughout the entire building's life cycle, have turned the attention of the architectural world to IT and technological innovations. (Hong T. et al., 2020; Jin R. et al., 2019; Nikmehr B. et al., 2021)

Among the most popular digital technologies are those related to the three-dimensional representation of buildings and the survey of architectural heritage; the use of laser scanners, total stations, Unmanned Aircraft System (UAS), digital

photogrammetry and modelling software have simplified and speeded up task of graphing, allowing greater control in design processes.

Information technology tools that support all those involved in decision-making's architectural project have also become popular because of their ability to simulate the end results of a building process. More and more skilled technicians are taking advantage of computer technology to organize construction sites, design systems, collect and store documentation and devise new forms (parametric architecture). (Hong T. et al., 2020; Jin R. et al., 2019; Llatas C. et al., 2020)

In the construction industry, the greatest benefits have come with the introduction of Building Information Modelling (BIM), which has enabled the digitalization of all phases of the building life cycle by incorporating the time dimension into the project. Thanks to this variant BIM can simulate the entire process and allows the preliminary identification of possible problems (construction defects, energy performance, conflicts between workings...) and the definition of the best possible solutions with immediate benefits on the sustainability of the construction process and the success of the interventions. (Cursi S. et al., 2022; Hauashdh A. et al., 2022; Hong T. et al., 2020; Nikmehr B. et al., 2021)

A concrete example of the potential of BIM in the construction sector is the recent work carried out by Studio Berlucci s.r.l., an engineering company based in Brescia, which carried out the entire restoration of the Polirone Monastic Complex in San Benedetto Po (MN, Italy) by relying completely on BIM and producing a detailed 3D model of the complex with all the information collected. (Al-Muqdad F. et al., 2023; Banfi F., 2021; Belmondo S., 2018)

In addition to BIM, other useful tools for predictive diagnostic of building's damages and performance are modern smart technologies: AMI - Advanced Metering Infrastructure, IoT - Internet of Things, AI - Artificial Intelligence, DSS - Decision Support System, ML - Machine Learning. (Hong T. et al., 2020; Llatas C. et al., 2020; Nikmehr B. et al., 2021)

These tools, with the help of appropriate sensors, devices and equipment, even allow real-time data collection (e.g. IAQ - Indoor Air Quality, indoor environmental quality) and taking advantage of big data progresses, powerful computing and artificial intelligence can produce a digital twin of the building optimizing its performance throughout its life cycle. (Hauashdh A. et al., 2022; Hong T. et al., 2020; Nikmehr B. et al., 2021)

## **2.1 Interoperability between tools and their limitations**

The many different types of information needed for architectural design have led to the continued implementation of digital technologies to increase interoperability between tools and to provide more performance in the design simulations. (Cursi S. et al., 2022; Hauashdh A. et al., 2020)

Interoperability between tools defined by the ISO/IEC 2382 as the “capability to communicate, execute programs, or transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units” allows a multidisciplinary approach to architectural design by combining the functions of different IT tools.

Starting from the BIM, which using the IFC (Industry Foundation Classes) format lends itself well to the easy transfer of data between one system and another (Cursi S. et al., 2022), plugins have been developed to allow the collection of different types of information (3D model, materials and construction techniques, temporal data, construction site documentation...) in a single platform through the integration of the BIM software with additional IT tools (GIS - Geographic Information System, graphic software, database, CDE - Common Data Environment...). (Cursi S. et al., 2022; Hauashdh A. et al., 2022; Yang X. et al., 2020)

Several experiments have demonstrated the effectiveness of interoperability between computer tools and software in the management of construction processes, but the coexistence of different types of data that are not always compatible is the major obstacle due to the partial or total loss of information during file transfer or to the difficulty in comparing data.

Additional application limitations of computer systems mostly refer to the field of restoration and maintenance of architectural heritage. The main difficulty in digitizing a detailed restoration project lies in the management of a huge amount of data of different nature that, through critical analysis, must lead to the definition of the best preventive and planned maintenance actions to preserve the memory of the building heritage.

However, the application of BIM and Heritage BIM (H-BIM) in maintenance operations is still developing and is based on more theoretical than practical approaches. This is because of the existence of little digital documentation for existing architectural assets, which has been acquired through different modes and tools that do not allow homogeneous data collection and make the data comparison and transfer operations difficult. (Cursi S. et al., 2022; Hauashdh A. et

al., 2022; Hong T. et al., 2020; Llatas C. et al., 2020; Lubelli B. et al., 2018; Nikmehr B. et al., 2021; Yang X. et al., 2020)

To overcome this problem, the research and the method and/or procedures of analysis should be systematized to obtain comparable results that allow the interaction between the data and their digitization (Shvaiko P. et al., 2013).

### **3 Tools for architectural heritage's conservation**

As well as in the construction of a new building it is essential to assess its energy performance and construction phases beforehand to avoid wasting time and resources, in the same way it is important to make preliminary assessments for architectural heritage restoration and maintenance work using the tools currently available (Cursi S. et al., 2022; Hong T. et al., 2020; Jin R. et al., 2019; Llatas C. et al., 2020).

Since restoration and preventive and planned maintenance interventions involve a wide range of professionals with different skills, each of them must be up to date on research innovations and must be able to easily find all the information needed to intervene on the architectural heritage.

Various experiments have attempted to develop information systems and tools that could facilitate the decision-making process of professionals involved in architectural heritage conservation.

Among these experiences it is worth mentioning the Risk Map developed by the Italian "Istituto Superiore per la Conservazione ed il Restauro" (ISCR), which aims to provide information on the state of conservation of architectural assets and their factors levels of vulnerability and risk (distinguished into "individual vulnerability" and "territorial danger"). This tool is configured as a Geographical Information System associated with a special database in which each asset is catalogued by means of sheets, distinguished by categories of assets, which collect information regarding the state of conservation and the registry of the architectural asset (type, intended use, location, age of construction...). (AA.VV., 2013; Beni Culturali, Carta del Rischio)

A similar project is the one developed within the Interdisciplinary Research Program "Venezia 2021," which aims to provide indicators and descriptors useful for the assessment of the vulnerability of the built heritage in order to enable the definition of a restoration project that moves toward a preventive approach to ensure the preservation of the assets in the long period. (AA.VV., 2021)

In addition, the experience conducted within the inter-university research program "SCN\_00520 Product and process innovation for sustainable and planned maintenance, conservation and restoration of the cultural heritage MIUR Smart Cities and Communities and Social Innovation" (Bernardo G. et al., 2021; Guida A. et al., 2018; IES) developed the digital platform HeMaIn (Heritage Maintenance Innovation) for the management of the maintenance process in collaboration with the IT company "TAB Consulting".

### ***3.1 Toward an open knowledge platform tool for architectural heritage conservation***

In light of the needs emerged from the study of the research state of the art to preserve and safeguard the architectural heritage's life, this research activity aims to contribute to the development of innovative tools and methods for preventive and planned maintenance for the preservation of architectural and cultural heritage: intervene on the preservation of architectural heritage also affects the preservation of the movable property stored in (Acordon A., 2013; Lucchi E., 2018; Rossi M., 1982). In particular, the work aims to contribute to the development of operational protocols based on currently available best practices for the restoration of buildings affected by capillary rising damp, a phenomenon that causes different kinds of deterioration in architectural artifacts of historical and artistic interest (Castelluccio R. et al., 2019; Franzoni E., 2014; Lubelli B. et al., 2018; Rossetto M., 2013).

It has become clear how the proper management of the complex preliminary phase of knowledge of the building has an important impact on the definition of the restoration project and its effectiveness and durability; therefore, through the critical analysis of the restoration interventions carried out on case studies in which CNT® (Charge Neutralization Technology)-Domodry® was applied, that is currently the most effective method for the resolution of rising damp (AA.VV., 2020; Castelluccio R. et al., 2019). The research methodology adopts a multidisciplinary approach and includes the analysis of the entire restoration process of the architectural heritage: historical/archival survey, material/constructive survey, pathological survey, planning and diagnosis of interventions and planning of preventive maintenance phases.

In order to preserve and safeguard the architectural heritage's life it is essential to set up a management and maintenance plan for the restoration and recovery

process that, in accordance with the restoration principles and the sustainability demands (environmental, economic, and social) identifies every action, procedure, and material needed for the definition of the restoration project, which must arrive at the determination of interventions and their verification of effectiveness to ensure the durability of the obtained results. For this reason, it is essential to combine a suitable restoration project with a diagnostic and monitoring plan to verify the state of conservation before and after intervention (AA.VV., 2020), relying on an open knowledge platform tool that simplifies and speeds up the design process and continuous updating on current innovations.

Another challenge related to the development of an open knowledge platform tool lies in the certification and traceability of information uploaded and reprocessed by different stakeholders (Eppinger E. et al., 2021; Murray-Rust P., 2008). For this purpose, many IT tools have already been equipped with systems that allow visualization of the source and author of the data and guarantee the intellectual property of the same. An example is "Blockchain" technology, which makes possible the development of applications where different parties can enter information into an open and implementable database without needing a central control and verification entity (Cursi S. et al., 2022; Nikmehr B. et al., 2021).

The scientific literature and the research state of the art, regarding the restoration of buildings affected by rising damp, offer few and inconclusive information that are difficult to compare (Lubelli B. et al, 2018); for this reason, the research aims to bring together all the information and results obtained in a digital platform, configured as an open knowledge platform tool, which has the dual objective of making information accessible to support the preventive maintenance's processes of the architectural heritage and to act as an incubator of innovations for overcoming the limitations of currently available materials and technologies.

As a matter of fact, there is still no open and implementable digital platform that allows in a single database a critical overview of the existing tools, methods, processes and materials to support the development of preventive and planned maintenance and to plan all the phases of a restoration project.

#### **4 The digital cataloguing of information**

In order to identify all the "Best Practices" useful to define a restoration process, it is essential to compare and analyse in detail numerous case studies.

Therefore, it is necessary to define from the beginning how to collect and catalog information for an orderly work that can also support future experiences.

To develop the open knowledge platform tool, it was decided to start with the setting up of a "model sheet" that would provide clear and shareable indications on how the information should be found and how the data should be organized to ensure homogeneity and comparison of the same.

A survey of current cataloguing methods, forms, protocols and guidelines developed from experience was conducted. Specifically, two cases were selected for the development of this specific research activity.

A first case is the "Catalographic Standards" of the ICCD (Central Institute for Catalog and Documentation). (ICCD; Tucci R., 2018) These standards aim to simplify the acquisition of knowledge about the archaeological, architectural, landscape, historical, artistic and demo-ethno-anthropological heritage through the introduction of special tools and rules that allow homogeneous cataloguing in the Italian territory.

Catalogued data are entered into a General Catalog Information System (SIGECweb) that manages the entire flow of information. This web-based platform is accessible only to registered and associated users who can perform certain activities depending on the user profile with which they have been associated with the system: administrator, cataloguer, verifier, reading user and consultation user.

A second case is represented by the information system developed by the Central Institute for Restoration (ICR) with the aim of providing scientific and administrative support to the institutions responsible for the protection of cultural heritage (Accardo G. et al., 2005; Cultural Heritage).

This information system consists of a Geographical Information System (GIS), which exploiting a statistical approach provides information on the state of preservation of assets and their risk and vulnerability factors. The platform, equipped with a system of databases, alphanumeric and cartographic, is implemented through the compilation of specific sheets available on the appropriate website.

These sheets are differentiated according to the area to be analysed (Environmental sheets, Historic centre sheets, Underwater sheets, Vulnerability - seismic sheets, Vulnerability - state of preservation sheets) and refer to the ICCD Catalographic Standards.

Based on these experiences, it was decided to create a new "Model Sheet" that would meet the needs of this research activity and conform to the national catalographic system (ICCD) so that the information and results obtained can dialogue with SIGECweb.

Therefore, the rules provided by the ICCD were followed in the realization of the sheet, while for the information on the state of preservation of the architectural heritage, reference was made to the "Vulnerability Sheet - State of Preservation" created by the ICR.

The sheet, created with the support of the open software "Obsidian v.1.1.16" (which operates on Markdown files and allows the creation of internal links for better management and comparison of information), is divided into two macro-chapters: registered data of the architectural heritage, architectural heritage description.

To develop the chapter of architectural heritage's registered data (Fig. 1), reference was made to what had already been developed by the ICCD's file on architectural heritage. Fields pertaining to the following aspects were included in this chapter: unique identification code, search level, subjects involved in the cataloguing, subject of the sheet, location, historical information, relationship with the context, legal status and constraints.

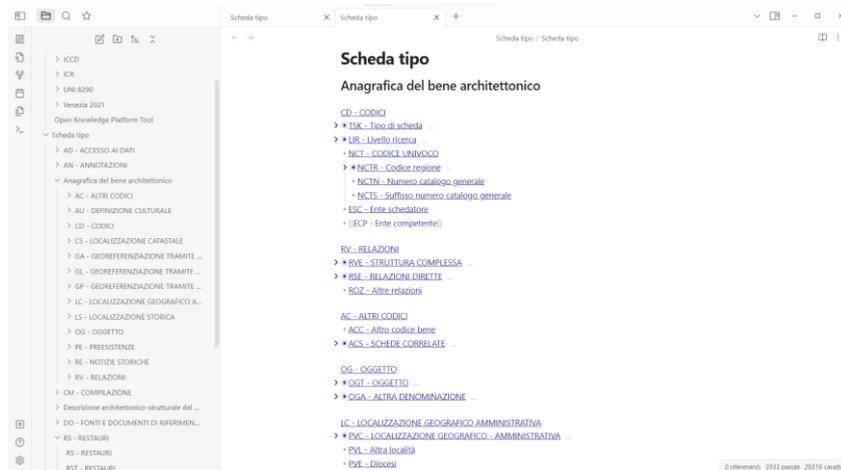

Fig. 1 Screenshot of the Model Sheet's "Architectural heritage's anagraphic data" section realized with Obsidian v.1.1.16 (authors' image)

For the chapter on architectural heritage description, we started by analysing what has already been done by the ICCD and ICR and came to the conclusion that both proposed sheets have a lack of information that have been filled by using the classification of the technological system introduced by UNI 8290.

The section about the architectural-structural description of the building (Fig. 2) was structured by decomposing the building system into the three information levels defined by the UNI 8290 (classes of technological units, technological units and classes of technical elements) to do not leave out any component of the architectural organism. For each class of technological unit, were included fields that specify the individual technological units and classes of technical elements analysed and provide information on the following aspects: type, location, construction technique, materials and inspect ability.

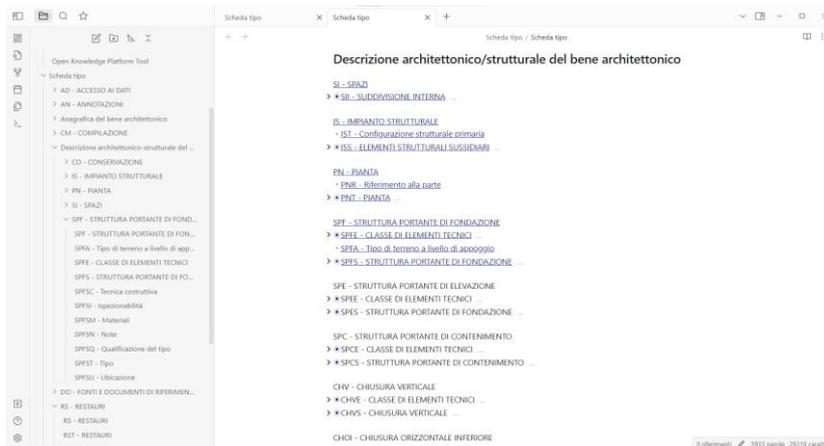

Fig. 2 Screenshot of the Model Sheet's "Architectural heritage's description" section realized with Obsidian v.1.1.16 (authors' image)

To better understand the state of conservation of every building's component an additional section (Fig. 3) has been integrated to each of them to add information about the conservation and the analysis of the existing phenomena of deterioration and alteration, inserting an additional focus on phenomena linked with the presence of moisture in the structure.

For the realization of this section, we started from the form provided by the ICR for the evaluation of the state of conservation of architectural heritage and integrated it with the classifications defined in the lexicon of the UNI 1182:2006 to standardize the data collected for future research developments.

This section allows the entry of information identifying the type of degradation or alteration, severity of degradation, percentage of spread, urgency and recommended interventions for the restoration of architectural elements.

A final section of the sheets wants to collect data and information regarding all restoration operations conducted on the architectural heritage and provides information regarding the types of interventions carried out, materials and techniques used. In addition, fields specifying the advantages and disadvantages resulting from each intervention should also be filled in.

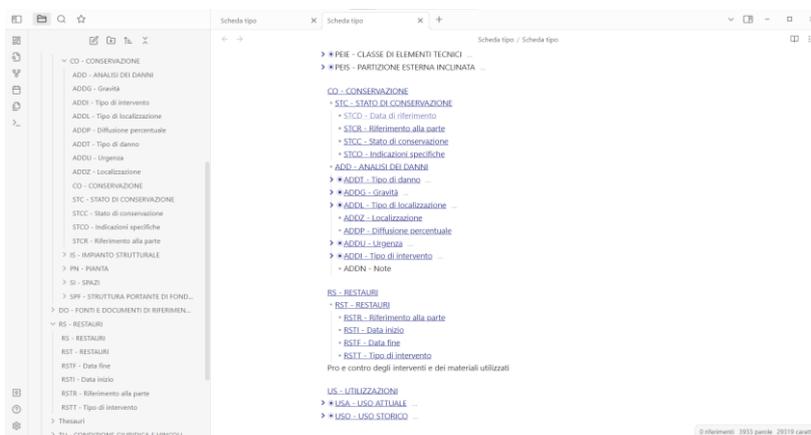

Fig. 3 Screenshot of the Model Sheet's "State of Conservation" and "Restoration" sections realized with Obsidian v.1.1.16 (authors' image)

## 5 Conclusions and future developments

The development of an open knowledge tool configured as an open and implementable platform will allow the organization of data and information for the identification of currently available "best practices" for the restoration of architectural heritage affected by the phenomenon of rising damp.

One of the goals of the open knowledge platform tool is to communicate with national cataloguing systems to permit the collection of as much information and experience as possible in order to constantly improve and update best practices for architectural heritage conservation.

For this reason, the platform could be managed with a blockchain system that allows anyone to increase the data available by opening new horizons for research and experimentation, as with SIGECweb. In this way it will be possible to

start a process of raising awareness among all stakeholders involved in the conservation of the architectural heritage.

Only by adopting a systematic and shared approach, based on the results of past experience and scientifically validated results, it is possible to move toward the definition of a standard of good restoration practices that takes into preventive and planned maintenance to support the decision-making process of all stakeholders involved in the heritage conservation process who will have at their disposal tools that will allow the optimization of time and resources for the benefit of the conservation process.

### Abstract

Circular economy is an economy model aiming to overcome the current linear economy and closing resources loop. Circular economy is still far from being widely widespread and implemented. The transition to circular economy is particularly tough in complex and highly fragmented sectors where information, materials and products' flows are interrupted multiple times at different stages. Among these complex and fragmented sectors, the building sector stands out given its high resource consumption and emissions. Collaboration is needed to implementation circular economy in the building sector. Indeed, collaboration enables to spot in advance any issues and/or mismatches that may arise along the whole value chain given that the different actors belonging to the value chain jointly collaborate since the starting design phase. We have focused on buildings' façade, as they are responsible for 10% to 20% of the total embodied carbon emissions of the building and they are external elements easy to be accessed, maintained and assembled. The different actors involved in the façade value chain have been identified, through action research methodology. Besides, the collaboration among the actors involved, on the one side, in the circular product development (i.e. exploration phase) and, on the other side, in the circular business model design (i.e. exploitation phase) have been detected. We posit

that (i) collaboration is key in order not to have mismatches along the whole value chain and be able to exploit the potentialities of circular economy, (ii) different actors are involved in exploration and/or exploitation phase performing the same or different roles, depending on their specific skills and resources.

## 1 Introduction

The current mainstream economy model is based on the “take-make-dispose” paradigm, i.e. on resources extracted from natural environment, exploited for products’ manufacturing and then disposed. The long term sustainability of this paradigm has been extensively debated (Biswas & Roy, 2015; Kristensen & Mosgaard, 2020; Murray, Skene, & Haynes, 2017) and more recently paved the way to an opposite paradigm, based on resources’ value preservation and products’ useful life extension (N. M. P. Bocken, de Pauw, Bakker, & van der Grinten, 2016; Geissdoerfer, Morioka, de Carvalho, & Evans, 2018; Kirchherr, Reike, & Hekkert, 2017; Merli, Preziosi, & Acampora, 2018), and named Circular Economy.

The transition from linear to circular economy is far from being completed, especially in sectors characterised by long value chain, high products’ complexity, resource consumption and emissions (Leising, Quist, & Bocken, 2018).

Among these sectors, the building sector stands out as being responsible for 33% of emissions, 40% of resources consumption and 40% of waste production worldwide (Ness & Xing, 2017). Moreover, the building sector is characterised by a long and fragmented value chain and a high complexity and durability of its final products (i.e. buildings) (Dewagoda, Ng, & Chen, 2022). Therefore, implementing circular economy in the building sector is challenging and calls for an open and collaborative innovation approach (Giorgi et al., 2022; Khitous Fatima, Urbinati Andrea, Chiaroni Davide, 2022; Köhler, Sönnichsen, & Beske-Jansen, 2022). Indeed, it requires all the companies belonging to the whole value chain to engage themselves in the transition from linear to circular economy (Genovese, Acquaye, Figueroa, & Koh, 2017; Ghisellini, Cialani, & Ulgiati, 2016; Seuring & Müller, 2008).

Moreover, the transition from linear to circular requires the involved companies to redesign the whole business model dimensions, namely value creation, value transfer and value capture. Circular economy principles have to be adopted in the whole business model. Indeed, not only the product/service must be designed according to circular economy principles but also the created value has to be properly transferred and captured through ad hoc circular managerial practices (e.g. product-service-systems) (Centobelli, Cerchione, Chiaroni, Del Vecchio, & Urbinati, 2020; Urbinati, Chiaroni, & Chiesa, 2017). In the value creation phase, it is needed to shift from the design of a linear product to the design of a circular product (Centobelli et al., 2020). A circular product design in the building sector has to consider many different features during its life cycle (e.g. remanufacturing, reusability) and requires new actors to be involved in the innovation process (N. M. P. Bocken et al., 2016). Indeed, the whole value chain must be aligned and involved (Farooque, Zhang, Thürer, Qu, & Huisingh, 2019; Leising et al., 2018). An open and collaborative innovation approach might be, therefore, an enabler for the circular design by engaging external actors (Jesus & Jugend, 2023; Köhler et al., 2022).

After having jointly designed the final product according to circular economy principles, the companies belonging to the buildings' value chain should jointly develop the proper business model, through which deliver and capture the value created (Centobelli et al., 2020). To design a proper circular business model, many aspects have to be taken into account (e.g. take back systems, product-service-systems) (Centobelli et al., 2020; Lewandowski, 2016) and the whole value chain needs to be involved in the business model design (Farooque et al., 2019; Leising et al., 2018). Also in this case, an open and collaborative innovation approach could be applied To engage all the needed actors in a common effort toward a shared circular business model (N. Bocken & Ritala, 2022).

Current literature about circular economy in the building sector focuses on (i) designs strategies and/or tool for circular buildings (Antwi-Afari, Ng, & Chen, 2022; van Stijn & Gruis, 2020), (ii) the level of application of circular principles in the building sector (Giorgi et al., 2022), (iii) the circular strategies that could be applied in the buildings' sector (Charef, Lu, & Hall, 2022; Chen, Feng, & Garcia de Soto, 2022; Dewagoda et al., 2022) and (iv) Life Cycle Assessment analysis (Antwi-Afari et al., 2022). All these perspectives contribute to enlarge literature on circular economy and the building sector and to improve the understanding of the role of circular economy in the buildings context.

However, to the best of our knowledge, the interplay between circular economy, the building sector and open and collaborative innovation is still a promising and emerging research field with only a few recent contributions (Charef et al., 2022; Chen et al., 2022; Giorgi et al., 2022; Oluleye, Chan, Saka, & Olawumi, 2022). The application of open and collaborative innovation in the circular buildings' context merits additional academic research. Hence, we aim to contribute to extant literature by (i) defining the actors collaborating to jointly design innovative circular buildings' components and business models and (ii) the roles performed by these actors in value creation, transfer and capture dimensions. Our research question is therefore: which are the collaborating actors and the roles performed to jointly develop innovative circular products and business models?

The remainder of this paper is organised as follows. Section 2 deepens the state-of-the-art of both circular economy in the building sector and open and collaborative innovation. Section 3 presents the methodology applied in this research paper. Findings are presented in Section 4. Finally, Section 5 provides conclusions, limitations and future research avenues.

## **2 State-of-the-art**

### ***2.1 Circular Economy in the building sector***

The conventional buildings construction industry follows a linear value chain and, given the complexity and specificity of this industry, materials and information flows are interrupted at each stage of the building value chain (Dewagoda et al., 2022; Giorgi et al., 2022). Consequently, long-term goals are rarely shared by the different players involved in the process resulting in an overestimation of materials used (Charef et al., 2022; Chen et al., 2022; Khitous Fatima, Urbinati Andrea, Chiaroni Davide, 2022). Given the impact of the building sector on the environment (as reported in Section 1), the building sector has been identified as a "priority area" for the transition to circular economy (Giorgi et al., 2022). Indeed, implementing circular economy in the building sector could reduce the usage of virgin material and emissions, by preserving resources' value and extending buildings' lifecycle (Ness & Xing, 2017).

Circular economy principles applied to buildings have been defined as "a lifecycle approach that optimizes the buildings' useful lifetime, integrating the

end-of-life phase in the design and uses new ownership models where materials are only temporarily stored in the building that acts as a material bank" (Leising et al., 2018).

However, the application of circular economy in the building sector is still not well developed in Italy as well as in other European countries (Giorgi et al., 2022).

External elements of a building are one of the most suitable for the implementation of circular economy principles in the building sector (Giovanardi et al., 2023; Hartwell, Macmillan, & Overend, 2021; Wouterszoon Jansen, van Stijn, Eberhardt, van Bortel, & Gruis, 2022). Indeed, among building's external elements, the building's façade stands out as being responsible for 10% to 20% of the total embodied carbon emissions of the building and the ease of access to such components facilitates maintenance, repair and disassembly operations, merging environmental, technical and business benefits (Giovanardi et al., 2023). This paper is therefore focused on buildings' façade, given their high environmental impact and ease of access, maintenance, repair, characteristics making façade one of the most suitable buildings' elements in which to implement circular economy principles.

The implementation of circular economy principles in the façade sector could be enabled by different circular managerial practices to be applied in the different circular business model dimensions. The first and fundamental dimension on which to act to design a circular business model is value creation. The main circular practice to implement circular economy principles in value creation refers to circular product design practices (N. M. P. Bocken et al., 2016; Centobelli et al., 2020; Sassanelli, Urbinati, Rosa, Chiaroni, & Terzi, 2020). The most relevant circular design practices, stemming from current literature, aim to extend product lifecycle and refer to (i) design for assembly/disassembly, (ii) design for modularity, (iii) design for prefabrication, (iv) design for standardization, (vii) design for accessibility, (viii) design for manufacture, (ix) design for reuse, (x) design for flexibility/adaptability (Charef et al., 2022; Chen et al., 2022; Eberhardt, Birkved, & Birgisdottir, 2022). These aforementioned design practices could entail the development of novel technologies and thus require a joint effort to benefit from the combination of the complementary skills and resources from the actors involved in the circular design process (N. M. P. Bocken et al., 2016). To transfer and capture the created value, ad hoc circular managerial practices could be implemented (Centobelli et al., 2020). The most relevant circular managerial practices, stemming out from current literature, aim to servitization strategies and

refer to (i) take-back systems (TBS), (ii) product-service-systems (PSS), (iii) traceability, (iv) sharing (Charef et al., 2022; Munaro, Freitas, Tavares, & Bragança, 2021). To effectively implement these circular design practices and circular managerial practices, the involvement and collaboration among the different actors of the façade value chain – and, eventually, new actors not nowadays part of the façade value chain – is key to convey circular economy principles all along the value chain, implement the servitization principle and thus circular economy (Charef et al., 2022; Eberhardt et al., 2022; Munaro et al., 2021).

## ***2.2 Collaborative and open innovation in the Circular Economy***

The transition from linear to circular economy calls for open innovation practices (N. Bocken & Ritala, 2022; Jesus & Jugend, 2023; Köhler et al., 2022). Indeed, open innovation practices are aligned with two key characteristics of the transition towards circular economy. On the one hand, open innovation leverages on external knowledge sources, not only internal ones, and these external knowledge sources are an important factor to implement circular economy practices (e.g. design for X) and manage to close resource loop, thanks to collaboration among different actors (Aarikka-Stenroos, Chiaroni, Kaipainen, & Urbinati, 2022; N. M. P. Bocken et al., 2016; Genovese et al., 2017; Ghisellini et al., 2016) . On the other hand, open innovation leverages on a value chain perspective, not only a company-focused perspective, and this value chain perspective is a paramount factor to be considered in implementing circular economy practices (e.g. product-service-systems) in order not to incur in mismatches among the different value chain's phases and products useful life's phases (Chen et al., 2022; Farooque et al., 2019; Khitous Fatima, Urbinati Andrea, Chiaroni Davide, 2022). Hence, open innovation could be an enabler of the transition from linear to circular economy by involving not only the focal company but also the whole supply chain in the transition toward circular economy and by proactively engage all the involved companies.

To maximize the value generated by open innovation, both exploration and exploitation activities must be taken into account. The former refers to an innovation development process enhanced by external knowledge sources, the latter refers to effectively capturing through the involvement of external actors the value created (Raisch & Birkinshaw, 2008; van de Vrande, de Jong, Vanhaverbeke, & de Rochemont, 2009). Both exploration and exploitation call for

collaboration, indeed there is the need to gather not only internal but also external knowledge sources, and for a value chain perspective in order not to have a too narrow focus (Lavie & Rosenkopf, 2005).

Thanks to open and collaborative innovation, companies can cooperate and jointly develop (i) the circular product design (through exploration activities) and (ii) a common and shared circular business model (through exploitation activities), in which value creation, value capture and value delivery are designed according to circular economy principles (N. M. P. Bocken et al., 2016; Centobelli et al., 2020; Urbinati et al., 2017).

We aim to understand if and how the actors involved in the circular product and business model design process have implemented open and collaborative activities (i.e. exploration and exploitation ones) in the transition from linear to circular economy.

### **3 Methodology**

The empirical base for our research has been provided through an action research approach, i.e. “an approach to research that aims both at taking action and creating knowledge or theory about that action” (Coughlan & Coughlan, 2002). In action research, researcher and practitioners are actively involved in a real world research processes, from research design to evidences and findings identification, aiming to advance both academic and practical knowledge (Checkland & Holwell, 1998; Whyte, 1991). Action research methodology has already been applied in the building sector, enabling close collaboration between the building sector’s practitioners and researchers and advancing both theory and practice (see e.g. Eriksson, 2010).

This paper is based on the active participation of researchers, to the “Envelope for Service (E4S) - Phase II” project. “E4S – Phase II” is the sequel of “E4S – Phase I” research project.

Both Envelope for Service – Phase I and Envelope for Service – Phase II rely on multi-disciplinary collaboration of designers, planners, engineers, consultants, technical specialists and scholars, representing both industry partners and academic partners. The main objective of the “E4S – Phase II” project was to design a circular business model according to the servitization principle to be applied in the façade sector. Through the collaboration of both academic and

industry partners involved in the research project, it was possible to identify a circular business model proposing buildings' façade as product-service-system.

The paper's authors took actively part to the development of the "Envelope for Service (E4S) - Phase II" following each project advancement, participating to the project meetings and proactively contributing to the development of an innovative circular business model in the façade sector.

#### **4 Envelope for Service project: overview and case study implementation**

The Envelope for Service project aimed at:

- i. Designing an innovative circular façade, considering the integration of circular economy design practices as early as possible in the product design phase,
- ii. Defining a circular business model to offer the developed innovative circular façade by involving not only the single company offering the façade to the final users but also the whole façade value chain actors,
- iii. Provide empirical evidence of the application of the Envelope for Service model in a real demo case in Italy.

As described in Section 3, both Envelope for Service – Phase I and Envelope for Service – Phase II rely on multi-disciplinary collaboration of both industry partners and academic partners. This collaborative and innovative environment enabled to identify (i) the different actors belonging to the façade value chain and (ii) the different roles performed by each actor in the design of the value creation, transfer and capture dimensions. Firstly, the key actors of the façade value chain were jointly identified by the project's partners in the following ones: integrated design consultancy company, façade manufacturer, service provider, facility manager, asset owner and final user. Each actor belonging to the façade value chain contributes in different ways to the exploration and the exploitation phase based on its specific skills and resources. For instance, the façade manufacturer contributes solely to value creation (i.e. the exploration phase), given its focus on façade's production activities. The façade value chain's actors and their roles in value creation, transfer and capture dimensions are discussed in Section 5.

The empirical evidence is based on a real word Italian testing project. This case study refers to the retrofitting of an existing building through the adoption of innovative façade modules. These modules are composed by controllable blinds,

a decentralized ventilation machine and a building integrated photovoltaic (BIPV) system. Moreover, the innovative façade modules are embedded with digital technologies that optimize daylight control, thermal heat transfer optimizing thus also energy consumption and comfort perceived by the buildings' occupants. Besides, the BIPV enables to produce electric energy and to, partly, self-consume it. The innovative façade design is modular and enables easy assembly and installation at the building premise easily adaptable to the specific building's characteristics. Considering the building's characteristic of the testing project, it is a residential social housing condominium, almost forty years old and located in central Italy, with four floors and more than ten flats. The application of the Envelope for Service concept, from a technology perspective, gives thus evidence of a promising innovative circular façade to be adopted in residential buildings generating both qualitative (i.e. improved comfort) and quantitative benefits (i.e. energy consumption reduction). Considering then the economic perspective, the investment cost of the innovative circular façade is higher than the investment cost of the traditional façade. The investment cost difference is relevant and the benefits achieved by reducing the energy consumption, and thus by reducing the energy bill, are not enough to counterbalance the investment cost differential, resulting in negative economic performance for the innovative circular façade.

## **5 Findings**

As described in Section 2.1, the building façade is one of the most suitable buildings' elements for the implementation of circular economy principles in the building sector, given its environmental impact and ease of access, maintenance, repair (Giovanardi et al., 2023; Hartwell et al., 2021; Wouterszoon Jansen et al., 2022). Hence, this paper focuses on building façade from two different perspective (i) the value creation perspective (i.e. exploration phase) and (ii) the value transfer and capture perspective (i.e. exploitation phase), based on the evidence emerged in the "E4S – Phase II" project. The former is presented in Section 5.1 and the latter is presented in Section 5.2. For both perspectives, we report the actors involved in the collaborative process, the actors' roles and the circular practices applied by each actor. The evidence emerged from both perspectives are then gathered in a research framework presented in Section 5.3.

### 5.1 Value Creation (Exploration phase)

Table 1 gives evidence of the actors involved in the value creation dimension (i.e. exploration phase) by describing their role in the design process and the circular design practices applied.

Table 1 – Exploration phase: main actors involved

<b>Actor</b>	<b>Role</b>	<b>Circular design practices</b>
Service provider	It acts as the technical project manager, gathering and providing all the relevant information (e.g. product requirements' needed by the final user) to the proper actor involved in the technical activities (i.e. in the design phase)	Design for modularity, design for accessibility, design for reuse, design for flexibility/adaptability
Façade manufacturer	The involvement of the façade manufacturer in the design phase prevents the risk of a mismatch between the design, the manufacturing and the installation phases and leads the development of manufacturing activities according to "design for X" practices	Design for assembly/disassembly, design for modularity, design for prefabrication, design for standardization, design for accessibility, design for manufacture
Integrated design consultant	Integrated design consultancy company provides strategic guidance on the whole design process, enabling the early identification of issues and threats. Integrated design consultancy company has thus to consider the needs of the different value chain actors involved, the façade's requirements needed, for instance, by the final user and the circular economy practices to be followed to design a circular product	Design for assembly/disassembly, design for modularity, design for standardization, design for accessibility, design for reuse, design for flexibility/adaptability
Final user	Final users interact with the service provider, providing them the final product desiderata and requirements to be satisfied according to their needs	-

The service provider acts as the focal point, the technical project manager collecting external and internal knowledge sources supporting the development of the innovative product. The involvement, in the design phase, of both the façade manufacturer and the integrated design consultancy company enables to avoid mismatches among design, manufacturing and installation phase, reducing wastes and inefficiencies (in accordance with Charef et al., 2022; Eberhardt et al.,

2022). Finally, the final users have an active role in this design process by providing to the service provider the desired characteristics to be met by the innovative product.

All the circular design practices identified in literature (see Section 2.1) were applied by the involved actors even if in different ways. Indeed, the service provider focuses more on the circular design practices enabling to adapt the technology to be developed to the different actors' needs (e.g. design for flexibility/adaptability). Moreover, the façade manufacturer focuses on circular design practices enabling not to have mismatches among design, manufacturing and installation phases, thus focusing on e.g. design for assembly/disassembly, manufacture. Finally, integrated design consultant focuses on both circular design practices considering the different actors' needs (e.g. design for flexibility/adaptability) and avoiding mismatches among the different lifecycle phases (e.g. design for assembly/disassembly).

Thanks to the collaboration between the actors involved in the exploration phase, the innovative circular façade has been developed. The innovative circular façade modules are embedded with digital technologies, that deliver performance improvement and enable the digitalization of the whole value chain. The façade can thus work as a system, with façade modules including many functional products and services, that deliver a pre-determined and customized performance. The benefits of applying digital technologies in the building industry are also reported by e.g. Giovanardi et al., 2023.

## **5.2 Value Transfer and Capture (Exploitation phase)**

Table 2 gives evidence of the actors involved in the value transfer and capture dimensions (i.e. exploitation phase), by describing their role in the business model and the circular managerial practices applied.

Table 2 – Exploitation phase: building's value chain actors involved

<b>Actor</b>	<b>Role</b>	<b>Circular managerial practices</b>
Service provider	The service provider retains the façade ownership along the whole lifecycle. Hence, the service provider is in charge of the maintenance and monitoring of the façade, in order to guarantee stable performances	Product-service-system

Integrated design consultant	Integrated design consultancy company supports the service provider in defining the KPIs to be monitored to guarantee the façade's performance	Traceability, system	product-service-
Facility manager	The facility manager acts in close collaboration with the service provider, supporting monitoring and maintenance activities and ensuring the adequacy of the façade's performances	Traceability	
Asset owner	The asset owner relies on the service provider, who has to ensure the agreed façade's performances	-	
Final user	Final users are in charge of the correct utilization of the final product, avoiding any misuse	-	

The service provider acts as a central player, the hub of the value chain, the customer's single point of contact.

The innovative features (e.g. modularity, digitalization) of the circular façade, make it suitable for the delivery of a Product-Service-System (PSS) package. PSS is one of the main managerial practices for value capture in circular business models (Centobelli et al., 2020). The implementation of PSS for capturing value from customers requires a close collaboration between producers and customers (Mendoza, Sharmina, Gallego-Schmid, Heyes, & Azapagic, 2017). Indeed, functionalities rather than ownership are delivered in PSS and consumers only own a license or a lease contract, moving from purchase to "pay-per-use" or "pay-per-performance" strategies (Centobelli et al., 2020). The PSS approach selection is aligned with what stems from the study by Charef et al. (2022), who posit PSS as an optimal solution for adaptability and flexibility to any changes, including changes occurring during the building's use phase, and overcome issues related to ownership changes.

Hence, the service provider retains ownership and responsibilities over these innovative circular façade systems during the whole lifecycle, enabling façade disassembly, refurbishment and reuse. The innovative circular façade modules should thus be offered through a one-stop-shop and performance-based model, leveraging on different partners, each providing specific competences. Integrated design consultancy company supports the service provider by defining the performance KPIs to be monitored. The facility manager collaborates with the

service provider supporting monitoring and maintenance activities and ensuring the adequacy of the façade's performances.

Apart from product-service-system, the other circular managerial practice applied in the exploitation phase refers to traceability, applied to track over time the performance achieved by the façade and give evidence of them to the final users. Performance tracking is also a key enabler for performance-based contract application, given the possibility to measure the achieved performance and compare them to the target performance to be achieved according to the performance-based contract (Yi, Lee, & Kim, 2017).

Finally, given the similarities between the skills required and the business model applied, Energy Service Companies (ESCO) have been identified as the proper service provider. Indeed, ESCo already have in their current business model, applied in the energy efficiency market, the key characteristic (i.e. performance-based contract offered leveraging technical and managerial partnership) needed in the circular economy market (Carbonara & Pellegrino, 2018; Huimin, Xinyue, & Mengyue, 2019; Yi et al., 2017).

### 5.3 A comprehensive picture of actors involved and roles performed

To gather the findings emerged, we developed an ad hoc framework summarizing the actors involved in the two phases and their roles. Figure 1 shows the actors involved in exploration and exploitation phases differentiating between actors with the same role in both phases and actors with different roles in the two phases.

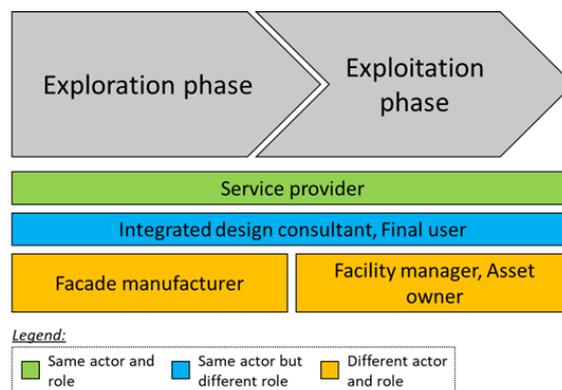

Figure 4 – Research framework: actors involved in the exploration and exploitation phases and their roles

The service provider, i.e. the ESCo, is the only actor which is involved in both phases performing the same role. Indeed, in both phases it is the single contact point for the final users performing project management activities (either from a technical perspective, in the exploration phase, or from a managerial perspective in the exploitation phase). Hence, the service provider emerges as the key actor enabling the offering of the innovative circular façade.

The integrated design consultant and the final users are involved in both phases but with different roles. The former acts in the exploration phase as a strategic guidance on the whole design process, whereas in the exploitation phase as the designer of the KPIs to be monitored. The latter acts in the exploration phase as an external knowledge source, whereas in the exploitation phase properly as the final user of the developed technology.

Finally, the façade manufacturer is involved only in the exploration phase, given its focus on the production phase of the innovative circular façade, and the facility manager and the asset owner are involved only in the exploitation phase, given their focus on the usage phase of the innovative circular façade.

The close collaboration, in the exploration phase, among the service provider, the integrated design consultant and the façade manufacturer emerges also in the article by Hartwell et al. (2021), together with the role of the final users as external knowledge source. The service provider's focal role is the combination of the evidences of Giovanardi et al. (2023) and Hartwell et al. (2021), who give evidence of the important role of the service provider respectively in the exploitation and the exploration phase. Hence, we posit the critical role of the service provider in both exploration and exploitation phase with a managerial role. Facility manager and asset owner have an active role only in the exploration phase, in accordance to Giovanardi et al. (2023) and Hartwell et al. (2021).

Conversely, the actors involved and the roles performed in the linear façade value chain are much more scattered and independently performed one from each other. Indeed, in the linear façade value chain, the service provider is not part of the façade value chain. The value creation is performed solely by the integrated design consultant, which is not involved in value transfer and capture. The two focal actors of the linear façade value chain are the façade manufacturer and the facility manager. These two actors have direct contact with the final customers, who buys the façade. The linear façade value chain is thus highly fragmented, with the different actors involved only in specific phases of the whole value chain.

## 6 Conclusions

Our paper contributes to the literature in the interplay between circular economy and the building sector, with reference to buildings' façade, highlighting the key role of open and collaborative innovation in implementing circular economy principles in the façade value chain. Indeed, collaboration enables to jointly develop innovative circular product and business model and to identify in advance issues and/or mismatches that may arise along the whole value chain. For instance, the close collaboration between designers and manufacturers enables not to have mismatches between design and production phases by considering the whole product lifecycle when designing the circular product.

Through the action research methodology, we identified (i) the key actors involved in the façade value chain, (ii) each actor's role in the jointly and collaborative development of the innovative circular product (i.e. exploration phase), (iii) each actor's role in the jointly and collaborative development of the innovative circular business model (i.e. exploitation phase). We gathered the evidence emerged in a research framework, pointing out the actors involved in the exploration and exploitation phases and the role performed distinguishing among actors focused on a single phase and performing a specific role, actors involved in both phases but with different roles and actors involved in both phases performing the same role.

We posit that open and collaborative innovation is an important factor to be considered in the transition from linear to circular. However, several challenges have still to be tackled to fully exploit the potential of open and collaborative innovation when implementing circular economy principles in the façade value chain. Some anecdotal challenging aspects emerged from our action research and could represent potential future research areas to be further investigated. These challenging aspects are (i) the needed for proper KPIs and indicators to align the different actors of the value chain toward common circular principles, (ii) the need for proper collaboration forms and contracts to ensure not only a short-term perspective (and short-term objectives) but also a long-term perspective (and long-term objectives), (iii) the need for a proper benefits' sharing mechanism between the service provider and the final users.

Finally, our paper is based on empirical evidence thus the main limitation could be represented by the bias given by the perspective of the companies, and people, involved in the Envelope for Service project. Moreover, the findings are

referred to the Italian context, given the national boundaries of the Envelope for Service project, and the here presented findings could be further enlarged and compared with evidences from different European countries.

### **Abstract**

This paper aims to investigate the impacts of food safety drivers on food safety climate of Italian agrifood companies. We empirically tested the relationship among food safety driver, leadership, internal communication, resources, and risk awareness. From March to May 2022, we gathered survey information from 168 Italian companies engaged in the agri-food industry. Results suggest that food safety drivers enhance each dimension of the food safety climate. This study is the first one that analyses the impact of food safety drivers on each food safety climate component, deepening the knowledge of the components of food safety climate in the Italian context. The main limitation of the present study is that we collected data from a single European Country and results cannot be generalized.

**Keywords** – Agrifood, Food Safety Culture, Food Safety Climate, Drivers, Italian Firms

**Paper type** – Academic Research Paper

### **1 Introduction**

The agrifood has been defined by the EC as the combination of the primary sector and the food industry (EC, 2007). It stands out as one of the most important sectors in the European Union because of its contribution in terms of economic output and employment (Food Drink Europe, 2020), particularly in Italy (CREA, 2022) where a number of products are among the Italian excellences

representative of the "Made in Italy". Moreover, worldwide - including Italy - micro and small-sized enterprises (SMEs) represent the majority of agri-food companies (Banterle et al., 2016; Bentivoglio and Giampietri, 2016; Cesaroni et al., 2021). Global trends for the future of the agrifood system have forced companies to revise their business models (Tell et al., 2016; Zouaghi & Sanchez, 2016; Del Baldo, 2022) due to the growing attention paid by governments, NGOs and the civil community to sustainability, climate changes, food safety and health in the light of the effects which their production has upon health, natural resources and the communities in which they operate (Hartmann, 2011; FAO, 2019).

In this vein, food safety has come to the fore in driving agrifood companies to integrate it within their corporate strategies and implement food safety management systems (FSMS) (De Boeck et al., 2017) to take into account social, environmental, ethical, and human rights issues in collaboration with their stakeholders. On the regulatory front, in Europe, new principles for food safety control were established already in the 2000-2010 decade (Tomasevic et al., 2013). Nonetheless, throughout the years, instances of consumer food poisoning and outbreaks have persisted (European Parliament, 2019; Griffith, 2006), with the majority of these incidents attributable to food handler errors and/or non-adherence to food hygiene or safety procedures (Powell et al., 2011; Wright et al., 2012). Consequently, some researchers shifted their focus from a formal and technically driven FSMS to a more human-centric aspect of food safety, as demonstrated by the emergence of concepts like food safety culture and food safety climate (Powell et al., 2011; Taylor, 2011; Yiannas, 2009). However, both the scientific literature and empirical evidence regarding food safety remain limited (De Boeck et al., 2015). One of the key aspects is understanding whether and how the drivers pushing companies to adopt food safety practices and systems actually facilitate the creation of a food safety climate within the company. Therefore, this paper aims to investigate the impacts of food safety drivers on four "components" of the food safety climate of Italian agrifood companies. More precisely, we empirically tested the relationship among food safety driver, leadership, internal communication, resources, and risk awareness. Results suggest that food safety drivers enhance each dimension of the food safety climate. The paper is organized as follows: section 2 introduces the literature background and the literature framework, section 3 describes the methodological approach, section 4 presents and discusses the main results drawn from the empirical analysis, while section 5 points out conclusions and implications.

## 2 Literature review

Food safety has been defined as “the condition of the foodstuffs in all stages of production, processing and distribution, required to guarantee protection of consumer's health, also taking into account normal circumstances of use and information available for the food stuffs concerned” (Baert et al., 2011, p. 941). Shifting the attention from the “techno-managerial dimension” (control and assurance activities and processes) to the “human routes” of food safety, the concepts of food safety culture and food safety climate (Gilling et al., 2001) have been introduced (De Boeck et al., 2015, 2017).

Food safety culture has been conceived as “serving an overarching, sense-making context for the creation and maintenance of food safety perceptions, attitudes and beliefs (Zohar, 2011). Namely, food safety culture has been defined as “the interplay of the food safety climate as perceived by the employees and the managers of a company (so called ‘human route’) and the context in which a company is operating” (De Boeck et al., 2015, p. 243).

Safety climate is typically described as the perceived importance or significance of safety within an organization or work unit, as seen by employees. This concept stems from individual perceptions and arises when workers interpret or assign meaning to their work environment (Zohar, 2011). As these perceptions become common among employees within the same work unit or organization, safety climate can be measured not only at the individual level but also at the group level. This suggests that safety climate is a collective phenomenon characterized by shared perceptions among employees (Zohar, 2011). These shared perceptions represent characteristics of the work unit or organization.

Food safety climate is commonly defined “as the perception of the individual employees regarding the food safety situation in their company”. Namely, it has been defined in terms of shared perception of leadership, communication, resources and risk awareness (de Boeck et al., 2015). Therefore, food safety culture represents the bigger framework of which food climate is a component and can be interpreted as “the interplay of the food safety climate as perceived by the employees and the managers of a company and the context in which a company is operating” (De Boeck et al., 2015, p. 243).

According to Griffith et al. (2010) food safety climate includes four main components: leadership, internal communication, resources and risk awareness. Leadership can be described as the understanding of how well an organization's

leader can involve employees in adhering to hygiene and safety practices, as well as achieving compliance with the organization's objectives, vision, and standards related to cleanliness and food safety (Griffith et al. 2010). Organizations with superior leaders tend to be more productive and competitive (Griffith et al., 2010). Considering that an organization's climate originates at the top and cascades downward leaders should inspire employees to adhere to hygienic and food safety practices while establishing clear goals related to food safety and hygiene. It is also important for leaders to pay attention to employees' feedback or concerns regarding hygiene and food safety. Additionally, when employees feel that their opinions are valued and respected (Yiannas, 2009), they are more likely to be engaged and motivated. Internal communication is understood as the degree to which information related to hygiene and food safety is disseminated within an organization.

Leaders should have open lines of communication with their staff in order to ensure that they are aware of their tasks and responsibilities. This is especially important when it comes to stressing the importance of cleanliness and food safety. Leaders should communicate in a straightforward manner that is appropriate for the recipient's educational level. Allowing food handlers (operators) to freely address cleanliness and food safety issues with their bosses is another aspect of effective communication. This encourages organisational transparency and may have a good effect on the environment for food safety (Griffith et al., 2010). Employees are more likely to adopt this view if they are often reminded of the value of sanitation and food safety. Posters, placards, and other materials should be used to repeatedly emphasise the need of cleanliness and food safety (Yiannas, 2009).

Resources pertains to the perception of the availability of both tangible and intangible assets needed to maintain hygienic and food-safe operations, such as time, personnel, infrastructure, and education or training. When an organization provides adequate and skilled staff to manage hygiene and food safety, it allows each team member enough time to work in a hygienic and food-safe manner. This support can lead to a heightened motivation to maintain hygiene and food safety practices (Griffith et al., 2010). Also, the quality of the final products is probably greater when workers are not always under pressure. The availability of the essential infrastructure for preserving cleanliness and food safety, as well as the allocation of enough financial resources to support these efforts, are other indications of organisational support. Another aspect mentioned by Griffith et al.

(2010) is risk awareness, which refers to the organization's knowledge of hygiene and food safety issues and its capacity to successfully manage them. For an atmosphere of food safety to be good, risk perception is essential (Griffith et al., 2010). Workers need to be aware of hazards so they can weigh them in everyday decision-making. Employees will feel less stressed and that the company is succeeding if they have faith in the organization's food safety management system. They may be inspired to continue their commitment to food safety and cleanliness by this trust (Zhu & Akhtar, 2014). Overconfidence should be avoided, though, since it might result in an underestimation of the hazards to food safety (Griffith et al., 2010). Ultimately, it is vital for both leaders and employees to be risk-aware to ensure they have a realistic understanding of potential risks and respond appropriately (Griffith et al., 2010). If employees perceive leaders as overestimating or exaggerating hygiene and food safety risks, they may be less inclined to work in a hygienic and food-safe manner.

Drivers that motivate companies to adopt specific food safety practices and systems can be traced back to both internal and external factors (Palazzi and Sentuti, 2021). Among these, there are the improvement of corporate image and reputation (Aung & Chang, 2014; Corallo et al., 2020); the consistency with top management values (Schwartz et al., 2012) and the performance improvement prospects (Aung & Chang, 2014; Chan & Chong, 2013; Corallo et al., 2020).

Leaders are held more accountable for promoting and supporting food safety when the company's image and reputation are prioritised. To accomplish this, it is necessary to foster an organisational culture that prioritises food safety above all. The company's internal communication needs to be more open and honest if it wants to improve its image and reputation in the food industry. This has the potential to increase teamwork, raise awareness of food safety practises, and facilitate the exchange of helpful useful information for that purpose. Therefore, a business with public perception and credibility enhancement goals is more likely to allocate the resources essential to guarantee food safety. When it comes to food safety, businesses that care about their image pay closer attention to risk management and take greater precautions as incidents or scandals can seriously damage their image and reputation. To protect their reputation and customer trust, businesses exercise extreme caution when it comes to handling food safety issues.

Aligning management values and goals with operational procedures ensures consistency with the ideals of top management. Leaders in an organisation are

more likely to prioritise food safety by setting an example when their own values align with those of the business, inspiring and motivating others to do the same. Furthermore, when top-down communications are clear and consistent with their values, staff members have a better grasp of the significance of food safety and are more likely to share information, discuss difficulties, and work together to accomplish the company's food safety goals. If this is the case, the corporation will be more likely to invest in the appropriate tools and controls, fostering an atmosphere where workers can do their jobs well and ensuring the safety and quality of products. Finally, people are becoming more aware of the risks associated with food. Workers are expected to identify and report any issues they come across as well as actively participate in risk management. The connection of leadership's values and operational practises in this area promotes a culture where food safety and risk management are given priority. Long-term success of a firm may depend on its commitment to food safety, which will be given priority by management when performance improvement is the main objective. With internal communications that emphasise the free exchange of information, goals, and progress relevant to food safety, employees will be motivated to collaborate in order to achieve their objectives and enhance the performance of the business. Investing in resources like sufficient equipment and monitoring and control systems to guarantee food safety will be crucial to the success of any firm. Food safety mishaps and scandals, which could harm the company's brand and performance, will be avoided as a result of the company's increased focus on risk management. We therefore hypothesized that:

*H1: drivers (DRIVER) have a positive impact on leadership (LEAD);*

*H2: drivers have a positive impact on internal communication (COMINT);*

*H3: drivers have a positive impact on resources (RESOURCES);*

*H4: drivers have a positive impact on risk awareness (RISK).*

### **3 Methodology**

The population of companies has been extracted from the Atoka database, and includes the sectors of Agriculture, Manufacturing and Fishing. A total of 4614 companies were extracted, of which 3177 without certifications and 1437 with certifications. Two questionnaires were administered: the first was addressed to the entire population of companies, while the second was aimed at investigating specific aspects of companies with certifications. From March to May 2022, we

gathered survey information from Italian companies engaged in the agri-food industry. 168 companies around 14% of the 3177 firms participated in the study. All of the questions were completely filled out, so none were disqualified. Approximately 4% of the businesses had up to 9 employees, 73% had 10–49, and 21% had between 50–249 workers, while the remaining 2% counted more than 250 employees. Scales for Food Safety Climate were taken from Boeck et al. (2015) while scale for driver was adapted from previous works of Aung & Chang (2014), Chan & Chong (2013), Corallo et al. (2020), Schwartz et al. (2012).

We tested reliability, convergent and discriminant validity of the scales (Hair et al, 2014). No items were dropped because all the factor loading are above the recommended threshold. Results are shown in Table 1 and Table 2.

Table 1: Reliability and convergent validity

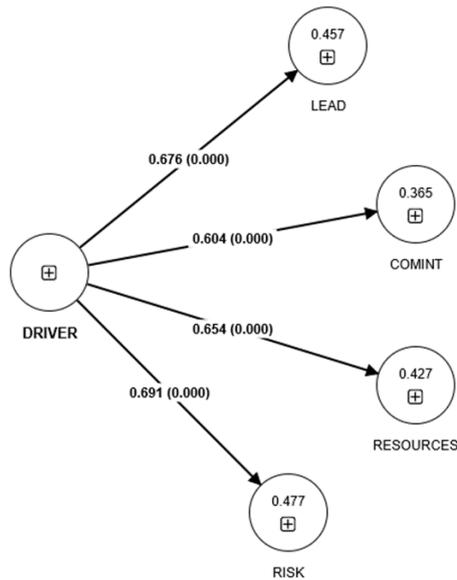

<b>Inherent variables</b>	<b>Items</b>	<b>Loadings</b>	<b>Cronbach's alpha</b>	<b>Dillon-Goldstein rho</b>	<b>AVE</b>
COMINT			0.909	0.917	0.789
	COMINT1	0.947			
	COMINT2	0.950			
	COMINT3	0.861			
	COMINT4	0.785			
DRIVER			0.878	0.892	0.805
	DRIVER1	0.841			
	DRIVER3	0.926			
	DRIVER4	0.921			
LEAD			0.893	0.911	0.757
	LEAD1	0.793			
	LEAD2	0.914			
	LEAD3	0.883			
	LEAD4	0.886			
RES			0.891	0.913	0.753
	RES1	0.863			
	RES2	0.885			
	RES3	0.823

RISK			0.958	0.959	0.888
	RISK1	0.936			

	RISK2	0.950			
	RISK3	0.946			
	RISK4	0.939			

Table 2

	Fornell-Larcker				
	COMINT	DRIVER	LEAD	RISK	RES
COMINT	0.888				
DRIVER	0.604	0.897			
LEAD	0.823	0.676	0.870		
RISK	0.799	0.691	0.832	0.943	
RES	0.768	0.654	0.789	0.832	0.868

We utilized PLS-SEM, a structural equation modeling method. This variance-based technique does not necessitate a normal data distribution (Hair et al., 2014) and is ideal for exploratory research, as it can handle complex models (Benitez et al., 2020). Furthermore, PLS is the most appropriate choice when the data's nature as a common factor or composite is uncertain, as it generates less estimation bias compared to CB-SEM. To assess the statistical significance of outcomes such as path coefficients, Cronbach's alpha, HTMT index, and R-squared values, we employed a bootstrap algorithm (Hair et al., 2014).

Results (Figure 1) show that all the hypotheses are supported (Table 3). Specifically:

- H.1 DRIVER -> LEAD: evidence support H3 ( $\beta=0.676$ ,  $p=0.000$ ) confirming that DRIVERS have a positive impact on leadership (LEAD).
- H.2 DRIVER -> COMINT: evidence support H3 ( $\beta=0.604$ ,  $p=0.000$ ) confirming that DRIVERS have a positive impact on internal communication (COMINT).
- H.3 DRIVER -> RESOURCES: evidence support H2 ( $\beta=0.654$ ,  $p=0.000$ ) confirming that DRIVERS have a positive impact on resources (RES).
- H.4 DRIVER -> RISK: As we hypothesized DRIVERS have a positive impact ( $\beta=0.691$ ,  $p=0.000$ ) on risk awareness (RISK).

#### **4 Conclusions**

This study investigates the impacts of food safety drivers on four "components" of the food safety climate of Italian agrifood companies.

We discovered that various factors influencing food safety interact with food safety climate elements. The presence of these factors, and the interactions between them and the food safety climate variables, all combine to make food safety a top priority in the workplace. To maintain a high standard of food safety and improve overall performance, businesses need to actively promote these drivers and keep them aligned with the food safety climate components. Long-term sustainability of this equilibrium depends on businesses' vigilant monitoring of their food safety performance and responsiveness to shifting market needs.

On the one hand, this study analyses the impact of food safety drivers on each food safety climate component and allows to deepen the knowledge of the components of food safety climate in the Italian context. On the other hand, it represents the first survey of the Italian context that provides interesting insights useful to improve the knowledge of agrifood companies on food safety drivers and impacts, being that the study is part of an interdisciplinary research project funded by the University of Urbino aimed to understand how agrifood companies interpret the issue of food safety, how they internalize it in strategic choices and implement it in their business activities and supply chain relationships and how they communicate it to stakeholders.

The main limitation of the present study is that we collected data from a single European Country and results cannot be generalized.

### Abstract

Very often, sustainability is rooted in the genes of companies, establishing in-house programmes and projects that aim to achieve a level of sustainability over time that is integrated into corporate strategies.

The concept of sustainability initially originated in relation to the environment but recently it has been also implemented in other areas such as social impact and good governance. These three macro aspects are recognised by the acronym E.S.G - Environmental, Social, Governance - and are also indicators that allow to analyse the activity of a company, not only on financial aspects, but also from an environmental, social, and good governance perspective.

Companies will have to move from a model in which they simply consume materials, energy, time, and human resources skills to one in which they instead manage a responsible relationship with materials, energy, and people values. It will be necessary to go through a very important transition to prepare their organisation, their production infrastructure, their people, and their governance to support this new model.

The role of the PM in these transitions is of fundamental and absolute importance.

The research will focus on the following topics:

- Identification.
- PM & Sustainability.
- Environmental.
- Social.
- Governance.

The purpose of the entire research is to analyse the current situation and to assess the maturity of project managers and organisations with regards to the topic of sustainability,

measuring in particular ESG (Environmental, Social and Governance) aspects and establishing whether these criteria are used within the project management context. With this data and information, it will be possible to identify which components have the greatest potential for improvement, and it will be possible to make project managers and organisations aware of project sustainability aspects.

The Department of Innovative Technologies (DTI) of the University of Applied Sciences and Arts of Southern Switzerland (SUPSI), as a training and research institute, will therefore be able, on one hand, to define courses or study programmes to fill these gaps; on the other hand, to continue to disseminate useful information and content on the subject and to raise awareness in organisations of the importance of sustainability in project management.

**Keywords:** sustainability, project manager, role, ESG, sustainability project

**Paper type:** Academic Research Paper

## 1 Introduction

Very often, sustainability is rooted in the genes of companies, establishing in-house programmes and projects that aim to achieve a level of sustainability over time that is integrated into corporate strategies.

The concept of sustainability initially originated in relation to the environment but recently it has been also implemented in other areas such as social impact and good governance. These three macro aspects are recognised by the acronym E.S.G - Environmental, Social, Governance - and are also indicators that allow to analyse the activity of a company, not only on financial aspects, but also from an environmental, social, and good governance perspective.

Companies that choose to adhere to the E.S.G. protocol with international standards (e.g., the UN Sustainable Development Goals) are going to focus on these three macro aspects, guaranteeing the compliance with certain measures and setting goals to be pursued in the medium and long term.

Companies will have to move from a model in which they simply consume materials, energy, time, and human resources skills to one in which they instead manage a responsible relationship with materials, energy, and people values. It will be necessary to go through a very important transition to prepare their organisation, their production infrastructure, their people, and their governance to support this new model.

The role of the PM in these transitions is of fundamental and absolute importance, and for this reason, the Department of Innovative Technologies (DTI)

of University of Applied Sciences and Arts of Southern Switzerland (SUPSI), launched this study in September 2022, focusing on how the role of the PM can be a key player in corporate sustainability goals.

## **2 Methodology**

### ***2.1 Design/methodology/approach***

We developed our study through a survey, which targeted a selected group of companies located in Switzerland and Italy, which operate in different sectors, are of different sizes, ranging from small, medium, large, and operate both locally and globally.

The survey was conducted through an online form of 25 questions. The answers were then analysed by the research participants; the data were first analysed in their complexity and then analysed in detail to focus on certain themes.

More specifically, we decided to focus our research on Ticino (Italian part of Switzerland) and Lombardy (northern Italy). This is because these two regions have a lot in common in terms of the economic situation and the types of companies that are present. In addition, these two regions constitute the catchment area of SUPSI, the promoter of this research.

Previous SUPSI Project Management graduates were also invited to participate in the survey.

The survey covered the following topics:

- Identification: Information about the context in which the participant operates, information about the company and its structure and how it integrates sustainability policies into the company, often linking them to their brand.
- PM & Sustainability: Information on how the PM is integrated in the activity of achieving Sustainability goals, information on how the PM can intervene within the company to raise awareness and promote E.S.G. issues.
- Environmental: How PM can impact sustainability on an ecological level related to the environment
- Social: How PM can implement aspects of social sustainability on Diversity, Equity, and Inclusion issues

- Governance: How PM's contribution can generate value and positively impact the various levels both from an organisational and strategic point of view and good governance by creating innovation, research, and incubation.

## **2.2 Goal of the research**

The purpose of the entire research is to analyse the current situation and to assess the maturity of project managers and organisations with regards to the topic of sustainability, measuring in particular ESG (Environmental, Social and Governance) aspects and establishing whether these criteria are used within the project management context.

What emerged from our research is that only large companies have resources dedicated solely to the topic of sustainability; small and medium-sized companies, on the other hand, must somehow make do with the resources they already have in house. Very often, therefore, it is the project manager who finds himself in this role. Even in the case of large companies, however, a control and monitoring role is still assigned to the project manager.

For this reason, it was important for our research to interview project managers.

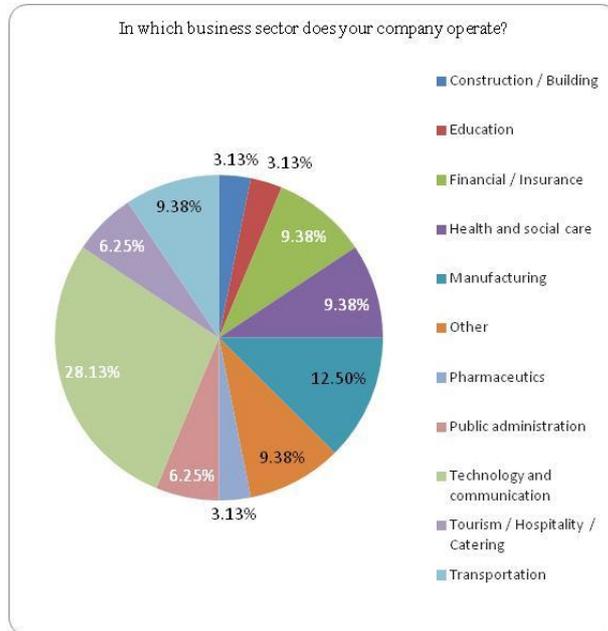

## **3 Results of the survey**

In this chapter we will describe the results obtained by considering the interaction

between the survey questions according to the objectives set.

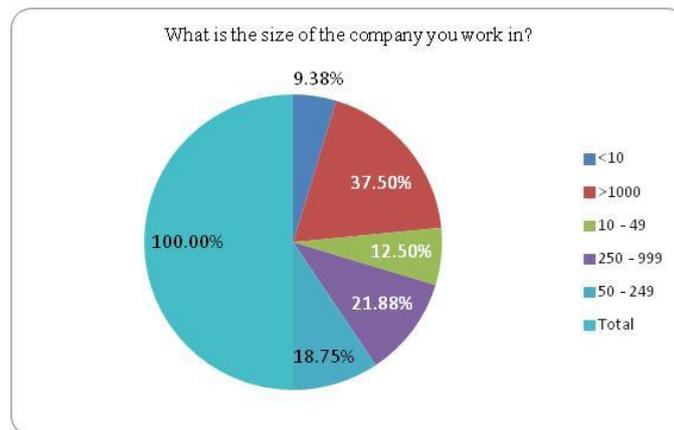

### **3.1 Identification**

Referring to the identification area, the results show that a large proportion of the respondents, 28.3%, work in the technology and communications sector. The remaining sectors that see a good number of employees are Manufacturing with 12.5% followed by Finance / Insurance, Health and Social Care, Transport / Circulation all with 9.38%.

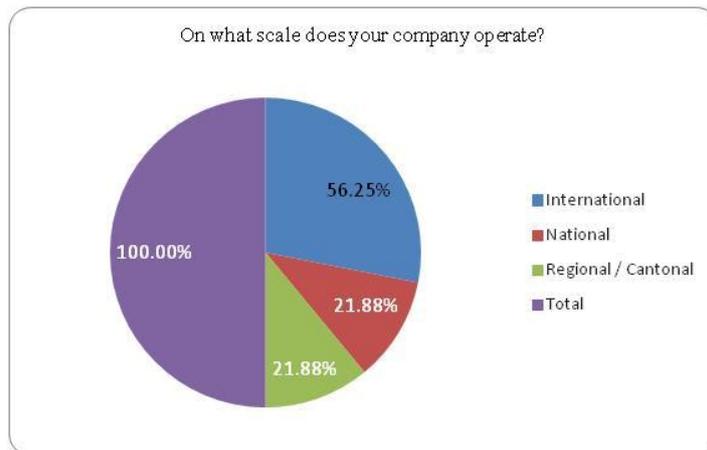

3.1.1 Identification – Company sector

Most of the organizations that took part in the survey have a size of 1000 employees or more (large organizations) with 37,50% of respondents. Other categories have similar values.

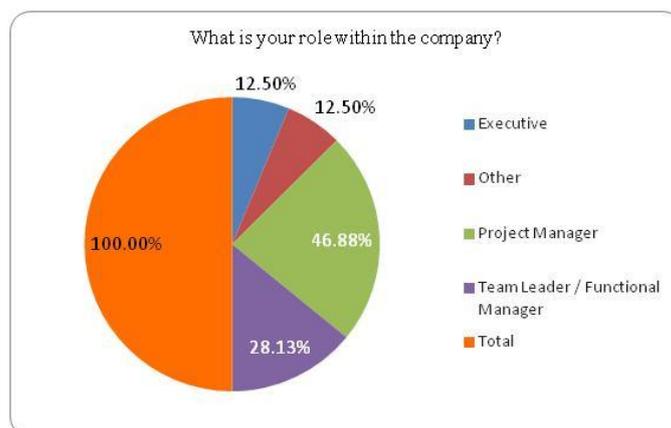

3.1.2 Identification – Company size

Most of the respondents work in companies that operate on an international scale, with 56.25% of respondents. We can see that the National scale and regional scale are similar with the 21.88% of respondents.

3.1.3 Identification – Company scale of operation

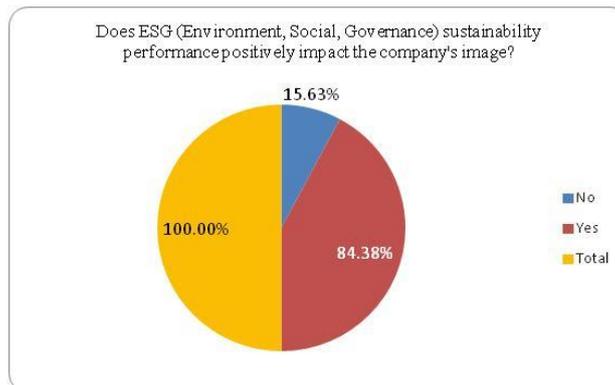

Most of the respondents are employed in the company as project managers; 46.88% of the respondents belong to this category. We also see a good proportion of team leaders/functional managers, 28.13%.

3.1.4 Identification – Roles of the respondents

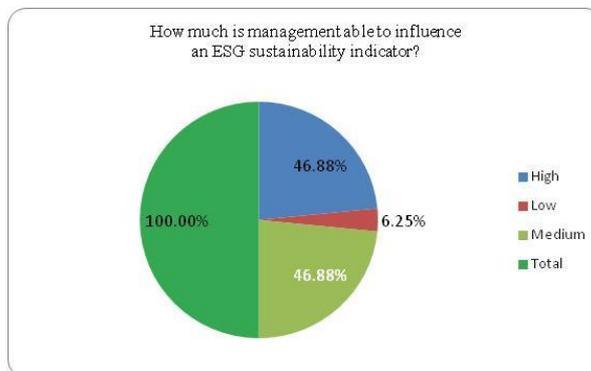

A large proportion of respondents believe that ESG (Environment, Social, Governance) sustainability performance has a positive impact on the company's

image. As many as 84.38% of the respondents, in fact, found the impact to be positive.

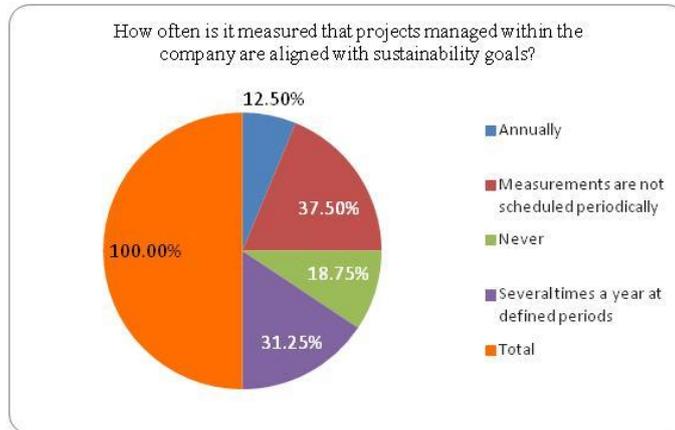

3.1.5 Identification – Impact of ESG factors on company's image

As far as management influence is concerned, only a very small percentage of 6.25% considered it to be zero with respect to ESG indicators. Almost all respondents believe that management can influence an ESG sustainability indicator.

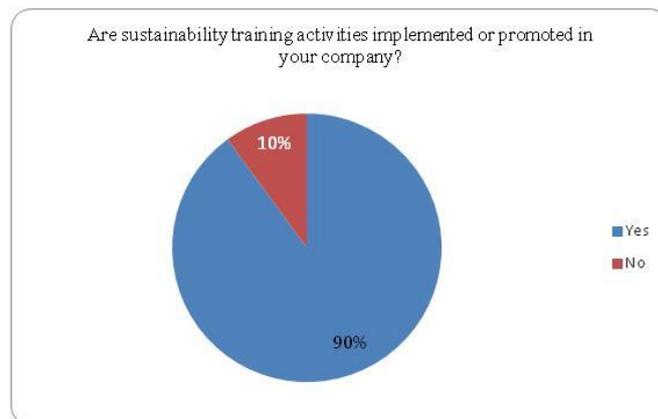

3.1.6 Identification – Influence of the management on the ESG factors

Another question in the survey aimed to establish how often the alignment of managed projects with sustainability goals is measured. It is good to appreciate that in 81.25% of the cases, measurements are actually carried out.

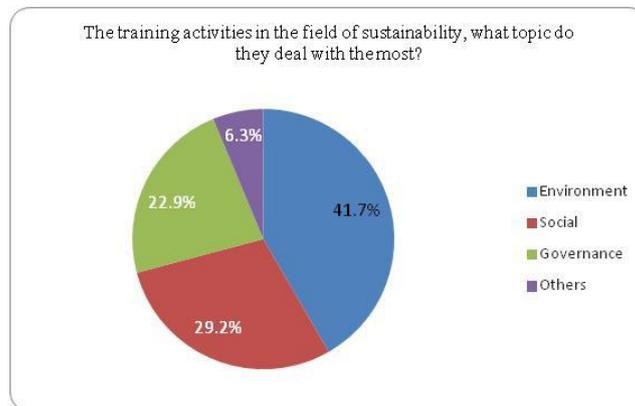

3.1.7 Identification – Frequency of monitoring

Finally, the survey showed that in 90% of companies, training activities dedicated to sustainability are implemented or promoted.

3.1.8 Identification – Presence of training activities

In 41.7% of the cases, it is training in the environment sphere, while in 29.2% of the cases, it is the social sphere that is concerned. The governance sphere closes with 22.9%.

3.1.9 Identification – Topics of training activities

### 3.2 Project managers and sustainability

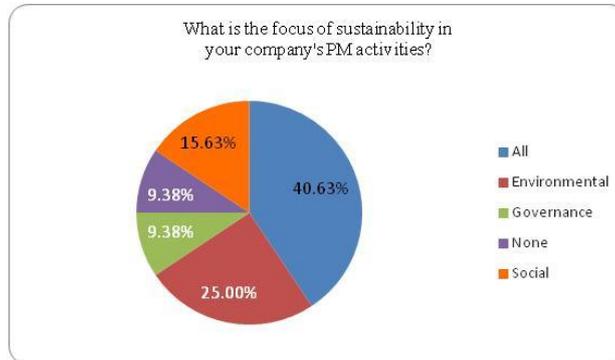

When we talk about sustainability, we mean the possibility of executing a project, which involves the balance between resource consumption and resource regeneration. But we also mean the possibility of performing an action that can satisfy our needs, without compromising the possibility for generations to come to do the same.

We could divide the whole concept into three parts:

1. Environmental sustainability: its prerogative is to ensure the stability of the environment and our planet, therefore, to maintain ecological and respectful processes that do not pollute or waste.
2. Social sustainability: it consists of balancing the available resources without compromising the possibilities for generations to come.
3. Governance sustainability: the development of integrated and rigorous sustainability is based on a solid and efficient governance structure. This is the basis for initiating a solid process of shared value creation between the parties.

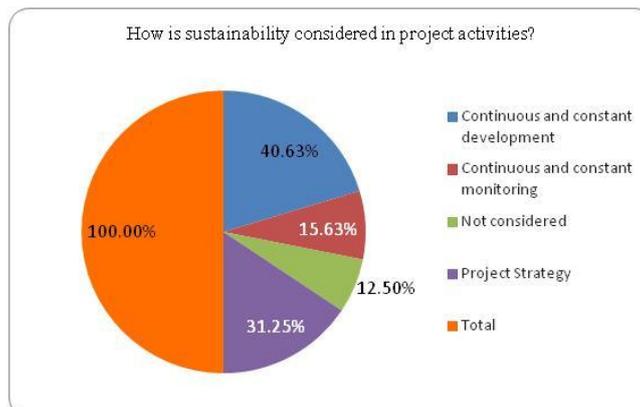

All the companies interviewed are unanimously supportive of this concept. Sustainability is therefore taken into account in a project, so that it can be developed and adapted to current needs.

The chart 3.2.1 aims to understand what the focus of sustainability is in companies.

3.2.1 PM and Sustainability – Focus of company's PM activities

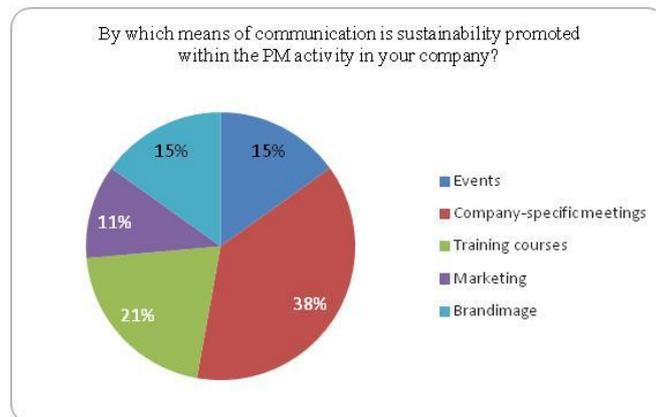

The majority of the companies surveyed give unanimous importance to all parts, demonstrating a great deal of responsibility for creating sharable and sustainable results. If we were to look at individual topics, environmental sustainability is the one that is taken into consideration the most; this highlights a greater sensitivity to the environment and pollution of our planet. The social theme is also of undoubted importance in a project in order to develop and complete it. Governance, on the other hand, is given marginal consideration. Finally, it is pleasing to note that the total absence of sensitivity to sustainability is a marginal condition, 12,50% of the companies involved in the survey.

3.2.2 PM and Sustainability – Sustainability in project activities

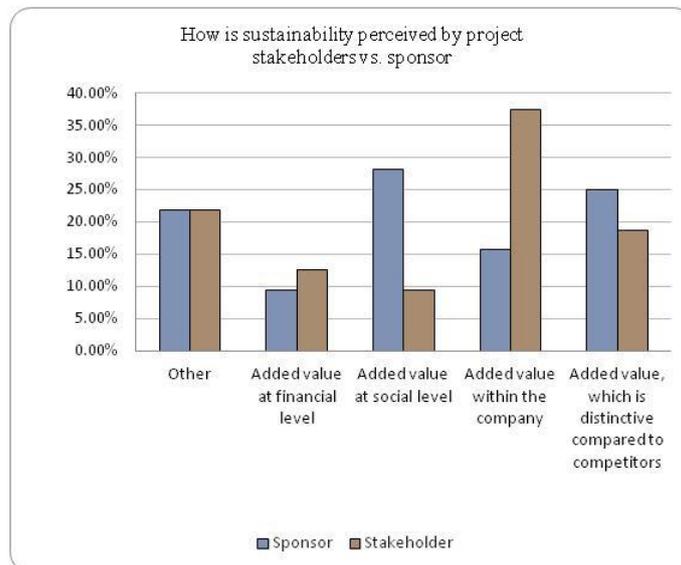

As can be seen in the graph 3.2.2, the majority of respondents see sustainability as continuous and constant development; there is a continuous commitment to improvement, documentation, and discussion in order to enhance and deepen

every aspect. As we see in the graph, sustainability is also seen as an integral part of the project strategy; it is here that decisions can be influenced in order to achieve the set sustainability goals. The monitoring factor is also important; this confirms that companies want to have a monitoring process that assesses whether the set aspects are actually achieved.

*3.2.3 PM and Sustainability – Sustainability promotion*

When it comes to the promotion of sustainability in the company, the graph 3.2.3 shows that in most cases (38%) this takes place during specific company meetings. On these occasions, employees are explained in detail about the company's efforts and various sustainability-related activities are promoted. Moreover, in the case of large companies, these take the form of important moments of confrontation between various departments. Other equally popular means of communication are events (also open to external audiences), information paths and brand image activities. Pure marketing is not as popular as a tool; this is understandable, since marketing is usually used for external communications, whereas more specific and customized tools are used for communications to employees, in this case to project managers.

3.2.4 PM and Sustainability – Sustainability perception

The chart 3.2.4 compares sponsor and stakeholder perceptions of value and highlights the objectives they have on sustainability. Stakeholders are more interested in creating added value within the company, while for sponsors this is not a priority area. On the contrary, the Sponsor tends to put more emphasis on the social aspect, believing that it is the contribution to society as a whole that gives more prominence to their project. Finally, both parties consider the distinctive added value compared to competitors to be relevant. In this sense, it is the common opinion of stakeholders and sponsors that conscientiously setting and committing to sustainability values can give advantages in terms of visibility and reliability towards customers. The added value on the financial level, in the end, is only marginally taken into consideration; undoubtedly setting sustainability goals can lead to an increase in turnover and margin, but these are not the main drivers of sustainability in project management.

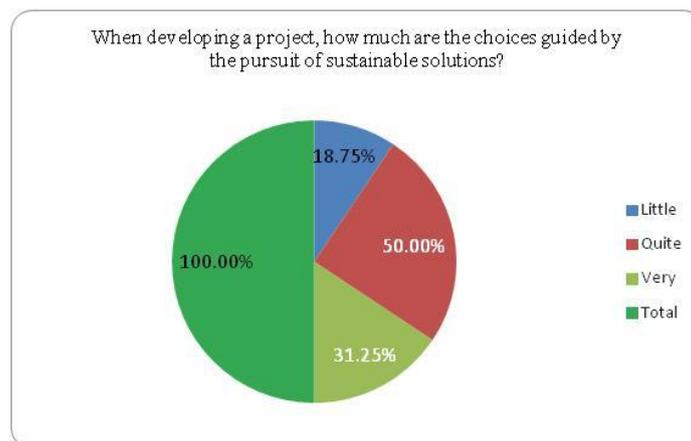

### 3.3 Environmental

Concepts related to environmental sustainability were certainly one of the first aspects introduced in companies as they are very concrete and tangible actions by the entire society.

The concept of environmental sustainability refers to the entire process of change in which the utilization of resources, the investment plan, the orientation of technological development and institutional changes are all in tune and enhance the current and future potential to meet society's needs and expectations.

This means not only being green or emitting less CO<sub>2</sub>, but a whole process that considers waste, the market (demand), the life cycle of a product (durability), the materials/resources used, and the production process.

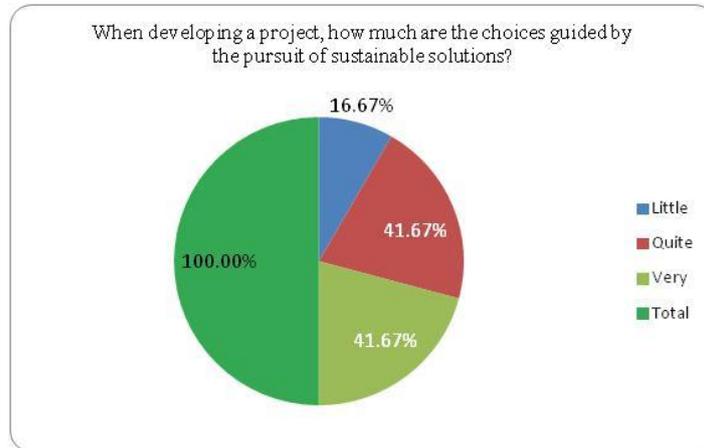

Consequently, at the beginning of a new project, these aspects must be analysed and taken into account to achieve the objectives and help the company to be sustainable during the evolution of the project and in the life cycle of the future product or service once the project is completed.

3.3.1 Environmental – Sustainable solutions during project development (total sample)

Taking the global sample of respondents as a reference, 68.75% of them state that little (18.75%) or quite (50%) consideration is given to the search for sustainable solutions during the project phases, so it does not seem to be an established, consolidated practice to assess sustainability aspects from the beginning of a project.

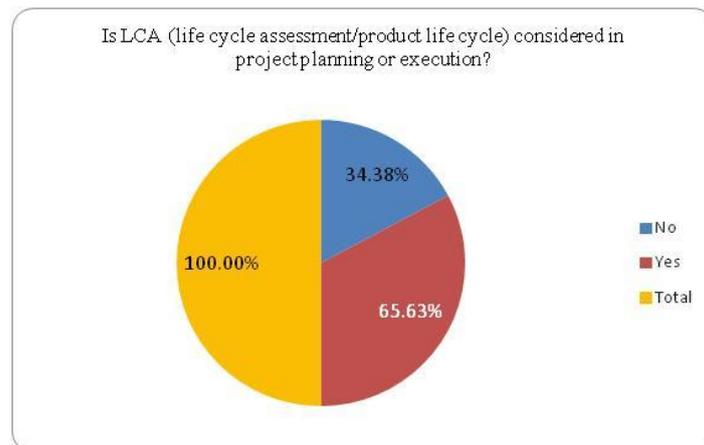

If we filter our sample, we notice that company size influences this practice. Indeed, large companies (>1000 employees) indicate that for 41.67%, sustainability aspects are highly considered during the design phases, so there seems to be a greater sensitivity on this issue.

3.3.2 Environmental – Sustainable solutions during project development (big companies with more than 1000 employees)

Life Cycle Assessment (LCA) is a methodology for assessing the environmental impacts associated with all phases of the life cycle of a commercial product, process, or service. The chart 3.3.3 shows that 65.63% of the companies in which our respondents operate, LCA is considered, compared to 34.38% who do not take these aspects into account.

Again, filtering by company size shows that the larger the company, the more life cycle assessment is considered during the design stages to have a more sustainable product, service, or process.

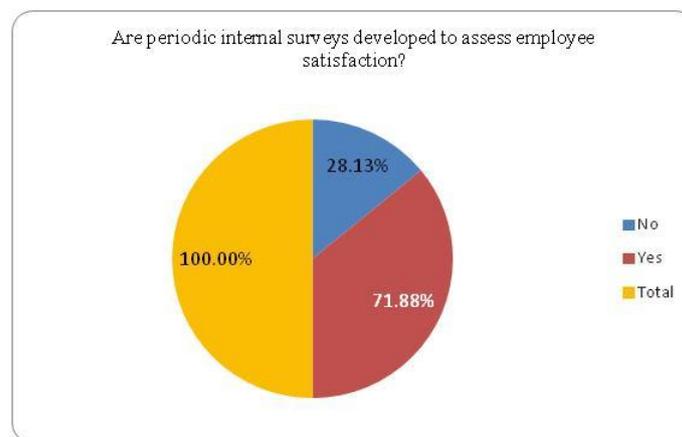

3.3.3 Environmental – LCA consideration

### 3.4 Social

Large organisations consider the social impact for their employees, and in recent years, even SMEs are making efforts to adopt a socially sustainable philosophy that influences the market to their advantage.

As we can see from the chart 3.4.1, 71.88% of companies develop surveys to understand the needs of their employees.

3.4.1 Social – Employee satisfaction monitoring

Conducting periodic surveys to assess employee satisfaction is important for several reasons:

- Internal surveys can help the PM to identify possible problems and to organize a clearer and more precise workflow, such as: processes, list of activities to be carried out, timelines, identification and exchange with stakeholders and choice of KPIs to monitor the progress of the project.
- For the PM, regularly collecting feedback from the team and acting on the results can help improve the retention of the team working within the project.
- Creating a fulfilling work environment increases productivity and quality of work and generates the lowest number of errors within the project, speeding up internal processes, tracking the progress of the project, increasing the well-being of the team, communication transparency brought by the PM, but above all the focus on the most valuable activities.

- Satisfied employees improve the reputation of the company and the ability to attract new specialized talent to join the project team.

In addition, the company that assesses the satisfaction of its employees can create benefits packages tailored to their needs; unfortunately, as we can read from the chart above, 28.13% of organisations do not consider a screening on the well-being and needs of their employees.

Companies that aim for social responsibility maintain a complex balance between ecological philosophy, personal convictions, and the goal of achieving maximum productivity.

In this sense, a duality of non-financial factors related to the social responsibility of PMs must be considered, which interact with each other for business success:

- On one hand, we find the company and the environment in which it operates. Here, the PM has the ability to improve customer relations and create greater loyalty; enhance brand image and brand reputation with investors; help reduce legal and regulatory risks; and develop better performing external relationships based on mutual satisfaction.
- There are several practices that companies together with PMs can adopt to become socially sustainable, for example:
  - engaging in social responsibility projects, such as donations to non-profit organizations.
  - sponsorship of charity events or volunteer programmes.

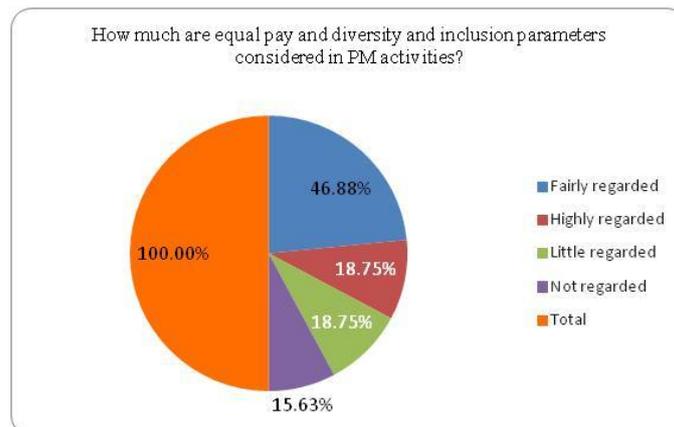

On the other hand, organizations can also work to improve conditions for their employees, such as providing fair wages; health benefits; workers' rights and gender equality; a healthy and functional work environment; safety at work; satisfied employees; improved turnover; attracting new talent and inclusion of people.

Again, there are many tools that a company can adopt in cooperation with PMs in the development of activities, in order to gain solid engagement in the work team and provide good welfare. Here are some examples:

- insurance policies for health, life, disability, and other contingencies.
- wellness programmes including gym, yoga classes and nutritional counselling.
- work flexibility with the option to work from home, have flexible working hours or share work with colleagues.
- on-site childcare or discounts for external services.

- training and professional development to help employees improve their skills and advance their careers.
- financial incentives such as bonuses, awards, salary increases or stock options.
- counselling and assistance with personal or family problems, psychological support, or legal advice.
- paid leave and time off for family emergencies, holidays, or sick days.
- collaborative networks such as platforms for linking various digital tools and sharing materials and projects, chat rooms, videoconferencing, corporate social.

From the chart 3.4.2, we can see how much the PM's activities consider equal pay, gender equality and the inclusion of people in project teams.

3.4.2 Social – Equal pay, diversity, and inclusion as parameters

Within the survey area, only 18.75% of the companies are visibly oriented towards sustainability and the PM implements crucial factors in creating a cohesive and motivated team to achieve project goals as effectively as possible.

To ensure social sustainability, appropriate measures must be taken, such as:

- the systematic review of recruitment and promotion policies, including those of work teams.
- staff training to prevent unconscious bias.
- the creation of a safe and inclusive working environment in the operational team.
- the introduction of parental leave policies.

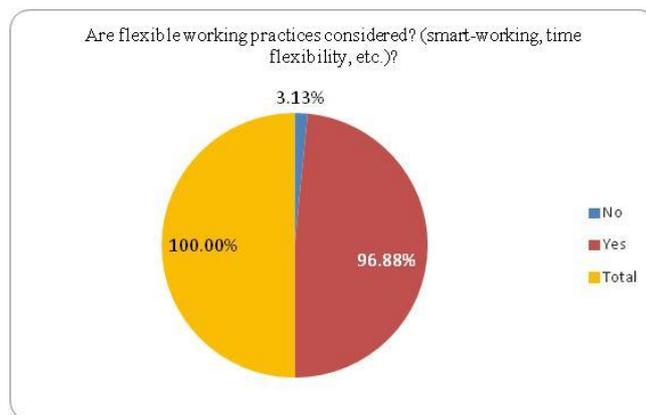

- other reconciliation measures such as work life balance that facilitate teamwork and limit conflicts.

In summary, attention to the equality variables is crucial to the success of the project, as they contribute to a collaborative, innovative and motivating working environment that fosters good results.

46.88% of the companies apply these criteria sufficiently, but not yet satisfactorily. In the end, we can clearly see that many organizations are not in line with the ESG indicators aimed at sociality. In fact, 18.75% consider the above-mentioned aspects too little and 15.63% totally neglect the fundamentals of employee welfare, projects, and the organization itself.

In the last chart 3.4.3, however, we see that as many as 96.88% of organizations apply flexible forms of work.

Responses to the changes that have taken place in recent years have accompanied this evolution with dynamic scenarios and different approaches from the traditional organization.

3.4.3 Social – Flexible working

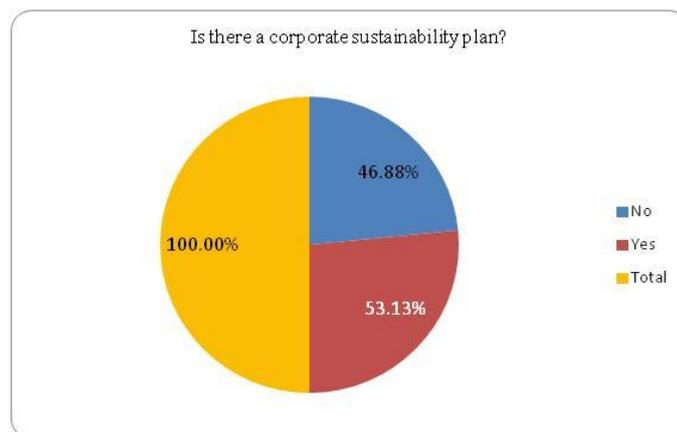

Smart working and work flexibility in project development are now part of corporate welfare policies that bring both benefits to employees in terms of improved work life balance, and to companies in terms of reduced maintenance costs, reduced absenteeism, and productivity growth, but above all it creates the desire to increase engagement, attraction of so-called talents, and bringing within the new modality an improvement in organizational well-being and business processes.

Therefore, putting the person at the centre and building relationships based on trust and mutual development between PM and employee embraces this new approach to work and contributes to providing multiple personal and professional benefits.

### 3.5 Governance

Project management is a critical factor for the success of any initiative, including those with sustainability objectives. Project managers play a crucial role in the governance of a project, and their decisions can significantly impact the sustainability outcomes of a project. Therefore, it is essential to understand the role of project managers in achieving sustainability objectives and the governance structures that facilitate their decision-making processes.

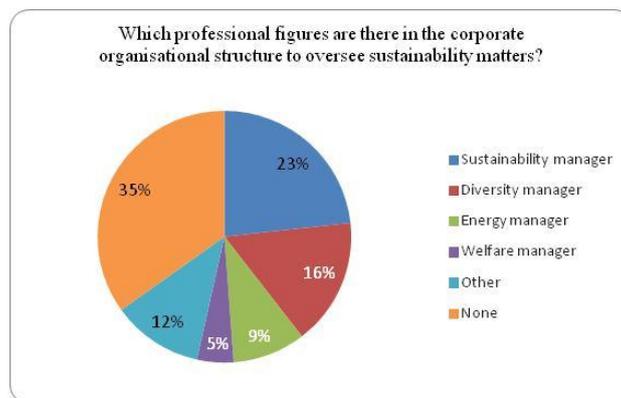

As the chart 3.5.1 depicts, almost half of the companies included in the survey have not a corporate sustainability plan. Conversely, the 53% indicated that their company has a plan in place, meaning this information can be used to gain insights into the current state of sustainability practices in the surveyed companies. These insights could be used to understand that the development of strategies to improve sustainability practices in the business world is not yet common practice.

3.5.1 Governance – Corporate sustainability plan

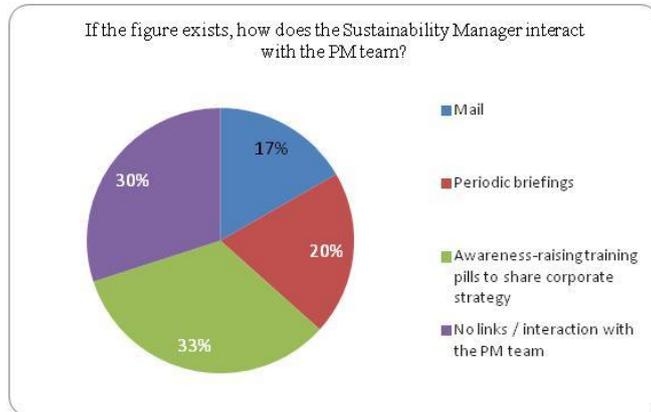

The following chart 3.5.2 shows how the different professional figures are distributed within the companies, if any. Almost 35% of the companies surveyed have no person responsible for sustainability issues. The other percentages are

distributed as follows: 23.3% by the Sustainability manager, 9.3% by the Diversity manager, 4.7% by the Welfare manager and 11.6% by other figures within the company. These values allow us to better understand the maturity of these companies and their attitude towards sustainability. The results suggest that there is a growing trend among companies to assign responsibility for sustainability to at least one person.

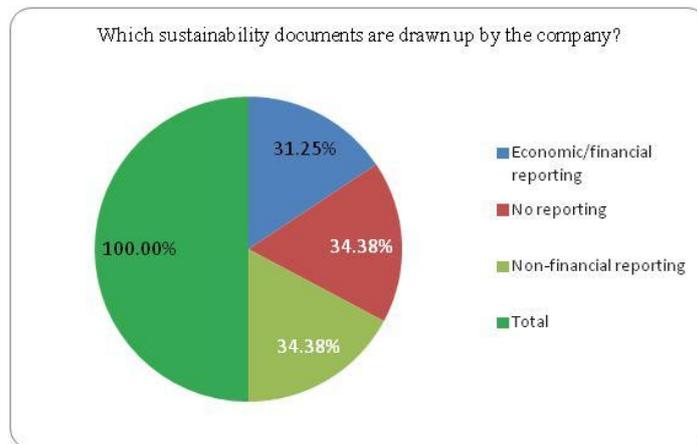

3.5.2 Governance – Professional figures to oversee sustainability

The chart 3.5.3 may explain how communication to and from the sustainability manager to the project management team usually works. Most are handled through awareness-raising training and the sharing of company strategy (33.3%). About 20% of companies organize regular meetings to discuss sustainability issues and 16.7% use written form, such as e-mail. What remains is that almost 1/3 have no interaction between the sustainability manager and the PM team. This situation lays the foundation for improvement in terms of communication and collaboration between the sustainability manager and the PM team in many companies.

3.5.3 Governance – Interaction between sustainability manager and PM team

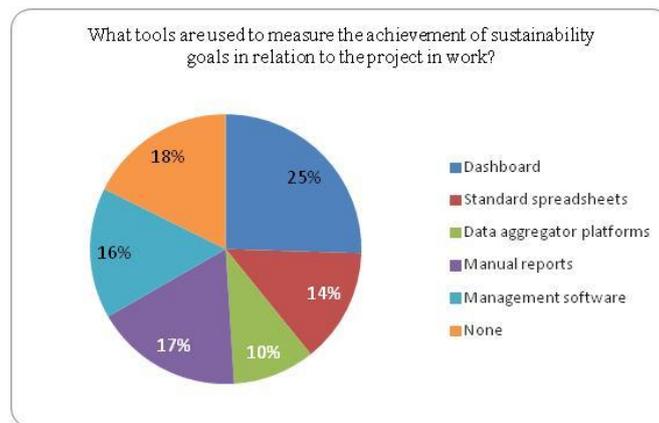

This chart 3.5.4 can help us understand if there are companies that write sustainability-related documents and which ones. As illustrated, the division is one third for each of the fields, i.e., financial reports, non-financial reports, and no reports. This information can be useful to understand the extent to which companies are reporting on their sustainability practices.

3.5.4 Governance – Sustainability documents

One of the most important charts is the 3.5.5 below, which shows that for 25.5%, dashboard tools are the most used to measure and verify the achievement of sustainability goals, followed by manual reporting (17.6%). Management software and spreadsheets are used by 15.7% and 13.7% of the companies respectively, while data aggregation is used by 9.8%. Furthermore, for about

17.6%, there are no measures to understand the achievement of objectives. This leads to the conclusion that there is still room for improvement in the use of tools and systems that can help companies understand the status and results of their sustainability targets.

3.5.5 Governance – Measuring tools

### 3.6 Additional feedback

To further confirm the validity of the survey responses, we asked an experienced project manager to comment on some specific topics.

We interviewed Stefano Santambrogio, who now holds the position of “Continuous improvement and sustainability manager” at Argo Heraus, a company with more than 15,000 employees, which operates internationally in the metallurgy and precious metals sector.

Santambrogio believes that the survey results are quite representative of the current situation of companies regarding sustainability management. However, there are some areas where, in Santambrogio’s opinion, companies could focus more on improving their sustainability practices.

In particular, Santambrogio believes that the interface between the sustainability manager and the project management team is of key importance for the integration of sustainability into the core activities of the company. Therefore, companies should invest in training and raising the awareness of the project management team on sustainability and corporate strategy.

Furthermore, the use of automated measurement tools could be an important step to monitor the achievement of sustainability goals and to identify areas for

improvement. Companies should consider using dashboards, management software and data aggregator platforms to improve their sustainability management.

Finally, Santambrogio believes that reporting and promoting a culture of sustainability are important to improve transparency and communication with stakeholders. Companies should consider drafting sustainability documents and invest in training and awareness-raising for all employees on sustainability.

In general, Santambrogio's opinion is that companies should actively engage in integrating sustainability into their core business activities and promote a more sustainable future. Taking these actions could be an important step towards this goal.

#### **4 Conclusions**

Large international companies have led the way by adopting ESG goals as a corporate philosophy in order to boost their attractiveness and reputation. The PM activity, a focus in organizations undergoing transformation, plays a central role in aligning project management and support for sustainability goals.

To support these objectives, new specialized figures such as Sustainability, Diversity, Energy and Welfare managers have emerged to ensure targeted skills, minimize errors and training costs, and create added value for the company and the product/service.

Active and effective communication regarding the monitoring of achieved sustainability results also plays a primary role in ensuring that stakeholders are always informed about the economic and cultural efforts that the company implements on a daily basis during the course of its operations.

This summary document makes explicit how companies are structuring (or intend to re-structure) their operations to minimize any possible sources of negative environmental, social, and economic impact.

Implementing and promoting a business strategy devoted to sustainability and supporting consumers who increasingly seek out companies in line with these values reinforces the following benefits:

- better cost management.
- more careful use of economic and non-economic resources (raw materials, diversity, inclusion).
- better control of problematic situations.

- increased quality of products and services.
- positive effects on corporate reputation.
- greater stakeholder adherence.
- new possibilities for innovation and economic development.

Following the example of large companies, today even SMEs are moving towards a more sustainable philosophy, investing in change and their project managers taking on an increasingly multifaceted role to ensure that projects are aligned with ESG sustainability goals.

Sustainability has therefore become a key factor in project management and represents an important strategic asset for companies, but also and above all for investors who recognise its importance by selecting companies that have solid policies towards employees and thus invest in those with the best prospects for growth and lowest risks.

The PM must ensure that projects are implemented in a sustainable manner, using renewable energy sources, reducing waste and residue, and minimizing pollution, biodiversity protection, work ethics, health, worker safety and other ESG factors.

To achieve and maintain the principles of environmental, social and governance sustainability, an appropriate checklist must be implemented:

- Has the company embraced an environmental policy with clear commitments and constant monitoring?
- Has the organization directed management and employees to determine and design environmental policies?
- Are environmental policies continuously monitored and improved?
- What actions are taken to ensure health and safety in the workplace?
- Have policies and standards for respecting diversity and preventing discrimination been determined?
- Have employees and managers been trained to follow the rules of the chosen safety policy?
- Has positive collaboration between the company and the community been promoted?
- Is the board of directors diverse and inclusive?
- Is there a committee to promote compliance with ESG criteria?
- Are there systems in place to measure ESG performance?

The checklist must be incorporated into all activities and policies that may impact the organization's sustainable change.

In particular, he/she must work with the organization's various departments to ensure that ESG policies and strategies are integrated into decision-making processes and projects to ensure strategic alignment and monitoring of progress. He/she must contribute to the creation, enhancement, and dissemination of a sustainable culture, communicate transparently and regularly on the impact of progress towards sustainability goals within the project and the company, propose and implement sustainability-related initiatives to increase awareness and accountability of his/her team. Finally, the PM must strengthen the link between internal and external communication, creating connections between different stakeholders.

For PM and project implementation this is a radical change, but what does this mean for companies?

Analysing the responsibilities of the PM as described above, it becomes clear that those organizations that cannot afford a specialized managerial figure dedicated to the topic of sustainability must rely on their PM, who will have to:

- indicate guidelines for behaviour and cultural change whereby trust autonomy, delegation and freedom become the basis for building a new working relationship.
- employ new technologies to overcome obstacles and manage information to always make it accessible.
- support the acquisition of new knowledge and skills in order to do their own job by applying ESG concepts within projects.

Ultimately, PMs, in order to be able to implement sustainable projects consistent with corporate policies and ESG criteria, should possess skills that are complementary and evolving to the role, otherwise they risk 'Green Wishing', i.e., how PMs would like to but are not able to because they lack adequate training that would lead them to apply these criteria with confidence, ease and involvement.

Therefore, as the survey also shows, there is a need to provide companies with ongoing training paths that are as modular and PM-specific as possible, promoting structured methods to align company policies with an ongoing execution roadmap, so as to track performance against strategies, objectives, costs, human resources, investments, and results. Training must relate to artificial intelligence and automation, learning through the introduction of innovative management tools that are at the same time agile in terms of application such as:

management software, dashboards, data aggregator and reporting platforms, but also AI and automation devices.

Lastly, but very important is the synergy/connection between figures specialized in the implementation of a sustainable strategy and project teams. Here again, the figures who play a major role in the conception of a medium/long-term sustainability strategy must raise awareness and increase techniques and working methods to combine the strategy with project objectives and activities.

Otherwise, there is a risk that the PM will only define environmental and short-term aspects, losing the vision of an overall design in a sustainable sense and trespassing into greenwashing.

Therefore, looking to the future, the knowledge and competence to achieve ESG objectives will be indispensable in the project manager's operational activity, which will become increasingly centred on the development of adaptive organizations.

### **Abstract**

The importance of right speed, effectiveness, efficiency and learning in Multi Business Model Innovation (MBMI) is vital to meet today's Volatile, Uncertainty, Complex and Ambiguous (VUCA) challenges to survive as a business in Business Model Ecosystems (BMES). VUCA events coursed by external and internal sources make some of the big challenges in 2023 to businesses.

How can businesses under these "VUCA World conditions" do high quality MBMI and knowledge management? How is it possible to stay positive and influence MBMI participants and teams in these processes to be and stay optimistic, create and capture knowledge - to increase their MBMI output, performance, competence, capability and courageous appetite on doing MBMI?

This paper investigates the impact between a positive mindset and knowledge innovation MBMI processes in BMES's influenced by VUCA Events. The impact of positivity is studied in 3 MBMI cases as competences to endure challenging MBMI processes influenced by different kinds of VUCA Events. From the cases a transfer of knowledge from tacit into explicit and internalized knowledge is outlined. The involved persons demonstrate preference for socialization processes, learning in pairs and groups as learning and creating by doing. They are very easy to internalize what they have learned in the VUCA. This corresponds to the hypothesis that a positive mindset is a predictor for success in MBMI.

The research is conducted in the view of Knowledge Management, MBMI and psychological theory – particularly the concept of positivity as fundamental for better creating and increasing learning and knowledge creation – the vital “raw material” in all MBMI and especially in a VUCA world. Our research shows that individuals embedded in networks and teams and with a general mood of positivity strengthens the MBMI processes. The paper finds that knowledge about the impact of positivity is very useful in MBMI processes influenced by VUCA.

**Paper type** – Academic paper

## 1 Introduction

Businesses today are challenged by a world of increasing Volatility, Uncertainty, Complexity, and influenced by Ambiguity – (VUCA) (Warren, 1985). Coronavirus pandemic, war in Ukraine, global material and resource prices, volatile and unsecure deliveries, sudden unexpected attacks and cyber attacks, global push to complex and ambiguous Circular Green Business Model transformation (Pieoroni, 2019; Bocken, 2020) make it very complex to operate and survive as a business today.

It lays a continuous pressure on change of businesses' Business Models (BM) and to keep optimism among employees, users and customers, networks and those responsible for Multi Business Model Innovation (MBMI) difficult. It increases even further compared to previous years the pressure and importance of high speed (Fine, 1999), right speed (Lindgren 2017), effectiveness, efficiency and learning in MBMI (Lindgren, 2018). VUCA gives significant challenges to Businesses BM design, reconfiguration, and development (Lorenzo, 2017).

**V** = Volatility means **nature and dynamics of change**, and **the nature and speed of change forces and change catalysts**. Volatility is the changing dynamic in a set of economic, environmental and social-categorization situations. The dynamic can change due to any shift in situations, whether it is economic, environmental, social, technical, biological or anything of the like. It can be triggered outside or inside the business, or in the Business Model Ecosystem (BMES) (Lindgren, 2016). It has proven to be very difficult to find the specific component that causes the change in situational economic, environmental and social-categorization (Schick, 2017) – the VUCA Event. Studies of 63 SME's in

Greenbizz project (Greenbizz 2022; Lindgren, 2022) showed many different VUCA Events with multi-causalities.

**U** = Uncertainty means **lack of predictability, the prospects for surprise**, and the sense of awareness and understanding of issues and events. Uncertainty in MBMI projects and processes is when the availability or predictability of information is unknown. Uncertainty often occurs in volatile BMES's that are complex in structure involving unanticipated interactions and relations that are significant in uncertainty. Uncertainty may occur in the intention to imply causation or correlation between internal business units, external business units, the MBMI project and other MBMI projects, of a social perceiver, a target user, customer, network or even employee(s). Situations occur with lack of information or lack of causation open for a fundamental uncertainty (Bodenhausen, 2009).

**C** = Complexity in a VUCA means **multiplex of forces, the confounding of issues, no cause-and-effect chain and confusion** that surrounds businesses. Complexity in MBMI refers to the degree of interconnectivity and interdependence of AS IS BM's and the proposed change in interconnectivity and interdependence of TO BE BM's and AS IS BM's in multiple BMES's, BM's and their BM dimensions and components (Lindgren, 2018) in certain MBMI projects, MBMI tasks and/or MBMI processes.

**A** = Ambiguity means **haziness of reality, the potential for misreads**, and the **mixed meanings of conditions; cause-and-effect confusion**. Ambiguity in MBMI is when the general meaning of something in a MBMI project or process is unclear even when an appropriate amount of information is provided. Uncertainty refers to relevant information in a MBMI project or process is unavailable, whereas ambiguity occurs when information is present, but the overall reason and meaning is unknown. Both uncertainty and ambiguity exist in MBMI projects and processes. In MBMI research, the concept of ambiguity determines, why and how a MBMI solution has been designed, reconfigured and developed, and secondly, the research process hypothesises on details not present in order to reveal the tacit knowledge in the solution.

VUCA increases the necessity to do more collaboration, cocreation and cooperation (Brandenburger, 1996) in designing, reconfiguring and developing BM's in opposition to how some businesses (Børsen 2021, Berlingske 2021) and even societies paradoxically react today (Intelligencer 2022, Foreign Relations 2022). This gives greater BM opportunities – but also increased possibilities to change and create BM's that can meet the challenges and request of VUCA faster

and with higher quality. This compels businesses to reconfigure, design and develop BM's in new and different ways to survive VUCA Events. As Mike Harris (2020) said: "Lack of preparation creates business risk".

In today's BMES's, doing MBMI right is therefore extremely difficult and only half the battle. Businesses need to execute at speed - intensely pursuing MBMI strategy with confidence and discipline as the BMES's changes continuously" (Lindgren, 2018). Businesses must prepare themselves for tomorrow's "VUCA World" and this means continuously experimenting with new tools and new methods to do a right speed MBMI in an efficient and effective way. Lifetime of the businesses BM's today hasty become obsolete and outdated (Lindgren, 2018).

## **2 VUCA and The Multi Business Model Innovation (MBMI) concept**

No business is an island (Håkonson, 1989) and no BM stands alone. It is related to other BM's (Lindgren, 2016) through tangible and intangible relations internal and external the business. The same with BMES. That is why VUCA "hits" not just on one single business and BM, but most often other BMES, Businesses, Business Units and BM's with "high speed". The MBMI concept, proposed in 2004 (Markides, 2004), took its point of entry from the basic approach that **any business can have more BM's** as either operating BM's (AS IS BM) and/or BM's under design or reconfiguration (TO BE BM) (Lindgren 2018). TO BE BM's can also be **intangible** or even **tangible related** to AS IS BM's and therefore it is important, especially in "VUCA Worlds", to search for the TO BE BM's of tomorrow, even before they have been set into MBMI process.

Our hypothesis is that VUCA can hit on all 7 levels of MBMI (see figure 1):

*On Business core business (the grey box in the centre), on BM Portfolios, BM's, BM Dimensions, on BM Components or even on the MBMI and development process (MBMI Time).*

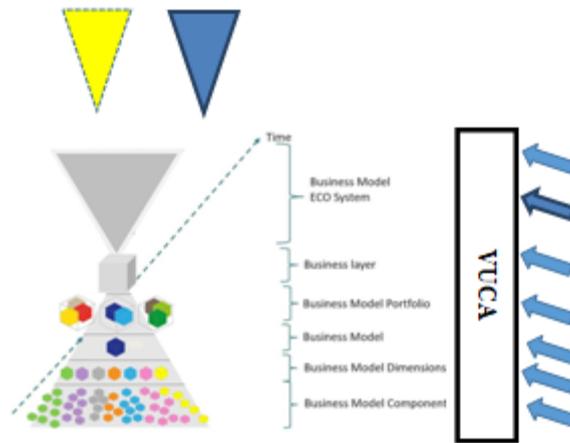

Figure 1. The 7 BM levels in BMI inspired by (Horn Rasmussen & Lindgren, 2016)

Today, MBMI processes influenced by VUCA are carried out by people. Tomorrow, it might be different (Lindgren 2021), since more MBMI projects are, in part, taken over by machines. This requires the ability to learn, create and capture knowledge faster, smarter and more sustainable. This article focus on the human beings involved in the MBMI VUCA processes.

### **2.1 Creating and learning in VUCA**

MBMI projects under influence of VUCA are demanding mental processes, and the solutions can be very controversial to standard norms, culture, trends and business practice. Our postulate is that the MBMI participants need a positive mindset, and for this purpose, positive psychology's offers insights in positive thinking even in negative situations, since research shows that positivity is fundamental prerequisite for the urge to learn and create knowledge (Knoop, 2010, 2013, 2016).

Knowledge management (Nonaka & Takeuchi, 1995) defines learning as four kinds of knowledge creating:

Table 1. Four kinds of knowledge management: tacit to explicit and explicit to renewed integrated tacit (Nonaka & Takeuchi, 1995).

	Tacit to 	Explicit
Tacit from  	<b>Socialization:</b> behaviour, peer learning by transferring of knowledge from tacit to tacit	<b>Externalization:</b> visible and distributed tacit knowledge as explicit (texts, drawings, video, checklists, whiteboard etc.)
Explicit	<b>Internalization:</b> explicit knowledge integrated into the learners as new behaviour, new competencies	<b>Combination:</b> Analysis of knowledge with other explicit knowledge (articles, reports, papers, books etc.)

In VUCA, the core information centre of learning is non-existent. Often there is no prior experience or a peer to learn from – and you have to innovate a new beginning (Cousins, 2018). Knowledge is often ‘outdated’, and in a leadership perspective, VUCA calls for VUCA-skills – Vision, Understanding, Clarity, Agility in order to cope with VUCA challenges (Lawrence, 2013).

This leads us to question: How to outline a competent MBMI mindset capable of coping with challenging VUCA situations. Why do some people just bring in radical and even disruptive MBMI solutions - others do not? Psychological research highlights that it is impossible to be positive, and, in the very same moment, feeling negative emotions (Fredrickson, 2009; Garland et al, 2010). In our terms, it means that it is hard to do MBMI, while the participants feel negative emotions and want to run away. Research in MBMI, shows, that happiness is a prerequisite for MBMI processes (Valter, 2018).

Psychologically, human beings flourish when they are able to handle both negativity and positivity, and not letting negative thinking take over their minds. This makes them languishing (Keyes, 2002; Seligman, 2012; Dweck, 2017). Some people are easier to enter negative thinking, and they will often see themselves caught in a sense of bad feelings and ‘learned helplessness’ (Seligman & Maier, 1967). This is a concept of human beings not able to act emotional freely, but are captured in negative thinking – with the result of stress, depression, low self-esteem, conflicts, anger and so forth (Garland et al, 2010; Seligman, 2012; Fredrickson, 2013a).

Below, the System Model illustrates the symbolic meaning of personal growth, well-being and motivation for learning and creating. At the top, the result of the psychological process is an increased competence in learning and increased

creativity. These achievements rely on basic well-being processes of inner motivation and a drive for personal growth, which are fundamental needs for all human beings (Knoop, 2016, Deci & Ryan, 1985).

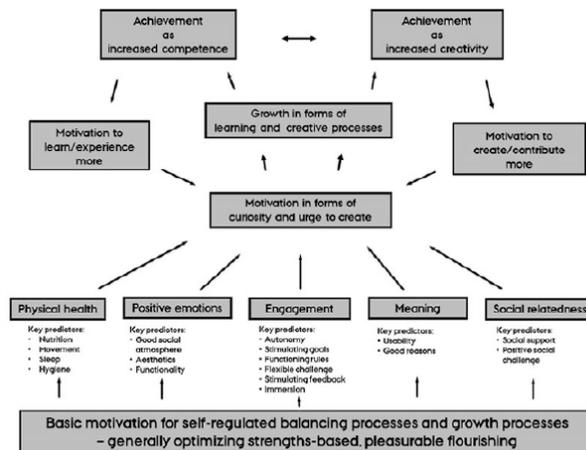

Figure 2. System's model of human flourishing (Knoop, 2016): How well-being predicts learning and creativity, which in turn predicts well-being. Physical health is omitted in our research.

### 3 Research Design and Research Methodology

These reflections have led us to the following:

- How do positive emotions influence MBMI and MBMI processes take place in BMES's influenced by VUCA?
- Do the participants' mental state of positivity have an impact on MBMI success and output?

The research was designed on a mix of methods. Case 1 was studied by literature and case methods, and later, in combination with participative action research methods. The participative action research method (Chevalier, 2013; Bryman and Bell, 2011) formed the framework for case 2 and 3, since the researchers were actively involved in the MBMI process, either as participants and/or supervisors to the MBMI.

### 4 Cases

3 different cases were studied in 3 different BMES's influenced by VUCA Events from 2010 to March 2023. The cases were elected out of several MBMI cases with

particular focus on characteristics of positive thinking in challenging VUCA situations.

#### **4.1 Case 1. The Midtjyllands Airport MBMI Case**

Midtjyllands Airport (MA) is located in central Denmark and is located within the Air Base Karup, which is the primary base of the Royal Danish Air Force.

*Picture 1. Midtjyllands Airport*

Due to its history, MA uses the runways, air traffic control, and fire department of Air Base Karup to ensure flight operation. MA is located in Jutland between 3 main competing airports; Billund Airport, Aalborg Airport and Aarhus Airport. The region around the airport is distinguished through its high number of businesses. Some of the biggest businesses in Europe have their domicile closely located to the airport. These businesses operate internationally with several departments and daughter businesses around the world. Their number of international travels per month is higher than the national average in the area. Available international flight paths are considered as crucial service for more than half of the businesses in that region. For that reason, the businesses demand short trips and day-to-day return but also long distance trips to global airport hubs in Europe. The Mayor share of all airport users is business people (80%), who travel to meetings, conferences, etc., while the minor share consists of private people (9%) and commuters (7%), who travel frequently back and forth to work, and others (4%) (Midtjyllands Airport, 2019)

##### **4.1.1 MA - VUCA 1: Norwegian Air stops to fly and Operator Cimber Sterling declared bankruptcy and canceled all flights on 3 May 2012**

In 2010 approximately 350.000 passengers used the MA. In autumn 2011, Norwegian announced that they would stop flying at Karup airport. Norwegian could not earn money on the route. With Norwegian's exit was Karup Airport on a

negative track road as it would lose 10 mill DKK in turnover. Without flights by Norwegian there was only Cimber Air left to service the passengers, but this stopped in May 2012, when Cimber Air went bankrupt.

*MA - MBMI Solution 1:*

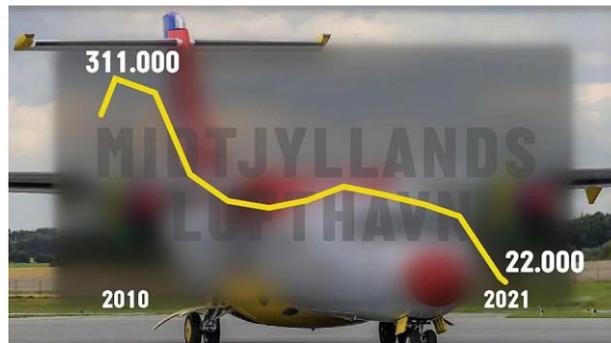

Late 2012 MA's situation was so bad that the owners – nine municipalities around the airport - had to support with an economic help of 10 mill. DKK. It was money given to get the airport on a right track again. The airport was claimed important for the Mid and West Jutland area the Mayor of Holstebro Municipality announced. After the worst year ever since 2013 the Karup airport was again drained for money and the airport expected a deficit in 2014 of 5,8 Mio. DKK. The airport had to get another million investment and the 9 municipalities support with another 12 Mio. DKK in deficit guarantee to secure the airports survival the next 3 years.

It seemed that the investment helped and soon after Norwegian Air began again to offer cheap tickets to recruit more customers to fly from MA. The passenger number increase and the Danish DAT began to fly on March 2015 domestic flights on Karup. DAT took over the domestic route from Norwegian. The expectation was that DAT would reach about 250.000 passengers from Karup pr. year. However, MA reached a deficit of 6,1 Mio. DKK. It was needed to get up to 200.000 more passengers to balance the economy at MA. A re-branding strategy was proposed with a new name instead of Karup Airport. A promotion plan was proposed and introduced to double the number of passengers. The new name Midtjyllands Airport was decided and implemented. A new CEO was at the same time presented.

However, the change of name, promotion and CEO did not work as expected. Numbers of passengers did not increase as expected. Only 134.000 passengers flew to and from the Airport in 2018 – a decrease of 8% related to 2017. In the first half year of 2019 a further reduction of 16,5 % was realized.

**4.1.2 MA – VUCA 2: Coronavirus pandemic close the airport 2020**

In March 2020, all airports – including MA - were hit by the coronavirus pandemic. All flights to and from MA were cancelled and firstly in August 2020 reopen. A month later DAT closed their route due to coronavirus and too few passengers. Later the route opened again, but was closed in December 2020 resulting in only 29.000 passengers in 2020 – the worst year for MA ever.

Picture 2. Passenger number development in Midtjyllands Airport.

*MA - MBMI Solution 2:*

MA chose to close down MA and wait for new opening possibilities.

#### 4.1.3 **MA – VUCA 3:** Energy Prices increase 2020 - 2022

Gas and electricity prices started to raise extremely in 2021 and 2022. This hurts MA very badly.

*MBMI Solution 3:*

MA began to investigate the energy consumption with 2 groups of researchers at AU – BTECH – CET and CGC. With CET they made a deep analysis of energy and a top journal on top of this work (Bujok, 2022) was created. In Greenbizz project (Greenbizz 2022) an investigation with sensors spread out on all machines and energy consuming technologies was implemented. The results of the MBMI solution was not finally gathered early 2023 but some solutions looked very positive.

#### 4.1.4 **MA VUCA 4:** Largest Customer DAT–Flight carrier announce to stop operating within 3 month

DAT, the largest Air Flight carrier to Midtjyllands Airport, announce that it will stop operating by December 2022. Passenger drop as seen in figure 3 caused by the DAT management decision.

*MBMI Solution 4:*

After the coronavirus pandemic the flights were again running from MA, but the financial situation was too difficult and the deficit too high. A new board with Mayor from Viborg Municipality as chair announced a new beginning and a new strategy. The board wanted to increase the numbers of flights and make the flights/airport green. Ant the board wanted to do some new investments. MA

CEO began negotiating with a new airplane operator, but meantime the board decided to close the airport.

**4.1.5 MA – VUCA 5: CEO position closed down 2022**

The new MA board decided to lay the CEO of MA off and several of the employees as well.

*MBMI Solution 5:*

The new MA board decided to lay the CEO of MA and several of the employees off to save costs. At this moment (2022) the operators paid 142 DKK pr. passenger that travel from MA plus a start tax for the airplane and cost for the handling of passengers. Thereby MA was the most expensive airport in Denmark. By the new initiative, the board expected it would be easier to get a new operator for MA.

Table 2. Positivity, creativity, learning and relatedness in the MA-case.

<b>VUCA Events</b>	<b>Positivity</b>	<b>Creativity</b>	<b>Relatedness</b>	<b>Learning</b>
VUCA 1 - 5	The CEO seems very positive and has new ideas to solve the airport in collaboration with the region's largest players even though he is no longer employed at the airport.	The MA CEO takes informal meetings in his network in order to present 'crazy' solutions to the problems in the airport economy. He is highly innovative and by his creativity the airport survived longer than expected.	It seems like the CEO has an informal network of collaborator(s) outside the business with whom he finds inspiration and support to solve the VUCA.	The MA CEO learns from doing in chaos. Tacit knowledge is explicit to the public (tv, newspapers), while the CEO draws on his informal network. Even though the airport is closed, he is highly motivated to continue his task. MBMI solutions are incremental and radical (see enclosure 1).

**4.2 Case 2. The Salling Autogenbrug MBMI Case**

Salling Autogenbrug (SA) is a family-run business. Auto recycling is the business of scrapping, dismantling cars and other vehicles that are no longer suited for driving.

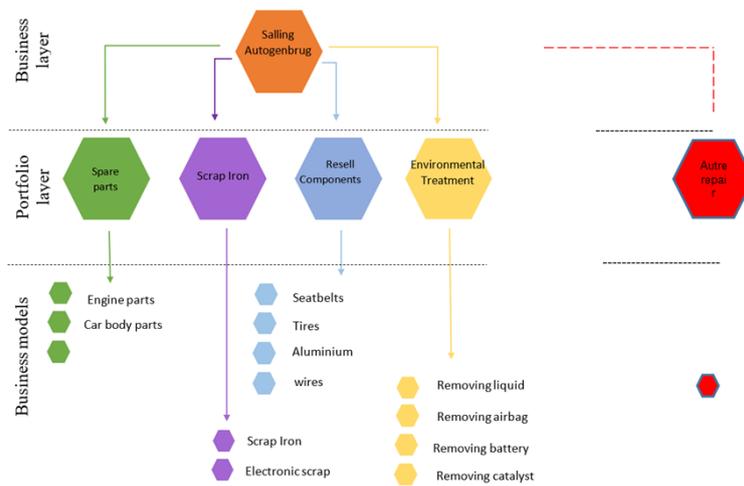

Figure 3. SA's BM portfolios.

The business models of SA can be structured in 5 main portfolios; Spare parts, Scrap Iron, Component resell, Environmental Treatment and Auto repair. All cars received at SA are today manual sorted into

- A cars – cars that can be serviced and repaired and sold as used cars
- B cars – cars that some parts can be sold for spare parts
- C cars – cars that can only be dismantle, scraped, and send for up, down or recycling

A strategic business decision was made when relocating the business so SA would no longer offer Auto repair services from 2022 as shown in the figure 4. SA at its previous location in a village in West Jutland was authorized to scrap a maximum of 10 cars at a time but SA has since then grown and today have the authorization to maximum 1500 vehicles. The SA warehouse held more than 30.000 quality controlled spare parts and the garage had a licence to do environmental treatment and dismantling. In 2009, the ownership was handed over to two sons of the founder. In 2019, the sister Lise joined the management team.

#### 4.2.1 SA VUCA 1: Volatile procurement prices on resources and materials, 2020 - 2022

Prices officially and unofficially on scrapped cars turn out to increase dramatically especially in the beginning of 2019 – 2022.

*MBMI Solution 1:*

A new SA strategy, where management began to bulk scrapped cars and metal to take advantage of the raising prices. This hurt liquidity, but at the same time increased the income to SA due to sold cars.

#### **4.2.2 SA VUCA 2:** *Volatile prices on AS IS BM's – metal, C-scrapped cars 2020 - 2022*

Prices on metal and C-scrapped cars began in early 2020 to be very volatile, especially in 2021 – 2022. This seemed to be a relation between scrap procurement prices of used cars and the prices on metal and scrapped cars. Further, the raw material prices began to show steep up-going price trends due to coronavirus pandemic and war in Ukraine.

##### *MBMI Solution 2:*

SA management immediately understood that they could get an advantage out of the price situation and began to bulk the c-scrapped cars.

#### **4.2.3 SA VUCA 3:** *Burn down of business, 2021-2022*

In February 2021 the owners met a burning platform in the most literally sense: a violent fire destroyed both a large new warehouse and one of the two garages of the SA Business.

*Picture 3. The warehouse with all the spare parts burned down.*

##### *MBMI Solution 3:*

Instead of rebuilding the fire-destroyed buildings, the SA management decided to move to a new location. After 4 months, a new business possibility came up. The SA management took the chance to buy a 3 times larger auto recycling business in a larger town, Skive, in West Jutland. 8 months after some heavy renovation and rebuilding, the new recycling business SA opened in March 2022.

Picture 4. The siblings, management of SA, and main entrance to the business in Skive.

The location had been rebuild into a modern auto recycling business and the revitalization of the SA business was finished. SA hereby established a new business headquarter and production with new storage perfectly fitting SA's businesses vision and needs in short and long term perspective

#### 4.2.4 **SA VUCA 4:** *New Green transformation request/ruleset – 2021 – 2023*

SA created a vision to become Denmark's most green auto recycling business of scrapped cars. However, this was a very complex strategy to fulfill, when trying to optimize green, business and social economic – triple bottom line (Ezkowiths 2008) – at the same time in a very conservative BMES. The siblings decided to increase material recycling of scrapped C - cars to a higher recycling level – from 30% to 10% "clean" related to existing standards for C-scrapped cars in the BMES. SA had for several years focused on the possibility to reuse, up, down and recycle more materials and resources from C-scrapped cars, but had not yet found a BM set-up and particular a scale-up setup that was commercially interesting and sustainable.

##### *MBMI Solution 4:*

SA together with a business consultant from network partner Business Skive (municipality organization) decided to find some funding to kick-start the MBMI project. SA together with a business consultant achieved to find the funding and started to gather a small MBMI group to solve the MBMI project Scale-up C-scrapped cars. An expert on resource and materials, a customer that schrades the C-scrapped cars and an expert on business model cases where invited to participate.

4.2.5 **SA VUCA 5: Volatile prices on recycling material - tires, glass, seat foam etc., 2022**

As the MBMI solution 4 began to take form SA was hit by suddenly volatile and uncertain prices on recycling materials like tire, glass, foam e.g. Instead of having positive prices on tires the prices on tire turned suddenly to a negative price – SA had to pay money “to get rid” of the tires.

*MBMI Solution 5:*

SA together with a network partners in MBMI 4 solution decided to find new ways new MBMI solutions, new network partners and customers to work with the materials and resources taken out of the C-scraped cars.

4.2.6 *SA and VUCA Events*

Table 3. Positivity, creativity, learning and relatedness in the SA - case.

<b>SA VUCA Event</b>	<b>Positivity</b>	<b>Creativity</b>	<b>Relatedness</b>	<b>Learning</b>
SA VUCA 1 – 5	Moving to another site was seen as a blessing dressed like a disaster. The siblings took the challenge to renew the business' vision and the family's purpose in the local and global social life.	A 'crazy' idea of merging a very black and conservative industry with the green, climate agenda.	Rooted in family values and, in particular, the sister's passion for green energy and climate the two brothers took in the new ideas to transform the business into green. The siblings are very focused on the business' position as a local player for the region's economic and sustainable growth.	Tacit knowledge is transferred into explicit by branding the business (website, social media) with focus on socializing, externalizing and internalizing of new visions. Learning and creating from the fire is a negative destruction turned into positivity. MBMI solutions are incremental and radical (see enclosure 1).

4.3. **Case 3. The DHD MBMI Case**

BFB was founded in 2013 with the name NCJU, and it was hosted at the Business BV. In 2018, the name was changed to DHD and adapted as one of 18 divisions in DHD Global. DHD did basic and applied service through a global, collaborative, cross-/interdisciplinary research and business network. DHD had 4 business portfolios as seen in figure 7.

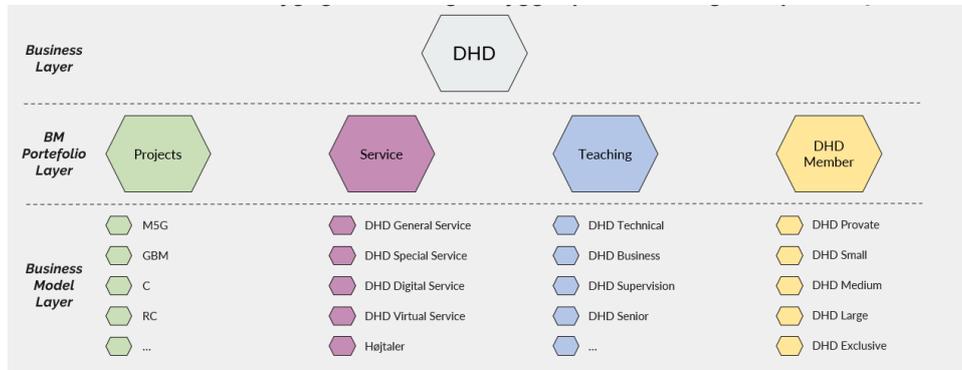

Figure 4. The DHD's BM portfolios.

DHD facilitated the headquarter of DHD, and have more than 10 cross-/interdisciplinary projects. DHD was at December 2022 involved in projects for about 3 Mio. EUR and had an internal turnover of 1 Mio. EUR pr. year. DHD had 30 employees engaged.

DHD was organized on the roots of JG, established in 2003, and JDI, established in 2008. JG and JDI both gained through 2003 – 2014 some very large projects and it was therefore natural to merge JG and JDI together, as their businesses were complimenting each other on service, projects, funding activities, conferences, education, industry collaboration and many other areas.

#### 4.3.1 **DHD – VUCA 1:** CEO JG not to be continued employed – 2013/2014

In 2013, it was announced unexpectedly to CEO JG that his contract as CEO would not be prolonged.

##### *MBMI Solution 1:*

However, CEO JG wanted to continue his task, and in 2014 he was offered a joint full time CEO in DHD together with former CEO JDI. A split CEO position. DHD head office at the same time moved the residence of BV.

#### 4.3.2 **DHD – VUCA 2:** Internal competition begins between business units at BV, 2016 - 2022

Internal business units within BV started to compete with DHD and tried to eliminate and prevent DHD to have general business activities – these are mandatory service activities in BV – and to forbid DHD to get into strategic important service activities, management positions and internal investments possibilities as well. The background was some old rivalry from a 2013 MBMI

process. DHD started to lose influence internal BV and to lose management positions at BV. A new manager was elected to BV and the former manager of BV service activities was reelected to service management positions. BV Management soon take over management and service positions held by DHD previously.

*MBMI Solution 2:*

DHD began to negotiate with BV management but without success. DHD began to search for other service activities internal BV and external BV both in a national and an international scale.

**4.3.3 DHD – VUCA 3: Internal split DHD - business unit**

One minor fraction of the DHD group started in 2018 to negotiate secretly with BV management aiming to break out of DHD and establish a new business unit. Several internal meetings with top management resulted in a final decision to split the DHD into two - DBD and DHD both physically and business wise.

*MBMI Solution 3:*

DHD moved to new location and began to brand DHD division heavily externally. Branding internally BV was tried, but without great success, since this task was controlled by the top BV management and the central BV communication department. After several attempts, DHD decided purely to focus on global and international branding and promotion.

**4.3.4 DHD – VUCA 4: Important BM's are taken away from DHD**

New and revised management at BV began to marginalize DHD and take over core BM's from DHD. DHD was rejected to operate several BM's. These BM's challenged young DHD employees, because if they cannot operate these BM's activities they would not be able to qualify for advancement and fixed positions in BV. Some of the employees at DHD considered leaving DHD, although they were deeply involved in many DHD projects.

*MBMI Solution 4*

DHD made a tender to one important BV BM service activity – GJ BM - operated by BV, which soon was rejected by the BV management. DHD began international service activities. M5G, GB and C Projects initiated these initiatives.

#### 4.3.5 DHD – VUCA 5: Close down of Business Unit

Top Management at BV decided within 5 days in December 2022 to close down DHD with effect 1. February 2023. Arguments were not public, and there were no communication to the DHD management about the reasons. DHD did not get any official information on beforehand, but unofficially information had been floating to some of the DHD employees some months before it happened. The DHD-labs closed and removed within few days by order from the BV management, while the researchers, DHD management and employees observed the break down without any information or any possibilities to intervene.

##### *MBMI Solution 5:*

DHD management started a process of analyzing the situation and tried to find positive solutions out of the VUCA. Networks and divisions were partners in this process.

#### 4.3.6 DHD and VUCA Events

Table 4. Positivity, learning, creativity and relatedness in the DHD-case.

<b>VUCA Events</b>	<b>Positivity</b>	<b>Creativity</b>	<b>Relatedness</b>	<b>Learning</b>
DHD VUCA Event 1 - 5	DHD CEO's focus on opportunities and global purpose of the DHD BM's and collaboration with DHD divisions. Challenges over the years and the closing of the DHD division is seen as a positive and natural development of the DHD's business focus issues.	Going global is a solution which implies collaboration with partners, networks, old and new colleagues including a new perspective on industry: Research is not necessarily an academic tasks but a project together with partners. New kinds of funding and competencies are developed.	DHD offers international BM's for customers from India, Pakistan, Norway and Sweden with external funding. DHD enters new collaboration with other businesses in order to host the DHD headquarter. Some of these partners are not traditional BV and DHD business partners.	Visions, creative analysis and relationships are basic components of the chaotic history of the DHD. Each time there seems to be a solution, it is obstructed from outside. All kinds of learning in knowledge management is in use – primarily based on scientific research methods. MBMI solutions are incremental and radical plus one disruptive (see enclosure 1).

## 5 Findings

Results from the VUCA Events in the 3 cases are organized in accordance to concepts from the above mentioned theories: VUCA, the MBMI processes and BMES layer, the model of knowledge management, learning and creating.

In all cases the VUCA hits the core business, but in accordance to MBMI the 3 cases perform at different MBMI layers (see figure 1). In enclosure 1, it is summarised: Case 1 and case 3 act at the Business and BMES' level – case 1 in the national BMES, and case 3 in the international BMES. Case 2 works within its own Value Proposition and at costumer and user level. Case 1 and 3 focus primarily on establishing new networks. Different BMI solutions – incremental and radical – fit all cases, including a disruptive in case 3. In all cases networks – digital, virtual, physical – change rapidly and even paradigmatically, since the industrial era's understanding of relationships no longer functions in their cases.

In sense-making and knowledge management processes, the involved persons act different. In case 1, the MA CEO acts alone by tacit to tacit relying strongly on his informal network and relationships in this socialization process. In case 2, the SA management relies on family and local values in a process from tacit socialization to externalized knowledge about the VUCA. In case 3, both tacit socialization, externalization and combinations like analyses and published research in a process towards a new organizational structure globally and internationally with new partners, new academic links and new social networks.

The participants' positivity show that they constantly look for opportunities, even in chaos. None of them enters into negative and conflicting negotiation style with their business partners – on the contrary, it seems that an important business attitude is friendliness, openness, curiosity, collaboration and grid.

## 6 Discussion

How and why do these MBMI participants and teams react with positivity in VUCA? Secondly, how are these reactions transferred into cultural and personal learning competencies in the business – by the means of socialization, externalization and internalization. Our study is based on observations and interviews with the participants. This opens for a discussion about the validity and reliability. On the other side, the 3 cases are so 'extraordinary' and VUCA that they may open for new views on scientific methodology that corresponds VUCA. We are not yet able to define or quantify, why the participants act and behave as they

do, but by mixed methods including our own position as action researchers we can identify some tendencies (Bryman & Bell, 2011).

In doing so we use theories about learning and creating of knowledge by socialization, internalization of knowledge, externalization and combinations as important learning factors (Nonaka & Takeuchi, 1995; Knoop, 2010, 2013, 2016). Added to this, it seems that the participants are in a positive spiral of creativity and learning in networks – and not in negativity and learned helplessness (Seligman & Maier, 1967). This seems to be crucial for the outcome in the cases, which are not foolhardy. The participants stay calm and safe – alone or in teams – and act within existing frameworks of incremental and radical innovation. The issue is, what could disruption have proposed of total new solutions, though risky.

What kind of learning is observed in the processes? In general, all participants learn from the chaos they meet. Even though some of the learned knowledge is not useful and even destructive, the participants continue to look for new paths by the help of formal and informal relationships. Tacit knowledge transferred rapidly into implemented knowledge by externalization of values, relatedness and visions (case 1 and 2). In case 3 the process is more slowly and academic, as a global and international combination of knowledge transferring. This slow speed corresponds badly with the speed of VUCA. On the other side, it opens for a deeper analysis of tacit VUCA structures.

The mix of research methods used in our study is not optimal. It is a first research setup to get a preliminary understanding of VUCA and impact. Future VUCA, related to MBMI solutions and persons'/teams' handling of these, will be studied deeper in a larger case sample. An obvious discussion is, whether all VUCA Events identified in this paper really are VUCA events or additional definitions can be developed.

## **7 Conclusion: Relevance and contribution**

VUCA Events can come and "hit" from internal and external the business. In previous VUCA literature, it seems as if VUCA Events mainly comes from outside the business. The 3 VUCA cases in this paper with in total 15 VUCA Events seem mainly to be exposed on Volatility (V), Uncertainty (U) and, secondly, on Complexity (C), whereas Ambiguity (A) is smaller. We also notice that the VUCA Events hit on different levels of the business but the events hit mostly on the BMES, BBM and BMD level – and seldom on the MBMI Process.

MBMI solutions were mainly concentrated on incremental and radical MBMI – only one example of disruption. MBMI processes to solve the VUCA challenge were carried out mainly in teams, which means that the main persons impacted by the VUCA Events made the MBMI solutions together with his or hers near networks. This contributes to the fact that the participants seemed to behave positively with a high focus on learning and creating meaningful activities out of the volatile and complex situations. Their learning competencies relied fundamentally on tacit knowledge transferred by socialization into implementation (case 1) and with some (visual, written) externalization (case 2). In case 3 we notice all phases in the knowledge management model with a strong focus on explicit knowledge by combined methods in an academic context.

The involved persons demonstrate a focused preference for socialization and relatedness in processes, learning in pairs and groups as learning and creating by doing. They are very easy to internalize what they have learned from the VUCA situations. We notice a very little focus on models, written documents and other externalized media in two of the three cases. These observations correspond to the hypothesis that positivity is a predictor for success in MBMI.

## **8 Further Research**

In order to examine the participants' psychological profile we will add a psychometric test (Big Five) on a larger sample. As mentioned above, there are individual differences in our cases. Curiosity, openness, agreeableness, conscientiousness, creativity, disruption tolerance and motivation seem to be important personal characteristics in combination with a high IQ, which correlates positively with the ability to cope with complexity (Neisser et al, 1996; Horstmeyer, 2019; Pangaribuan et al, 2020).

### **Abstract**

Durability, adaptability, and reduction and valorization of waste are the main goal of the European guidelines on circular design of building. These objectives impose a real paradigm shift in design from the current on-off logic to a continuum building design that includes preventive and planned maintenance, deconstruction design, selective demolition and up-cycling of materials and building components. In circular design, building is conceived as an organic whole of functional parts, which in turn can be broken down into construction materials. The integrated methodology of BIM and the Material Passport (BIM-MP) is the emerging digital tool both in the perspective of circular design and in the context of the sustainability of heritage conservation interventions.

The digitalization of information with the support of BIM-MP tool enables the creation a digital passport for the construction and for single materials. It allows the construction modelling at different scales of detail, from individual components down to materials. The digital passport reports as generalities the initial performance characteristics and updates them during the whole life cycle by making "visas" that indicate transformations and variations of functions and performances. It gives an identity to each component of the construction, which at the end of its life becomes a repository of materials, opening urban mining scenarios that safeguard natural resources and reduce the amount of demolition waste. The provision of a compulsory Digital Product Passport in the European Union for building materials according to the recent Eco-design for Sustainable Products Regulation will foster the development and adoption of the BIM-MP methodology.

The recent European regulatory context and the new approach to building continuum design outline new scenarios of integration between building heritage conservation and

new construction with the emergence of a new transversal ethic of sustainability based on knowledge of materials and their circular use in construction. Circular design and building heritage conservation require the same methodological approach with the involvement of different disciplinary fields for the acquisition of a range of information at different scales of detail and different perspectives of analysis. In both cases, the deeper the knowledge of the construction and its components, the greater the possibility of prolonging its life and regenerating its value. Digital tools allow sharing skills and expertise, given the possibility of effectively managing and bringing together roles and professional figures that in the past worked in isolation, with little collaboration.

Circular design reformulates the connections imposed by the criterion of *hic et nunc* between construction and the life of materials that neither begins nor ends with their use in a building. In Italy, many buildings belonging to the built heritage are in a dilapidated state or in many cases to the state of ruins. The implementation of heritage materials passport can transform the loss of building heritage into a potential gain, going beyond the timeline and beyond the confinement of place in a continuous history of use, deconstruction and reuse. Building heritage no longer salvageable can become a bank of precious materials as a unique and unrepeatability testimony of cultural heritage.

**Paper type** – Academic Research Paper

## 1 Introduction

Construction is one of the driving sectors for the development of world economies. Unfortunately, it is also one of the production sectors with intensive energy and raw materials consumption and high generation of demolition and construction waste (Gorgolewski, 2008; Alwan et al., 2017; Hossain, 2018; Bernardo, 2022). Currently, building design ends with the completion of the construction according to an on-off logic and both construction maintenance and management of its end-of-life are postponed until later (Atta et al., 2021). Moreover, the revolutionary innovations of digital technologies are still not widespread and exploited. For all the reasons stated above, construction is one of the priority sectors in the strategic actions outlined by the European Green Deal (COM 2019). The European guidelines on circular design of building introduce new buildings requirements and indicate the digital technologies as key-strategic tools for the adoption of circular economy models in the construction sector (COM, 2020). Durability, adaptability, and reduction and valorisation of waste are the main goal of the building circular design. In circular design, building is

conceived as an organic whole of functional parts, which in turn can be broken down into construction materials. These new objectives impose a real paradigm shift in design from the current on-off logic to a continuum building design covering preventive and planned maintenance, deconstruction design, selective demolition and up-cycling of materials and building components (Bernardo, 2021).

In the light of the new European regulatory framework, the work explores the possibilities of integration between circular construction design and cultural heritage conservation and valorisation.

## **2 BIM-MP tools for continuum building design**

Building Information Modelling (BIM) and Materials Passport (MP) are the emerging digital tools for continuum building design and sustainable construction (Honic et al., 2019; Honic et al., 2020; Atta et al., 2021). BIM allows the management of the huge flow of information during the entire construction life cycle and the creation of Materials Passport. This latter one gives a digital identity to materials and building components, reporting all their initial generalities and updating them with 'visas' that shows their maintenance and all the function and performance changes.

The origins of the terminology Building Information Modelling date back to the seventies although its first applications occurred in the eighties. In 2018, the International Organization for Standardization (ISO) issued the first global standards "ISO 19650:2018 - Organization and digitalization of information about building and civil engineering works, including building information modelling (BIM)" that has put in order all the standards implemented at national level by providing a unique definition at international level for the exchange of data and common protocols for the sharing of information between the various operators of the construction industry (Dassori, 2020). The International Alliance for Interoperability, renamed buildingSMART in 2007, was one of the first players to set common standards. The association developed the neutral model of building data along the building life cycle named IFC (Industry Foundation Classes). It is an open format, not controlled by any house software, now used in the BIM field for the exchange of information. Even today buildingSMART is one of the reference bodies for BIM and collaborates in the drafting of ISO standards participating in

the technical committee ISO/TC59/SC12 - Organization and digitalization of information about buildings and civil engineering works.

By breaking the mold of traditional digital modelling, BIM undertakes information modelling in parallel with geometric modelling by storing data in a common data environment. Geometrical modelling in BIM has some substantial differences compared to other digital modellings (Dassori, 2020). The first one is that a BIM model does not consist of simple lines but everything that is drawn carries a multitude of information. For example, a wall drawn in BIM is not only a geometrical representation, but it also contains information about the stratigraphy, the materials used and their properties. In addition to this, the modelling is parametric and for this reason the change on a material or element is carried over into the whole model. Another relevant aspect is that from the simple 3D model in BIM it is possible to automatically extract all the graphical drawings needed to present the project (plans, elevations, details, axonometries, etc.). Moreover, even the smallest change to the model is directly applied to all the project boards with a clear saving of time and reduction of errors.

With BIM technology, one or more models of a building are developed through parametric digitization that can support the design, construction, use, maintenance and end-of-life phases, enabling better analysis and control than manual processes. BIM design manages the entire flow of information from the concept of the construction to its end of life and enables integrated design with the management of complex and simultaneous relationships and changes in roles and operations between project teams.

In the recent scientific literature, the integrated methodology of BIM and the Material Passport (BIM-MP) is the emerging digital tool both in the perspective of circular design and in the context of the sustainability of heritage conservation interventions (Koutamanis et al (2018); BAMB 2022).

The digitalization of information with the support of BIM-MP tool enables the creation a digital passport for the construction and for single materials. It allows the construction modelling at different scales of detail, from individual components down to materials. The digital passport reports as generalities the initial performance characteristics and updates them during the whole life cycle by making "visas" that indicate transformations and variations of functions and performances. It gives an identity to each component of the construction, which at the end of its life becomes a repository of materials, opening urban mining scenarios that safeguard natural resources and reduce the amount of demolition

waste. Moreover, the development of open digital platform based on BIM-MP tools could allow the accessibility, the implementation and updating of constructions information by all stakeholders. Vertical interoperability with other digital tools, such as software for Life Cycle Assessment or structural calculations, is one of the aspects that deserve further development for a real exploitation of the potential offered by BIM-MP digital tools. Another challenge is the transparently track information to ensure the validity and property of digital data.

### **3 EU Digital Product Passports**

Eco-design takes the complete life cycle of products into account and represents the new frontier of sustainable design. According the principles of circular economy, apply to all phases of a product's life cycle, with the aim of reducing waste and its overall environmental impact: from the sourcing and use of raw materials, which must be reusable, biodegradable, recyclable and non-toxic; to their processing in the production process and distribution, which must comply with the EU eco-design directive (Directive 2009/125/EC), in terms of energy efficiency (reduced energy consumption in the production phases) and reduced environmental impact. The raw materials and energy consumption of the product and the possibility of reuse also contribute to defining it as eco-friendly and sustainable: the product's life cycle must be extended as far as possible, through recycling and/or reuse of its components. Alternatively, the product must be biodegradable, so that it is completely within the natural cycle.

LCA (Life Cycle Assessment) methodology assess the entire life cycle of products and how they 'interact' with the environment, including the phases of pre-production (origin of materials), production, distribution, use and reuse, and final disposal. This is an internationally standardised procedure according to ISO 14040 and 14044. At the basis of the LCA logic is the system perspective that allows the complexity of the supply chain, upstream and downstream of the production process, to be understood and managed. Critical points, *hot point*, in the entire product life cycle are then identified, in order to hypothesise solutions aimed at saving and recovering energy and materials.

One of the most significant challenges of the LCA is inadequate or even lacking information transfer between different stakeholders across value chains. To overcome this limitation and enhance the traceability of products and their components, in March 2022, the European Commission has introduced the Digital

Passport of Products (DPPs) as legal requirement over the next few years in the proposal of Eco-design for Sustainable Products Regulation (COM 2022). Construction materials together with electric vehicles, industrial batteries and textiles are the priority products for the implementation of DPPs. Digital Product Passport refers to a digital profile given to an individual product including business information, its origins and authenticity, sustainability of production and all information related to its life cycle in the supply chain of circular economy. DPPs can be valuable tools for enabling quick and convenient access to and sharing of product-related information. By scanning the tag (e.g. QR code), producers, consumers, waste operators and public agencies can easily access and possibly also upload relevant and targeted information for other stakeholders. This would come with multiple benefits. For example, easy access to information could empower consumers to purchase more circular products or inform repairers on how to fix used devices.

Chapter III of the proposed regulation on the eco-design of sustainable products outlines the general and technical requirements for the creation, access and sharing of digital product passports.

DPPs must be connected to a digital data carrier in line with standard ISO/IEC 15459:2015 by means a unique identifier and the information must be open standard, machine readable, structured, searchable by any stakeholder. The specific data requirements for DPPS of each individual product category are still being defined. A consultation process with industry partners is currently underway. Indeed, the definition of the passport requires the collaboration of the entire supply chain and the definition of crucial information that could prevent a product from being wasted. In addition, one of the key issues to be resolved is the protection of information ownership rights and corporate privacy. The development of blockchain technology can be the decisive tool to ensure the disclosure and accessibility of results on the one hand and the protection of property rights and privacy on the other hand.

#### **4 Circular economy and heritage materials valorisation**

The new models of circular economy and the digital tools for sustainable construction open new scenarios and opportunities in the field of heritage conservation. According to the current scientific approach to restoration, the historical and artistic value of the construction should be preserved by preserving

the materials of which it is made according to the criteria of minimum intervention, compatibility, reversibility and recognisability. The knowledge of materials and construction techniques is only functional in maintaining the epiphany of the image of the construction, whose value remains rigidly anchored according to the criterion of *hic et nunc* to the place and time of construction (Bernardo, 2021). However, the widespread degradation of the heritage, in many cases reduced to the state of dilapidated buildings or ruins, together with the awareness of the scarcity of resources, give the materials of which the construction is made an intrinsic value that goes beyond keeping the building alive. Circular economy and continuum building design offers the possibility of a reformulation of the connections between construction and the life of materials that neither begins nor ends with their use in buildings or specific locations. The reuse of heritage materials and building components can transform the loss of construction into a potential gain, going beyond the timeline and beyond the confinement of place in a continuous history of use, deconstruction and reuse. Construction that is no longer salvageable becomes an urban quarry of materials that have an even higher value than newly produced materials as part of the tangible heritage. The circularity of materials reduces the amount of demolition rubble and promotes economies of scale based on recycling and valorisation of heritage materials. An innovative example of the up cycling of built heritage materials is the spin-off Opalis (an anagram of the word spolia) of the Belgian company Rotor DC, which created a digital inventory of materials recovered from building heritage (Rotor DC, 2022). The up cycling of heritage materials can also stimulate the creative design of new sustainable buildings. The Resource Rows housing complex designed by architect Anders Lendager in the city of Copenhagen is one of the most striking examples. The patchwork façade of the complex was built by reusing masonry panels from the deconstruction of the industrial complex of the city's Carlsberg brewery (Fig.1).

*Figure 1. Patchwork façade of the Resource Rows residential complex built with masonry panels from the deconstruction of the Carlsberg Brewery, Copenhagen, Denmark. Photo by Mikkel Strange. Source <https://www.theguardian.com/cities/2020/jan/13/the-case-for-never-demolishing-another-building>*

Another example of up-cycling of heritage materials that deserves special mention is the C. K. Choi building of the Asian Research Institute on the campus of British Columbia University in Vancouver (Canada). The building was constructed in 1996 to a design by Matsuzaki Wright Architects and is known to be among the first green buildings in Canada to receive several awards for efficient use of resources and energy conservation. The building consists of five identical blocks with curved roofs that recall the forms of Asian architecture and large glass surfaces that provide natural light to the interior spaces (Fig. 2). In a recent paper, Susan M. Ross highlighted one of the lesser-known sustainability aspects of the C.K. Choi building design (Ross, 2020). The load-bearing structure of the solid brick and timber building was constructed entirely from recycled materials. Bricks from demolitions carried out in the city of Vancouver were used for the masonry. The timber structural elements were salvaged from the deconstruction of the adjacent 1941 Armoury building owned by the university, which once housed students during their military service. The technical characteristics and state of preservation of the wooden lattice structure of the Armoury were assessed prior to the deconstruction of the building. The results obtained from the preliminary investigation influenced the design of the C.K. Choi building, which recovered most of the wooden structural elements with a pioneering experiment of up-cycling heritage materials. The reuse of the wooden

beams of the Armoury in the construction of the Asian Research Institute also has the value of a reparation for the wrong suffered by Canadian students of Japanese origin who lost their student status with Japan's entry into World War II.

*Figure 2. Building C. K. Choi of the Asian Research Institute on the Campus of British Columbia University in Vancouver (Canada)*

*Source: <https://sppga.ubc.ca/about/core-partners/#IAR>*

The knowledge of built heritage materials applied to the use of new digital tools opens new frontiers in the field of research and valorisation of heritage materials. The implementation of a heritage materials passport would make it possible to register all the information that expresses both the historical value of the material as well as its original technical properties and its state of preservation for possible reuse that goes beyond keeping the material within the original construction. The heritage materials passport can make a significant contribution to the emergence of the third paradise conceived by artist Michelangelo Pistoletto (Fig. 3). The third paradise represents a third dimension of reconciliation and synergy between the natural and artificial worlds created in the industrial age with the development of technological innovations. It is a powerful tool that has considerable implications both for the preservation of the memory of the past and for the sustainable development of communities.

*Figure 3. The Third Paradise. Papier-mâché artwork by Michelangelo Pistoletto. Entrance hall of the Matera University Campus, University of Basilicata.*

#### **4 Conclusions**

The recent European regulatory context and the new approach to building continuum design outline new scenarios of integration between building heritage conservation and new construction with the emergence of a new transversal ethic of sustainability based on knowledge of materials and their circular use in construction. Circular design and building heritage conservation require the same methodological approach with the involvement of different disciplinary fields for the acquisition of a range of information at different scales of detail and different perspectives of analysis. In both cases, the deeper the knowledge of the construction and its components, the greater the possibility of prolonging its life and regenerating its value. Digital tools allow sharing skills and expertise, given the possibility of effectively managing and bringing together roles and professional figures that in the past worked in isolation, with little collaboration.

The BIM-MP is an important digital tool for sustainable construction as it offers the opportunity to create open digital platforms for recording all materials of a building. The provision of a compulsory Digital Product Passport in the European Union for building materials according to the recent Eco-design for Sustainable Products Regulation will foster the development and adoption of the BIM-MP methodology.

In the next future, we could devise a materials cadastre, that we called "matastre", where the registration of the material passport provides all useful information for the circular use of building materials and components.

In Italy, many buildings belonging to the built heritage are in a dilapidated state or in many cases to the state of ruins. The implementation of heritage materials passport can transform the loss of building heritage into a potential gain, going beyond the timeline and beyond the confinement of place in a continuous history of use, deconstruction and reuse. Building heritage no longer salvageable can become a bank of precious materials as a unique and unrepeatable testimony of cultural heritage.

## Abstract

Personal data has become one of the main sources of value in data-driven business. Personal data plays an increasingly important role in building sustainable competitive advantage but also effects both the way services are being created and provided to users as well as how they are being utilized. Business analytics, cloud computing and platform business logic are seen to emerge in the 'industry of content', i.e., audio and visual broadcasting. This study explores the platform-based business logic behind user experience centric, data-driven services and illustrates how digital convergence impacts the nature of business in the case of broadcasting industry. We further identify mass personalization as one of the key outcomes for how personal data is used to create compelling user experiences with the use of analytics.

**Keywords** – Personal data, analytics, mass customization, broadcasting, data-driven

**Paper type** – Academic Research Paper

## 1 Introduction

Digitalization has been considered as the single most pervasive global enabler for new business. It has affected both the way services are provided to users as well as how they are being utilized. Cloud computing, artificial intelligence (AI) and platform business logic are seen to emerge also in the "industry of content",

more commonly known as audio and visual broadcasting. Digitalization has impacted the role of customers and consumers of the services built on those enabling technologies (Xu, Kemppainen, Ahokangas and Pikkarainen, 2020). In addition to accelerating the development of enabling technologies, increase in the amount of available personal data and advancements in business analytics are creating more and more market turbulence and at the same time presenting new business opportunities, such as novel data-driven personalized offerings. Creating value to customers has for sure always been there (Bonnet and Westerman, 2021), but the elements needed to create compelling offerings and experiences have changed in digitalization. One may even claim that digitalization as a phenomenon is experienced rather than - how it has traditionally been approached - as a perceived cause (Fors, 2010). The positive effects of personalization of content and services on customers' emotional engagement and customer satisfaction have been widely reported (e.g. Pappas et al. 2014, Cheung et al., 2015, Lambillotte et al., 2022). Emotional engagement can therefore be claimed to be as essential as technology in the creation of customer experiences (Bonnet and Westerman, 2021).

With the penetration of smart mobile devices as ubiquitous platforms for prosumerism, people are transforming market participation on the personal, social, and global levels. During Covid-19 shutdowns, the role of real-time media and consumption of data peaked even further, speeding up digitalization processes in many other industries as well. As a result, the capability to adjust value creation processes and business models based on holistic customer understanding has become one of the core drivers for companies' business success and economic sustainability. The role of personal data is particularly relevant in the broadcasting industry. The change in user behavior and how people today consume both audio and visual media, impact the whole process of broadcasting, from content creation and production to management and distribution (Hirschmeier, Tilly & Beule, 2019). The role of enabling technologies in creating highly personalized interactions in real time (Bonnet and Westerman, 2021) has emerged as a dominating competitive edge, which inevitably changes the logic of both service provisioning and utilization (Pikkarainen, Koivumäki & Iivari, 2020; Cusumano, Yoffie and Gawer, 2020; Sorri, Seppänen, Still and Valkokari, 2019).

The challenge of real-time service provisioning and utilization has highlighted the need to view traditionally siloed industry contexts, such as broadcasting, from

much wider perspective – those of platforms and ecosystems. It has been argued that platform-based digital markets can alter the way companies generate and deliver value to end customers (Cennamo, 2019; Cusumano et al. 2020). The purpose of platforms thus is to “facilitate the multi-party exchange of products, which can be goods, services, or even social currency” (Sorri et al. 2019), in the creation of novel value while ensuring value capture. Data, viewed as a new renewable resource and its conversion to information and knowledge is a key game-changer for broadcasters, as broadcasters are operating with all of the aforementioned elements of platforms: utilizing audio data and digital infrastructures in the creation of engaging services for consumers. However, very little research has been conducted in the context of radio broadcasting (Hirshmeier, Tilly and Beule, 2019).

Accordingly, in order to address this gap in academic research, the research question of this study calls “*how does personal data change business logic in the broadcasting industry?*” In order to answer the research question, this conceptual study explores the logic of platform-based business behind persona data-driven services and illustrates how digital convergence, personal data and advances in analytics impact the transformation audio broadcasting business.

The rest of this study are structured as follows. First, we will review the main concepts

## **2 Platform business logic**

Digitalization can be defined as the use of digital technologies to change a current business model and provide new revenue and value generating opportunities (Iivari, Ahokangas, Komi, Tihinen & Valtanen, 2016). Today’s emerging digital technologies cover technologies such as artificial intelligence (AI), 5<sup>th</sup> generation (5G) and future 6<sup>th</sup> generation (6G) mobile network communications, cloud computing, Internet of Things (IoT), augmented (AR) and virtual reality (VR), machine learning (ML) and blockchain. These technologies are becoming increasingly converged in today’s digital markets, and function as the key enablers for various types of digital platforms. McIntyre and Srinivasan (2017, p. 143) state that “platforms can be conceptualized as interfaces—often embodied in products, services, or technologies—that can serve to mediate transactions between two or more sides.” Digital platforms can therefore be explained as software-based external platforms that consist of extensible

codebase of a software-based system that provides core functionalities, shared by modules that are interoperating with it and the interfaces through which they are interoperating (Ghazawneh and Hendfridsson, 2015, pp. 199; Sorri et al. (2019).

Key elements of digital platforms include data, algorithms, components and interfaces (Iivari, Ahokangas, Matinmikko-Blue and Yrjölä, 2021; Yrjölä, Ahokangas and Matinmikko-Blue, 2019b). The increasing volume of data and the power that comes from converting this data into information and knowledge has transformed contemporary business in many industries (Xu et al., 2020). Computing power has equally been turned into economic tools with algorithms operating on the raw data. Components are add-on elements that add functionalities to platforms. Interfaces, e.g. application programming interfaces, specify how platforms and components interact and exchange information via predefined and well-documented standards (Katz and Shapiro, 1994).

The challenge for the broadcasting industry alike is that the engineering tradition has placed components and interfaces either at the core or periphery of the system (Iivari et al. 2021). Iivari et al. (2021) also reviewed that modularity can decrease coordination and transaction costs across the module boundary, while interface standardization can decrease the asset specificity of modules. This modularity could be a game-changer for broadcasters, if they manage to build more user-centric mind-sets, as broadcasters are operating with all of the aforementioned elements of platforms: utilizing audio data and digital infrastructures in the creation of services for consumers.

However, the business models of the broadcasting industry can equally prevent the full utilization of digital platforms and cloud-based technologies, as traditionally, audio and visual media have functioned in their separate siloes. One approach in breaking these siloes is to reconceptualize business models in platform context. For instance, Weil and Woerner (2015) proposed four types of business models in the digital context: first, a supplier model that works in a value chain of another company, second, a multi-channel model that causes firms to restructure across several digital and physical touchpoints to serve their customers, third, a modular model that builds on plug-and-play interfaces to complement their offerings, and fourth, an ecosystem model that builds a customer-centric platform to facilitate ecosystemic interaction among customers. Here, cloud technologies enable the breaking of silos and the transformation from supply chain model to both multi-channel and modular models.

The key is to build understanding on the concept and role of platforms, as the logic of business determines how to reap the benefits enabled by cloud technologies. Therefore, whenever we are discussing digital platforms, we also need to acknowledge the role of business models. As stated by Chesbrough (2010), even a mediocre technology can succeed with a great business model, but a great technology may fail if it has a poor business model. We argue that what comes to the business of content and user experience, these both have to be in line – if there is a missing file at any phase of the audio content delivery or any information is lost (Neumann & Roca, 2004), it may cause severe quality issues and even harm the brand of end user service providers. Therefore, both technical platform modularity and architecture and service modularity and architecture (Yrjölä, Ahokangas, & Matinmikko-Blue, 2019a; Yrjölä et al., 2019b) need to be considered when combining the economic and engineering viewpoints in digital platform context. Indeed, platforms in academic research have an inherently dualistic perspective to business (Gawer, 2014), as they comprise quite separate economic and engineering streams of literature. Within economics, platforms are viewed as two-sided or multi-sided markets that connect supply and demand, whereas in engineering they serve as modular technological designs for facilitating innovation. Digital convergence addresses how these different elements of platforms, previously held in individual silos, come together, interact and enable the creation of new kinds of products and services.

### **2.1 Convergence and modularity**

Convergence (Xu et al., 2020) in the radio industry means that audio is no longer the only context radio broadcasters operate in, but all forms of media are coming together. This is the core of new user experience-driven services. How then convergence and platform logic enabled by the cloud then can be manifested in the broadcasting industry when technical modularity allows the back-end and front-end systems to be developed and operated separately, even by different players (Jacobides, Cennamo and Gawer, 2018). Business models as a concept can be explained through the perspectives of value proposition, creation and capture, through opportunity exploration and exploitation as well as through competitive advantage (Xu et al. 2020). The dualistic perspective to technical and service modularity and architecture can therefore be coined from the perspective of complementarity (Xu et al., 2020; Teece, 2018), where a successful user

experience in a platformic context can be considered as the successful end-result of technology and opportunity complementarities (Xu et al., 2020). Technology complementarity enables modularity from systems and interoperability perspective whereas opportunity complementarity ensures a user-centric approach to service provisioning and service modularity.

Convergence and modularity of broadcasting industry can further be analyzed by looking at the different type of services provided in the digital context. Wirtz, Schilke and Ullrich (2010) proposed four typological business models for Internet-based companies. Each of the four types of business models entail varying value propositions and revenue models: connection (e.g., wireless connectivity or a fiber) that enables interaction, content (e.g., data or information) that can be transferred over the available connections, context (e.g., search or location) that provides situational awareness of the activity in question, and commerce (e.g., marketplace and platforms) for data, information, or context over the available connectivity.

In the Internet-of-Things context, Iivari, Ahokangas, Komi, Tihinen and Valtanen (2016) have noted the roles that infrastructure and hardware, platforms and data, devices and equipment, and applications and user interfaces play for the provisioning of digital services. When applied to the context of broadcasting industry, connection is manifested in different options for broadcasters to reach their target audience and enabling interaction, whether it's via Internet streaming, satellite distribution or traditional terrestrial radio frequencies. As a technology provider for broadcasters, a key enabler of cloud technologies is that traditionally highly (closed) supply chain -driven operating models can now be divided based on the content – the end user value.

Once connection architecture or options have been reviewed, content can be run on top of it. Key questions for industry players is to determine what is the content being provided for customers to utilize that they want to transfer over the available connections? What is the needed format? As a 3rd party content provider, for example, what kind of marketplace or supply-and-demand-type platform is required to operate at the commerce level? Whether it's infrastructure and hardware, platforms and data, devices and equipment, or applications and user interfaces, they all play a role in the provisioning of digital services. The so-called 4C layered perspective on digital business models raises the question of horizontal and vertical or even oblique business models (Iivari et al. 2016, Ahokangas, Matinmikko-Blue et al. 2019). From platform perspective, these

business models can be considered as use-case specific vertical business models, service-specific horizontal business models and the mixture of both aforementioned business model concepts.

Cloud technologies have the power to be at the heart of platform-based business logic, as connectivity and connection is the backbone that everything else builds on. Cloud-based infrastructure and web-based user interface architecture, for example, enable interfaces to operate separately from playout units, which revolutionizes the way radio stations can control their on-air playout. However, it is important to note that cloud technologies are not necessary to replace all other in-house technologies, but to complement existing technical capabilities (c.f. Xu et al., 2020, Teece, 2018). By embracing the cloud as part of product or service architecture, it is possible to develop and deploy the back-end broadcast systems in a variety of public cloud, private cloud, virtual, physical, or hybrid operating models, irrespective of distribution channels (terrestrial, satellite, web-based streaming or through mobile telecommunications networks) how end users access the media content, whether through platforms or company-specific services, or how they consume media in terms of end-user devices or applications. Convergence in the broadcasting industry means that use cases can be as diverse as there needs, but they can all be based on the same modular architecture.

Furthermore, as cloud-based technologies enable full and fast rollout of remote broadcast operations even for large broadcasters without any heavy on-site infrastructure, but at the same time also enable the rise of start-ups, as access to technology know-how or resources no longer prevent the creation of meaningful user experiences. Hence, operating in platforms can become an important source of competitive advantage for new ventures. However, this requires the understanding of the previously discussed differences between technical and service modularity and how to capture this understanding and turn that into opportunities and business advantage with business models. Modularity, convergence and complementarity also ensure the ability to react fast to market changes in order to provide seamless broadcast operations, as service providers need to be able to easily create, manage, replace or change content in real-time and simultaneously plan and manage their assets for future programming. Cloud technologies can therefore ensure the actors to have all the tools easily accessible irrespective of time and location in order to provide relevant content for meaningful user experiences (Bonnet and Westerman, 2021; Hirschmeier et al.

2019). It indeed is about bringing real-time digital user experiences to both audio and visual media production.

## **2.2 Drivers for cloud-based operations**

The role of user experience is particularly relevant in the broadcasting industry. Whether we talk about live radio shows executed from remote studios, podcasts you can listen to on-the-go or personalized radio ads, people want content they can relate to, and meaningful experiences. Content may be king, but user experience is queen. This change in user behavior and how modern people consume their media, impacts the whole process of broadcasting, from content creation and production to management and distribution. The role of technologies in creating highly personalized interactions in real time (Bonnet and Westerman, 2021) has emerged as the dominating competitive edge in many other industries as well, changing the logic of both service provisioning and utilization (Pikkarainen, Koivumäki & Iivari, 2020; Cusumano, Yoffie and Gawer, 2020; Sorri, Seppänen, Still and Valkokari, 2019).

The so called back-end technologies that enable the development of such user-centric services are often lagging in the audio and visual media industry (Hirshmeier, Tilly and Beule, 2019). The reason for this is that until recently, long purchase cycles and slow public tendering processes especially in the public broadcasting sector, have resulted in the provisioning of large broadcast IT systems, built with multi-tier, client-server configurations and fixed installations, that were heavy, time-consuming and expensive to maintain. The need to place the audio playout close to the audio infrastructure has been a must. These have prevented flexible, proactive broadcast operations and made it challenging to meet the demands of end users. The wide gap between service provisioning and utilization especially in the radio broadcasting industry has created a large contradiction in the delivery of media services to end users, as the adoption of new technologies within a single industry varies greatly even in the provisioning of a same end-user service.

The Covid-19 crisis has further highlighted the necessity to manage and control broadcast operations anywhere, whether at home, on company premises or in the field, forcing many operators to change their whole logic of operations overnight. Although the transition towards mobile rather than studio-controlled environment was already taking place, the pace of transformation was much

slower at the systems architecture point of view and technology service providers were challenged in meeting the demands of their customers. Cloud technologies and web-based architectures have been considered as an answer to the prayers for catching up with end-user and customer demands, as they move the business logic and interfaces to back-end servers and enable the use of browser-based workstations. Virtualization and cloud technologies have made dedicated servers almost obsolete, thus disrupting the old logic of doing business and technology provisioning (Irwin, 2020).

However, if user experience has then become the competitive edge in the front-end but the systems "under the hood" have not followed the digitalization bandwagon in the same pace, how can broadcasting companies ensure their business, not only survive the digitalization wave, but also prosper, in the midst of digital transformation? All these technological advances require new kinds of service-based business models, whether the players are start-ups or large media houses. This challenge of simultaneous service provisioning and utilization has highlighted the need to view traditionally siloed industry contexts from platform perspective.

### **3 The transforming business logic of broadcasting**

The sections above brought the attention of platforming convergence from technology and service provisioning point of view. However, overall, from digitalization perspective, it is important to acknowledge that the pace of transformation is different, not only in between different industries but also in between different organizations belonging to the same industry. Based on the initial literature review conducted for this paper, it was surprising to discover that for such a highly technology-enabled industry, very little, if any, research has been done from business perspective, as also Hirshmeier et al. (2019) discussed in their research. The need for focusing more on the business approach in researching broadcasting transformation is highlighted in the literature review article by Medina, Mazaira and Alén (2022). They note that while the innovation in the broadcasters' business model has been mainly related to innovation in the value offer and innovation in the value architecture, such as offering innovation, convergence and technological development, there is a clear gap in the holistic business model research. For example, they highlight that there is a need for novel revenue model solutions which complement the emerging business

models. The need for emphasizing the business aspects is even more important as the industry is moving towards personal data driven mass-personalized offerings. This raises a question of whether digital transformation and digitalization of broadcasting technologies in fact is taken for granted both in industry and academia. Yet, digital transformation touches all aspects of modern society (Xu et al. 2020, Hirshmeier et al. 2019).

Therefore, we conceptualize the drivers of digital transformation in broadcasting two-fold. First, the pull from the market and the need to create more personalized, user experience -driven services. Second, technology providers also experience push from the business customer side in the form of changing purchasing cycles and more precise and specific demands towards real-time consumption of digital services. The role of technology provider in this context is often a double edged sword – on one side, technology providers are able to create awareness and educate on the benefits of the cloud but at the same time balance between old operating models in which most revenue is based on.

As this study is conceptual in nature, we rely on industry observations and secondary data collection of both online and print material regarding overall technology transformation (Irwin, 2020; Hirshmeier et al., 2019). Therefore, as this study explores how personal data impacts the industry's business logic transformation, the decision-making process model of AIDA was applied, as illustrated in Figure 1 below. AIDA is a marketing term and refers to awareness – interest – desire – action. This model can be utilized to explore how new service concepts and business ideas can be absorbed, as well as describe the decision-making process of broadcasters when acquiring new technologies and IT systems. Specifically, we wanted to understand the dynamics of transformation in more detail, and how the concepts of opportunity exploration and exploitation and value creation and capture evolve towards competitive advantage based on personal data-driven and user experience-driven services.

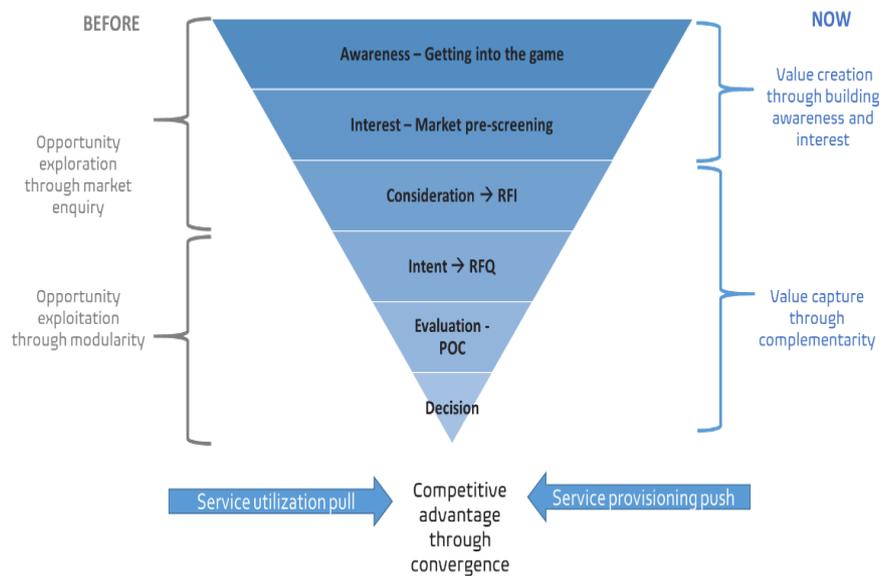

Figure 1. Illustration of broadcasting industry business logic transformation with applied AIDA framework

The traditional commercial process for acquiring technologies for media content production followed long, even one to two year purchasing and public tendering cycles. As the process was long, there was a lot of room to impact the content of specific tenders and orders after the initial contact was made. Hence, building awareness of broadcasting content production services was quite general, and the tailoring of legacy technologies and services was dominant. It was “enough” to pass the market pre-screening phase to be considered as a potential technology provider in the request for information (RFI) phase. Often, decisions for final offers (RFQ, request for quotation) were already finetuned in collaboration during the market enquiry phase, and the evaluations of the suitability of the technologies in terms of specific customer requirements and proof-of-concepts (POC) for requested services, such as talk, music, news or commercials, were already defined and evaluated during closed purchasing processes. The end process that led to final decision for broadcasting systems was then often shorter and faster. Contracts were often 10-15 years long, which meant that the agility to respond to changing consumer needs in terms of technology has been slow and difficult.

A big driver for broadcasting industry transformation has been the emergence of over-the-top (OTT) platform service providers like Spotify, Netflix, Amazon and Google, that have not only challenged the business of traditional visual broadcasters (i.e., TV and film) but also audio, i.e., radio broadcasting, as the availability of real-time content through end user devices has become mainstream medium even in cars.

Technology and service modularity, interoperability and complementarity aspects need to be tested, verified, and productized before any official decision can be made also because consumers' role as active service utilizers has equally increased as a result of real-time data. This has led to the emergence of as-a-Service type business models also in broadcasting (see e.g., Mäkilä, Järvi, Rönkkö and Nissilä, 2010; Malgoyard, 2018). However, as Hirschmeier et al. (2019, pp. 5021) revealed in their exploratory study, the general broadcasting industry is much further behind than other media industries as "the radio broadcasting industry to be in a digital paradigm shift that is similar to what happened in the music industry and the film industry 15 years ago". Therefore, understanding industry transformation is indeed two-fold, as emerging technologies, such as the cloud, and the convergence of technologies overall, have also changed broadcasting technology process up-side down. In service provisioning, companies need to be more agile, and those that have been fast to transform and embrace new technologies, have been able to respond to changing needs of the market, as the functionalities for software systems need to be demonstrated and validated with real life use cases already early on.

#### **4 Conclusions**

This paper explored how digital transformation and convergence are manifested in the context of broadcasting industry from the perspective of how personal data-driven services drive the transformation towards platforms and modularity. We conclude that the need to build more personalized services creates a simultaneous service provisioning push and utilization pull impacts the business logic of broadcasting industry especially in technology convergence, modularity and complementarity. As broadcasting industry has not been widely explored in academic research (Hirschmeier et al., 2019), in deriving the framework, general secondary data sources on the industry were gathered and used to build our analysis. Therefore, the biggest weakness of our study is its lack of empirical

grounding, but in the same vein, it offers fruitful new research avenues, especially in understanding the dynamics and transformation of traditional supply chain towards value networks.

The main theoretical implications of this research relate to the study of platforms and business models in a novel industrial context. Further on, digital transformation has widely been discussed at ecosystems level, however, a more thorough cross-industrial approach could benefit in understanding the antecedents and drivers of digital transformation. Emerging technology research highlights convergence, so how is broadcasting industry linked to other domains, such as Internet-based business and the OTTs, telecommunications and the media sector overall. Business model research highlights the role of contextualization in order to understand emergent phenomena, and unraveling the controversies and dynamics of the broadcasting industry in particular, can contribute to the discussion of platformic business models in the context of industry convergence and digitalization (Xu et al. 2020).

The practical implications of this study helps business developers and managers operating in the broadcasting industry to understand the building blocks of user experience and how they can utilize this knowledge in order to build competitive advantage for better decision making. Here, especially entrepreneurial start-ups could further seek to exploit the opportunities and capture the value of technologies by applying how the different elements of user experience can be applied in the design of those experiences, how different data sources could be utilized in improving the quality of services, pricing and revenue models and especially, how engagement to both real-time live and on-demand audio content especially can be improved as a source of competitive advantage (Bonnet & Westerman, 2021). The concept of simultaneous service utilization and provisioning directs future research towards empirical explorations both at service and service delivery network level. Personal data in this study was explored as a driver for service creation and industry transformation, however, more research is needed on how companies access, utilize and control consumer data in broadcasting services and the development of mass-customized services. These draw attention to the role of business analytics as a key enabler for these services, but also to legal and ethical concerns over personal data, such as the role of GDPR and MyData. Even though cloud technologies enable the transformation of the business logic towards user experience from technical modularity and architecture point of view, overall transition of the industry that also incorporates

the business perspective is centered around the concept of value, which comes from meaningful user experiences and emotional engagement.

### **Abstract**

Businesses must digitally transform their organizational mindset to stay competitive and gain sustainable competitive advantage. Previous studies revealed that to achieve digital transformation (DT), organizations require strategic dynamic capabilities (DC) in order to discover new opportunities, sense and measure potential threats, exploit external inputs, and deal with new digital environments.

However, the path to a complete theoretical and empirical understanding of the digital DC domain is yet in its early days. Moreover, prior research has largely concentrated on organizational DC internally, thus paying little attention to inter-organizational processes and not considering the requirement of new people for the development of the latter.

In recent years, academic research has revealed that collaborations between different parties based on the choice of specific and strategic partner are key factor for the effectiveness of the improvement process of strategic innovation capabilities. Universities, especially entrepreneurial universities, are suitable partners for the transfer of both knowledge and ideas, as well as for the development of business innovation.

Framed on these premises and based on a longitudinal case study carried out within an Italian university initiative, the goal of this study is to provide evidence that university-industry collaborations (UICs) are fruitful and key means to support and manage the exchange of stakeholders' digital knowledge within an ecosystem and to develop digital capabilities across the involved firms.

Results show that cross-border academic, industrial, and institutional interactions involve innovative and valuable processes able to develop critical DT dynamic capabilities, also suggesting empirical guidelines to educators, professors, and practitioners to structure and expand the innovation ecosystem between universities, businesses, and institutions.

This study also offers managers and SMEs practical advice on digital transformation and an empirical model to help businesses compete and improve their strategic positioning through internal process digitization and business model innovation..

## 1 Introduction

To remain competitive and develop new income streams in a world where almost everyone has access to the internet, businesses must digitally alter their operations (Teece, 2023). The use of emerging digital technologies, including as mobile, AI, the cloud, blockchain, and IoT, is known as digital transformation (DT) (Fitzgerald et al., 2013), a phenomenon that increase client satisfaction, streamline processes, and develop revolutionary company ideas and innovative business models. Therefore, digital transformation must be included in business roadmaps (Cappa et al., 2021; Vial, 2019). For this reasons, organizations need strategic capabilities to accomplish digital transformation (Nambisan et al., 2017; Nasiri et al., 2020; Teece, 2018, 2023). These capabilities are known as dynamic capabilities (DC) in the strategic management literature. Teece et al. (1997), divided dynamic capabilities into three main categories: sensing, seizing, and transforming/reconfiguring (Teece, 2007, 2023), and they represent the micro-foundations of sustainable enterprise performance and competitive advantage.

According to Teece (2023), empirical studies using DC to investigate the processes of digital transformation, have just lately acquired pace. This observation was also supported by a recent SLR done by Mele et al. (2022). However, there hasn't been enough theoretical and conceptual development in the literature on digital DC up to this point (Ghosh & Srivastava, 2022), specifically if we considered organizational routines conceptualization (Ellström et al., 2022; Teece, 2023). Additionally, the majority of research (such Warner & Wäger, 2019) concentrated mostly on large businesses, ignoring small and medium companies (SMEs) that are characterized by restricted resources to carried out a digital transformation path (Battistoni et al., 2023). Additionally, inter-organizational dynamics were not taken into account in research, according to Annarelli et al. (2021).

As stated by Teece (2023, p. 121) "new capabilities typically mean the introduction of new people". In light of this, choosing the right partner is equally crucial to the process' success (Hewitt-Dundas & Roper, 2018). Universities are excellent agents for the transmission of knowledge and ideas, as well as the creation of business innovation (Moretti, 2019; Costa et al., 2021; Secundo et al., 2017, 2019, 2020). The development of these innovative processes can be carried out through challenges and ideas competitions (de las Heras-Rosas & Herrera, 2021; Nicolajsen et al., 2019). However, despite the increasing interest on the topic, the understanding of the role of digital-oriented university-industry collaborations in improving digital transformation DC is still lacking. Furthermore, studies have been heavily focused on the advantages for businesses as a result of the ideas' quality, level of innovation, or competitive advantage (de las Heras-Rosas & Herrera, 2021), avoiding an ecosystem perspective, which is one of the novel research focuses (Costa et al., 2021).

In order to fill the abovementioned gaps, this paper answers to the following question:

*How can collaboration programs involving SMEs and university students allow the continuous development of DC useful to manage digital transformation processes?*

The purpose of this study is to offer demonstration that university-industry collaborations (UICs) are successful and essential tools for managing the knowledge exchange between stakeholders.

The DC theory (Teece, 2007, 2023; Teece et al., 1997; Vanhaverbeke & Cloudt, 2014) serves as the theoretical framework for this study, which takes an

explorative and qualitative approach based on case study methodology (Yin, 2009). The empirical longitudinal research looks at two iterations of the Open Challenge by Enterprise (OCbE) program, which was created by the LUM University Giuseppe Degennaro in collaboration with the Italian Association of Young Entrepreneurs of Confindustria Bari-BAT. By including many players from the regional university and entrepreneurial environment, the cooperation aims to support digital innovation of local Apulian SMEs.

The OCbE was established to help local firms undergoing digital transformation and business model innovation. Association managers and company owners sought help from students, academics, and researchers to address their need for innovation. The initiative resulted in the creation of a general framework centered on digital DC, which offers methodological recommendations for digital knowledge transfer in SMEs focused on innovation. Thirteen local SMEs, 146 students from two university courses, and 40 teams worked together on a total of 40 digital innovation projects during the two OCbE editions. Students and businesses may benefit from developing their digital knowledge and competencies, enhancing their skills and knowledge in DT, project management, company development, and innovation management. The project shows how cross-border connections between academia, industry, and institutions can lead to innovative and valuable procedures, and the theoretical base of the DC framework can be improved to serve as a paradigm for business schools (Teece, 2023). The research offers ideas on how to organize and broaden the innovation ecosystem between firms, institutions, and universities. Students from universities that take part in the OCbE can use their innovative ideas. Through internal process digitization and business model innovation, this study provides managers and SMEs with actionable guidance on digital transformation and an empirical methodology to aid organizations in competing and improving their strategic posture. The article is organized as follows: Section 2 contains the literature review; Section 3 describes the research methodology, Section 4 illustrates the main findings, and Section 5 presents discussions and implications of the study. Finally, the paper concludes by providing suggestions for future studies in Section 6.

## **2 Literature Review**

### ***2.1 Digital Transformation Capabilities***

Digital technologies enable businesses to create value, develop sustainable strategic positioning, and gain a competitive advantage by understanding new segments' needs and trends. But this requires strategic capabilities to navigate digital devices and manage new digital environments. By doing so, firms can identify new possibilities, assess risks, and take advantage of disruptive technologies (Benitez et al., 2020; Nasiri et al., 2020; Vial, 2019). Additionally, businesses may integrate, reconfigure, and adapt organizational structure, resources, and internal processes to the new patterns of Industry 4.0 when they use these capabilities in a dynamic and fluid manner.

The term "dynamic capabilities" (DC) refers to a class of capabilities that are emerging as a dynamic evolution of the Resource-Based View (e.g., Penrose, 1995; Rubin, 1973) and drawn from the Schumpeterian view of innovation (Schumpeter, 1934; Teece, 2023). DC were first conceptualized by Teece et al. (1997) as special, difficult-to-replicate capabilities that allow rapid adaptability to changes in the external environment.

Teece (2007) identified three main categories of DC: sensing capabilities, seizing capabilities, and transforming activities/reconfiguring capabilities. Sensing capabilities relate to those capabilities that allow "to identify technological opportunities in the external environment"; seizing capabilities refer to "the mobilization of a company's resources to exploit these opportunities". Lastly, transforming activities/reconfiguring capabilities relate to "the continuous renewal of the organization by adapting, reconfiguring, and renewing the current resource base". The disruptive spread of the digital revolution over the past ten years has accelerated scholarly research on digital DC at both the empirical and conceptual levels (e.g., Cannas, 2021; Chirumalla, 2021; Ellström et al., 2022; Jantunen et al., 2018; Soluk & Kammerlander, 2021; Warner & Wäger, 2019; Witschel et al., 2019). To better understand the relationship between DC, business model innovation/adaptation, micro-foundations, and associated activities, Witschel et al. (2019) carried out several case studies. The authors identified 13 vital competencies, emphasizing the importance of DC as crucial and necessary enablers of business model innovation and reaffirming the strategic relevance of identifying, seizing, and altering DC to navigate environmental upheaval.

Empirical research on the digital DC development process across major incumbent enterprises in conventional sectors was conducted by Warner & Wäger (2019). The research revealed that organizational culture, collaborative strategy, and business model innovation all depend on agility as a crucial mechanism. By discovering nine sub-capabilities associated with the high-level triple domain of (1) sensing, (2) seizing, and (3) transforming, the authors also expanded the DC domain. In order, they are as follows: (1a) digital scouting; (1b) digital scenario planning; (1c) digital mentality crafting; (2a) strategic agility; (2b) rapid prototyping; (2c) balancing a digital portfolio; (3a) navigating innovation ecosystems; (3b) redesigning internal structures; and (3c) improving digital maturity.

In order to contribute to the growing understanding of DC as enablers for business model innovation, Chirumalla (2021) conducted a multiple case study on two European steel manufacturing firms. The study resulted in the development of a framework for creating digitally enabled process innovation DC (Chirumalla, 2021, p. 19).

Soluk & Kammerlander (2021), through 127 semi-structured interviews with 15 Mittlestand family firms conducted a multiple case study showing that DT consists of a three-step process: (1) process digitalization; (2) product and service digitalization, and (3) business model digitalization. The DT process involves different technologies and different necessary DT capabilities.

In order to uncover routines for sensing, seizing, and reconfiguring dynamic capacities that allow DT in businesses, Ellström et al. (2022) performed an explorative qualitative research based on in-depth interviews and focus groups. The investigation produced the six-domain categorization listed below: Inside-out digital infrastructure sensing and cross-industry digital sensing are included in the sensing dimension. Establishing corporate boundaries and developing a digital strategy are referred to as seizing. Last but not least, the reconfiguration activities are characterized as DC processes that breakdown DT into specific projects and establish a uniform digital infrastructure.

Another crucial point made by Teece (2023) is that alliances, partnerships, and other types of collaboration may close capacity gaps in companies as new capacities frequently need the addition of new employees and expertise. To successfully collaborate with other stakeholders and contribute to the creation of new ideas, concepts, and technologies, knowledge transfer and exchange are essential (Secundo et al., 2020). Furthermore, innovation is a key component in

this context (Chirumalla, 2021; Soluk and Kammerlander, 2021). The latter is carried out by integrating new digital knowledge that can enable the creation of digital organizational routines (i.e., digital dynamic capabilities); regardless of whether these steps are carried out, the output will be the digital innovation of the organization's business model (Teece, 2018). As a result, according to Osterwalder & Pigneur's (2010) concept of business model innovation, creativity can be defined as the integration of novel knowledge inputs into the current business model that enables a positive change (radical or incremental) of the latter and, as a result, the development of novel value propositions, novel business structures, processes, methods, and marketing strategies (Edison et al., 2013). In order to do this, knowledge transfer emerges as a crucial and fundamental element for the creation of digital transformation capabilities and digital business model innovation, which "requires the introduction of new people" (Teece, 2023, p. 121).

## ***2.2 University-Industry collaborations and their role in innovation processes***

In their study, Costa and Matias (2020) assert that digital transformation has significantly impacted the way businesses compete and innovate due to their limited resources and expertise in managing digital technologies. To generate digital knowledge and innovations, organizations are increasingly turning to more open and collaborative innovation mechanisms like crowdsourcing and co-creation. This aligns with the DC framework, which emphasizes outside-in processes over inside-out ones, as suggested by Teece (1997) and supported by Vanhaverbeke and Cloudt (2014).

Nevertheless, despite a number of advantages, outside-in innovation processes, i.e. innovation processes in which the source of innovative ideas can be drawn from external parties, can be impacted by a number of challenges connected to the complexity and variety of stakeholders engaged, as well as the likely presence of their conflicting interests (Czinkota et al., 2014; Kaufmann & Shams, 2016; Secundo et al., 2019, 2020).

According to various authors, including Clark et al. (2015), Ebner et al. (2009), and Secundo et al. (2017), incorporating universities and other higher education institutions as project partners can help overcome challenges faced by businesses. This approach is related to the concept of crowdsourcing (Strazzullo et al., 2022), and collaborations between universities and companies, known as

“Universities-Industry Collaborations” (UICs), are considered one of the most effective ways for businesses to improve innovation processes and gain advantages in skills and knowledge (Hurmelinna, 2022). By working together, businesses and universities can create a trust-based symbiotic win-win relationship driven by converging interests and objectives, without the potential for intra-organizational competition or opportunistic behavior (Costa et al., 2021). Moreover, the idea of the entrepreneurial university, promoted by authors such as Elia et al. (2017), Fayolle & Redford (2014), Klein & Pereira (2021), and Secundo et al. (2017), suggests that universities should pursue education, research, and institutional activities that promote social and economic development in a mutually beneficial way.

An entrepreneurial university, according to Fuster et al. (2019), is one that strongly supports the entrepreneurial activities of researchers, students, and graduates in addition to teaching and conducting research. It also has strong ties to the business community, governments, and other institutions. The academic entrepreneurship activities of entrepreneurial universities are generally acknowledged in the literature as playing a crucial role in maintaining regional growth (Miller et al., 2018). The newest types of digital academic entrepreneurship include cross-industry research initiatives, spinoff activities, and prototyping assisted by digital technology (Rippa & Secundo, 2019). Within this framework, educational curricula are revised to encourage local innovation and entrepreneurship. Building on existing partnerships with various social actors, including businesses and governments, is necessary and carried out to accomplish this goal. Among the advantages of such joint programs is an increase in the quality and quantity of data available for use in academic research, the development and improvement of students' entrepreneurship through immersion in entrepreneurial contexts, and the opportunity for universities to expand their public-private partnership network (Elia et al., 2017; Hurmelinna, 2022; Secundo et al., 2017). Companies may have access to cutting-edge scientific and technical expertise as well as the creativity and inventive ideas of young, resourceful students via university-industry partnerships. Moreover, via UICs, businesses may strengthen their innovation risk structure by sharing organizational process development with academic institutions, harnessing their specific research skills, and incorporating them into innovation initiatives and organizational enhancements (Elia et al., 2017; Fayolle & Redford, 2014; Hurmelinna, 2022; Nauwelaers, 2011; Secundo et al., 2020).

According to Secundo et al. (2020), UICs follow an outside-in strategy: the majority of projects are carried out through concept competitions or innovation challenges, through which the company innovation funnel is opened to external university expertise at the early stages of idea development and business planning. The UICs method is comprised of several phases: often, businesses articulate an innovation need or objective, followed by the inclusion of university students, professors, and university partners in the solution's creation. Universities supply knowledge, creativity, and research science, while businesses contribute their own resources, such as specialists, corporate personnel, and company premises. The process may conclude with the challenge and the selection of the best project, or it may continue with the application of the invention on the market through research and scientific initiatives. According to Hurmelinna (2022), this sort of university-firm crowdsourcing is quite new (e.g., the 2010 Idea Crossing Innovation Challenge and the ThyssenKrupp: Formula Student Germany). In the subsequent years, the trend gathered speed, accelerating the worldwide growth of projects and engaging professors and students in open business model invention competitions becoming a key source of technical innovation and economic growth has gained traction.

### **2.3 Research gap**

According to prior research, enterprises, and organizations are required to establish organizational DT roadmaps in order to adapt to the contemporary digital environment.

Digital DC are important for strategic renewal and competitive advantage, but hard to acquire in-house due to the rapid evolution of the digital environment. External expertise and knowledge-sharing channels, such as joint innovation efforts with entrepreneurial universities, can support the development of digital knowledge. Entrepreneurial universities may play a strategic role in enabling digitally dynamic organizational capabilities within a digital innovation ecosystem involving enterprises and organizations.

Surprisingly, up to date, the literature has not still offered clear evidence of this statement. Moreover, studies on DT-DC have mostly offered abstract arguments, making it difficult for business leaders to understand what organizational measures are needed for a successful digital transformation (Ellström et al., 2022). Also, according to Teece (2023) and others (e.g., Ellström et al., 2022; Ghosh &

Srivastava, 2022), a strong lack concerns the fact that most studies investigated DC as specific managerial actions related to micro-foundations or ordinary capabilities (e.g., Warner & Wäger, 2019; Yeow et al., 2018), thus not properly investigating the DC domain as organizational routines.

Moreover, according to Annarelli et al. (2021), research have generally concentrated on organizational capacities on the inside, whereas inter-organizational processes and the significance of digital capabilities have received less attention.

The development of the DC framework necessitates more research from this viewpoint, which the current study adopts.

Finally, a significant shortcoming is the surprise neglect of small and medium companies in most research, which concentrated mostly on big organizations (e.g., Warner & Wäger, 2019) or to a very modest amount on medium firms (e.g., Ellström et al., 2022). In light of these considerations, it is vitally necessary to expand the examination of the means by which SMEs may adopt a digital transformation roadmap and create digital DC, taking into account that their limited resources might impair the efficacy of process development (Battistoni et al., 2023; Ragonnaud Guillaume, 2021).

### **3 Methodology**

#### ***3.1 Research design***

Based on these premises and through the theoretical lens of the DC theory (Teece, 2010, 2018; Teece et al., 1997; Vanhaverbeke & Cloudt, 2014), and viewing the latter as organizational routines as proposed by the most current development of the framework (e.g., Ellström et al., 2022; Kindermann et al., 2022; Teece, 2023), this research employs an exploratory, empirical, and qualitative longitudinal case study approach (Yin, 2009).

To examine new research fields (e.g., DT and DC (Mele et al., 2022)) and answer "how" and "why" research questions, "case-based exploratory methods are best suited for" (Eisenhardt, 1989; Soluk & Kammerlander, 2021, p. 7).

Based on these premises, this study empirically investigates the extent to which the digital-oriented collaborations between SMEs and entrepreneurial universities can leverage the development of enterprise's DT-DC. The unit of analysis for the present study is the enterprise.

The research approach is divided into two phases: the desk phase and the field phase. The objective of the desk phase is to examine the literature on the emergence of the DC relevant to the DT process and the collaborative mechanisms for strategic renewal. Field phase, based on direct engagement and participant observation (Yin, 2009) of the authors, intends to observe the primary processes and principles associated with the examined phenomena, in which the authors engaged as a researcher and students' tutors. The empirical and longitudinal investigation is performed through the analysis of two editions of an initiative carried out from 2020 to 2022 by the Apulian LUM University Giuseppe Degennaro in collaboration with the Italian Association of Young Entrepreneurs of Confindustria Bari-BAT, i.e., "OCbE". From 2020 to 2022, OCbE involved 13 enterprises and more than 100 students.

### **3.2 Data collection**

Multiple methods were used to collect data to ensure triangulation (Eisenhardt, 1989) and capitalize on the synergistic effects of combining various investigative techniques and reduce the bias of a single observation in relation to multiple data use (Tarrow, 1995).

The process of data collection includes three phases. The first was characterized by the collection of primary data with the author's direct engagement in OCbE initiative. Following this, the primary outcomes of the completed projects were analyzed to extract insights and deduce conclusions regarding the process behind the growth of organizations' digital DC.

The data collection process has three phases. The first involves collecting primary data through field observations of an initiative. The second involves gathering secondary data from various sources to evaluate the project's core qualities, purpose, and objectives. The third phase is ongoing and involves conducting semi-structured in-depth interviews with key informants using a reliable and coherent methodology. The process follows six steps, including planning, creating an interview protocol, training data collectors, collecting and analyzing data, and disseminating findings.

In order to prevent a dearth of evidence, many important informants (enterprises and faculty members) were selected; informants have been and will be contacted in advance of interviews.

Between February and June 2023, two interview sessions have been and will be conducted, recorded, and transcribed.

The first session was conducted between February and March 2023 with academics and faculty members; the second session round, which will be performed between May and June 2023 will include the firms' members who guided the coaching sessions of students during the project's development. Companies have been chosen among the participants of the case initiative's first and second editions..

The modalities of conduction of the interviews are planned according to the request and availability of businesses' and faculty members with a maximum duration of one hour.

Interviews include 3 open-ended questions for enterprise members and 4 open-ended questions for faculty members. The interview sample included 2 university professors and are planned to include 10 firms members that followed the team as enterprise coach.

Sampled firms have been chosen to represent the initial sample of participants in the case project. Through participation in the two final workshops of the initiative, which were respectively held on 26 May 2021 (I edition) and 25 May 2022 (II edition) at LUM University, information on the characteristics of enterprise project challenges and expected outcomes, as well as the details of the individual teams assigned to each firm, were also gathered.

### **3.3 Data analysis**

The data collected about the case initiative have been analyzed using a three-step process following Strauss and Corbin's (1998) recommendation. The first step involved the preparation of all the data gathered through interviews with faculty members. The data have been transcribed and disaggregated, and the relevant theoretical foundation evaluated. Descriptive coding have been used to classify the data, then reduce and organise them to link the project's processes and players and their interactions with literature insights on UICs..

Data collected from interviews with company members will be analyzed using the same method as mentioned earlier. Firstly, they will be transcribed for a better organization. Secondly, a general reading of the entire set will be performed, followed by its disaggregation to identify the macro-regions of DT-DC

developed.. Finally, the data will be coded descriptively, reduced, and organized in context to arrive at the final categorization.

The organization is expected to allow the assessment of the collected evidence in terms of DT-DC into the three-aggregate dimensions and relative subdimensions drawn from the literature, respectively: (1) digital sensing capabilities, (2) digital seizing capabilities, and (3) digital reconfiguring activities for DT.

In accordance with Eisenhardt (1989), the final step of the analysis concludes with an additional series of interactions between primary and secondary data.

The ultimate goal is to design a framework that links the OCbE stages with the UICs funnel's theoretical foundations.

In addition, in accordance with the theoretical underpinnings of the advanced arguments, the study is expected to outline the connections between the latter and the development of DT-DC as organizational routines among the participating firms.

#### **4 Findings**

The OCbE, as a business innovation competition organized by the LUM University with the Italian Association of Young Entrepreneurs and local Apulian businesses, aims to promote U-I contamination, develop student entrepreneurial spirit and creativity, and foster cultural growth. The first edition focused on smart technologies, retail 2.0, and marketing and communication, while the second edition expanded to include industrial services and agri-food. Teams are evaluated using weighted technical, communication, and interaction criteria. The project involves different actors and stakeholders, including students, with various motivations for participation, such as gaining practical experience, cooperating with local enterprises, and winning a prize.

OCbE involves multiple stakeholders, including Apulian businesses, managers, university professors, LUM University, and the Italian Association of Young Entrepreneurs of Confindustria Bari-BAT.

The second and third types of stakeholders are managers and business experts who mentor innovation project development of team members. This helps Apulian businesses in improving their DT roadmaps and knowledge of digital technologies, enhancing their competitive positions, and ability to orientate themselves towards new market trends.

Students' youthful and forward-looking attitudes, along with interactions with research organizations like LUM University, motivate and provide strategic synergies for the process of business model innovation and digital transformation.

University professors, mentors and tutors facilitate student teams in participating and defining TO-BE business models and digital transformation roadmaps, while LUM University is the project sponsor and Italian Association of Young Entrepreneurs of Confindustria Bari-BAT, the partner institution. The partnership allows LUM University to strengthen its alliance with local enterprises and institutions, thus enhancing the entrepreneurial profile of the university. The program also helps to build a new entrepreneurial fabric, stimulates ideas, creativity, and business skills, and promotes digital transformation technical curricula among young people. For the Italian Association of Young Entrepreneurs of Confindustria Bari-BAT, the program provides the chance to develop strategic ties with local research institutes and embrace new types of innovation in local enterprises.

#### ***4.1 The process of Open Challenge by Enterprise***

From the interviews results, it was possible to identify the process of the OCbE and the roles of the actors involved in it. The process consists of 7 steps, including a call for project, project selection, team composition, immersion, expanding, criteria selection and feedback, and prototyping.

Initially, firms are asked to participate in OCbE, after which they create project challenges for university students. University professors then announce the initiative program to the students, after which diverse groups of no more than five or six students each are formed and associated with a firm. The immersion phase follows, during which students become fully immersed in the business world of reference and understand the challenge they need to develop a digital solution for. The expanding, criteria selection and feedback, and prototyping stages follow, during which teams develop the project work and interface with entrepreneurs and experts. The teams also learn the methodological tools and procedures of business model innovation and digital transformation evaluation during their university lectures. Once the proposal has been verified, the teams move on to the prototyping phase according to university course assignments.

Through this process, students gain a deeper knowledge of digital business dynamics and how to create a digital-based business model innovation.

Teams have to undertake a series of tasks related to digital transformation evaluation and business model innovation as part of the project's execution. The teams use digital readiness and assessment tools to evaluate the organization's digital infrastructure and identify areas in need of improvement for incorporating digital innovation. They use business process modelling frameworks to map out the current and future configurations of processes that will incorporate digital innovation. Finally, a digital transformation roadmap is created based on the proposed business solution and critical KPIs to enable continuous monitoring and strategic alignment of planned results. Various tools such as Digital Maturity Model, Digital Platform Pyramid, and APQC Process Classification Framework (American Productivity & Quality Center, 2021) are utilized to execute these tasks. The Business Model Innovation dimension is simultaneously developed with the evaluation tasks for digital transformation, using business model design methodologies learned in the course. Teams use ideation techniques to resize project proposals to fit the organization's needs and infrastructures. They plot AS-IS and TO-BE business models using Design Thinking tools developed by Osterwalder & Pigneur (2010), as well as identifying new components of the nine building blocks of the Business Model Canvas. They validate their process through industry and competitive environment analysis using the Porter's 5 forces framework (1979) and the Environment Scanning Model. Teams evaluate the project outputs and the proposed business model using SWOT Analysis, the Business Model Evaluation Model, and the CSS Test.

The prototyping phase ends with teams creating mock-ups and a project portfolio, which is presented in a pitch session at LUM University in May. During the feedback phase, professors and firm members give their opinions and an external jury evaluates the project. Finally, the winning team is announced in the awarding phase.

#### ***4.3 Dynamic capabilities for digital transformation: organization perspective***

The descriptive coding, reduction and organization of firm members interview results are expected to provide the identification of different routines that firms developed through and after the participation in OCbE. These are planned to be subsequently grouped into second-order themes as foundations of digital DC.

Lastly, according to the literature on DC previously analyzed in Section 2, the organization is planned to provide their inclusion into the main third-order dimensions of the DC framework.

## **5 Discussion and implications of the study**

The case study analysis of OCbE highlights the importance of collaboration between universities and industries to develop DC for SMEs to manage DT. The initiative triggered three phases: Inspiration, Research & Ideation, and Development & Evaluation. The process involves opening corporate borders to external knowledge sources like student teams and incorporating novel models based on the constant contamination of ideas. This aligns with the conceptual arrangement of the innovation processes.

In terms of information transfer mechanisms, the findings clearly demonstrate an Outside-In approach to innovation design (Chesbrough, 2003). This is consistent with the theoretical frameworks of UICs (Secundo et al., 2019,2020; Vanhaverbeke & Cloudt, 2014).

The importance of the participation of several players from different ecosystems, such as industry, universities, and institutions, as a catalyst for the success of the process is made abundantly evident.

In light of this, OCbE can be viewed as an open and intensive innovation booster, particularly in terms of development and creation of business innovation ideas for the included organizations. One of its primary characteristics is because it was created within a research context, such as the university one, emphasizing the previously examined benefits that derive from UICs (Costa et al., 2021), and empirically applied through the convergence of three main ecosystems: industry, university and institution, respectively. In addition, it is evident that the interaction between the various players throughout the stages is crucial to the development of the final output.

Lastly, the significance of this innovative program as a methodological initiative based on the concepts of UICs in the development of sensing, seizing, and reconfiguring capabilities, thereby incorporating the theoretical references of the DC framework, is expected to be found evident. The participation of various parties in initiatives such as the one analyzed in this study can trigger the ongoing construction of those specific dynamic routines, which, according to Teece (2014, 2023), are one of the most essential resources for the creation of a

sustainable competitive advantage in an environment as volatile and unpredictable as the actual digital one.

The study contributes to existing literature on university and corporate partnerships in facilitating outside-in knowledge transfer systems (Costa & Matias, 2020). It offers empirical evidence on the role of entrepreneurial universities, such as the Apulian LUM University, in enhancing the entrepreneurial mindset and industrial innovation, leading to the social and economic development of the local community (Elia et al., 2017; Fayolle & Redford, 2014; Kuratko, 2005). The results provide valuable insights for executives and policymakers to promote social innovation and digital knowledge among SMEs, considering the limited resources they have (Battistoni et al., 2023; Ragonnaud Guillaume, 2021). The study also emphasizes the importance of establishing an entrepreneurial ecosystem involving government, local institutions, private and public organizations, universities, and research centers to foster long-term value creation for the societal community (European Commission, 2020).

## **6 Conclusions and suggestions for further research**

As an extreme case study, there are limitations to this approach. The first may be characterized by its exploratory and case-focused nature. Future research might analyze similar projects by studying the many types of initiatives undertaken by colleges and corporations.

In addition, OCbE emphasized the deployment of business model innovation by adopting a digital innovation foundation. Additional contributions could examine comparable initiatives in different contexts, as well as in other faculty departments (engineering, IT, etc.), in order to validate the findings of this study with reference to the UIC open innovation initiatives.

Moreover, it would be beneficial to examine the long-term contribution of firms' participation in such initiatives in terms of organizational performance, innovation performance, and firms' capabilities, utilizing qualitative or mixed-method approaches, and to extend the same focus of analysis to the students involved.

### **Abstract**

Local governments can have a prominent role in steering local level actions for sustainable development. To actively pursue sustainable development, local governments need to not only to generate sustainability performance information to target their actions and demonstrate their effects towards sustainability but integrate it as part of their managerial practices and consider sustainability performance information as part of their routine management and decision-making. Due to the complex and ambiguous nature of sustainability as well as institutional features of the local government organizations – and the contradictions and tensions between these two - the integration of sustainability performance information as part of managerial practices of local governments can be challenging.

We interviewed 46 key individuals who had played active roles in the integration process of sustainability performance information into the management practices of 18 different local governments in Finland and used the interview records to explore why is it challenging to integrate sustainability performance information into managerial practices in local government. Through our data, we outline five common challenges in the integration of sustainability performance information as part of the managerial practice: (1) Ambiguity and multiplicity of sustainability performance, (2) Cultural barriers and politicization of performance, (3) Siloed organizational structure and practices, (4) Unclear role of sustainability performance information, and (5) Technical difficulties in performance measurement and management

**Keywords** – Sustainability, Local governments, Performance information, Managerial practices

**Paper type** – Academic Research Paper

## 1 Introduction

As concerns over the state of the planet have grown, sustainability has risen as a new management objective across the sectors of society. “Global goals – Local actions” as a common catchphrase presented in sustainable development policy programmatic exemplifies the role of local-level interventions to global sustainability challenges. Although sustainability is a complex societal challenge that requires broad societal participation of all sectors, the role of local government has been identified as prominent in fostering sustainability, creating local solutions to global challenges, and in leading by example (Ball et al. 2014, Guarini et al., 2021). As sustainability is seen as an increasingly evident aim for public administration, management actions and practices assessing public policies, strategies, and actions toward sustainability are increasingly needed.

Local governments need to produce sustainability performance information to understand their own performance, identify areas of improvement, steer the implementation of national and local policies, demonstrate accountability to various stakeholders, and communicate their progress (Bebbington & Unerman, 2018; Sobkowiak, Cuckston, & Thomson, 2020; Kaur & Lodhia, 2019). Integrating sustainability performance information into the managerial practices of local governments is crucial in advancing sustainability as a new management objective and steering local-level developments towards a more sustainable future. However, previous literature displays that this is not a simple task, and several factors can hinder the deployment of new accounts as part of the

management of local government organizations. Therefore, more research on barriers and challenges in the integration of sustainability performance information as part of managerial practices is needed.

To uncover the challenges related to the integration of sustainability performance information into the managerial practices in local governments, we employ a qualitative and inductive research approach. Through a series of semi-structured interviews of sustainability specialists, financial managers, strategic managers, and branch managers representing local governments in Finland, we explore why is it challenging to integrate sustainability performance information into managerial practices in local government. Based on the content analysis of the interview records from interviews with 46 key individuals representing 18 different local governments in Finland, we outline five common challenges in the integration of sustainability performance information as part of the managerial practice: (1) Ambiguity and multiplicity of sustainability performance, (2) Cultural barriers and politicization of performance, (3) Siloed organizational structure and practices, (4) Unclear role of sustainability performance information, and (5) Technical difficulties in performance measurement and management.

This paper proceeds as follows: In the next chapter, we aim to review extant research on sustainability performance information and managerial practices in public sector organizations. In the third section, we describe our research approach and methodology. In the fourth section, we outline the five challenges in the integration of sustainability performance information based on the interview data. Finally, we discuss the results in the fifth section, present our conclusions, and provide suggestions for future research on the topic.

## **2 Literature background: Sustainability performance information and managerial practice**

Sustainability performance commonly refers to economic, social, and environmental performance, described as "triple-bottom-line" or "the three pillars of sustainability performance" (Purvis et al. 2019). However, there is no simple answer to what sustainability performance means in any given context (See Meadowcroft, 2007), and the term covers a range of different types of performance information such as performance in connection with natural resource conservation and emission levels; other environmental activities and initiatives; aspects of employment; occupational health and safety; community

relations; stakeholder involvement; economic impacts of the organization other than those financial measures used in the financial accounts (Adams et al., 2014).

Although, the Global Reporting Initiative (GRI 2013) states that sustainability accounting, including reporting, is a process of measuring and communicating sustainability performance and of being accountable to internal and external stakeholders for an organisation's social, environmental and economic performance, sustainability performance has not received wide academic attention. Generally, there is a stream of literature addressing the issue of sustainability in accounting. While, sustainability accounting is not the mainstream of accounting scholarship, over the years literature has grown (e.g. Kaur & Lodhia 2018). However, prior research on sustainability accounting in the public sector is limited and it is still in the early state (Greco et al. 2012). Typically, sustainability is studied from the viewpoints of accounting practices and/or reporting. These two can be seen as different parts of the same coin or as separate actions. Sustainability accounting can be understood as an information management and accounting method that provides high-quality information to demonstrate the progress of an organisation moving towards sustainability. Whereas, sustainability reporting is about formalised means of communication, aimed to disclose the organisation's sustainability performance. (Kaur & Lodhia 2018.) Main emphasis in the prior studies has been on sustainability reporting, for instance implementing different reporting standards or guidelines (e.g. Larrinaga-González & Pérez-Chamorro 2008; Vinnari & Laine 2013). Moreover, prior studies have addressed the reasons and explanations for why not to use reporting standards or guidelines and the extent of the use (Greco et al. 2012; Greco et al. 2015; Goswami & Lodhia 2013; Hossain 2018; Niemann & Hoppe 2018). For instance, Greco et al. suggest that cultural differences, such as 'power distance' and 'uncertainty avoidance', have an impact on sustainability reporting practices in local government.

Interestingly, Greiling, Traxler and Stötzer (2015) recognize the increasing emphasis of the sustainability reporting and development of those reporting practices in the public sector since the 1990's. The research of the topic seems to focus on sustainability reports as a production of information and the previously mentioned focus extent of the reporting. Thus, there seems to be a research gap in the use of sustainability performance information as a part of the managerial actions in public sector and thus local governments.

### **3 Methodology**

To explore the question of why it is challenging to integrate sustainability performance information into managerial practices in local government, we focused on Finland as an empirical context and gathered data through semi-structured interviews of the key representatives responsible for the production and integration of sustainability performance information into the managerial practices in their organizations.

Finland provides an interesting context for the study as the local governments have a high degree of autonomy in the Finnish administrative system. Along with other Nordic countries, Finland has been a frontrunner in the promotion and implementation of various global sustainability policy programs and gained international recognition in global rankings. Furthermore, the information infrastructure in Finland is highly developed. The biggest municipalities in Finland have publicly committed to Agenda2030, and the Local Government Act (410/2015) emphasizes that municipalities must advance financial sustainability of municipal activities, advance well-being and arrange services for their residents in financially, socially and environmentally sustainable ways.

Altogether we interviewed 46 key individuals representing 18 different local governments chosen from the 25 largest municipalities in Finland. The pool of interviewees included 13 financial managers and 14 branch managers or representatives, 8 sustainability specialists, 7 strategic managers, and 2 representatives of ownership and steering, and 2 representatives of municipally owned corporations. We anticipated that the large municipalities in Finland have engaged more extensively with both the production and integration of sustainability performance information. Interviews were conducted through Teams between October 2022 and March 2023 both as individual and group interviews (2-3 interviewees). The interviews focused on questions such as how sustainability performance information is produced and to what purposes, and how is it integrated into strategic planning, budgeting, and annual reporting and as part of the managerial practices in the local governments, and what kind of managerial practices have formed around sustainability accounts. The interview data provided diverse perspectives from various managerial levels. The interview records were transcribed verbatim for analysis.

In analysing the interview transcripts, we followed interpretative approach and adopted hermeneutic analysis circle (cf. George 2021). First, the transcripts were

read by researchers individually as a whole to understand the text and its parts. Each researcher interpreted the data on their own by seeking to inductively identify the barriers and challenges of the integration of sustainability performance information as part of managerial practices of local governments. After this, we gathered to discuss our understandings of the data and develop joint categories based on our individual interpretative experiences.

#### **4 The five challenges in the integration of sustainability performance information as part of managerial practice in local governments**

Through inductive exploration, we identified five common themes related to the challenges in integrating sustainability information into managerial practices in local government: (1) Ambiguity and multiplicity of sustainability performance, (2) Cultural barriers and politicization of performance, (3) Siloed organizational structure and practices, (4) Unclear role of sustainability performance information, and (5) Technical difficulties in performance measurement and management.

##### **4.1 Ambiguity and multiplicity of sustainability performance**

Previous literature highlights the ambiguous and multiplicity of meanings that performance as a social construct often assumes (Lebas & Euske, 2006). The ambiguity and multiplicity of the interpretations of what sustainability performance stands for by different individuals across local governments were evident from the interview data. As one of the interviewees note, "it is not so clear how the concept is understood or what is meant by it." The ambiguity of the concept became visible also as an uncertainty regarding the interview themes and at times interviewees wanted to make sure that they understand sustainability in the 'right', like one interviewee puts it in the very beginning of the interview:

*"The first thing, I ask you very quickly that I understand your point correctly, is there a definition of sustainability in this research? Is this common, all related, human well-being related and all, energy, water, food, activities, training, equality, all of this related, endurance, or? I'm sorry, I might be asking a stupid question." (Financial director)*

According to the interviewees, conceptions of sustainability within the local governments varied, and traditionally sustainability was understood narrowly as

environmental protection or against climate change, as the following extract from the interview data display:

*"---- from the central administration point of view, and look at our city strategy, we have right, let's say words there. But I think the definition of those words is not clear for everybody in that sense that for example one of the values we have in our strategy is" responsibility". However, I wouldn't say that it is always there when decision-making is concerned. So, I would say that there is not a clear understanding of how we as the city... what it means to be responsible. However, in terms of this sustainability as a word, I believe that most of the decision-makers put together the words sustainability and sustainable development goals and climate work. They are the same issue for them, so they see it in a quite narrow way --- and it kind of makes it difficult, I mean it takes so much communication to make it understood at the general level in decision-making, what sustainability includes, that it has these different dimensions." (Strategic manager)*

Furthermore, the interviewees noted that there were different priorities between the performance dimensions. Several interviewees noted that economic sustainability was considered a priority in decision-making. While ecological and social sustainability were monitored, they were not given as much weight as economic performance in management. Due to the ambiguity and multiplicity of the sustainability performance at the conceptual level and varying prioritisations an understanding of the interrelations of the economic, ecological, and social dimensions of sustainability performance users could interpret performance information in various ways. The challenge from the management perspective was that "you can come up and say anything with the data quite easily" (Strategic manager). "If the members of an organization do not share the same view of performance, actions cannot be coordinated and resources may be wasted" (Lebas & Euske, 2006, p. 132).

#### **4.2 Cultural barriers and politicization of performance**

According to our data, rather than adopting international frameworks as part of performance management of sustainability, local governments focused on local strategic priorities and produced localized understandings of what sustainability as a performance objective meant for the city.

*"I feel that the politicians, they don't want to use that much like different frames coming from outside as they want to do their own policy."*

*"I think they [focus areas] came from the strategy work. Because first they published the city strategy, which is 13 different themes and very like broad political, more like political paper. And they realized that to implement we have to prioritize. To choose something. And I think these are the themes that are the most important for the mayors. For mayor and for the deputy mayor. And maybe - I don't want to say that but, of course, it feels a little bit like there is one for every deputy mayor. Something for every deputy mayor."*

*"You need to look at the main organization. Why? What is the main purpose of a municipality? How should the organization work? And then you bring in these qualities or these values like sustainable development. If you make it the other way around then as this is a representative democracy with elections then these values might change, and then you drop the whole unit or the engine."*

What performance information should be produced, how, and how much weight it should be given as part of the decision-making was shaped by local political agendas. The politicization of performance, according to the interviewees, was one of the challenges when key actors tried to integrate sustainability performance information as part of managerial practices, as the following extracts from the data display:

*"--- it means that it [sustainability] can become a political debate before whatever elections so that right-wing parties think that this is something that the greens [Green party] do." (Strategic manager)*

Due to the voluntary nature of sustainability performance information production and use in local governments and the politicization of performance, interviewees at the times experienced difficulties in their attempts to develop and introduce new performance measurement and management tools and frameworks. This work was typically done through internal working groups dedicated to sustainability programmatic, which had to be able to get the city boards and mayors to support their agenda. Interviewees stated, for example, that: "Sometimes it's difficult to take things forward to the City board" and that they are "selling this [new performance management framework] to the mayor" and "trying to create this kind of atmosphere, right atmosphere for it".

### **4.3 Siloed organizational structures and practices**

The interviewees noted that the organisational structure of the local governments was fragmented – as one of the interviewees noted “I think it is very difficult to see us [the city] as an organization”. While the central management of local governments generally considered that the branches and municipally owned companies are the best experts on their own operations, the fragmentation of conceptualisations and practices related to sustainability performance across the local government organisations made central management of sustainability performance challenging. Branch and corporate managers were influenced by sectoral programmes, rationales, and practices, and, according to the interviewees, different branches and corporations were at different stages in terms of measuring and managing their sustainability performance. Aggregating performance information from different parts of the organisation to understand the performance of the local government as a whole therefore often led to a collection of divergent descriptions of various activities conducted by different management units, which, from the management perspective, made the overall state of the progress hard to evaluate. Furthermore, as one of the interviewees stated: “when we do it [gathering of sustainability performance information] by collecting it through various people and systems it is quite a job”.

Moreover, while there are official executive teams representing different branches in attempt to break the silos, there are seldom opportunities for building a shared understanding of sustainability performance information nor sustainability per se, like one of the interviewees says:

*“In the executive team work of the municipality, during ten years of experience, I have not found myself in a situation in which we do a wide-ranging conceptual analysis [laughter] that we have defined this sustainability.” (Financial director)*

Sustainability was integrated into the city strategy in many cities as a central strategic objective, but because of the siloed organisational structure and the ambiguity of sustainability as a concept in the strategic documents, the subjectivist interpretations of sustainability performance by the managers responsible for the implementation of city strategy at different parts of the organisation hindered central strategic steering and oversight. Several interviewees from the central management considered the dilemma of on the other creating a system of organization-wide oversight of the progress by

mandating the use of certain performance frameworks and metrics, and on the other hand, allowing the key actors freedom to produce performance information most relevant for them.

#### **4.4 Unclear role of sustainability performance information**

Interviewees noted that due to the complexity and multiplicity of the underlying phenomenon, the production of sustainability performance information was quite a challenge and the local governments had to rely on external information and expertise to produce new metrics and approaches. This sometimes led to the generation of sustainability performance information that was not used and had no practical implications in management, as the following extract displays:

*“We have noticed that we have been buying in data, material, and reports a hell of a much but not using them so much. So now we have actually cut off a lot of material and data that we are that we have been using or buying or not using so much but buying anyway and now we have the set in the strategy indicators that we are following, and then we have these VLR indicators as kind of additional, separate, but it's enormously big.”*

The interviewees highlighted that the local governments had both limited resources and limited capabilities in information generation, and the available resources should be used resource-wisely: Produced information should serve a clear purpose and become integrated as part of management, not exist in its own realm. In some municipalities, based on the data, it seems that sustainability performance is also interpreted through the existing information channels, or at least there is attempts to this:

*“Of course, this economic sustainability comes through the financial statements and others quite clearly, and once we have had a separate sustainable economic programme. And, of course, when we have a budget in the process, we also have the objectives of these other pillars, so they will also be reported, the objectives that have been set. In addition, we have these welfare reports on social sustainability, and then the environmental accounts are drawn up in a certain way every year.” (financial director)*

Ideally, sustainability performance information could serve multiple audiences and inform both internal and external stakeholders of the state and the progress of local governments against both local and global sustainability goals. However,

the multiple potential users of information and the lack of a clear view of who the local governments were accountable for their challenged the integration process.

#### ***4.5 Technical difficulties in performance measurement and management***

In addition to above challenges, interviewees noted that producing sustainability performance information was a challenge in itself. Because the local governments had limited resources and capabilities to produce sustainability performance information, they often relayed on external experts and information sources in generating the information. In addition to fitting the indicators to work in the local contexts, the local governments had to consider what kind of indicators were possible to maintain with resources and time available. Furthermore, the choice of indicators was considered critical, as the indicator reflects the actual aim toward which managerial practices become aligned with.

- Constructing accounting object should be construction of actual performance object > Starts to shape the underlying understanding of sustainability – Performativity

### **5 Discussion and concluding remarks**

Based on the interviews of 46 key individuals who have played active roles in the integration of sustainability performance information into the management practices of 18 different local governments in Finland, we have outlined five key interlinked challenges in the integration process stemming from the ambiguous and complex nature of the underlying phenomenon the local governments are trying to manage, and the institutional features of the local government organizations.

Firstly, sustainability is ambiguous, complex, and multidimensional concept, and therefore constructing a shared understandings of what sustainability performance means in the local context, according to the interviewees, took a lot of effort. Because local governments as organizations are not uniform and typically have various functions, establishing centralised practices was challenging. Since performance information was not mandated but voluntary, its integration as part of managerial practices and the role it should play in the decision-making could become contested, and key actors had to “make the case” for the information production and use. Due to the limited resources and capabilities, the interviewees emphasised that the sustainability performance

information that is produced needs to have true value and relevance as part of management of local government organizations, and, at its best, could serve multiple stakeholder groups simultaneously.

Our results display that sustainability performance information is not a neutral management object: Instead, we observe a recursive relationship where the local rationales shape sustainability performance and sustainability performance in turn shapes local rationales and priorities. The integration process of sustainability performance information as part of routine managerial practices of local governments is shaped not only by the institutional and organizational structures of the local governments but also by the conscious efforts of various professionals.

### **Abstract**

Under current conditions, the development of digital technologies is largely supported by modern universities (University 3.0), which are of particular importance in the formation of digital potential. Within the framework of the presented research, the role of modern universities in achieving the goals of digitalization is considered, taking into account the current knowledge dynamics. In the context of this work, universities 3.0 refers to universities that include educational, research and an entrepreneurial functions. The entrepreneurial function is the missing link in the innovation value chain. Thanks to it, modern universities are a source of digital transformation of the economy, which is reflected in the results of the study. The emphasis on the entrepreneurial component of the universities makes it possible to reveal their role in the process of digital transformation of the economy to a greater extent.

**Keywords** – University 3.0, modern university, full life cycle of innovation, entrepreneurial activity, digital transformation

**Paper type** – Academic Research Paper

## 1 Introduction

Digital development occupies the leading role in the current economic priorities. In particular, this is evidenced by the global Innovation Index (GII) [World Intellectual Property Organization (WIPO), 2022], covering about 80 indicators related to infrastructure and knowledge creation in each country and the NRI (Network Readiness Index) index, characterizing the degree of readiness of the economy for digital transformations. This process, being one of the key catalysts of change, is accompanied by the introduction of unique digital technologies, the emergence of new approaches to the formation and development of knowledge, the improvement of infrastructure, the development of innovative enterprises [Goldfarb, A., Tucker, C., 2019]. Modern universities are directly involved in the presented processes, which are connected with the educational mission, the mission of research and entrepreneurship [Karpov, A. O., 2016, Secundo, G., Rippa, P., Cerchione, R., 2020].

Digital transformation is a continuous complex process that affects a significant part of companies and even goes beyond them [Vial, G., 2021]. At the same time, universities are an important part of this process in terms of creating unique digital products [Khitskov, E. A., et al 2017].

On this basis, the following hypothesis was formed: Modern universities engaged in entrepreneurial activities contribute to digitalization by participating in all links of the innovation value chain, taking into account the identification of society's priorities.

Thus, the purpose of the study is to identify the nature of the impact of entrepreneurial activity of universities on the process of digital transformation. Based on the set goal, the following tasks were solved within the framework of this study. Firstly, the analysis of the environment conditions of the innovative potential realization of modern universities were carried out. Secondly, the nature of modern universities in terms of innovation activities was studied. Thirdly, the dynamics of the strengthening of the role of universities in the context of the development of digital potential was investigated.

## **2 Literature review**

### ***2.1 The emergence of an entrepreneurial university and academic entrepreneurship***

Throughout the existence of universities, their role has undergone a significant transformation [Redford, D. T., Fayolle, A., 2014, Carl, J., Mentor, M., 2021]. To date, there are five main types of universities, depending on their conditioned role [de Lucio, I. F., Martínez, E. C., Cegarra, F. C., Gracia, A. G., 2000], namely: academic university, classical university, social university, business university, and entrepreneurial university. In the first half of the 1980s, the concept of entrepreneurial universities became generally accepted, and thanks to works highlighting the role of higher education institutions in economic growth and social development, the topic attracted the attention of leading researchers [Rippa, P., Secundo, G., 2019].

A special contribution to the development of the theory was made by H. Etzkowitz, who introduced the term into use [Etzkowitz, H., 1983]. However, now there is still no consensus on what entrepreneurial universities are. Nevertheless, in modern research, entrepreneurial universities are most often understood as a support structure for researchers and students focused on the creation of new enterprises. After all, in addition to teaching and research functions, entrepreneurial universities are focused on the implementation of entrepreneurial projects [Duruflé, G., Hellmann, T., Wilson, K., 2018, Klofsten, M., Fayolle, A., Guerrero, M., Mia, S., Urbano, D., Wright, M., 2019]. According to the position of P. Rippa, G. Secundo, formed on the basis of earlier works, scientific cooperation with industry, patent work, implementation of ideas in new companies, education of highly qualified specialists in the field of entrepreneurship and work with business incubators are the tools that universities use to achieve their entrepreneurial configuration [Rippa, P., Secundo, G., 2019].

Thus, the issues related to entrepreneurial universities and academic entrepreneurship are quite new in the context of modern science and require special attention. Based on the latest research presented earlier, it can be concluded that entrepreneurial universities are characterized by a special entrepreneurial function, which distinguishes it from the other types of university.

## **2.2 Entrepreneurial universities as a source of digital transformation**

Modern digital technologies, which are represented, in particular, by the Internet of Things, Big data, Cloud and Cyber solutions, Artificial intelligence, are currently an important component of the activities of every organization, regardless of the form of ownership [Secundo, G., & Lombardi, R., 2020]. Digital technologies contribute to the transformation of innovation activities, processes and results accompanying them [Hull, C.E., Hung, Y.T.C., Hair, N., Perotti, V. and DeMartino, R., 2007, Zaheer H., Breyer, Y., Dumay, J. and Enjeti, M., 2019]. Based on the intersection of academic entrepreneurship and modern digital technologies, digital academic entrepreneurship is formed, upon which unique socio-economic and technological phenomena arise [Secundo, G., Rippa, P., & Cerchione, R., 2020].

Entrepreneurial universities, according to literary analysis, have a relationship with the process of digitalization, exerting a direct influence on it, which is reflected in several aspects [Toniolo, K., Masiero, E., Massaro, M., & Bagnoli, C., 2020]. First of all, entrepreneurial universities in the field of digital technologies are characterized by attention to the development of digital by-products and graduate startups, the formation of entrepreneurial competencies [Secundo, G., Rippa, P., & Cerchione, R., 2020], which indicates the radical impact of digital transformation on academic entrepreneurship. Secondly, universities contribute to the creation of a digital environment to stimulate digital academic entrepreneurship by providing students with necessary tools for trial activities [Garcez, A., Silva, R., & Franco, M., 2022]. Thirdly, universities are an agent of the transfer of relevant knowledge and technologies [Toniolo, K., Masiero, E., Massaro, M., & Bagnoli, C., 2020]. It also contributes to the elaboration of modern digital technologies. An integral part of the digitalization process is the entrepreneurial component aimed at the formation and development of startups, support their initiatives.

On this basis, it can be concluded that entrepreneurial universities contribute to the formation and development of digital technologies.

## **3 Research methodology (Data collection; data analysis)**

The methods of bibliometry, collection and processing of relevant data were chosen. The criteria for selecting sources were their theoretical and practical significance, relevance, reliability, as well as objectivity. Within the framework of

the bibliometric analysis, the main sources were such resources as ScienceDirect, Emerald, SpringerLink.

The collected information is processed using statistical functions of MS Excel. The data obtained are analyzed by estimating the mean and standard deviation, ranking and calculating the correlation. Thus, the method of collecting and processing relevant statistics is necessary to confirm or refute the hypothesis that modern universities contribute to digitalization through the creation and implementation of innovative digital products.

#### **4 Research results**

Within the framework of the current study, the peculiarities of the entrepreneurial university's influence on achieving the goals of digital transformation have been identified. They are based on authoritative ratings, sustainable development strategies and individual digital transformation initiatives.

The method of bibliometric analysis occupies a special place in the research of the universities. From the academic papers published on the topic in question, the directions reflecting the research agenda were highlighted. Based on a random sample, a wide range of academic papers related to the period from 2015 to 2022 has been analyzed. All of them are presented in English and have a high citation index. Based on the results of the analysis, the keywords and research directions characteristic are demonstrated.

In particular, the analyzed academic papers trace a close relationship between entrepreneurial universities and the commercialization of knowledge. The research also highlights the role of transformation of universities under the influence of external and internal factors. The idea of commercialization of university research and the process of knowledge transfer is also emphasized in the papers of M. F. Arroyabe, M. Schumann, C. F. Arranz [Arroyabe, M. F., Schumann, M., Arranz, C. F., 2022].

The presented research directions reflect the current trends in the development of entrepreneurial universities. For instance, the keywords "Economic growth", "Knowledge", "Innovations", as well as synonymous words are most often found in studies related to 2022. They are no less typical for earlier time periods. So, in 2021, a significant part of the papers was devoted to literary analysis, technology and knowledge transfer research in the context of entrepreneurial universities.

However, the term "Entrepreneurship" is found in the keywords of the most of the analyzed papers, which suggests that entrepreneurship is one of the leading activities for this category of universities.

According to the results obtained, in 2022, a special place is given to innovation in entrepreneurial universities. Thus, in a knowledge-based economy, universities are gradually being transformed into entrepreneurial universities.

The idea is supported by the fact, that entrepreneurial universities and innovative development are very popular topics in the resent year the field of knowledge in question. Universities, according to earlier works, are part of the innovation ecosystem, building relationships with public and private organizations [Guerrero, M., Urbano, D., 2012].

The Table 1 presents the results of the bibliometric analysis, reflecting the most relevant topics in the period from 2015 to 2022, as well as the corresponding keywords identified based on the evaluation of 80 works. According to this Table, the topics change significantly from year to year, as does the object, the subject of the study, as well as the methods used in the process.

Table 1. Key research directions

<b>Year</b>	<b>Research directions</b>	<b>Key words</b>
2022	Entrepreneurial universities and innovational development	Economic growth, Knowledge, Innovations
2021	Transformative change in higher education	Technology and knowledge transfer, Literature review, Entrepreneurship
2020	Entrepreneurial university development	Academic entrepreneurship, Quantitative Analysis, Triple Helix, Partnership
2019	Entrepreneurial universities and strategy	Internal and External Factors, Strategy, Entrepreneurship, Third mission
2018	The entrepreneurial university as an engine for sustainable development	Academic entrepreneurship, Sustainability, University ecosystem
2017	Entrepreneurial university: a case study	Triple Helix, Higher Education, Commercialization,
2016	Entrepreneurial universities in the region	University-business Relationships; Global Universities
2015	Educational Transformation and the Role of the Entrepreneurial University	Higher Education, Academic Entrepreneur, Transformation

At the same time, digital technologies play an important role in the issues of innovation in an entrepreneurial university, as mentioned earlier [Secundo, G., & Lombardi, R.; 2020]. The relationship between entrepreneurial universities and

digitalization is reflected through statistical analysis of publicly available data. In the course of the research, a list of the leading entrepreneurial and innovative universities in the world are selected. This is largely illustrated by the data of the PitchBook analytical platform [Official website Pitchbook, 2023)], Scimago Institutions Rankings compiled on the basis of Scopus data, QS World University Rankings by Subject 2022: Computer Science and Information Systems, created with the support of Elsevier [Official website QS World University, 2022)].

According to the study the development of the entrepreneurial component reflects how many entrepreneurs study at the university, as well as the number of their companies that received the first round of venture financing in the period from January 1, 2012 to October 21, 2022. The ranking of universities by the level of development of the Computer Science and Information Systems direction largely reflects the university's contribution to the development of the digitalization process both from the training of highly qualified specialists in the IT field and from the perspective of the development of the research component. Thus, the scores presented are based on the assessment of academic reputation, the reputation of the employer and the impact of research. The bigger the sum of points, the higher the position of the university in the ranking.

To support the idea a correlation analysis of the number of company founders and the QS World University assessment in the field of Computer Science and Information Systems was carried out. The correlation coefficient is 0.63. According to the data obtained, the stronger the university is in the field of Computer Science and Information Systems, the more university graduates will become founders of start-ups or startups. On this basis, a correlation graph is presented below, visually reflecting the existing relationship between the data sets.

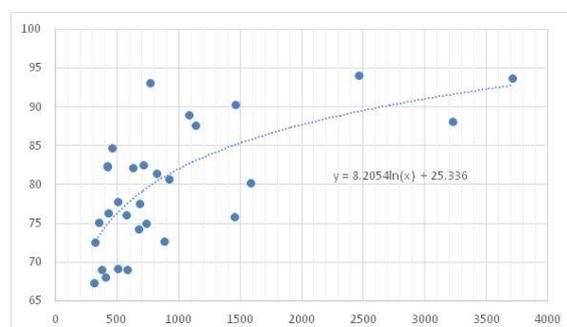

Fig.1. Correlation analysis of the number of company founders and QS World University estimates

A significant number of startups carry out their work in the digital sphere, for example, Nubank, Chime, Didi Global, DoorDash, Open AI.

Information, presented in the Table 2, allows a more holistic assessment of the role of universities in the development of digital entrepreneurship. This is the data of the PitchBook analytical platform [Official website Pitchbook, 2023], Scimago Institutions Rankings compiled on the basis of Scopus data, QS World University Rankings by Subject 2022: Computer Science and Information Systems, created with the support of Elsevier [Official website QS World University, 2022)].

QS World University scores in the field of Computer Science and Information Systems average 79.62, which in the framework of the presented sample slightly exceeds the median value of 79 points. At the same time, the standard deviation is 7.91 points. Massachusetts Institute of Technology is a leader in Computer Science and Information Systems education (94.1 points). Also, there are 2,459 founders of companies among its graduates. In comparison with Stanford University, where 3,710 graduates have become founders of companies, the QS World University Ranking scores differ only slightly, amounting to 93.7.

The data ranked by the number of startup founders, on the basis of which the analysis was performed, are presented in the table below. The results of the analysis reflect the essential role of the entrepreneurial component in the context of the work of universities. Especially, it is characteristic of Computer Science and Information Systems field of knowledge.

Table 2. Entrepreneurial universities-leaders in the field of Computer Science and Information Systems education

<b>University</b>	<b>Founder count</b>	<b>Company count</b>	<b>QS World University Ranking: CS</b>
Stanford University	3710	2808	93,7
Harvard University	3222	2713	88,1
Massachusetts Institute of Technology	2459	1863	94,1
Columbia University	1586	1402	80,2
University of California, Berkeley	1459	1202	90,3
University of Pennsylvania	1456	1244	75,9
University of Cambridge	1133	939	87,6
University of Oxford	1083	905	89
New York University	923	853	80,7
University of Chicago	880	762	72,7
University of California, Los Angeles (UCLA)	818	714	81,5
Carnegie Mellon University	764	626	93,1

University of Michigan, Ann Arbor	735	613	75
Cornell University	715	595	82,5
University of Texas at Austin	678	581	77,6
University of Southern California (USC)	676	595	74,3
Imperial College London	628	526	82,2
Johns Hopkins University	582	493	69
Yale University	576	487	76,1
Duke University	508	435	69,2
University of Illinois, Urbana-Champaign	506	408	77,8
University of Toronto	462	363	84,7
Georgia Institute of Technology	431	376	76,3
Tsinghua University	421	394	82,4
University of Washington	420	346	82,3
Boston University	405	366	68,1
University of Wisconsin-Madison	376	311	69,1
University of California, San Diego	354	290	75,1
University of Maryland, College Park	322	280	72,6
Technion - Israel Institute of Technology	314	260	67,3

Thus, the relationship between the entrepreneurial potential of universities and their role in the process of digitalization was identified. The research achievements of universities, the high level of training of specialists, the reputation of the university in the field of Computer Science and Information Systems favorably affects the development of entrepreneurship, including in the field of digital technologies.

According to the goals of digitalization, it was revealed that today there is a need for universities to participate in entrepreneurial activities. Next, the paper presents an analysis of the role of universities in the process of digitalization of the economy. Modern universities have a positive impact on digital transformation, creating a basis for the development of intellectual capital, which distinguishes them from universities of older formation. So, the results obtained confirm the hypothesis put forward earlier: modern universities engaged in entrepreneurial activities contribute to digitalization by participating in all links of the value chain, taking into account the identification of society's priorities. However, there is still a debatable issue concerning the differentiation of universities and the preservation of the sustainability of innovative potential in matters of digital transformation. And it creates the basis for future research.

## 5 Discussions

In modern conditions, priorities in the scientific and technological sphere are considered in direct connection with the development of a long-term strategy for sustainable development [Grebennyuk, A. Yu., Pikalova, A. G., Sokolov, A.V., Shashnov, S. A., Kayvo-oya, Ya., 2016], as well as individual digital transformation initiatives [Tomičić Furjan, M., Tomičić-Pupek, K., Pihir, I., 2020]. The concepts of digital business are aimed at the elaboration of new business models, the creation of unique associations, the formation of new ecosystems, the commercialization of innovative products [Pihir, I., Tomičić-Pupek, K., Tomičić Furjan, M., 2019]. Universities 3.0 play an important role in the presented process [Carayannis, E. G., Morawska-Jancelewicz, J., 2022]. Digital transformation has a direct connection with universities in the issue of development [Tomičić Furjan, M., Tomičić-Pupek, K., Pihir, I., 2020].

The model of a modern university combines educational, research, design and innovation, socio-cultural activities of higher education, as well as entrepreneurial activities [Boehm, C., 2022]. Entrepreneurial activity through the creation of innovative digital products taking into account the needs of society is a key value, thanks to which modern universities contribute to digitalization. At the same time, there are universities, that carry out only research activities, generate knowledge and contribute to their dissemination and training of highly qualified personnel [Etzkowitz, Leydesdorff, 2000]. In the context of earlier universities' concept, their influence on the process of digital transformation is less reflected [Coskun, Y. D., 2015]. Universities are aimed at the commercialization of knowledge, but do not take into account the nature of the market, the need for a product. The entrepreneurial function is missing here. In the context of the presented hypothesis, only modern universities can influence the achievement of digitalization goals through entrepreneurship activity as a very important stage of the whole innovation life cycle.

## 6 Conclusion

As a result of the study, the hypothesis had put forward was confirmed on the basis of a bibliometric analysis, as well as by evaluating the average value and standard deviation, ranking and calculating the correlation of data from the number of company founders and the QS World University assessment in the field of Computer Science and Information Systems. As a result of the analysis,

patterns of development of theoretical issues related to entrepreneurial universities were revealed, in particular, their role in the formation and development of innovative potential. Moreover, the relationship between the entrepreneurial potential of universities and the assessment of QS World University in the field of Computer Science and Information Systems is reflected.

Thus, the goal has been achieved and identification of the impact of university activities on the process of digital transformation has been revealed.

The presented results has formed the basis for future research. In accordance with the plan of future research, it was decided to study universities 3.0 in the context of particular areas of entrepreneurial activity, which can contribute to elaboration more detailed approach to the role of universities 3.0 in the process of rapid changes in the business landscape under digitalization.

### **Abstract**

COVID-19 pandemic significantly has changed the behaviour of customers and businesses, and influenced the development of technologies. Technologies that provide opportunities for remote interaction in various spheres of human activity have gained unprecedented scale, including FinTech technologies. COVID-19 has accelerated digital trends, as well as significantly changed the behaviour of customers who began to prefer digital payments, banking applications, etc.. Companies around the world have rethought the value of modern technology, with a huge potential to create a unique personalized offer in a time and place convenient for the client. Obviously, new opportunities have emerged for the FinTech industry. Current market conditions and social distancing practices have impacted each category of FinTech companies differently, with unique challenges that need to be addressed. The unique strengths, knowledge and skills of FinTech companies give them great advantage and flexibility to overcome challenges. The question is how FinTech companies can use their unique knowledge to take advantage of new opportunities in the future. It is interesting to analyze the most recent data available in order to understand in which direction FinTech technologies are moving. FinTech is constantly evolving, adding new technologies and opportunities. The purpose of the work is to identify the most promising technologies in the field of FinTech. To do this, it is important to analyze the views of the scientific community through an analysis of the latest research in this area. The business view of technology has been analyzed by studying the dynamics of patents in this area.

**Keywords** – FinTech, Innovations in the field of knowledge, Patent analysis, Consumer preferences, Market analysis.

**Paper type** – Academic Research Paper

## 1 Introduction

The world is increasingly faced with events that can be considered a "black swan". Thus, the COVID-19 pandemic has significantly changed the behavior of customers and businesses, influenced the development of technologies, including FinTech technologies. Thus, Global FinTech's investments in the first half of 2020 amounted to \$25.6 billion with 1,221 transactions (Pulse of Fintech, 2020). At the same time, the main segments of FinTech by transaction value in 2020 were distributed as follows: first place digital payments, then personal finance, alternative lending, alternative financing (79 Key Fintech Statistics, 2020). The unique strengths, knowledge and skills of FinTech companies give them a great advantage and flexibility to overcome difficulties. The question is how FinTech companies can use their unique knowledge to take advantage of new opportunities in the future.

According to the KPMG International report (Pulse of Fintech, 2020) during 2017-2020, interest in FinTech cooled, so, since the end of 2019, the overall global investment activity (venture, private and M&A) in FinTech, global venture activity in the field of financial technologies, global M&A activity in the field of financial technologies has fallen. This may be due to the fact that the main players were waiting, assessing the impact and development of the pandemic, but it may also be due to the blurring of boundaries between financial technologies, large technology providers and platforms. Studies shows that although in 2019 only 1% of the US population had a digital account, a year later, in 2020, almost 25% of the population chose a digital-only account (Avasthi, 2021). In this new digital environment, the FinTech sector was opening up new opportunities in 2021 and beyond. The results of the study (Tut, 2023) show that for emerging markets, FinTech not only partially mitigated the negative impact of the COVID-19 pandemic in the first quarter of 2021, but also accelerated consumer adoption of FinTech and digital adaptation, especially in the third and fourth quarters of 2022.

Digital innovations challenge the traditional way of providing financial services to companies; the so-called FinTech phenomenon refers to startups that use the

latest technology to offer innovative financial services. Consider the total cost of investments in FinTech companies around the world (Fig. 1).

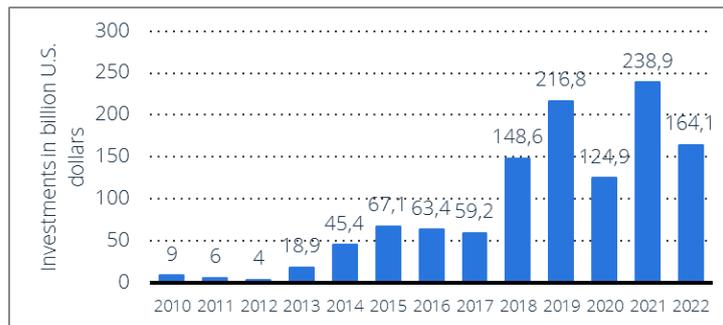

Fig.1. Total value of investments into fintech companies worldwide from 2010 to 2022 (in billion U.S. dollars) - Source: The Pulse of Fintech H2 2022, page 8. PitchBook; KPMG. Statista.com

The total value of investments in FinTech companies worldwide increased dramatically between 2010 and 2019, when it reached US\$ 216.8 billion. However, in 2020, investments of FinTech companies decreased by more than a third, falling below 125 billion US dollars. The value of investments increased again in 2021 to almost \$239 billion. 2022, however, was another slow year for FinTech.

Due to its heavy reliance on large amounts of data, the financial services industry is ripe for the breakthrough offered by new technologies. Large volumes of historical data on banking, insurance, mortgage and financial trading have been integrated with deep learning algorithms to automate routine tasks, reduce risks, prevent fraud and generate new ideas.

The purpose of the work is to identify the most promising technologies in the field of FinTech. To do this, it was necessary to analyze the views of the scientific community through an analysis of the latest research in this area. The business view of technology has been analyzed by studying the dynamics of patents in this area.

In this regard, the following research questions have been raised:

*RQ1: What are the most promising technologies in the field of FinTech?*

*RQ 2: What are the risks and prospects of this technology?*

The goal includes several tasks:

1. Review of literary sources and identification of the most popular technologies in the field of FinTech.

2. Conduct a patent analysis of the technologies identified at the first stage of the study.
3. Based on the results obtained, draw a conclusion about the risks and prospects for the development of technologies in the field of FinTech.

## **2 Methodology**

In the course of the study, a consistent review of the literature was conducted. The sources were searched in the databases: Google Scholar, ResearchGate, IEEE Xplore Digital Library; Wiley Online Library; ACM Digital Library; MDPI; Springer; Scopus. The search period was not limited by years. Patent statistics on blockchain technology were also analyzed from the moment of its first appearance to the present. The search was conducted by patent offices. The country breakdown shows where the patents were registered. Keywords were searched in the title, patent annotation, as well as in the text of the patent application. Patent statistics were provided by Orbis Intellectual Property to Bureau van Dijk. The statistics of the [www.statista.com](http://www.statista.com) resource were also used.

We understand that the research methods used have the following limitations: patent analysis provides information with a delay, so it does not show the latest trends. This limitation is partially compensated by the fact that the first stage uses the analysis of the latest scientific research, including those that are still "in print". That is, at the first stage of the study, we have the opportunity to determine the current trend, and then, at the second stage, to supplement the identified trend with patent analysis.

## **3 Theoretical background**

Before proceeding directly to the study, it is necessary to understand the definition of the concept of "FinTech". Technology has always been a part of the financial world, since the 1950s, when credit cards and ATMs appeared, and to the present, when artificial intelligence and blockchain technologies are actively used. Technologies have begun to play such a significant role in finance that a specific term has appeared to describe the intersection between them, that is, FinTech. FinTech refers to the application of new technological advances in the products and services of the financial industry. The definition is quite broad and includes "innovative ideas that improve financial service processes by offering technological solutions in accordance with various business situations, while ideas

can also lead to new business models or even a new business" (Di Pietro et al., 2021). Other authors define FinTech as a new type of computer algorithm that is currently difficult to implement (Barocas and Selbst, 2016). The term financial technology, or FinTech, came into use in 2014 (Pedersen, 2015). According to KPMG (Statista, 2023), the term "FinTech" is used to describe innovative start-up companies operating in the financial sector that use modern technological solutions in the financial services sector to offer products with improved digital capabilities and provide broad access to financial products at a lower price than traditional players.

Some authors distinguish the concepts of FinTech, InsurTech and blockchain technologies separately (Chakravaram et al., 2021 a,b). But we can't agree with that because FinTech is an industry and blockchain is a technology. Other authors include blockchain technology and cryptocurrencies in the concept of FinTech (Dranev, 2019). KPMG International identifies Payments, Insurtech, Regtech, Wealthtech, Blockchain/cryptocurrency and Cybersecurity as FinTech segments (Pulse of Fintech, 2020).

The authors Wang et al., 2021 systematized the directions of FinTech, identifying 9 dimensions (Table 1).

<b>FinTech dimension</b>	<b>Technologies within the direction</b>
Network channel dimension	Mobile banking, Online Banking Service, Internet Banking, E-bank
Resource allocation dimension	Internet loan, Internet lending, Network investment, Online lending, P2P loan
Internet technology dimension	Internet of things, Vehicle interconnection, Mobile Internet, 5G, Mobile communication
Big Data dimension	Big Data, Data Mining, Big Data Analysis, Big Data Application
Distributed technology dimension	Cloud Computing, Cloud Platform, Digital Currency Bitcoin, Blockchain Technology
Risk management dimension	Internet insurance, Internet financing, Network financing, Online financing, Network insurance
Security technology dimension	Biometrics, Fingerprint Identification, Iris Recognition, Face Recognition, Voice Recognition
AI dimension	Artificial Intelligence, Intelligent Robot, Natural Language Processing, Machine Learning
Payment dimension	Mobile Payment, Third Party Payment, QR Code Payment, Network Payment

Source: Wang et al., 2021.

Within the framework of this study, we accept FinTech as a concept that includes all of the above concepts, including Insurtech, Regtech, Wealthtech.

A large number of studies are devoted to the use of blockchain technologies. Many authors single out this technology as a technology that will play a key role in the development of the financial industry (Bouri et al., 2020, Aylin and Ahmet, 2020, Kabulova and Stankevičienė, 2020, Deng and Wu, 2021, Agarwal et al., 2021, Bhasin and Rajesh, 2021, Avasthi, 2021, Zhao, 2021, Wang et al., 2021, Le et al., 2021 Ali et al., 2023, Khan et al., 2023 van der Linden and Shirazi 2023). At the same time, the scope of application of this technology is extremely wide: secure information exchange, digital currency, asset tracking and management, digital identification, compliance with regulatory requirements, financial flow tracking, digitization of documents and protocols, licensing and credentials, asset tokenization, product supply chain tracking, payments/transaction processing, contract management, internal control, protection against counterfeiting. Options for using blockchain technology in organizations around the world in 2021 are shown in Fig. 2.

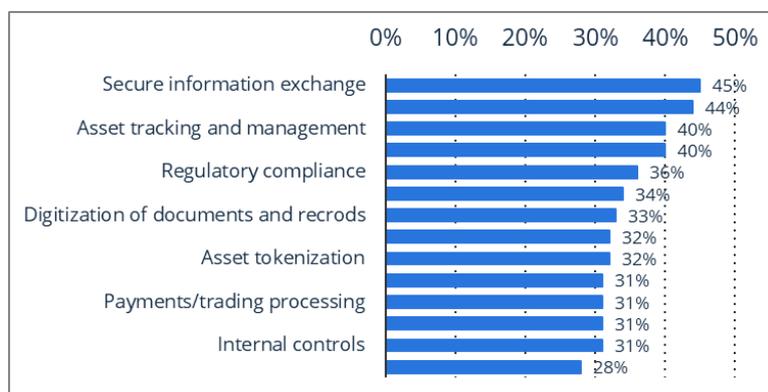

Fig.2. Blockchain technology use cases in organizations worldwide as of 2021

Source(s): Deloitte

Blockchain technology occupies a special place in a number of FinTech technologies. It's been a long time since it's just a word to attract attention. The year 2020 has become a trigger of innovation for many countries of the world, in which there is an active discussion of technology in a practical way on a number of issues related to business, the state and society as a whole. For example, a law on digital financial assets was adopted in the Russian Federation, a roadmap for the development of distributed ledger technology was approved, many

government agencies were involved in working with blockchain: the tax, customs service, Bank of Russia and others. Thus, it can be argued that the recognition of blockchain in the state environment has already come. The state and business already treat technology as a given, but nevertheless, an understanding of specific use cases, potential benefits and possible consequences has not yet been formed.

It is also widely believed that robotic consultants and recommendation systems will play a leading role (Martínez-Plumed et al., 2021, Priyono & Azhar, 2021, Mankins et al., 1995). For example, the Liu 2020 study considers the technology of robotic consultants as a new model of investment and financial management based on Internet platforms, artificial intelligence and quantitative trading technologies. The study examines how to standardize the Robo-consulting platform, effectively control financial risks in the investment process and protect the interests of investors - an urgent problem in the Robo-consulting industry. The papers Bunnell et al. (2021) and Unzueta et al. (2021) analyze the FinTech recommender system. The study by Chen et al. (2021) examines the technology of predict stock prices for the next period. This technology can also be attributed to robotic consultants, as a hybrid model based on machine learning for stock forecasting and an average deviation model for portfolio selection. In particular, this model includes two stages: stock forecasting and portfolio selection. Using the Shanghai Stock Exchange as a sample for the study, the results obtained demonstrate that the proposed method surpasses traditional methods (without stock forecasting) and benchmarks in terms of profitability and risks. The Nieves, 2021 study presents a hybrid method of recommending financial products: joint filtering in combination with content filtering. This task involves learning intelligent algorithms to create the right recommendations for each client. The expected results are a forecast with a high degree of accuracy due to the integration of a hybrid method that provides personalization of products offered by the bank.

A number of studies address the issues of accessibility of financial services using mobile money (Senyo & Osabutey, 2020, Al Nawayseh, 2020, Zhang et al., 2020). The issue of access to financial services is considered one of the main problems that societies face during crises, the above-mentioned studies attach great importance to the availability of financial services, thanks to FinTech technologies, emphasize the social component of FinTech development.

Sustainable development has become an important topic because of the environmental damage caused by economic activity. In this scenario, FinTech can

help improve the use of resources and ensure sustainable economic development. To better understand this relationship, panel data from 66 countries were collected for the period 2010-2021. The Green Growth Index (GG) was developed and its relationship with several FinTech variables was analyzed. The results show that the popularization of the Internet and Findex have a positive impact on "green" economic activity, while carbon emissions have a negative impact. Population growth and unemployment can also affect green growth. Importantly, this study highlights the need for policymakers to promote the adoption of financial technologies to achieve greener economic growth (Awais et al., 2023).

The article Ceaparu (2021) analyzes Fast Data and Big Data technologies as the most promising within FinTech. Bunnell et al. (2021) considers Big Data as the most promising technology.

Summing up the above, it can be reasonably argued that the research and analysis of the blockchain technology market within the framework of FinTech seems relevant and timely.

#### 4 Patent analysis

Table 2 shows the indicators of the introduction of FinTech services worldwide in 2019 by category. China has been a leader in banking and payments, with 92 percent of FinTech adoption by small and medium-sized enterprises in this category.

Table 2. Leading countries for fintech adoption 2019, by category

County	Banking and payments	Financial management	Financing	Insurance
China	92%	91%	89%	62%
U.S.	52%	49%	41%	31%
Mexico	49%	36%	31%	23%
South Africa	47%	43%	34%	26%
U.K.	41%	37%	34%	24%
Total	56%	51%	46%	33%

Source: BI Intelligence

The figure 3 shows the cost of venture financing of financial technologies worldwide in 2021 by sector.

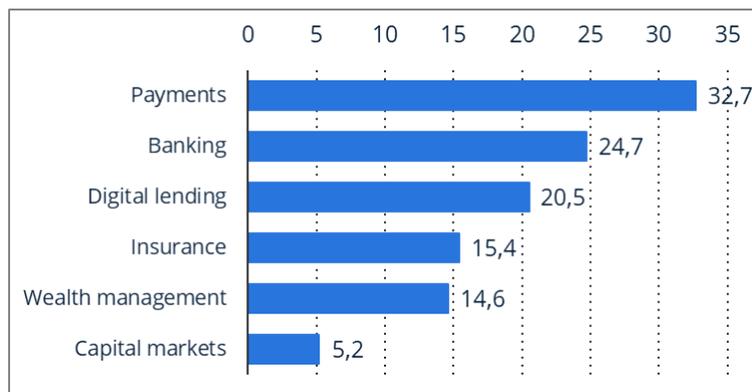

Fig. 3. Value of venture capital-backed funding in fintech worldwide in 2021, by sector (in billion U.S. dollars)

Source: CB Insights

In 2021, FinTech companies specializing in payment services were the most funded FinTech companies in the world. Financing raised through investment deals with venture capital in FinTech companies operating in the payments segment amounted to about \$32.7 billion. It was followed by FinTech companies specializing in banking and digital lending.

New technologies such as blockchain, artificial intelligence, big data and other technologies can significantly improve the quality of risk control, optimize financial transactions, improve customer service, optimize the credit process, customer evaluation model, etc.

We will conduct a patent analysis on blockchain technology. Patent analysis has been conducted for the last since the advent of the blockchain (the Bitcoin system, which appeared in October 2008, became the first application of blockchain technology) to the present. However, the bulk of patents began to appear after 2015. At the moment, the absolute leader in the number of patents in the field of blockchain is China (8,027), followed by the USA (6,414), in third place is the World Intellectual Property Organization (WIPO) (3,748).

The number of patent applications for blockchain inventions filed publicly worldwide in 2020, according to the leading company, is shown in Fig. 4.

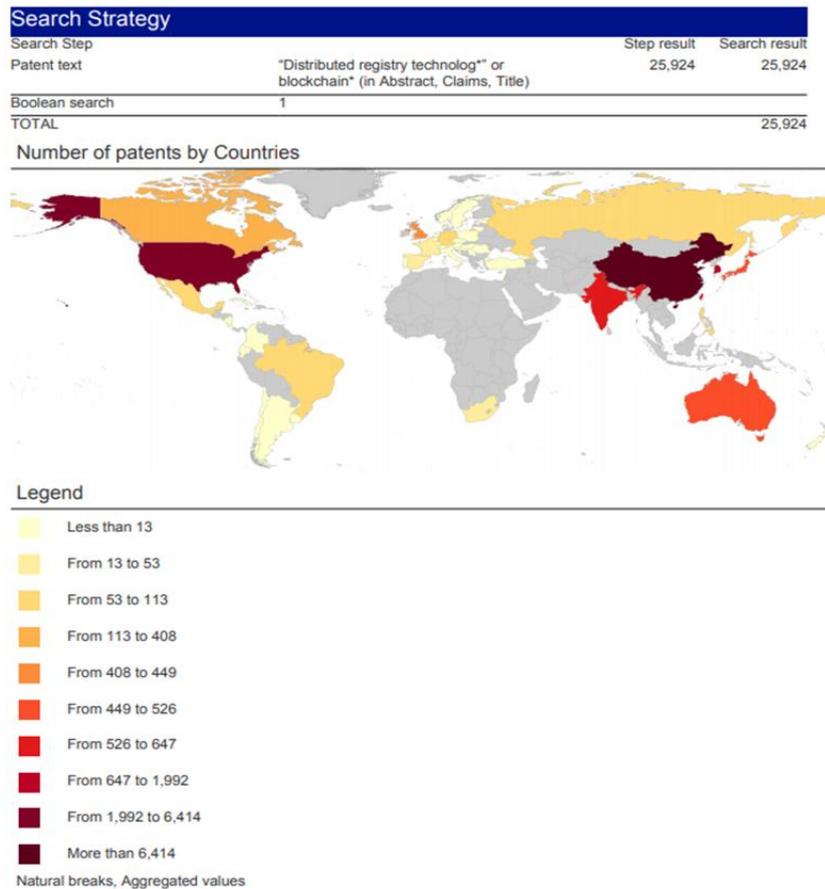

Fig. 4. Search for the keyword "blockchain", world map  
 Source: Orbis Intellectual Property (Bureau van Dijk)

In 2020, global spending on blockchain solutions reached \$4.1 billion. The growth of spending on blockchain solutions has been jeopardized due to the outbreak of coronavirus (COVID-19), but still remains quite high - spending for 2020 is more than 50 percent higher than in the previous year. According to forecasts, spending on blockchain solutions will continue to grow in the coming years and will reach almost \$18 billion by 2024 (Statista, 2021). Global spending on blockchain solutions from 2017 to 2024 (in billions of US dollars) is shown in Fig.5.

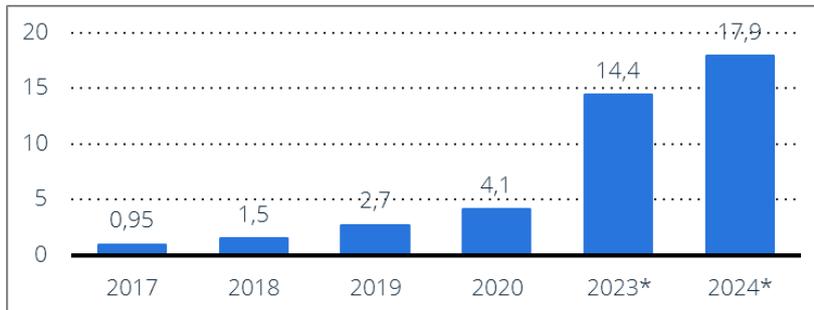

Fig. 5. Spending on global blockchain solutions in 2017-2024 (in billions of US dollars).  
Source: www-statista-com

Distribution of global blockchain patents in 2021, by country is shown in Fig.6.

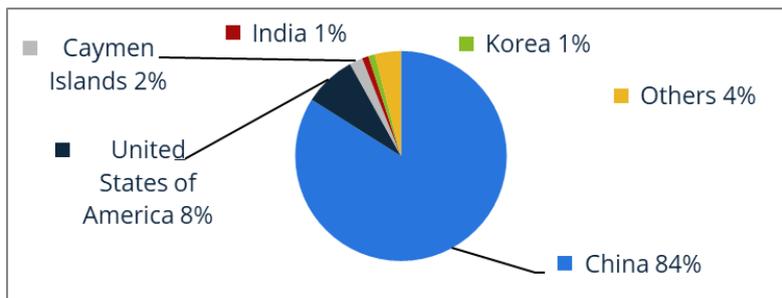

Fig. 6. Distribution of global blockchain patents in 2021, by country  
Source: Statista.com

It is obvious that interest in the technology is growing. Consider the distribution of the blockchain market value worldwide in 2020 by sector (Fig.7).

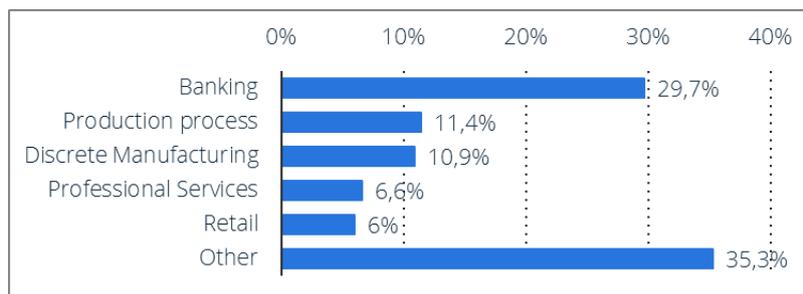

Fig.7. Share of global blockchain market value in 2020 by sector  
Source: Statista.com

The largest consumer of blockchain technologies is the banking sector, which occupies 29.7% of the blockchain market in 2020.

## **5 Discussion and conclusion**

Recent challenges have shown that the FinTech sector needs to be flexible and innovative, learn from previous periods and create knowledge-based innovations. We consider contactless payments as a new payment model around the world, embedded financing (from payments to loans, insurance and mortgages, companies now offer embedded services adapted to individual customer needs), the desire to create new partnerships within business ecosystems, the introduction of cryptocurrencies (countries are considering the possibility of introducing digital national currencies). COVID-19 accelerated digital trends, and also significantly changed the behavior of customers who began to prefer digital payments, banking applications, etc., which stimulates further investments in FinTech.

We are witnessing the rapid development of technology, the need to hire additional staff, in this regard, expert networks are becoming more and more popular. So, Blockchain 1.0 has turned into Blockchain 4.0, and Blockchain 5.0 appears. Blockchain 5.0 allows you to perform operations in both private and public spheres and can be used by government agencies, commercial and private organizations. We are talking about the widespread use of this technology in the life of society. Blockchain is a promising technology that has gained huge popularity by revolutionizing peer-to-peer information exchange, combining cryptographic principles with decentralization, immutability and transparency.

*RQ1: What are the most promising technologies in the field of FinTech?*

As a result of the conducted research, it was revealed that blockchain currently occupies a privileged place in the structure of FinTech.

*RQ2: What are the risks and prospects of this technology?*

In this regard, the opinion of Han, L. (2020), who studied the relationship between the trust mechanism and the iterations of the currency system from the era of early civilization to the present day, is interesting. The author delved into the history and evolution of the "money format", illustrated the changes associated with the concepts of "TRUST" and "CONVENIENCE" as a timeline. As a result, I concluded that the final path of money is bitcoin and cryptocurrency.

By itself, blockchain technology has the ability to ensure mutual trust in a system where it could not have been initially. However, it also has disadvantages, criticism, for example, as the possibility of a consensus, when it becomes possible to manipulate the blockchain in the interests of a related group of persons. There is also a risk of data substitution and mutual responsibility.

On the other hand, the financial technology environment tends to change rapidly, so it moves away from large and heavy "megalithic" buildings and strives to create a mosaic of microservices. In this regard, it is possible to use blockchain technology in a different way that would meet the demands of time and circumstances, maximize the strengths of the technology and level the "Achilles' heels" of the blockchain.

Recent challenges have shown that the FinTech sector needs to be flexible and innovative, learn from previous periods and create knowledge-based innovations.

### **Abstract**

The purpose of this study is to examine the impact of digitalization (DG) and knowledge sharing (KS) on the financial performance (FP) of French companies, with a focus on the mediating role of corporate social responsibility (CSR). A survey was conducted among a sample of French companies, and the data was analyzed using structural equation modeling PLS. The results of the study indicate that DG and KS have not a positive impact on the FP of French companies. Furthermore, CSR completely mediates the relationship between DG and FP. These findings suggest that French companies should focus on improving their digital capabilities and promoting KS among employees, while also paying attention to their CSR activities, in order to enhance their FP.

**Keywords** - Digitalization, Knowledge sharing, CSR, Financial Performance, Dynamic capabilities

## 1 Introduction

DG and KS are two key factors that can contribute to the success of modern organizations. DG enables companies to streamline their operations, improve customer service, and increase their competitiveness (Kraus et al., 2021; Bouncken et al., 2018). KS, on the other hand, can help companies develop new products and services, improve production processes, and solve problems more efficiently (Lin & Lee, 2006).

However, the benefits of DG can be limited by inequalities in access to information, security and privacy risks, and the inability of firms to fully exploit their knowledge potential (Teece, 2018). In this context, CSR can play an important role in mediating the relationship between DG and FP.

CSR implies that companies take into account the social and environmental impacts of their activities and commit to creating value for all stakeholders (Carroll, 2015). With respect to DG, CSR can encourage collaboration, transparency, and accountability in the use of digital technologies (Kiron et al., 2019). For example, CSR can help companies design more ethical and privacy-friendly information systems, build customer trust and loyalty, and increase their ability to innovate by collaborating with external partners (Nambisan and Baron, 2019). In addition, CSR can encourage KS internally and externally, thereby promoting organizational learning and business competitiveness (Liao et al., 2019).

However, the impact of these factors on the FP of companies is not well understood. Moreover, the role of CSR in mediating this relationship has received limited attention in the literature. Therefore, this study aims to fill this gap by exploring the impact of DG and KS on the FP of French companies, with a focus on the mediating role of CSR. We examine this relationship using data collected from 118 French companies on DG, KS, CSR and FP. We showed that CSR can contribute to strengthening the FP of firms by fostering a culture of innovation and cooperation, and by encouraging the diffusion of knowledge throughout the ecosystem.

## 2 Dynamic Capability Model

The theory of dynamic capabilities is an important reference for understanding the mechanisms that allow companies to adapt to environmental changes. It highlights the ability of companies to create, extend, and reorganize their resources and competencies to adapt to new market conditions (Teece, 2018). The choice of the dynamic capabilities theory to address the concepts of DG, KS, CSR, and FP is justified by its relevance as a theoretical approach emphasizing the importance of flexibility and adaptability in achieving corporate performance (Trabucchi et al., 2018). Indeed, increasing DG has a significant impact on companies, requiring rapid adaptability to maintain competitiveness. Companies must be able to create, extend, and reorganize their resources and competencies to exploit DG opportunities and defend against threats (Wang and Ahmed, 2007). The dynamic capabilities theory highlights the importance of creating new capabilities and developing existing ones for sustainable performance.

Moreover, KS is considered a key element for enhancing a company's dynamic capabilities. DG offers new opportunities to facilitate internal collaboration and communication, which can strengthen knowledge creation and capacity development (Li, Zhang, and Yang, 2019). However, for DG KS to contribute to a company's performance, it is essential to consider CSR. In fact CSR can play a mediating role in the relationship between DG, KS, and corporate performance by encouraging ethical practices and improving the company's perception by its stakeholders. Thus, the study conducted by Jamali and Mirshak (2007) on CSR in the context of developing countries highlights that CSR can contribute to improving the company's reputation, which can strengthen stakeholder trust and stimulate company performance.

In light of all these elements, dynamic capability theory seems to provide a rich and legitimate framework for understanding the complex relationship between DG and KS, and their impact on FP with a focus on the mediating role CSR.

### **3 Theoretical Background and Hypothesis**

#### ***3.1 Digitalization and Financial Performance: An empirical Literature Review***

McKinsey (2018) stated that in the past five years, more than 80% of companies had launched new DG initiatives to keep up with competitive pressures. While DG is thought to promote companies to perform better by allowing them to adopt more efficient, transparent processes with improved mechanisms of data collection and management to reduce costs and generate more revenues and profits, its impact on financial stability is not as obvious.

The Financial Stability Board (2017) emphasized the fact that there is a need to consider two main areas of risk engendered by the digital development. These are:

1. Micro-financial risks: the main focus of this area of risk is on the poor governance of digital processes which may negatively impact the provision of services. Also, the cyber risk and how it could increase due to the potential intense digital connections between various entities, particularly if important activities commands from different companies are dependent on the same third party.
2. Macro-financial risks: These risks tend to threaten the stability of different digital systems together. The most critical point is the contagious nature of the caused distress which may escalate and impact the whole economy. Also, due to the fast features of DG an overreaction to the rapid flow of news may create excess volatility that negatively impact economic growth. Major moral hazards may also be created by highly connected entities which could alter the market structure limiting the possibility of other providers interfering to resolve the any related issues.

Guo and Xu (2018) departed from acknowledging the potential as well as the drawbacks of DG to examine its impact on the operational and FP of 2254 Chinese companies in the manufacturing sector over the period 2010 to 2020. Using multiple linear regression analysis with different measures of performance, namely profitability and productivity they concluded that digital technologies do have a positive impact on both operational and FP.

Abou-Foul et al., (2020) examined the relationship between DG, servitization and FP using the Structural Equation Model with a sample of 185 manufacturing companies in the US and Europe. FP was measured via three variables which are revenues generation, market value and profitability. Both DG, servitization were found to have a direct positive relationship with FP.

Cherkasova and Slepushenko (2021) claimed that in Russia, DG is a pressing issue which needs to be investigated in relation to the FP of companies. The authors used multisectoral data of 482 companies over the period 2017–2019 to test whether or not the FP measured by operating profit margin is impacted by the (0–100) DG Index of McKinsey, with 0 being no DG and 100 representing the maximum DG. Their multiple regression analysis results showed that overall, there is a positive influence of DG on FP.

Jardak and Ben Hamad (2022) & Wroblewski (2018) both studied the relationship between digital maturity and FP empirically in Sweden with 23 and 24 companies respectively. Their results indicated that it is not evident for DG to have a positive impact on performance. In fact, Jardak and Ben Hamad (2022) found a weak negative impact of digitalisation on operating performance. This somewhat validated Wroblewski (2018) earlier conclusion that ROA and ROE are negatively influenced by Digital maturity in Sweden.

A recent study from Indonesia conducted by Gusti (2022) also aimed at investigating the role of digital capability and digital orientation on FP with data collected from 200 Micro, Small, and Medium-sized (MSMEs) companies. Their regression analysis results indicated that a significant positive relationship was found between DG and FP.

*H1 : Digitalization impacts positively financial performance.*

## **2.2. Knowledge Sharing and Performance**

KS is the practice of sharing information, skills and experiences between individuals or groups. This practice can have a significant impact on organizational performance (Jennex, 2008; Nonaka et Takeuchi (1995). Indeed, by sharing their knowledge and skills, individuals can contribute to the achievement of common goals and increase the quality and efficiency of work (Wasko et Faraj, 2005).

KS can also have a significant impact on the FP of companies. Several studies have shown that KS can help companies achieve cost savings, reduce expenses,

and increase revenues. For example, Wang and Noe (2010) found that KS can help companies reduce training costs and improve production quality, which can translate into increased profits. Similarly, Szulanski (1996) demonstrated that KS can help companies avoid costly mistakes and solve problems more quickly, which can also lead to significant savings.

KS can also help companies innovate and develop new products and services, which can contribute to increasing revenue and improving FP. Lin and Lee (2006) found that KS can help companies create innovative products and services by promoting collaboration and creativity among employees. Likewise et al (2002) prove that KS can help companies develop new products and services by fostering innovation.

Moreover, KS can help companies improve their reputation and brand image, which can result in increased customer loyalty and sales. Hansen and Von Oetinger (2001) emphasized the importance of KS in creating a strong and positive brand image for companies. Similarly, Cabrera and Cabrera (2005) showed that KS can help companies improve their reputation by providing high-quality products and services.

Finally, KS can also help companies develop strategic partnerships and alliances, which can contribute to increasing revenues and improving FP. Grant (1996) highlighted the importance of KS in creating effective partnerships and strategic alliances. Likewise, Cummings and Teng (2003) demonstrated that KS can help companies collaborate with other businesses to develop new products and services and to reach new and larger markets.

*H2. Knowledge Sharing impacts positively financial performance*

### **2.3 The Relationship between Digitalization and CSR**

DG and CSR greatly promote the competitiveness of companies (Orbik and Zozuláková 2019). The stakeholder theory is the most mobilized theory to examine the association between CSR and DG. It states that companies undertake voluntary practices based on ethical, legal, environmental, economic and social actions for the benefit of different stakeholders (Freeman et al., 2010, Spence et al., 2016, Carroll, 2018).

Nowadays, companies can no longer ignore their social responsibility. DG supports this need (Ramirez-Peña et al., 2020). Indeed, digital technologies play a major role in improving the contribution of companies to sustainable

development and in strengthening relationships with stakeholders. This premise has been advanced by Santoalha et al. (2021) and Cardinali & De Giovanni (2022) who have shown the contribution of the use of digital technology in green practices.

Furthermore, digital transformation is pushing companies to be more attentive and transparent to their stakeholders (Paiola & Gebauer, 2020). The latter are increasingly demanding of companies (Schiavone et al., 2022). Accordingly, we postulate that a company's digital transformation increases the importance and influence of stakeholder demands, thereby increasing CSR participation. We therefore expect a positive relationship between DG and CSR, and we can propose the following hypothesis:

*H3. Digitalization impacts positively CSR.*

#### **2.4. The Relationship between Knowledge Sharing and CSR**

In the current context of global health and financial crises, companies seek to improve their sustainability practices and enhance their reputations as responsible corporate citizens. KS can play a critical role in advancing CSR efforts within organizations, by promoting collaboration and innovation, and creating opportunities for learning and growth. For example, research has shown that KS can lead to more effective CSR strategies and improved environmental performance (Fortanier et al., 2011; Nguyen et al., 2019). Additionally, sharing knowledge and best practices can help companies identify and address social and environmental risks in their supply chains (Van der Wiele et al., 2015).

Moreover, KS can foster a culture of transparency and accountability, which are key components of CSR. By openly sharing information about their sustainability practices and performance, companies can demonstrate their commitment to responsible business practices and build trust with stakeholders (Liu et al., 2021). Furthermore, KS can help companies engage with their stakeholders and incorporate their perspectives into CSR decision-making (Nair et al., 2021).

In addition, it is worth noting that KS can also help companies identify and respond to emerging social and environmental issues. By staying up-to-date with the latest trends and developments in CSR, companies can proactively address potential risks and opportunities. For example, sharing knowledge about the circular economy can help companies reduce waste and improve resource efficiency (Hart, 2017). Additionally, KS can promote ethical behavior and help

companies avoid reputational damage due to social or environmental misconduct (Pohl et al., 2019).

In summary, KS is a critical component of corporate social responsibility. It can facilitate collaboration and innovation, promote sustainability, and foster transparency and accountability. Therefore, companies should prioritize creating a culture of KS and invest in the necessary tools and resources to support it.

*H4. Knowledge Sharing impacts positively CSR.*

## **2.5. The Relationship between CSR and Performance**

The CSR- performance relationship has been revived the last decade given the interest in CSR (Van de Walle and Brice, 2011). The CSR strategy adopted by the company certainly also has financial and economic implications. A question of major importance for companies and academics alike is whether it is profitable to engage in CSR strategies. One of the main explanatory theories in this work is essentially stakeholder theory. It seeks to describe and limit responsibilities within the firm and considers that good FP is the result of good social performance.

Stakeholder theory views the creation of value at the level of a company as the result of a fruitful collaboration between the different stakeholders. In line with this analysis, (Pera et al, 2016 and Freudenreich et al, 2020) emphasize that value creation is a process that includes the participation of multiple stakeholders.

Efforts to satisfy these stakeholders gain competitive and performance advantages (Freeman, 1984). According to this economist, the ultimate goal of the firm is profit maximization. A favorable social context generates a good reputation for the company and positively impacts its value (Cheung, 2010).

Several works provide mixed results regarding the impact of social engagement on performance (Lins et al., 2017; Spence et al, 2011; Dupuis, 2008; Waddock and Graves, 1997; Yu and Choi, 2014; Chtourou and Toriki, 2017).

A classic stream of literature points to a negative relationship between CSR and performance ((Friedman, 1970; Aupperle et al, 1985; Chetty et al, 2015; Nguyen et al, 2015, Jahmane and Hofaidhllaoui, 2021). Sun (2012) states, for example, that CSR does not create value for the company, but it leads to huge burdens (Famiyeh, 2017) and expenses. Surroca et al. (2010) did not find a relationship between CSR and performance.

However, the majority of work argues for a positive impact of CSR on performance (Berland, 2007; Dupuis, 2008; Daudigeos and Valiorgue, 2010; Yu

and Choi, 2014; Cheng et al, 2014; Acquier and Aggeri, 2015, Robert et al, 2016; Choi et al, 2018; Devie et al. 2018; Tonmo et al, 2021). In this perspective, the engagement in CSR strategies is vital to achieve economic goals (Garriga and Mele, 2013), it increases the value even in some particular industries (Cai et al, 2012; Reverte et al, 2012).It helps to improve the image of the company and deny strong relationships with shareholders (Davis, 1973) or employees (DeRoeck et al 2014) and improves their productivity (Zhou, 2016) and consequently increases performance.

We can then propose the following hypothesis:

*H5. CSR impacts positively financial performance*

## **2.6. The Impact of CSR on the Relationship between Digitalization and Firm Performance**

According to Kim (2022), capitalism has long been driven by making profit. In many instances, this has been associated with business misbehavior, corruption, social exclusion and environmental damage. Hence, CSR might be used as a Buzzword for marketing purposes to divert the stakeholder's attention from those undesirable consequences (Piketty, 2020; Rocha et al., 2021)

Porter (2011) and Freeman (2013) were among the first to claim that CSR should not be perceived as an apology from companies for being driven by profit maximization. Rather, it should be built into the business model of any company for the purpose of value creation for the whole society.

This central argument has opened up new avenues for investigating the relationship between CSR and through both KS and DG.

De Galhaud (2016) stated that DG has unquestionably created a fertile ground for the provision of more sophisticated services in terms of both information availability and execution quality. It has also enabled the modernization of processes and practices through which businesses can sustain their performance and growth.

Orbik and Zozuláková (2019) suggested that DG is the umbrella under which new ways have to be embraced by companies to address their traditional challenges. This should eventually engender a better protection of the environment and also a reduction in pollution levels. For this to be achieved effectively, the society needs to change its culture and improve the awareness of all employees working in businesses (Kane et al. (2015) . However, digital

transformation could equally raise serious issues in relation to future employment, the ethical usage of technology and the development of working knowledge among employees. The study concluded that although the speed at which companies are changing in this digital era is unprecedented, CSR is the approach that ensures companies are responsible in their inside working environment besides their responsibility towards the society as a whole. This suggests that CSR plays a mediating role through which companies improve their business strategies and digital transformation and hence, their overall performance.

The importance of CSR and DG was also investigated by Forcadell et al., (2020) with a particular focus on Banks's performance. They argued that companies are increasingly under both competitive and social burdens in the way in which they embrace DG. From 13 developed countries and over the period of 2003–2016, they utilized panel data analysis with a sample of 112 large commercial banks to test the impact of DG and corporate sustainability on performance. They concluded that both variables when occurring together have a positive significant impact on market performance and efficiency of banks.

Similar results were found in a study by Ramos & Casado-Molina (2021) in which a multi-dimensional daily data of seven Spanish banking corporations related to consumer experiences was collected to investigate their impact on the digital Online Corporate Reputation (OCR). These variables included social responsibility, ethics, labour environment and profitability performance as well as attitudes and emotions expressed in social media. The results confirmed that emotion and attitude significantly influenced OCR. The most influential variable was found to be the ethics experience.

More recently, Alfalah et al., (2022) adopted multiple regression analysis to examine the relationship between performance, IT investment and CSR for the Saudi telecommunication sector. They analyzed the responses of 275 participants and concluded that there is a significant impact of investment in IT and effective corporate governance on performance. However, the linkage between investment in IT and performance is only enabled through the mediation role of CSR. Otherwise, no direct association between DG and IT investment was found.

The meditating role of CSR was also observed in recent studies investigating the relationship between KS and performance.

Vassilikopoulou et al., (2018), Elhussiny et al.,(2019) and Mavis et al., (2021) based their research theoretical framework on the CSR stakeholders theory. More

precisely they highlighted the importance of employees being the most significant internal stakeholders. KS among those internal stakeholders is believed to positively impact the performance of businesses at various levels ((Çolak and Şahin, (2019), Saifuddin et al., (2019), Lai et al., (2020) and Parry et al., (2021)).

*H6. CSR mediates the effect of digitalization on firm financial performance*

### **2.7. The Impact of CSR on the Relationship between Knowledge Sharing and Firm Performance**

Lee and Song (2019) investigated the importance of KS among 263 employees from 22 firms in South Korean hospitality sector and its impact on the CSR and performance. Using the structural equation modeling (SEM), they confirmed that KS has positive influence on the CSR of these firms which in turns influences positively their performance measured by a set of variables related to financial aspects, costumer and employee satisfaction as well as environmental facts.

Jilani et al., (2020) also acknowledged that KS optimizes the intensity of resources allocation which results in more sustainable performance of businesses. They utilized structural equation modelling with 287 responses of participants from 31 banks in Bangladesh. They tested whether or not knowledge hiding and employees' ambidexterity have a mediating feature in the proposed positive relationship between KS and sustainable performance. Their findings revealed that sustainable performance is significantly determined by KS among employees indirectly via the proposed mediated variables.

Zhang and Wu (2020) focused on ethical leadership in Chinese companies and its role in impacting CSR activities and performance. Based on the responses of 327 employees analysed via the structural equation modeling (SEM), they concluded that performance can be improved by CSR and ethical leadership which promoted KS practices within companies. Hence, KS impacted performance only through their chosen CSR mediator which is ethical leadership.

Aamir et al., (2021) also argued that employees who engage more with KS tend to have better ambidexterity and eventually contribute to the overall performance of companies. With 240 employees of manufacturing firms in Pakistan they tested the link between ambidexterity, KS and sustainable performance. Their SEM-PLS results revealed due to the mediating effect of employee's ambidexterity, KS had a positive significant impact on sustainable performance.

The authors of this paper found no recent studies which looked into the impact of KS on CSR and performance beyond the year 2021.

*H7. CSR mediates the effect of Knowledge Sharing on firm financial performance.*

### **3 Research Methodology**

All the hypothesis illustrated in this study were tested through the Partial Least Squares Structural Equation Modeling (PLS-SEM) approach. This technique is considered the most suitable for our analysis as the sample we used is considered relatively small ( $n = 118$ ) and we predict in our model dependent variables (Hair et al., 2017). Multiple items were used to measure each construct. All the items used were extracted from previous studies as summarized in the following table of reliability and validity.

118 retained valid surveys were collected from French companies between October and December 2022 using the non-probabilistic convenience sampling as the participants are easy to recruit and can represent the entire population of study (Matthews and Ross, 2010). Four reflective constructs are used in the analysis and evaluated on a five-point Likert scale (1 = I totally disagree; 5 = I totally agree). Invalid responses were removed to ensure a good measurement. Two independent variables Digitalization (DG) and Knowledge Sharing (KS) predicted the dependent variable (FP). CSR as a mediator was inserted in the model to explain in-depth direct relationships between DG, KS and FP.

The sample used in this study is composed of 47.5% males and 52.5% females. Most of the respondent are under 26 years old (67.8%) and qualified as non-executives' staff. Most of the respondents questioned in this study have under 5 years of experience (86.4%), (table 2). About 50% of the firms questioned are from service sector however only 8.5% of firms are industrial and 28% are commercial. Furthermore, most of the firms in our sample are operating in private sector (about 85%) while only 8.5% are public.

Table 2: Sample Characteristics

Characteristics	Groups	n	%
<b>Respondents</b>			
<b>Gender</b>	Male	56	47.5
	Female	62	52.5
<b>Age</b>	= <26 years	80	67.8
	>26-45 years	38	32.8

### **3.1 Running PLS Algorithm for measurement model**

Before assessing the significance of the path coefficients of the different structural links, two main stages were followed. The first one, is the measurement model evaluation which ensures reliability and validity through running PLS algorithm. Reliability and validity of the constructs are considered adequate when values of internal consistency (cronbach's alpha, composite reliability) and discriminant validity (AVE, Fornell-Larker) were satisfactory. Cronbach's  $\alpha$  and composite reliability were above the threshold of 0.7 which supports the good reliability of the constructs. All items with loadings under the threshold 0.7 were removed. However, outer loadings between 0.4 and 0.7 were kept as they didn't impact reliability and validity of the constructs' measurements.

Table 3: Reliability and validity

Codes of items	Items in questionnaire	Outer Loadings	Reliability		Validity	R <sup>2</sup>	HTMT
			Internal consistency reliability		Convergent validity		
			Cronbach's alpha	Composite reliability	Average Variance Extracted (AVE)		
<b>Corporate Social Responsibility</b> (Nguyen et al., 2021)							
CSR10		0.777	0.922	0.933	0.501	0.186	Yes
CSR11		0.611					
CSR13		0.789					
CSR14		0.780					
CSR15		0.659					
CSR16		0.736					
CSR17		0.660					
CSR18		0.705					
CSR19		0.579					
CSR5		0.706					
CSR6		0.739					
CSR7		0.800					
CSR8		0.749					
CSR9		0.706					
<b>Digitalization</b> (McKinsey & Company, 2016)							
Digit1		0.789	0.834	0.882	0.602	-	Yes
Digit2		0.815					
Digit3		0.739					
Digit4		0.665					
Digit5		0.851					
<b>Knowledge sharing</b> (Rajput and Talan, 2017)							
KS1		0.731	0.809	0.862	0.511		Yes
KS2		0.676					
KS3		0.666					
KS4		0.770					
KS5		0.781					
KS6		0.652					
<b>Financial Performance</b> (Yu et al., 2021)							
Fin_Perf1		0.899	0.906	0.934	0.780	0.132	Yes
Fin_Perf2		0.911					
Fin_Perf3		0.879					
Fin_Perf4		0.842					

All average variance extracted (AVE) measures exceed the threshold 0.5 which confirmed a good convergent validity of the constructs as the table above showed.

To examine the discriminant validity, Fornell and Larcker (1981) criterion and heterotrait-monotrait ratio (HTMT) (Henseler et al., 2015) were used. Hence,

square-root of the AVE values for each construct is above the highest correlation between two different constructs. For example, the square-root of the CSR is 0.718; Correlations between CSR-DG = 0.437, CSR-FP = 0.354 and CSR-KS = 0.282 are all above 0.718 which indicated good discriminant validity. (Hair et al., 2012; Henseler et al., 2016). Moreover, all HTMT values of the constructs are below 0.9 which supports that discriminant validity is satisfied (Henseler et al., 2015).

Table 4: Fornell-Larcker criterion

	CSR	DG	FP	KS
CSR	<b>0.718</b>			
DG	0.437	<b>0.774</b>		
FP	0.354	0.295	<b>0.883</b>	
KS	0.282	0.453	0.217	<b>0.715</b>

### 3.2 Running bootstrapping for structural model

To test the whole model, PLS-SEM approach was used. Results showed that only two direct links are significant. CSR impact significantly **FP** ( $\beta$  CSR  $\rightarrow$  FP = 0.270,  $t = 2.489$ ,  $f^2 = 0.069$ ,  $p = 0.013 < 0.05$ ). Moreover, DG impacts significantly CSR ( $\beta$  DG  $\rightarrow$  CSR = 0.389,  $t = 4.379$ ,  $f^2 = 0.150$ ,  $p = 0.000 < 0.05$ ). Impact of CSR on FP is considered low as the value of  $f^2$  is less than 0.15. However, the impact of DG on CSR is considered moderate as  $f^2$  is 0.15. Regarding the other direct links, they are non-significant as their p values are all greater than 0.05.

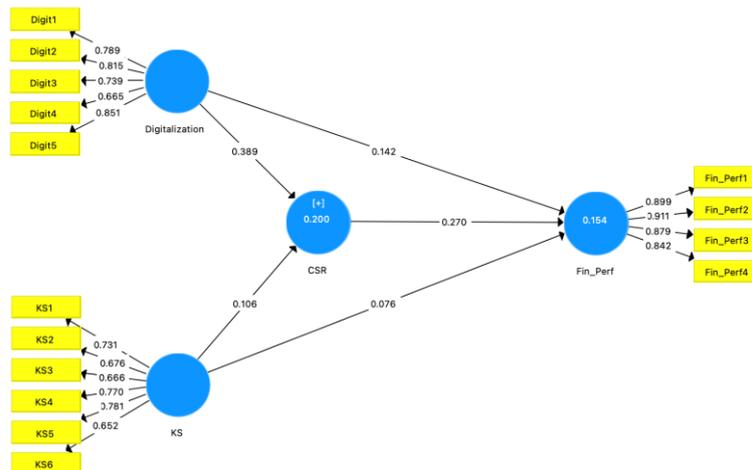

Figure 1: The structural model

Table 5: Results of the structural model path coefficients (significant links)

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics ( O/STDEV )	P Values	f <sup>2</sup>
CSR -> FP	0.270	0.279	0.109	2.489	<b>0.013</b>	0.069
DG -> CSR	0.389	0.402	0.089	4.379	<b>0.000</b>	<b>0.150</b>
DG -> FP	0.142	0.135	0.106	1.342	<b>0.180</b>	<b>0.016</b>
KS -> CSR	0.106	0.137	0.102	1.036	<b>0.300</b>	<b>0.011</b>
KS -> FP	0.076	0.093	0.135	0.567	<b>0.571</b>	<b>0.005</b>

In order to explain more the relationship between *DG*, *KS* and *FP*, indirect relationship mediated by the CSR was tested. As a first stage we test the direct link between *DG*, *KS* and *FP*. Then, the indirect impact between *DG*, *KS* and *FP* through CSR was evaluated to check if the mediation exists or not and what type of mediation that CSR can play (Zhao et al., 2010). Statistical results showed that CSR played a full mediation role in the relationship DG – FP as the indirect effect is significant ( $\beta$  CSR -> CSR -> FP = 0.105,  $t = 2.048$ ,  $p = 0.041 < 0.05$ ) whereas the direct effect is not significant. Moreover, CSR did not play any mediation role between KS and FP as the indirect effect between KS and FP is non-significant.

Table 6: Specific indirect links

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics ( O/STDEV )	P Values
DG -> CSR -> FP	0.105	0.111	0.051	2.048	<b>0.041</b>
KS -> CSR -> FP	0.029	0.040	0.036	0.798	<b>0.425</b>

To complete the picture of the path model relationships, this research considers unobserved heterogeneity in the analysis. This can lead to correct all conclusions and ensure the validity of results and generalized valid structural results (Sarstedt and Ringle, 2010). As a first step, finite mixture partial least squares procedure (FIMIX-PLS) was run. Results showed that two-segment solution considered as the best number of heterogeneous groups that takes into

consideration the practicability, the parsimony and the manageability of each class (Sarstedt et al., 2009; Sarstedt and Mooi, 2014; Becker et al., 2015). As a second step and after running Prediction-Oriented Segmentation procedure (POS-PLS) with the two-segment solution, results showed that  $R^2$ s of FP in segment 2, composed of 26.9% of the respondents, is very high (66.6%). However,  $R^2$ s of FP in segment 1 composed of 73.1% of the respondents, became low (19.6%). The Importance-Performance Map Analysis illustrates clearly the differences within groups and helps to provide managerial implications.

Uncovering unobserved heterogeneity across distinct groups showed the need to reconsider the segmentation to understand deeply the modeling of FP. For the full data set, FP is not importantly determined by DG, KS and CSR. Thus, across the unobserved heterogeneity, FP became highly explained in one segment. However, in another segment all predictors did not play an important role in explaining FP. These results underline the need to be open to the revealed differences.

#### **4 Discussion**

This article contributes to a better understanding of the factors influencing the DG and KS of French companies and their relationship with FP. The study on the impact of DG and KS on the FP of French companies with a focus on the mediating role of CSR revealed that there is no direct impact of DG and KS on FP. However, this does not mean that DG and KS are not important to companies. It is possible that the companies of our sample have not adopted effective DG and KS. Moreover, it seems that the measurements of the constructs used in this study should be improved and adapted to the context in order to detect the significant impact of DG and KS on FP.

In addition, CSR has demonstrated a full mediation role in the relationship between DG and FP. The results showed that CSR is a crucial element that explains how DG can positively affect the FP of companies. By engaging in CSR, organizations can enhance their reputation, build trust with stakeholders, and create long-term value. This can lead to improved performance in several ways, such as increased brand loyalty, customer satisfaction, and employee engagement. CSR can also help organizations attract and retain talent, which is increasingly important in the digital age.

Thus, other studies have shown that KS can have a significant positive impact on firms' FP. For example, Chen and Hung (2010) found that KS and learning in online communities can significantly influence members' innovative behavior. Similarly, Schneider and Spieth (2013) showed that sustainability-focused business model innovation can improve FP.

The results showed that a focus on CSR strategies can significantly improve FP through the process of DG. This suggests that French companies can benefit from integrating CSR into their quality-based strategic orientation in order to fully realize the benefits of DG. Overall, this result highlights the importance of considering CSR in DG efforts in order to achieve optimal performance outcomes.

CSR can be viewed as a management practice that aims to ensure that companies consider the social and environmental impacts of their business activities. Companies that adopt CSR practices can improve their brand image and reputation, which can lead to increased customer and investor loyalty, as well as increased profitability.

Overall, CSR can act as a mediator between DG and performance by ensuring that organizations take a responsible and sustainable approach to digital transformation, which can lead to improved performance and long-term success.

## **5 Conclusion and Recommendations**

The main purpose of this research paper was designed to study the impact of DG and KS on FP through the mediating role of CSR.

The results of this study showed that DG and KS have no direct impact on FP. However, CSR played a full mediating role between DG and FP. But, some other studies confirmed that DG and CSR are important factors in improving FP (Bocken et al., 2016; Hussain et al., 2017).

On a managerial level, the study could be relevant for companies seeking to improve their performance by using DG and KS strategies, and integrating CSR practices into their daily operations (Gao et al., 2018; Singh et al., 2019). Thus, the results of this study can help managers to implement more effective decisions making processes in order to improve their company's performance.

On a theoretical level, our research contributes to the literature by highlighting the importance of CSR as a mediating factor between DG, KS, and corporate FP. By combining these three areas, the study offers an innovative and enriching

perspective to better understand the complex links between these different variables through the theory of dynamic capabilities.

Finally, at the methodological level, this study has applied a rigorous methodology by collecting and analyzing data of representative sample. The statistical analysis approach used, verified the validity and reliability of the data which implies therefore rigorous and sound analysis.

In parallel, it is important to note that the results cannot be generalized. Further research works are needed to fully understand the role of DG and KS in the FP in French context. In addition, it is important to consider other factors such as organizational culture, leadership, and employee skills when analyzing the impact of DG and KS on FP.

### Abstract

The objective of this study is to determine the impact of the COVID-19 pandemic in Romania and whether the government's interventions and imposed policy measures helped to maintain economic equilibrium.

The crisis generated by the coronavirus pandemic has compelled the authorities to take measures to aid first the health system and then the national economy. During the lockdown, production ceased and economic activities were suspended, resulting in a fall in the volume of trade.

In this context, the paper's goal is to determine whether the applied measures were beneficial for the economic system and whether Romania is on the path towards recovery, but it will also analyse if it is necessary to establish a policy framework to prevent potential future exogenous shocks and what regulations could be adopted for a sustainable recovery that would help the economy, providing support for the future complementary approaches to monetary and fiscal policies.

The empirical analysis has been carried out for the period 2020:1 to 2022:9 on monthly frequency data for Romania. The model employed is a BVAR (Bayesian Vector Autoregression) that provides a simple yet effective way of modelling interactions between macroeconomic variables. In order to analyse the consequences of the mix of implemented policies, we examined and considered as exogenous shocks the NBR's monetary policy rate, the evolution of energy product prices, and the number of new COVID-19 cases.

The crisis caused by the COVID-19 is perceived as a health crisis that necessitates adjustments to public, fiscal, and monetary policies. Although the costs may be high at the moment, the changes will be effective in the future and may result in economic consolidation and a higher level of economic resilience for the Romanian market.

**Keywords** – COVID-19, resilience, public policy, monetary policy

**Paper type** – Academic Research Paper

## **1 Introduction**

As the epidemic represented an exceptional exogenous shock, the public, fiscal, and monetary policies implemented by the various European governments at that time were designed to stabilize the economy and prevent a collapse of the financial and commercial markets. However, once the medical impasse is overcome, and because the economies cannot be artificially aided, the mix of policies used during the pandemic, but especially the lockdown, must be reshaped and downgraded, because an economic environment with low, almost negative interest rates, low inflation, and high sovereign debt is not sustainable over the long term, with most crisis policies being used only in the short term to counteract the effects of an exogenous shock.

Due to the high level of uncertainty caused by the coronavirus, as well as its rapid spread, governments were forced to adopt the lockdown policy, which, as beneficial as it was from a medical perspective because it helped to prevent the disease's spread, was as harming to the economy by stopping the evolution of aggregate demand and slowing down production, implicitly decreasing aggregate supply, with the initial effect being an increase in unemployment and a disproportionate impact on small companies.

Even though the implemented policies during the pandemic provided immediate assistance to households, businesses, and economies in general, the effects of these actions on economic activity, unemployment, businesses, and economic confidence remains a central topic of research, as their long-term economic consequences are of capital importance for the near future. In the situation of Romania, where fiscal space is constrained, there is a possibility that the adopted policies would harm the economy in the long run if they are not closely monitored.

The rise of the covid pandemic had a favourable impact on the economy because it accelerated the implementation of existing technological procedures and promoted the development of new ones. The economy is constantly changing, and the pandemic has contributed to a road towards a "new reality". But the economic recovery is insufficient to repair the pandemic's devastation.

An initial effect of the imposed limits is the rise in public debt, but this has experienced a strong growth trend in the majority of countries due to their efforts to support the economy as a whole. However, even if a rapid return to the pre-pandemic scenario is envisaged, governments must be prudent and not greedy regarding the payment of public debt. An expansionist fiscal policy focused on investments is preferable, because at the moment the economy needs impulses to put itself on the normal trajectory and subsequently grow sustainably, moving towards a new era.

## **2 Literature Review**

Even if some of the government's measures are costly, they must be phased out because a sudden withdrawal of the aid during the pandemic could undermine the entire economic recovery, which is undesirable in an uncertain economic environment.

Fiscal incentives will not have immediate benefits if they are implemented late and the economic crisis is more intense. The efficiency of fiscal policy is dependent not only on the influence of the recession on consumer behaviour, but also on the level of public debt in relation to savings (Marinas, 2010). Public debt has a negative effect on economic growth and is greater in emerging economies due to their limited financing capability and underdeveloped markets.

Although the 2007 financial crisis and the coronavirus pandemic are distinct, they are frequently compared from the standpoint of the mix of monetary and fiscal measures that must be adopted during such crises (Jones, 2022). The author stated that the strongest economies in 2007 waited to take action at the earliest symptoms of the crisis, delaying economic recovery to the point that several nations were still recovering from the financial crisis at the start of the COVID-19 pandemic.

Perspectives are still mixed in the literature concerning whether or not monetary and fiscal policies complement one another, with most economists arguing that monetary policy is more effective than fiscal policy, and the most effective framework is represented by monetary domination and fiscal austerity.

However, the onset of the crisis generated by coronavirus altered the perspectives of numerous economists. When the European leaders decided to implement the lockdown to stop the spread of the virus, they were aware that it would shut down important sectors of economic activity, depress prices and

burden government borrowing, but they were also convinced that monetary policy alone is insufficient to stabilize the economy, and that a new fiscal policy approach is required.

The beginning of the COVID-19 pandemic was one of those rare moments in which consensus among policymakers was relatively easy to achieve (Ciufuentes-Faura, 2021). Economists may have had different viewpoints regarding the effects of a long-term disruption to the supply chain or regarding the necessity to implement certain measures, but they could not dispute the fact that the impact of such lockdowns regardless of whether they occurred domestically or in trade key partner countries would have significant implications for output, employment, and prices.

The pandemic is unprecedented in the current economic context. No economist has ever been subjected to the type of global restrictions applied by authorities to stop the spread of the virus, thus none of them can predict how the global economy will act once social isolation restraints are lifted (Chen et al., 2020). This new circumstance also showed that monetary policy can only succeed by adapting to the new challenges the global economy will face.

The evolution of tax revenue in the member states of the European Union was one of the central topics during the assessment of the policies during pandemic (Spulbar et al., 2022). Romania is one of the countries with the lowest rate of public revenue collection and formation. Even if this suggests an increase in the country's vulnerability, it is indisputable that the coronavirus outbreak had hit all European nations, which have witnessed an economic downturn since the beginning of 2020.

Before the outbreak of the coronavirus pandemic, Romania was in a sensitive fiscal position (Constantin, 2021). The crisis caused by the coronavirus epidemic exacerbated Romania's fiscal deficit and compelled the government to take measures that could have led to an escalation of the deficit. Despite the existing limited manoeuvring space, the government adopted certain measures, such as: the program for supporting small and medium-sized businesses - SME Invest Romania; technical unemployment benefit for the period of suspension of the employment contract; allowance for authorized natural persons or other professionals who do not have the condition of employers and interrupt their activity; and allowance for parents staying at home with children during the lockdown.

Despite the fact that, during the pandemic, economic forecasts were not very optimistic from the perspective of a sustainable return and a part of the literature claims that the behaviour of agents has changed permanently, recent studies have demonstrated that the majority of economies have outperformed expectations, and the different behaviour of agents can be viewed as positive and more balanced from the perspective of the transition to a less polluted environment.

Moreover, the COVID-19 effects on electricity consumption, economic growth, and economic agents' behaviour were examined due to their importance (Soava G. et al., 2021). The pandemic's long-term impacts on economic growth and energy consumption, one of the main pillars of sustainable economic development, may require government actions to combat the pandemic and economic collapse. The results showed that economic structure and openness affect resource availability. Government policies also affect non-household energy consumption, which boosts economic growth. Emerging countries, particularly Romania, were less energy-affected by the COVID-19 pandemic.

In Romania, the service sector collapse caused energy consumption to drop, but in more industrialized countries like Germany, Italy, and France, the impact was far less. Despite governments' efforts to manage the crisis, which range from social distancing, restricting transportation, and shutting down the economy, countries still experiencing pandemic outbreaks must develop effective policies to manage it.

Another interesting fact is that the pandemic health crisis harmed Romanian workers' mental health, not only the unemployment rate (Radulescu et al., 2020). In some articles, productivity growth through technological acceleration, mechanization, and automation of company processes, which were exacerbated by the pandemic, is noted and implied to have a positive impact on the labour market.

In the paper conducted at the International Monetary Fund, the authors assumed that the effect of fiscal policy announcements on economic activity across countries is relevant in determining the significance of the mix of policies implemented during the coronavirus pandemic (Deb P. et al., 2021). The results indicated that fiscal policy announcements have an effect on economic activity, particularly in the improvement of industrial production, boosts confidence of investors, and reduce the unemployment.

In another study, the authors claimed that the economic crisis caused by the coronavirus compelled nations to first adopt measures to improve public health issues, and then employ fiscal and monetary policies that they had not used previously (Efraim and Tzur-Ilan, 2020). After only one month of lockdown, macroeconomic forecasts indicated a 3% contraction of the global economy, and if the governmental measures to aid economic agents had not been implemented, it was likely that the shocks suffered by various economic sectors would have affected even more economies on a global scale. The results of the authors stated that the level of fiscal expenditures takes into account the size and development of nations, a fact that is also reflected in the high cost of anti-COVID-19 measures, which can reach up to 7 percent of GDP in developed countries and as little as 3 percent of GDP in emerging economies.

Unfortunately, the fiscal spending, including business assistance, helped "zombie" enterprises thrive and all of this because of a poorly targeted support policy. In addition, in the absence of fiscal aid measures for companies, their contraction and failure would have been even worse (Gourinchas et al., 2021). However, the return to the post-lockdown phase must be handled with caution and in a responsible way so as not to hasten the transition. In the context of increased leverage for both the public and private sectors, it would be necessary to pursue macroprudential, and monetary and fiscal policies that will be crucial for stabilizing the global economy.

As this extraordinary event was viewed as a combination of negative supply shock and supply disruption that exerted pressure on all economic sectors, the investigation's relevance lies in the change in the behaviour of economic agents during the pandemic (Cavallo A., 2020). The author asserts that inflation during the lockdown did not accurately reflect reality, with low-income households suffering the most while the wealthy experienced a slight deflation, resulting in a sharp spike in inflation inequality.

An interesting method is outlined in another research on public policy implemented by Sweden during the first year of the pandemic crisis (Krueger et al., 2020). The "Swedish solution" paradigm is characterized as allowing the virus to run its course without government intervention and allowing households to adjust their consumption behaviour on their own terms.

Additionally, a significant decrease in aggregate spending and an increase in aggregate savings were not unique in the United States (Bachas et. al, 2020). The decline in spending was attributable to job losses and social distancing

regulations, as well as the fact that households were required to remain at home with the exception of grocery shopping trips. Almost certainly, the direct consequences of the COVID-19 pandemic were the key element influencing overall declines in spending. In conclusion, the experts advised policymakers not to hasten the economic recovery, since nearly all consumption has returned mainly to fiscal incentives and support, and the abrupt elimination could generate a shock at the level of the whole economy.

A general problem not only during the lockdown in each country, but also during the period when there were restrictions was generated by the production chains and the inclination of some nations to try to produce domestically what they needed to use in order to replace some inputs which were difficult to reach in the certain countries. In the research of the authors (Bonadio et al., 2021), it was emphasized that the global economy is interconnected via multiple channels, not just distribution channels, and that transit restrictions imposed by each state have impacted economic sectors globally.

### **3 Empirical analysis, data estimation and results**

#### ***3.1 Empirical model***

The econometric analysis of the paper includes one empirical model represented by a Bayesian Autoregressive Vector (BVAR) model implemented to provide an individual analysis of the examined country and to illustrate how macroeconomic variables respond to an exogenous pandemic shock and whether the policy shock from the adopted government policies affected economic growth.

The Bayesian Autoregressive Vector was selected due to the benefits of imposing a priori beliefs and the absence of a requirement for stationary data in order to prevent the loss of crucial data and information from the time series (Litterman, 1986).

The study focuses on Romania, an emerging country and the analysis has been carried out for the period 2020:1 to 2022:9.

The variables under observation were chosen in respect with the theoretical economic criterion and following certain articles (Pinshi, 2020; Apergis and Apergis, 2021). The variables taken into consideration are represented by inflation rate, ROBOR rate at 3 months, industrial production, unemployment rate,

monetary policy rate implemented by NBR, labour productivity, nominal exchange rate, quotations of energy products, and the number of new COVID-19 cases.

The Bayesian technique allows the VAR models to use non-stationary data in order not to lose the information that can be neglected due to transformation into stationary data series. All variables enter the model in levels. The entire estimation procedure was carried out by employing the BEAR Toolbox (Dieppe et al., 2016) in MATLAB 2020.

Starting from the VAR model (Lutkepohl, 2005), we decided to treat as exogenous variables the quotations of energy products, the number of new COVID-19 cases and the monetary policy implemented by the National Bank of Romania in order to explain the significant contribution of the unexpectedly problems of changes that arise due to the coronavirus pandemic within the implemented model.

The Bayesian VAR methodology combines data and a priori model parameter information to create a distribution that accounts for both kinds of information (Koop, 2003). Bayesian econometrics treats each parameter as a random variable with a distribution probability.

Because the choice of a priori distribution is an important issue in the estimation of the model, in this research the Minnesota distribution was chosen.

Furthermore, the choice of the best Bayesian VAR model was made after computing the Bayes Factor and according to the model's stability characteristic. In the model it was included only one lag as specified by the Bayes Factor. Also, the posterior distribution is derived by Gibbs sampling with a total number of 5,000 iterations and a burn-in sample of 1,000 iterations.

The identification of shocks is carried out via Cholesky decomposition.

There were implemented the impulse-response function, the historical decomposition and the forecast error variance decomposition for the purpose of examining the pandemic effects over the emerging economy of Romania.

In the next section, we present the most important results of the empirical analysis and compare them to prior studies. In certain situations, the observed results were inconclusive or even statistically insignificant; hence, only the most significant results will be presented.

### *3.1.1 Impulse-Response Functions*

The impulse-response functions are used to characterize the response of one variable to innovations in another variable within a system, while the rest of the shocks are zero. Impulse-response functions were developed to provide a better explanation of the evolution of macroeconomic variables in response to an external shock.

The inflation rate responds to a shock in itself by decreasing, reaching a statistically significant bottom after 15 periods. Inflation reduces industrial production and productivity, but both dynamics are unfavourable and reach their minimum during the first ten months of the analysed period.

Contrary to expectations, an innovation shock to the unemployment rate does not affect inflation or the NEER.

Industrial production has shown a limited reaction to labour productivity shocks, declining since the first months examined. The other variables are not statistically significant and sometimes do not change.

The macroeconomy factors do not correlate as promptly with changes in the ROBOR 3M rate although its huge impact on the financial market. In the current model, an innovation shock in the ROBOR 3M rate does not affect unemployment, inflation, industrial production, productivity, or NEER.

Such as the ROBOR 3M rate, an innovation shock in the nominal effective exchange rate does not modify the other model variables. This can also be explained by the fact that NEER is an indicator that only capture relative value.

### *3.1.2 Forecast Error Variance Decomposition*

The forecast error variance decomposition aims to highlight the contribution of each shock to the volatility of a certain variable, and the percentage size of the shock will determine the magnitude of the changes in each variable. The shocks that were taken into consideration are represented by the evolution of energy prices, increasing monetary policy rate and the evolution of new COVID-19 cases, all of this occurred within the period under examination.

Table 1. Forecast Error Variance Decomposition

<b>FEVD</b>	<b>The evolution of energy prices</b>	<b>Monetary policy</b>	<b>Evolution of new COVID-19</b>
Inflation rate	38%	35%	10.8%
Industrial production	20.3%	27.3%	7.7%
Unemployment	34.8%	31.2%	7.9%
Productivity	21.3%	26.6%	7.6%
ROBOR 3M	38.8%	30.1%	10.2%
NEER	25.8%	30.2%	11.6%

Source: own calculations

Inflation is a variable that is highly impacted by all analysed shocks. The highest percentage of contribution to inflation's volatility is represented by the shock given by the evolution of energy prices that accounts for 38% of its variance, followed by the monetary policy shock that accounts for 35%, and the evolution of new covid cases contributes with only 10.8%.

At the opposite pole, the variables whose volatility is less affected by the studied shocks are industrial production and labour productivity. Even if this is noticeable, in the case of industrial production, the dynamics of energy price growth accounts for 20.3% of this variable's volatility, while the shock generated by new COVID-19 illnesses contributes only 7.7% to its volatility.

To a significant extent, the unemployment rate is also influenced by the monetary policy shock, even though a current pattern toward the formation of the inflation-wage spiral may be noticed as a result of rising prices and the decline in the purchasing power of individuals. In the case of the unemployment rate, the monetary policy shock accounts for 31.2% of its fluctuations, while the shock that was given by additional covid cases only explains 7.9% of its variation.

It appears that the adverse evolution caused by the increase in energy prices contributed with 38.8% to the variation in the ROBOR 3M rate and with 25.0% to the volatility of the NEER. Nominal effective exchange rate is an indicator for the country's competitiveness that characterizes the interaction with its trade partners, and in our empirical model, its volatility appears to be influenced by the internal monetary policy.

As a brief overview, we can state that, despite the fact that this is a controversial topic and the majority of analysts have linked a prospective economic contraction to this shock, the evolution of the appearance of new COVID-19 cases contributes with the lowest percentages to the volatility of the

analysed variables, whereas the shock given by the evolution of energy products' prices contributes with the highest percentages to the variation of the variables.

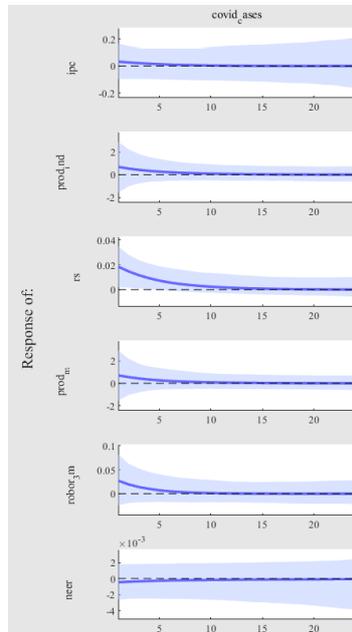

### *3.1.3 Exogenous Impulse-Response Function*

As a quick outline, the exogenous shocks in this empirical model are represented by the appearance of new cases of COVID-19 disease, the monetary policy conducted by the National Bank of Romania, and the rise in energy products' prices, in order to be able to analyse a complex framework. The variables' responses can be seen in the following graphs.

Although the monetary policy implemented by the National Bank of Romania is established within the country and it cannot be said that it could indirectly influence the macroeconomic variables that are considered in this analysis, we assumed the monetary policy shock to be exogenous because the COVID-19 pandemic occurred unexpectedly at a time when the monetary policy rate had remained constant at 2.5% since 2018 and had not been changed for nearly two years. The COVID-19 pandemic compelled central banks to implement a prudential strategy to help the whole economy during the quarantine period.

Through the exogenous shock represented by the appearance of new cases of COVID-19, we wanted to capture the government's public policy regarding the isolation of the citizens, the lockdown since the beginning of the pandemic, and the imposed social distancing. The health crisis could not have been predicted, and the financial factors rapidly responded to its intensification, making it difficult to control the spread of the virus until the vaccine became available.

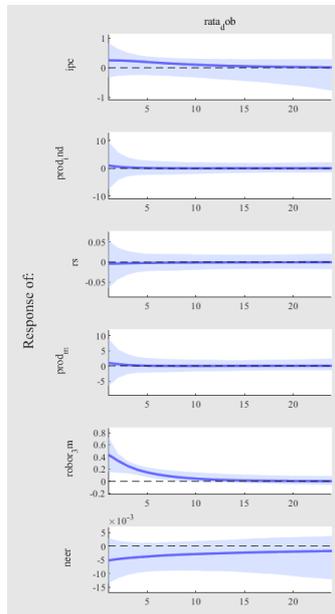

The war caused by Russia in Ukraine at the beginning of 2022 overlapped with a fragility of the economy that was preparing for the transition to green energy, and the sanctions imposed on Russia by the European Union and the purchase of oil from sources other than Russia led to a rapid increase in the prices of energy products, oil and natural gas. In the current model, the shock generated by the increase in energy prices is considered exogenous for the same reason of the impossibility of preventing the ongoing war.

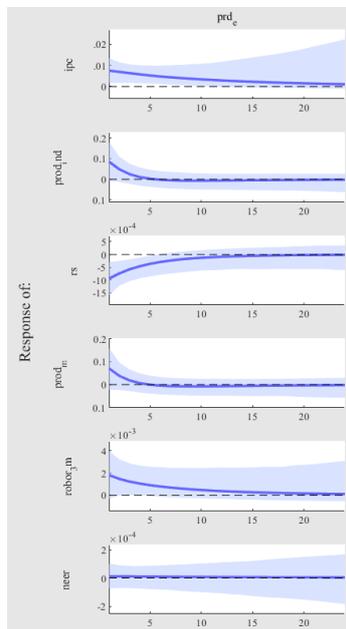

Graph 1. Impulse-Response function to the appearance of new cases of COVID-19  
Source: own implementation in MATLAB

The only variables in the empirical model that respond to a shock represented by the emergence of new coronavirus disease cases are the unemployment rate and the ROBOR 3M rate. The unemployment rate exhibits a positive trend, with a constant decline to 0.73% and a statistically significant minimum after 5 months. The same positive dynamic is also observed in the evolution of the ROBOR 3M rate.

With a monetary policy shock defined by a sudden change in its observed path, the ROBOR 3M rate maintains its positive dynamic, but declines by up to 5.47 percent after nine months. Contrary to expectations, the inflation rate does not respond to an adjustment in monetary policy. In contrast to the response of the ROBOR 3M interbank rate, the nominal effective exchange rate exhibits a negative trend but with a continuous increase over the analysed 24 months, with no statistically significant response.

Graph 2. Impulse-Response function to the monetary policy  
 Source: own implementation in MATLAB

Graph 3. Impulse-Response function to the rise in energy products' prices  
 Source: own implementation in MATLAB

As expected, the energy shock strongly influences the variables of the model. The responses of industrial production and labour productivity show a downward trend since the first studied months. With a shock generated by an increase in the prices of energy products, the dynamics of the unemployment rate reaches a minimum level from the first period, the negative dynamics persisting later throughout the analysed period.

#### *3.1.4 Historical Decomposition*

The historical decomposition of inflation rate reveals a downward trend until the end of the first quarter of 2022, which is supported to a very considerable extent by the unemployment rate. Labor productivity also contributes to this decrease, which recorded low levels at the beginning of the epidemic. NEER indicates a countercyclical role in moderating the decline in inflation, although the impact is minimal compared to the widespread impact of the pandemic at that time. At the end of the examined period, the trend of inflation shifts and enters an upward trajectory, which is influenced by the ROBOR 3M interbank rate, but also because of new cases of covid. Even if the vaccine helped in preventing the spread of the virus and the formation of new mild forms of the disease, it appears that both the war in Ukraine and the coronavirus pandemic have negatively contributed to an accelerated growth in the inflation rate.

Moving on, labor productivity cyclically contributed to the reduction in industrial production, which at the beginning of the outbreak was put under the sign of questioning due to the implementation of technical unemployment and the lockdown until May. Later, the decline in energy and fuel prices, followed by a time in which the economies stagnated, might contribute to a rise in industrial production, but only temporarily, as the rapid reopening of industries and businesses caused blockages in the production chain.

Moreover, NEER contributed unexpectedly and cyclically to the decline in labor productivity. Even if the reopening of borders resulted in a rapid return of economic development, it appears that productivity has not returned to pre-pandemic levels. In certain businesses, such as IT, productivity is deemed to be higher, whereas in industries requiring unskilled labor, productivity has fallen below its pre-pandemic level.

As anticipated and supported by economic literature, the adopted monetary policy rate supported the dynamics of the ROBOR 3M rate. Additionally, the

unemployment rate contributed cyclically to the decreasing trend during the first two years of the pandemic.

The historical decomposition of the unemployment rate indicates a decreasing trend through the second quarter of 2020, which is strongly supported by the ROBOR 3M rate. Industrial production implies a countercyclical role in the rise of the unemployment rate, but since the second quarter of 2021, monetary policy and productivity support a downward path. The fall in the unemployment rate is largely attributable to the ROBOR 3M interbank rate and the NBR's monetary policy. At the end of the analyzed period, the unemployment rate trend appears to remain steady.

Even if NEER is a relative value measure and hence cannot definitively indicate whether a currency is strong in real terms, it appears that the number of new covid cases has contributed to its upward slope over the studied period. Additionally, in 2022, industrial production contributed cyclically to the value increase. From the perspective of the evolution of energy prices, a countercyclical tendency cannot be noticed until the second quarter of 2021.

#### **4 Conclusions**

The coronavirus pandemic is regarded as an exceptional exogenous shock that, at the time of its emergence, triggered panic among the population. The nations had never before experienced such events, and the uncertainty caused by the rapid spread of the virus compelled authorities to take unprecedented action.

There were still good parts of the pandemic, such as the acceleration of digital transformation, the change of consumption habits and production patterns, which in the long term will be beneficial for the economy as a whole.

Although the lockdown period was viewed as beneficial at the time, particularly from the perspective of the health system, the social distancing restrictions led to a halt in demand and a decrease in production.

The empirical model reflected the fact that the inflation rate does not respond to changes in monetary policy, while the ROBOR 3M does. As a result of a disruption caused by the emergence of new cases of COVID-19, the unemployment rate and labor productivity fall in the first months analyzed. Also, industrial production and labor productivity decline significantly in response to an increase in energy product prices. In addition, the inflation rate is substantially affected by all shocks, with a large proportion of inflation volatility explained by

the evolution of energy prices, while industrial production and labor productivity are less impacted.

Our findings illustrate the limited effectiveness of the policies implemented during the pandemic and demonstrate how challenging it is to manage exogenous disturbances. Given the short period analyzed, it is reasonable to infer that the adopted policies were less effective in the short term, but that their effectiveness improved over the medium and long term.

As a conclusion, we can say that from a health point of view, social distancing and the imposed lockdown were effective, but they led to decreases in labor productivity, stoppage of production and limitation of demand. In addition, we believe that it is necessary to implement public policies in order to accomplish economic resilience, make investments in health, and develop the economy so that future health crises can be more easily managed.

### Abstract

The study of a country's environmental sustainability is an important topic because it allows an understanding of the causes and possible solutions for protecting the environment, human health, and natural resources. Among the drivers of sustainable development, there is also the national culture of the countries, which can play a significant role in the implementation of policies aimed at environmental sustainability and which has been the subject of several scientific studies. This paper is aimed at studying how national culture impacts a country's sustainability performance, starting from Hofstede's cultural dimensions (power distance, individualism, masculinity, uncertainty avoidance, long-term orientation, indulgence).

Unlike previous scientific literature, this work considers religiosity as one of the cultural variables that can impact a country's environmental performance. In particular, the two most widespread religions worldwide, Christianity and Islam, were taken into consideration. To evaluate the environmental performance of countries, we utilized the Environmental Performance Index (EPI), since it provides a data-based overview of the status of sustainability worldwide, using performance indicators related to climate change, environmental health, and ecosystem vitality. Additionally, our analysis incorporated socio-economic variables as normalizing factors, including gross domestic product per capita, employment rate, and educational level.

Our research investigates 96 countries across the globe, with 1,056 country-year observations taken into consideration for the period between 2011 and 2021. The study employs a dynamic panel data model that involves a two-step system-GMM. Our results suggest a strong relationship between cultural dimension and EPI.

## 1 Introduction

The recent Sixth Assessment Report of the IPCC (Intergovernmental Panel on Climate Change) highlights the persistence of environmental issues such as the unsustainable use of energy and land, the continuous increase in greenhouse gas emissions, and how climate change is responsible for atmospheric phenomena extremes, such as floods, droughts, and hurricanes (IPCC, 2023). There are several differences worldwide in the fight against climate change. Some countries have adopted ambitious policies and measures to reduce greenhouse gas emissions and promote the transition to a low-carbon economy, while others have made more limited progress.

Previous studies have shown that a country's environmental performance can be influenced by various factors, such as economic development, allowing more significant financial and technological resources to adopt mitigation measures for climate change (Antoci, 2009; Grossman and Krueger, 1995; Mukherjee and Chakraborty, 2013), as well as its social capital and human development (Grafton and Knowles, 2004).

More recently, some authors have been interested in understanding how national culture impacts sustainability. In this regard, some research was conducted at the company level and highlighted how national culture affects managerial attitudes, beliefs, and behaviors aimed at adopting environmental management practices (Calza et al., 2016; Song et al., 2018; Thanetsunthorn, 2014). At the country level, the relationship between cultural dimensions and sustainability performance has been the subject of earlier conceptual works (Dunning and Fontanier, 2007), focused on cross-country data (Husted, 2005; Kumar et al., 2019; Parboteeah et al., 2012; Park et al., 2007) or single country data (Okolie and Okoye, 2012).

Determining the influence of culture on human behavior is not simple, as culture is a complex construct that is difficult to accurately measure. To simplify its operationalization and to allow at least some aspects of culture to be more easily applied, researchers have suggested using cultural indices, among which

the most important and used are those theorized by the Dutch anthropologist Geert Hofstede (Hofstede 1980, Hofstede 2001). This cultural model was developed from a large-scale comparison of national cultures, by reducing the complexity of culture through its split into six significant dimensions (power distance, individualism-collectivism, uncertainty avoidance, masculinity-femininity, long-term orientation, and indulgence-restraint). Although this model has some criticisms, such as the methodological assumption (the hypothesis that the national population is a homogeneous whole), it is generally considered the most comprehensive framework of national cultures and is still one of the most used in cross-cultural research.

Among the cultural variables, an important role is attributed to religion. Previous research has found that religion influences many aspects of lifestyle that affect the environment, but no studies have analyzed how it impacts the country's environmental performance. This paper attempts to fill this gap.

Religion is widely considered a cultural proxy, being a value, a social norm, and an informal institution that contains beliefs that in turn influence the attitudes of individuals (Guiso et al., 2003). Religion also helps shape legal systems (La Porta et al., 1999) and plays a key role in understanding economic growth (McCleary and Barro 2003; Guiso et al., 2006), and corporate social responsibility (Du et al., 2014; Harjoto and Rossi 2019).

For these reasons, in this study, we also include religion as a cultural variable suitable for influencing the environmental performance of a nation. To measure the environmental performance of nations, we used the Environmental Performance Index (EPI), created by the Yale Center for Environmental Law and Policy and adopted by the main literature as aligned with the Sustainable Development Goals (SDGs) of the UN Agenda 2030 and useful for assessing the country's proximity to global sustainability targets (Kumar et al., 2019; Park et al., 2007). This index provides a data-driven summary of the state of sustainability around the world, using performance indicators referring to climate change performance, environmental health, and ecosystem vitality. Additionally, in our analysis, we include socio-economic normalizers, such as GDP per capita, employment ratio, and level of education.

We investigate 96 countries around the world for 1,056 country-year observations during the period 2011-2021. The study uses a dynamic panel data model involving a two-step system-GMM (Arellano and Bond, 1991; Blundell and Bond, 1998) because it is a powerful econometric tool that captures the two

components of endogeneity, namely, that which is attributable to unobservable heterogeneity and that which is associated with simultaneity (e.g., Wooldridge, 2002, and Wintoki et al., 2012).

This paper extends the literature in at least three ways. First, we consider the relationship between a country's environmental performance and cultural dimensions including religiosity. Secondly, we use a dynamic panel two-step system-GMM (Arellano and Bond, 1991; Blundell and Bond, 1998) because it is a powerful econometric tool that captures the endogeneity issues. Finally, to the best knowledge of the authors, the sample of this work is larger both in terms of the number of countries considered and in the historical series analyzed, considering that the previous literature only carries out cross-sectional analyses, except Peng and Lin which consider only three years (Peng and Lin, 2009).

The remainder of the paper is articulated as follows: section 2 presents the theoretical background and the development of the hypotheses; Section 3 describes the dataset and methodology; Section 4 provides the results of the regression analysis, and the last section discusses our conclusions.

## **2 Literature review and hypothesis construction**

The link between national culture and environmental sustainability has been analyzed by the main literature under many aspects. Some research was conducted at the company level, proving how national culture affects sustainability beliefs and perceptions (Tata and Prasad, 2015), environmental proactivity (Calza et al., 2016), and more broadly corporate sustainability practices (Miska et al., 2018; Ogundajo et al., 2022; Song et al., 2018; Thanetsunthorn, 2014). A large body of literature has focused on the impact of national culture on different disclosure systems, showing how corporate social disclosure levels are likely to be influenced by national cultures (Orij, 2010; Romero and Fernandez-Feijoo, 2013), in particular the integrated reporting (García-Sánchez et al., 2013; Vitolla et al., 2019).

At the country level, the relationship between cultural dimensions and sustainability performance has been the subject of earlier conceptual works (Dunning and Fontanier, 2007), focused on cross-country data (Husted, 2005; Kumar et al., 2019; Parboteeah et al., 2012; Park et al., 2007) or single country data (Okolie and Okoye, 2012).

In this work, to understand how cultural antecedents impact a country's sustainability, we refer to the framework of cultural dimensions developed by the Dutch anthropologist Geert Hofstede (Hofstede, 1980; Hofstede, 2001). According to Hofstede: "culture works as the mental software for humans, playing a significant role in forming their ways of thinking, feeling, and acting" (Hofstede, 2001). Determining the influence of culture on behavior is not simple, as culture is a complex construct that is difficult to measure accurately. To simplify its operationalization, Hofstede has developed six dimensions of national culture, based on which we have developed the research hypotheses described below.

### **2.1 Power distance**

This dimension expresses the degree to which there are social inequalities among people. According to Hofstede's theory: "People in societies exhibiting with a large degree of power distance to the hierarchical order in which everybody has a place, and which needs no further justification. In societies with low power distance, people strive to equalize the distribution of power and demand."

In societies with low power distance, individuals are more likely to participate in decision-making processes and feel more involved in global issues, including environmental sustainability. Conversely, in societies with high power distance, there is a greater divide between those in power and those in subordinate roles can lead to passivity towards social initiatives and debates on environmental sustainability. This means that people in such societies may be less likely to engage in discussions or act on environmental issues, due to a perceived lack of agency or influence. Several studies support the hypothesis that there is a negative relationship between power distance and environmental sustainability (Cox et al., 2011; Husted, 2005; Park et al., 2007; Peng and Lin, 2009; Parboteeah et al., 2012; Roy and Goll, 2014). Accordingly, we suggest the following hypothesis:

*H1. Power distance is negatively related to the country's environmental sustainability.*

## **2.2 Individualism**

Hofstede defines individualism as “a preference for a loosely-knit social framework in which individuals are expected to take care of only themselves and their immediate families [...] Its opposite, collectivism, represents a preference for a tightly-knit framework in society in which individuals can expect their relatives or members of a particular in-group to look after them in exchange for unquestioning loyalty.”

Regarding the impact of this dimension on environmental sustainability, some authors argue that in collectivist cultures, individuals are more likely to cooperate toward the long-term interests of society and engage in sustainable environmental actions and policies (Park et al., 2007; Parboteeah et al., 2012). On the other hand, some authors argue that individualistic societies value personal initiatives and are better positioned to respond to environmental problems through individual environmental initiatives reinforced by pressure groups (Cox et al., 2011; Dangelico et al., 2020; Husted, 2005; Onel and Mukherjee, 2014; Peng and Lin, 2009).

From the author's point of view, individualistic societies generate a more rapid awareness of future risks and are more likely to implement sustainability initiatives through social movements that can affect government policies. Therefore, we propose the following hypotheses:

*H2. Individualism is positively related to the country's environmental sustainability.*

## **2.3 Masculinity**

According to Hofstede's theory: “the masculinity side of this dimension represents a preference in society for achievement, heroism, assertiveness, and material rewards for success. Society is more competitive. Its opposite, femininity, stands for a preference for cooperation, modesty, caring for the weak, and quality of life. Society at large is more consensus-oriented”. Masculine cultures are more focused on achievement and competitiveness and tend to prioritize growth and profit over environmental concerns (Hofstede, 2001; House et al., 2004; Park et al., 2007; Parboteeah et al., 2012). These cultures tend to ignore future risks and believe that socially responsible actions have greater costs than benefits (Cox et al., 2011; Husted, 2005). This can lead to actions that compromise the

environment in favor of individual interests. Several authors propose that there is a negative relationship between environmental actions and masculinity, as measured by various cultural profiling methods (Husted, 2005; Park et al., 2007; Parboteeah et al., 2012; Peng and Lin, 2009). Consequently, we propose the following:

*H3. Masculinity is negatively related to the country's environmental sustainability.*

#### **2.4 Uncertainty avoidance**

Hofstede states that: "the uncertainty avoidance dimension expresses the degree to which the members of a society feel uncomfortable with uncertainty and ambiguity [...] Countries exhibiting strong UAI maintain rigid codes of belief and behavior and are intolerant of unorthodox behavior and ideas. Weak UAI societies maintain a more relaxed attitude in which practice counts more than principles". Countries with high levels of risk aversion tend to have a long-term outlook and are committed to the future, willing to make sacrifices to gain future environmental benefits from sustainable actions. Moreover, the deteriorating environmental conditions could adversely affect the health of society, leading to an unknown future for citizens in high uncertainty avoidance cultures. Therefore, they may be more likely to desire stable environmental conditions to reduce their risk and maintain their sense of security.

Empirical studies by Onel and Mukherjee (2014) and Roy and Goll (2014), have shown a positive link between risk aversion and environmental sustainability, indicating that more risk-averse individuals are more likely to engage in sustainable practices. We, thus, propose the following:

*H4. Uncertainty avoidance is positively related to the country's environmental sustainability.*

#### **2.5 Long term orientation**

Hofstede affirms that: "Every society has to maintain some links with its own past while dealing with the challenges of the present and the future. Societies prioritize these two existential goals differently. Societies that score low on this dimension, for example, prefer to maintain time-honored traditions and norms while viewing societal change with suspicion. Those with a culture which scores

high, on the other hand, take a more pragmatic approach: they encourage thrift and efforts in modern education as a way to prepare for the future". Countries that prioritize short-term benefits over long-term benefits may not engage in sustainable actions unless present benefits offset the costs. In contrast, long-term-oriented societies may be more willing to incur present costs if they estimate that the future benefits of sustainable actions outweigh the costs. Therefore, the long-term orientation can lead to a greater willingness to implement environmentally sustainable practices (Dangelico et al., 2020; Roy and Goll, 2014; Parboteeah et al., 2012). Accordingly, we propose the following:

*H5. Long term orientation is positively related to the country's environmental sustainability.*

## **2.6 Indulgence**

This dimension refers to the culture's tendencies regarding the fulfillment of desires. According to Hofstede: "Indulgence stands for a society that allows relatively free gratification of basic and natural human drives related to enjoying life and having fun. Restraint stands for a society that suppresses gratification of needs and regulates it through strict social norms". So far, a single study in the scientific literature has investigated the link between indulgence and environmental performance, hypothesizing a positive relationship (Dangelico et al., 2020). We disagree with this hypothesis, as people living in indulgent countries are driven to engage in pleasurable activities, spending more money and consuming more resources. In our view, this approach to a fun-oriented life leads to the dissipation of resources, with a negative impact on the environment. Consequently, we assume the following relationship:

*H6. Indulgence is negatively related to the country's environmental sustainability.*

## **2.7 Religiosity**

Another cultural variable that could influence a country's environmental performance is religiosity. However, so far, no studies have examined this relationship, and this paper aims to fill that gap. Previous works on religiosity focus on corporate environmental practices or their level of disclosure. For instance, Terzani and Turzo (2020) find that religiosity has an impact on

environmental company disclosure, and this effect is influenced by the country's dominant religion. Other studies have examined the impact of religiosity on citizens' prosocial and sustainable behaviors, although not considering the overall effect on a country's environmental performance. In this regard, the evidence in the literature is contradictory. For example, Schwartz and Huisman (1995) found that the religiosity of devotees to the Orthodox, Catholic, Protestant, and Jewish faiths correlated positively with benevolence, tradition, and security values, and negatively with power, success, and hedonism. Saroglou et al. show that religious people highly value principles that stimulate the protection of the social and individual order (2004). In the case of the Roman Catholic Church, the pro-environmental encyclical by Pope Francis led to an increase in belief in and moralization of climate change among the faithful (Shin and Preston, 2019). In the case of the Islamic religion, the work, which is not empirical but only conceptual, of Bsoul et al. (2022) traces a close correspondence between crucial teachings in the Qur'an and the requirements for environmentally sustainable living. On the other hand, the findings of Agudelo and Cortes-Gómez (2021) prove a negative influence of religion on sustainable and prosocial behaviors.

In this paper we take into consideration the two most widespread religions in the world, Christianity and Islam, assuming the following hypotheses:

*H7. Christianity is positively related to the country's environmental sustainability.*

*H8. Islam is positively related to the country's environmental sustainability.*

### **3 Research Methodology**

To investigate the relationship between a country's environmental performance and cultural dimensions, we build a sample composed of 96 countries, observed in the 2011-2021 period, for 1,056 country-year observations. The sample was generated by considering all countries for which EPI data was obtainable. Then, countries that lacked data for all cultural dimensions were removed. The list of countries included in the sample is provided in Appendix A.

In our analysis, we utilize EPI as the dependent variable to evaluate the environmental performance of each country. The EPI is a complex and multifaceted metric that aims to provide a comprehensive evaluation of a country's environmental performance. The index is based on a wide range of indicators that cover various environmental issues. Using 40 performance

indicators across 11 issue categories, the EPI ranks countries based on climate change performance, environmental health, and ecosystem vitality. This indicator provides a gauge at a national scale of how close countries are to establishing environmental policy targets. The EPI offers a scorecard that highlights leaders and laggards in environmental performance and provides practical guidance for countries that aspire to move toward a sustainable future.

As our independent variables, we use the six cultural dimensions of Hofstede's theory: Power Distance Index (PDI), Individualism (IDV), Masculinity (MAS), Uncertainty Avoidance Index (UAI), Long-Term Orientation (LTO), Indulgence (IND). Some studies suggest including religiosity as an additional cultural proxy of countries (e.g., La Porta et al., 1999; Guiso et al., 2003; 2006). Therefore, we also include three variables to capture the national culture by considering the predominantly practiced religion in the country. Our analysis takes into consideration the two most widespread religions worldwide, which are Christianity (CHR) and Islam (ISL). We also consider other religions, such as Buddhism and Taoism, in an aggregated manner, labeled as "OTHER".

Furthermore, in this study, three socio-economic variables have been taken into consideration as control variables: income, education, and employment. An established literature has highlighted that higher levels of income and education are associated with better environmental performance in countries. For instance, De Soto (1989) argues that poorer countries are less likely to invest in scientific research or environmental enforcement, leading to lower social and institutional capacity for environmental sustainability. Gnyawali (1996) observes that people in wealthier countries are better informed and can make greater demands on corporations for socially and environmentally responsible performance. This is because higher levels of education and income in developed countries lead to greater awareness and concern for environmental issues. Wealthier individuals and organizations also have greater financial resources to invest in environmentally-friendly practices and technologies.

As a measure of economic development, we use Gross Domestic Product (GDP) per capita and Employment Rate (ER), provided by the World Bank. In particular, the employment rate, defined as the employment to population ratio, is the proportion of a country's population that is employed. Employment refers to individuals of working age who, within a brief reference period, were involved in any activity that generated goods or provided services for pay or profit. The working-age population includes individuals aged 15 and older.

As a measure of the level of education, we use Gross Enrollment Ratio (GER) for tertiary school, which is a metric used to measure the level of participation of a given population in tertiary education. It is calculated by dividing the number of students enrolled in tertiary education, regardless of age, by the total population of the age group that officially corresponds to tertiary education. The UNESCO Institute for Statistics collects data on education from official responses to its annual education survey.

Considering the above dependent, independent, and control variables, the following equation describes our baseline econometric model:

$$EPI_{i,t} = \mu_{i,t} + \alpha_1 PDI_{i,t} + \alpha_2 IDV_{i,t} + \alpha_3 MAS_{i,t} + \alpha_4 UAI_{i,t} + \alpha_5 LTO_{i,t} + \alpha_6 IND_{i,t} + \alpha_7 CHR_{i,t} + \alpha_8 ISL_{i,t} + \alpha_9 OTHER_{i,t} + \alpha_{10} GDP_{i,t} + \alpha_{11} ER_{i,t} + \alpha_{12} GER_{i,t} + \eta_t + \varepsilon_{i,t}$$

This study uses a dynamic panel data model involving a two-step system-GMM (Arellano and Bond, 1991; Blundell and Bond, 1998) because it is a powerful econometric tool that captures the two components of endogeneity, namely, that which is attributable to unobservable heterogeneity and that which is associated with simultaneity (e.g., Wooldridge, 2002, and Wintoki et al., 2012). It addresses endogeneity problems with a set of lagged explanatory variables as instruments for the explanatory variables.

Table 1 provides a summary of the variables utilized in the study, along with their definitions and data sources.

Table 1. Variable Definitions.

<b>Variables</b>	<b>Definition</b>	<b>Source</b>
<i>Dependent Variable</i>		
EPI	Environmental Performance Index (range between 0 and 100)	Yale Center for Environmental Law & Policy
<i>Independent Variables</i>		
PDI	Power Distance Index (range between 0 and 100)	Hofstede's website
IDV	Individualism (range between 0 and 100)	Hofstede's website
MAS	Masculinity (range between 0 and 100)	Hofstede's website
UAI	Uncertainty Avoidance Index (range between 0 and 100)	Hofstede's website
LTO	Long-Term Orientation (range between 0 and 100)	Hofstede's website
IVR	Indulgence (range between 0 and 100)	Hofstede's website
CHR	A dummy variable that takes 1 if the prevailing religion is Christianity; 0 otherwise	CIA World Factbook
ISL	A dummy variable that takes 1 if the prevailing	CIA World Factbook

OTHER	religion is Islam; 0 otherwise A dummy variable that takes 1 if the prevailing religion is another; 0 otherwise	CIA World Factbook
<i>Control Variables</i>		
GDP	Gross Domestic Product per capita (in logarithmic form)	World Bank
ER	The employment to population ratio (%)	World Bank
GER	Gross Enrollment Ratio (%)	World Bank

#### 4 Descriptive statistics and results

Table 2 provides the descriptive statistics of all variables. We find that EPI on average (median) is equal to 61.61 (62.33), still far from the score of 100, which represents an ideal level of environmental sustainability in all sub-indicators of this index. We also find the average of variables CHR, ISL, and OTHER are 0.73, 0.19, and 0.06, respectively. This means that most of the countries in our sample are linked to the Christian religion and only a smaller part composed of Muslims. Furthermore, only a marginal proportion of countries adhere to other religions, such as Buddhism and Taoism. Table 3 provides the correlation for all variables. To evaluate the presence of multicollinearity, the Variance Inflation Factor (VIF) has been calculated. We found no multicollinearity concerns based on the rule of thumb of VIF less than 10 (Curto and Pinto, 2011; Husted, 2005).

Table 2. Descriptive statistics.

<b>Variables</b>	<b>Mean</b>	<b>Median</b>	<b>S.D.</b>

IND								1.0000	0.2268*	0.1989*	0.3260*	-0.2768*
ER									1.0000	-0.0534*	0.1434*	-0.3092*
GDP										1.0000	0.2532*	-0.3347*
CHR											1.0000	-0.7875*
ISL												1.0000

Table 4 describes the main findings of this study. In columns 1-4, we find that PDI, IDV, MAS, and UAI are positively and significantly correlated with EPI. On the contrary, the coefficients of LTO and IND are negative and statistically significant.

Interestingly, we find that religiosity has an impact on EPI. Specifically, we find that Christianity and Islam are positive and statistically significant, while the sign of the coefficient OTHER is negative and statistically significant. This means that Hofstede's cultural dimensions and religiosity have an impact on EPI. We also find that all control variables (GDP, ER and GER) are positive and statistically significant. The results of the regression provide a partial confirmation of our hypotheses. We can accept H2, H4, H6, H7 and H8. Vice versa, we must reject hypotheses H1, H3, and H5. Overall, our results suggest that cultural dimension has an impact on a country's environmental performance around the countries.

Note: The dependent variable in all models is *EPI*. Note: (\*), (\*\*), and (\*\*\*) indicate significance levels of 10%, 5%, and 1%, respectively. Robust Standard Errors are given in parentheses. Wald test is the joint significance of the reported coefficients. Sargan is a test of the overidentifying restrictions, asymptotically distributed as  $\lambda^2$  under the null of no correlation between the instruments and the error.

## 5 Discussion and conclusions

The paper aims at investigating how national culture affects a country's sustainability performance, using Hofstede's cultural dimensions. Unlike previous research, this study also examines religiosity as a cultural variable that may influence a country's environmental performance.

Regarding the cultural dimensions, we highlight the positive and significant impact of power distance, individualism, masculinity, and uncertainty avoidance.

In a culture with a high power distance, there may be greater attention to sustainability at the national level, as there is greater respect for the authority and leadership of the country. This could result in more effective public policies for environmental protection and greater attention to environmental issues in government decision-making processes. Furthermore, in a culture with a high power distance, there may be greater cooperation between the government, organizations, and businesses to address environmental challenges. This could

promote the creation of public-private partnerships and the sharing of knowledge and resources to address environmental issues more effectively.

Individualistic societies, where there is a strong emphasis on the interests of individuals, tend to have better environmental performance compared to collectivistic societies. This could be because individualistic societies tend to have values that support the formation of environmental groups, which put pressure on governments and companies to be more environmentally responsible and raise awareness about environmental issues across society. This finding is consistent with previous studies conducted by Dangelico et al. (2020), Lahuerta-Otero and González-Bravo (2018), Onel and Mukherjee (2014), Peng and Lin (2009), and Vachon (2010).

The research results are counterintuitive regarding masculinity, showing a positive impact on EPI. This result may be due to certain characteristics associated with masculinity, such as competitiveness, assertiveness, and a focus on success that can have a positive influence on a country's environmental performance. For instance, competitiveness could be used to promote sustainability and environmental responsibility among companies by rewarding those that adopt sustainable environmental practices. Assertiveness could be used to promote more stringent environmental policies and ensure compliance with environmental regulations. Additionally, a focus on success could be used to promote technological innovation and the development of clean technologies.

The expected positive impact of uncertainty avoidance is due because countries that have a high level of aversion to risk often have a forward-thinking perspective and are dedicated to investing in the future. They are willing to make sacrifices in the present to reap environmental benefits in the long term through sustainable actions. This finding is in line with some previous studies (Onel and Mukherjee, 2014; Roy and Goll, 2014).

We also find that religiosity is another meaningful cultural variable to explain the country's sustainability performance. Research findings demonstrate a positive impact of Christianity. This religion can have a positive influence on individual and collective environmental behavior, thus promoting a country's environmental performance. In fact, Christian ethics promote social justice, which includes the responsibility of taking care of other human beings and future generations. The influence of Islam on a country's environmental performance is also positive. Islam, through the concept of Khalifa (the "steward" or "protector" of the Earth), could promote greater individual and collective environmental

responsibility among its faithfuls, thus contributing to improving a country's environmental performance. In fact, some majority Muslim countries have already adopted strict environmental policies and laws, such as the introduction of protected areas or the promotion of clean technologies.

Finally, the importance of religiosity as a factor that influences a country's environmental performance cannot be ignored. Religions can provide an ethical framework that promotes responsibility towards the environment and humanity, and can influence individual and collective behavior, fostering the adoption of sustainable policies and technologies.

### Abstract

Recently, the positive role of digitalization capabilities in supporting organizational resilience has been stated, but there is still little empirical research focusing on how this relationship happens in practice.

This study aims to explore how digitalization capabilities can support organizational resilience through a qualitative approach. A single explanatory case study has been conducted two years after the COVID-19 pandemic in a big international company operating in the jewellery & fashion industry to identify the key practices adopted and the main digitalization capabilities developed during the emergency period.

Interesting solutions, which helped the company in facing the emergency and seizing new opportunities through digitalization, emerged from the results and include, but are not limited to: the usage of AI and automation in operations management and the introduction of a Digital Innovation Department, which significantly redesigned the organizational structure and the strategic direction.

**Keywords** – Digital transformation, Organizational resilience, Digitalization capabilities

**Paper type** – Academic Research Paper

## 1 Introduction

In recent decades, globalization has heavily shaped the transformations of markets, also through the development of technical, technological, and social innovations. As a matter of facts, in today's reality digitalization and digital transformation play a pivotal role in driving companies' strategies, especially if characterized by high levels of internationalization.

Specifically, digital transformation refers to the adoption of digital technologies to innovate business processes and models and to seize value creation opportunities (Kohtamäki et al., 2019). With the advent of COVID-19 pandemic, the digital transformation process of almost all companies experienced a sudden acceleration (Guryanova et al., 2021). Indeed, even if the digital transformation effort was already underway before the start of the pandemic, the latter has generated an urgent need to expand the adoption of digital tools and solutions in almost every organizational area (Rovinskaya, 2021).

The complex and turbulent context, generated by the pandemic outburst, threatened not only the success but also the stability of companies themselves, forced to pursue both innovation and survival at once. From this point of view, resilience assumes a fundamental importance, given its most common definition as the ability to resist and react to a shock and to recover after it has occurred (Carvalho et al., 2012).

Furthermore, it can be said that during the pandemic period, resilience witnessed an evolution in its key concept and characteristics, shifting towards a more complex and dynamic nature, depending on the context, and characterizing the interactions between individuals, organizations, and the surrounding environment (Kaye-Kauderer et al., 2021).

From the above considerations emerges how imperative it has been for organizations to invest in solutions that could address competitiveness while ensuring the sustainability of business over time, in a context demanding higher levels of digitalization and interconnection.

As already reported in academic literature, digitalization capabilities can represent a valid answer to these new and multi-faceted organizational issues that have emerged in the last years (Annarelli & Palombi, 2021; Dubey et al., 2023; Khlystova et al., 2022; Marshall et al., 2023; Robertson et al., 2022).

By definition, digitalization capabilities represent a set of solutions that allow firms to combine digital assets and business resources, while leveraging digital

networks (Annarelli et al., 2021), with the aim of supporting and fostering the competitiveness of firms. As a foundation of this research, we claim that these attributes (i.e., combination of digital assets and leverage of digital networks) can also support the development of organizational resilience.

Therefore, the aim of our research is to explore how digitalization capabilities support organizational resilience, by conducting a single explanatory case study in the luxury industry. We chose this specific industry since it has been one of the most impacted by the pandemic situation, especially for what concerns the need to reconfigure and reshape business models and market channels (Achille & Zipser, 2020).

The study is structured as follows. Section 2 contains the theoretical background and provides an overview of the concepts of digitalization capabilities, organizational resilience, and the relationships between the two; section 3 describes the adopted methodology, section 4 the qualitative results and, finally, section 5 provides discussion and conclusions.

## **2 Theoretical background**

### ***2.1 Digitalization Capabilities***

Digitalization capabilities have been defined as “organizational capabilities that allow firms to pervasively combine digital assets and business resources, and leverage digital networks, to innovate products, services and processes for organizational learning and customer value creation, and manage innovation for ensuring sustained competitive advantage” (Annarelli et al., 2021, p. 8).

These capabilities have recently acquired increasing attention for their significant role in enabling value co-creation with customers (Lenka et al., 2017), in integrating resources as a key link to open innovation (Wu et al., 2022), in enhancing digital export (Elia et al., 2021) and in providing a subsequent commercialization of data and a prolific interaction with sales and marketing functions (Ritter & Pedersen, 2020).

Moreover, capitalizing agility and operational adjustment agility through digitalization capabilities have been recognized as essential requirements to survive in the COVID-19 pandemic period (Li et al., 2022).

## **2.2 Organizational Resilience**

Although it is commonly recognized that there is no unique definition and index to describe the multi-perspective nature of organizational resilience, research on this topic from a strategic point of view, mainly concerned how ensuring firms not just survival but successful growth, alongside a competitive advantage in turbulent times (Carvalho et al., 2012; Hillmann, 2021).

Organizational resilience has been defined as the organizational ability to face disruption or unexpected events through strategic and operational management, pursued by a static and dynamic approach (Annarelli & Nonino, 2016). This allowed for an improvement of firm performance by enhancing organizational learning through the promotion of practices such as: experimentation, risk-taking, interaction with the environment, and participative decision-making (Rodríguez-Sánchez et al., 2021).

## **2.3 Digitalization capabilities and organizational resilience**

Recent studies, fostered by the pandemic emergency, conceptualized an important role of digitalization capabilities in the development of organizational resilience in different contexts. For instance, digitalization capabilities were associated with better organizational resilience in creative firms (Khlystova et al., 2022) and in SMEs (Robertson et al., 2022). Further, they were acknowledged to enhance other forms of resilience that concur with organizational resilience such as supply chain resilience (Dubey et al., 2023), cyber resilience (Annarelli & Palombi, 2021), and disaster resilience (Marshall et al., 2023).

However, existing research on digitalization capabilities and organizational resilience is based mainly on conceptual and review studies, leading to a lack of understanding about the mechanisms that enhance this relationship. This suggests the need for an empirical exploration on how digitalization capabilities can actually support organizational resilience.

## **3 Methodology**

We adopted the case study methodology to consider the complex interrelation of variables characterizing the interrelationship between the push toward organizational resilience and digitalization capabilities. The case study is the preferred method to investigate an empirical topic by following a set of pre-

specified rules and procedures; it allows a holistic and contextualized analysis, properly suited for exploratory research purposes, because it allows the identification of crucial variables while exploring a given phenomenon. This research employed a single case study design because it allows an in-depth examination of the chosen phenomenon through a single informative case (Eisenhardt, 1989; Yin, 1984).

For this study, we chose an Italian company operating in the fashion luxury industry: jewellery, watches, leather goods but also accessories, perfumes, and luxury hotels. This company is a symbol of undisputed excellence, and it is a large company with high levels of internationalization. Furthermore, for about ten years it has belonged to one of the best-known groups in the industry, which is the owner of over seventy globally successful brands.

The case study has been designed to ensure a high quality of research and methodological rigor. In order to reduce possible biases, and maximize validity and reliability, the objective of the research was to diversify data collection methods and sources (Eisenhardt, 1989).

### **3.1 Data collection**

We gathered data from primary (i.e., semi-structured interviews) and secondary sources (i.e., reports and archival data) which allowed us to understand how digital transformation occurred for the company under investigation, and to deepen the role played by digitalization capabilities. The process of data collection required about 2 months and involved mainly interviews with nine key informants. The key informants' profiles are detailed in the table below according to the order in which the interviews were conducted.

The sample consists of nine respondents who belong to different areas of the company and, sometimes, to different hierarchical positions. Mostly these are high-level managers, but there are also junior profiles who, however, have a broad perspective of the company.

Table 1. List of interviewed informants

	Key Informant
KI_1	Inventory Controller
KI_2	Events Coordination Senior Manager
KI_3	Logistics Specialist
KI_4	High Jewellery Logistics Manager
KI_5	Innovation and Transformation Director
KI_6	Innovation and Transformation Manager
KI_7	Innovation and Transformation Specialist
KI_8	High Jewellery Logistic Specialist
KI_9	Budget and Reporting Analyst

### 3.2 Interview protocol

The interview consists of nineteen open-ended questions, based on the work of Annarelli et al., (2021), that allowed to conduct an assessment of digitalization capabilities owned by the organization and the organizational resilience profile from different perspectives provided by the informants. More in detail, the interview covered the following topics:

- Improvisation:* The purpose of these questions is to understand if and how the observed company exploits improvisation to seek solutions following the occurrence of urgent situations in turbulent contexts.
- *Digital environment:* given the continuous and rapid evolution of the digital environment, these questions are used to understand whether the company correctly monitors the environment itself and the related emerging behaviours of users.
- *Digital assets:* this set of questions aims to establish whether the company can appropriately exploit the digital resources available, for example, to automate tasks or digitize processes.
- *Digitalization and strategy:* these questions are fundamental to define the relevance for the company of concepts such as digital innovation, digital leadership, and the development of IT capabilities.
- *Digital innovation habitat:* expanding the digital innovation habitat is essential for a cutting-edge company. The questions on this aspect are used to understand if the company in question pays sufficient attention to this issue and if this allows it to access otherwise inaccessible opportunities.

- *Digitalization of the supply chain*: with the questions in this section, we want to verify the goodness of data management along the supply chain and the connectivity of the latter.

## **4 Results**

### **4.1 Improvisation**

Although complete improvisation is not possible considering organizational constraints such as guidelines and protocols and many controls the organization is subjected to, the interviewees agree in recognizing the organization has exploited improvisation many times during the pandemic. For example, to face air and naval transports logistic problems, the firm signed agreements with partners that until then the company had yet to consider.

### **4.2 Digital environment**

The newly introduced Digital Innovation department, born a few months after the advent of the pandemic, continuously monitors, discovers, and explores the entire digital and technological environment collaborating with the IT function and external consultancy companies.

The IT area continuously makes updates, introduces new tools, and helps the staff to use them by promoting, for example, an education portal with online courses where employees are guided in using these tools.

At the same time, the company constantly carries out data analysis to provide relevant information in support of digital innovation. Specifically, it is crucial paying attention to the various generations of users and also to the different use they make of technologies to exploit properly the digital communication channels.

### **4.3 Digital assets**

The company uses artificial intelligence, (especially in production, logistics, and supply chain management), for object recognition. In the jewellery industry, recognizing a piece of a specific necklace that comes from a specific supplier might sometimes be a problem. The pieces that the company buys for a series generally come from different suppliers, but the necklaces are the same, so there

is a need to recognize the supplier from which each piece comes. To solve this problem, the company has created an artificial intelligence system that recognizes the incoming pieces with a high-definition camera and, consequently, manages to associate them with the correct supplier.

The company is adopting automation systems too. For example, it uses machines capable of scanning and reading the QR codes of pieces and products which are therefore recognized and correctly transferred between the various areas. Without these automated systems it would be necessary to carry out the same operations manually on the management system, generating a significant loss of time.

Digitalization in processes is almost always cost-effective for the company. During the pandemic, it was essential to adopt smart working and other methods that would allow to carry out the usual activities but "remotely". In fact, the company introduced in that period a system that has made it possible to sign contracts and invoices remotely and even more quickly, "it's much faster than searching all the corridors for signatures" (Events Coordination Senior Manager).

#### **4.4 Digitalization and strategy**

After the advent of the pandemic, great importance has been given to digitalization as an indispensable tool for creating and maintaining a competitive advantage. About this, the Innovation and Transformation Director reported:

*"More roads have opened, now the options are open, and we go by preferences or opportunities. The important thing is that there is the opportunity today".*

Also, in the marketing field, digital technologies have proved to be necessary to maintain the company's image and performance advertising and sponsoring events on social media.

The company continually seeks to reduce the rigidity of its organizational routines at all levels. The High Jewellery Logistics Manager explains how the goal is also to try to "do nothing, (...) to make all work more flexible, the more the machine does, the more the mind can occupy itself with other things". This means that the more the machine is able to deal with repetitive tasks, the more time is let to human beings for more productive activities. This, in turn, leads to better opportunities to find improvements to processes, for instance, giving the company higher flexibility and considerable advantages. The Innovation Team

deals exactly with innovation and transformation because without transformation there is little room for innovation, and vice versa. The enterprise system is becoming more and more integrated and well-connected to ensure an effective alignment between business strategy, operations strategy, and management.

#### **4.5 Digital innovation habitat**

According to the Innovation & Transformation Specialist "*the digitalization capabilities that emerged during the pandemic period give the company many new opportunities*". With the pandemic, everything has been greatly restructured, given the need to use digitalization much more. Now the habitat is much more fluid and, therefore, with the growth of numerous factors (i.e., suppliers, production, and sales increase) the flow becomes more complicated. Digitalization increases standardization, while the environment is rapidly evolving.

In recent years the fashion-luxury industry witnessed an exponential development. The group to which the company belongs has grown by 68% compared to 2019. Online events, for example, have made it possible to reach a much wider audience than before.

#### **4.6 Digitalization of the supply chain**

The deep experience and the numerous tools available for data management allow the company to have good connectivity along the entire supply chain, as the Innovation & Transformation Director explains:

"The integration between the various areas is guaranteed, organizationally and then digitally because the company owns integrated systems", however, the expertise of the person using the management system makes the difference.

The management of cross-functional process dependencies is almost always ensured while at the corporate level, there are more difficulties, hence the group is working on improving corporate-level communication practices.

### **5 Discussion and conclusions**

Results show positive effects of the digital transformation, introduced and incentivized by the COVID-19 pandemic, effects that have been experienced not only by the company itself but also by its entire network. The main positive effects include, but are not limited to, the quality of communication with distant

suppliers and clients due to the worldwide introduction of videoconference in the daily organizational routines and a significant organizational structure transformation. The organizational restructuring has included an essential growth of the e-commerce department and the introduction of the digital innovation department directly controlled by the innovation business unit.

The introduction of a dedicated department makes this case emblematic of how digital innovation is becoming structural after and because of the crisis time.

Figure 1 shows the key practices and solutions the company adopted during the pandemic period to develop digitalization capabilities supporting organizational resilience.

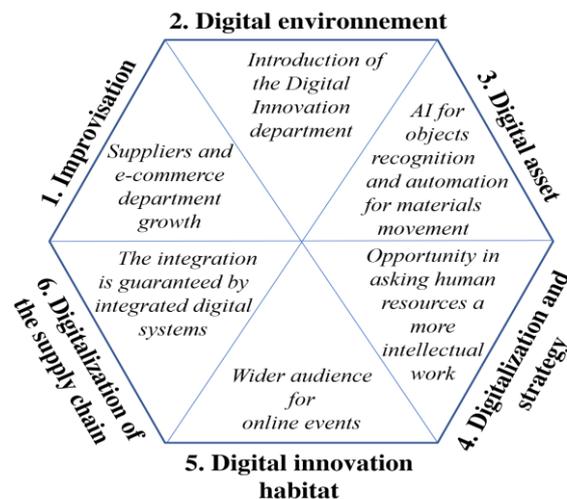

Figure 1 - How Digitalization capabilities support organizational resilience.

This research contributes to the digital transformation research field by showing the existence of a positive influence that digitalization capabilities can have on organizational resilience while focusing on an industry that has received little attention so far in this stream of research. From a managerial standpoint, implications can be derived on how to exploit more effectively existing capabilities, and eventually how to nurture new ones.

### Abstract

It is contested whether or not developing countries<sup>1</sup> can achieve economic prosperity through shifting from agricultural to industrial societies. In the face of uncertainty surrounding economic and technological development, policy makers in many developing countries formulate ambitious goals for digitalization and its positive impacts on accelerating structural change [Matthess et al, 2020]. With regards to digitalization, a wealth of studies investigates the relationship between digital technologies and their economic impacts, e.g., on productivity [Qiang et al, 2009], employment [Ju, 2014], or manufacturing [Kohtamaki, 2020].

The article is focus on the analyses of the capacity of a developing country as Republic of Moldova is to adopt and implement digitalization policies. In this regards we highlight that in recent years, the governmental e-Development efforts of the Republic of Moldova were guided by the national strategies "Electronic Moldova" (2005), the e-Transformation

---

<sup>1</sup> We use the term "developing countries" to refer to low- and middle-income countries according to World Bank Classification.

program (2011), Strategy of development of the ecosystem of the IT industry and digital innovation 2018-2023 and "Digital Moldova 2020" Strategy (2013), which aims to increase the competitiveness of the ICT industry at the regional level and improve the climate for digital innovation.

Why does the information technology sector represent an engine of social innovation and multilateral development of the country?

How necessary are e-Government services for the citizens from the poorest country in Europe?

In an attempt to answer these questions, the article will emphasize that in the Republic of Moldova, the ICT sector has become the main engine of digitization and innovation, and it is growing rapidly. In 2020, the IT industry reached a share of more than 3% in GDP, the share of the ICT sector in GDP being more than 7%, and the share of innovative enterprises represents 12.6% of the total number of enterprises. The share of ICT service exports reached 5% of total trade and surpassed traditional export fields (wines, textiles, etc.) in 2020, up 23% from 2019 and 184% from 2015; the sector employs approximately 1% of the total population of Moldova. It is little, but at the same time it is a very attractive sector for young people. (Strategy, 2022) With reference to the Electronic Government Agency, it is worth to mention that from 2011 until now, more than 100 e-Governance products have been successfully created within more than 20 e-Transformation and modernization initiatives of public administrative services, building a sustainable platform for the modernization public services and other innovations in governance.

**Keywords** – digitization, e-Government, innovation, services, development

**Paper type** – Academic Research Paper

## 1 Introduction

At the European Union level, one of the six priorities of the European Commission envisages the digital transformation of Europe by 2030. The priority "A Europe fit for digital age" (2019-2024) evolves around four cardinal points: Basic digital skills for min 80% of population; Digital transformation of businesses; Digital infrastructures; Digitalization of public services (key public services - 100% online). Effective enforcement of these rules will fundamentally influence public sector innovation in the coming years, so that they become a reality for citizens and businesses.

For the Government of the Republic of Moldova, one of the new activity priorities is the deep digital transformation of the country, at all levels. Digital transformation is mentioned as a priority in the government program of the current executive, including by establishing, for the first time, a position of deputy prime minister for digitization, with the aim of coordinating all efforts in the

reference field at Government level and, in particular, of the most important specialized institutions of the department: the Electronic Government Agency (AGE), the Public Services Agency (ASP) and the Information Technology and Cyber Security Service (STISC).

## **2 The information technology sector as an engine of social innovation**

Innovations in technology are increasingly impacting on almost every sector in the economy and all facets of humanity and society. [Oke & Fernandes, 2020] Industry 4.0 is advancing rapidly, and the Covid 19 pandemic crisis has changed digital transformation from a priority to a global imperative. Today, digitization is a pressing necessity and has enormous potential in solving the challenges facing Europe and the world at large. It is not for nothing that the European community is making significant efforts to prepare its businesses and citizens for a sustainable, more prosperous and human-centered digital future.

The digital transformation is an imperative of the time in all sectors of life and in all fields of activity of all states of the world, including the Republic of Moldova. For the Republic of Moldova, the digital transformation based on new technologies leaves no alternatives, other than active involvement in this process, in order to avoid the country falling behind in the competition at the regional, European and world level. The deep digital transformation has been declared a strategic priority, being a strong component of the current Government Program for the next four years. "Promoting digital tools in the economy and society; exclusion of the mandatory presentation on physical support by citizens and entrepreneurs of the documents issued by the authorities; implementation of automated public services, without the need for their explicit request, simplifying the interaction with the state".

The implementation of the strategies "Electronic Moldova" (2005), "Digital Moldova 2020", the "e-Transformation" programs, other policy documents, led to the creation of a solid infrastructure with a coverage of 99% of the population with Internet access. Half of public service users access services electronically and 127 out of 662 public services are accessible electronically. The ICT sector has become an engine of development, surpassing in the volume of exports traditional branches such as that of winemaking (the share of ICT service exports reached 5% of the total trade or 23.8% of the total export of services). During the

last 5 years the electronic communications market has had a period of dynamic competitive growth, positioning the country among top destinations on the dimension of high-speed Internet, accessibility. Comparing the share of the IT sector in GDP in 2020 of around 3.6% with that of 0.8% in 2013, when the IT sector was declared a policy priority, the dynamics are remarkable. A dedicated policy and legislative framework for information technology and digital industries has played a central role in its remarkable and dynamic evolution. The special fiscal regime of the 7% tax on single turnover, offered by the legislation to the virtual IT park in Moldova and the wide range of eligible activities, including research and development in the field, gave a significant boost to the development and caused an increase of four times between 2015-2020, surpassing the telecommunications sector.

Although many positive results were obtained, the UN E-Government Knowledgebase survey [5] on the e-Governance Development and e-Participation Indices, for the year 2022, placed the Republic of Moldova on 72nd and 47th place respectively out of 193 countries (fig.1,2)<sup>1</sup>, this being below the average of the EU and all Eastern Partnership countries, which means that additional efforts are needed to keep the country competitive on the dimension of digital development.

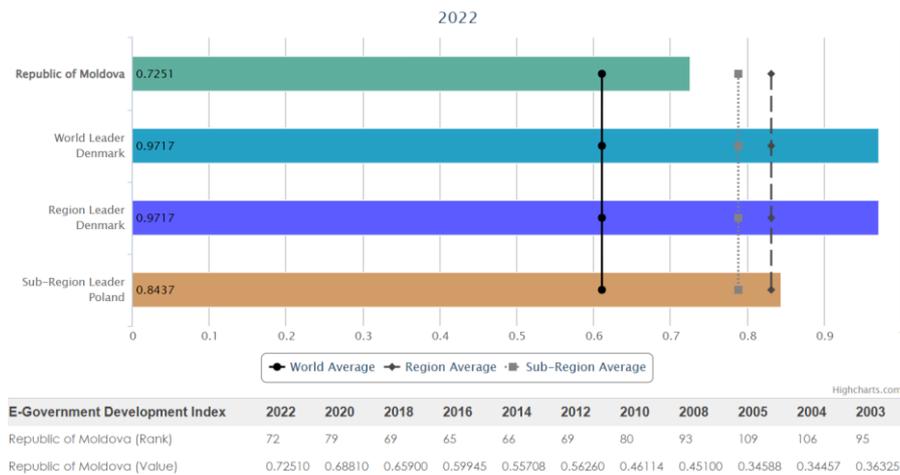

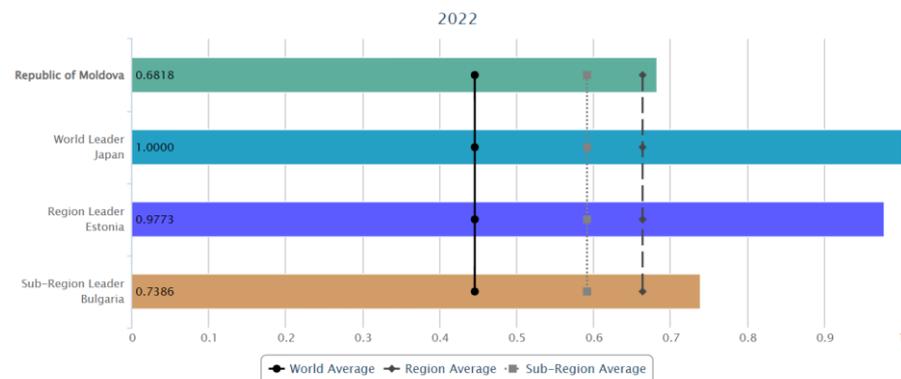

Figure 1: E-Governance Development Index

<sup>1</sup> Source: UN E-Government Knowledgebase. <https://publicadministration.un.org/egovkb/en-us/Data/Country-Information/id/139-Republic-of-Moldova>

E-Participation Index	2022	2020	2018	2016	2014	2012	2010	2008	2005	2004	2003
Republic of Moldova (Rank)	47	55	37	50	40	38	58	116	151	123	102
Republic of Moldova (Value)	0.68180	0.76190	0.85960	0.66102	0.62745	0.39470	0.20000	0.06818	0.00000	0.01639	0.03450

Figure 2: E-Participation Index

The final report on the implementation of the Action Plan of the "Digital Moldova 2020" Strategy mentions that "there are positive developments in creating the conditions for the implementation and use of electronic services, the development of digital skills; the legal framework was created to improve connectivity and network access, removing critical constraints on the ICT business environment. At the same time, there have been certain delays or failures in the implementation process of the Strategy and the Action Plan, a series of challenges and problems persist, caused by both objective and subjective circumstances: insufficiency of material and financial funds, insufficiency of resources qualified human, delays and inactions. The biggest challenge being the lack of financial resources"[6].

With the conclusion of the "Digital Moldova 2020" Strategy in 2020, appeared an urgent need to rethink a new digital transformation strategy, with a "whole society" approach, i.e., with the involvement of citizens, central and local public administration, academia and the private sector, for whom, according to [Savić, 2019] digital transformation means doing things differently — creating a completely new business model by using modern information and IT technologies.

The Concept of new Digital transformation strategy of the Republic of Moldova for the years 2023–2030 (STDM, 2030) it is a citizen-centered document aimed at improving people's well-being. The basic mission of the strategy is to achieve effective public governance, competitiveness and innovative transformation of

the economy and society, i.e., innovative and inclusive digital society, based on a modern infrastructure with digitally educated people, pro-digital governance, a business community that fully uses digital opportunities, as well as a collaborative environment for stakeholders that encourages the innovative work of all people and ensures sustainable human development. The aim of the strategy is not only to transform all public services into digital space, but to rethink and redesign them where possible, reducing the need to submit requests or information that the state already knows. The strategy will also address ways to ensure a secure cyberspace, which will contribute to improving the socioeconomic development of the Republic of Moldova, so that all citizens of the country can enjoy all the benefits of a secure and resilient cyberspace. Generalizing, the most important objectives of the Digital Transformation Strategy 2023-2030 are as follows: creating a functional digital state by limiting to the maximum the interference with the human factor, bureaucracy and corruption; creating an interconnected digital state (especially with the European community) by participating in the strongest global networks in the digital field; the development of a digital society through education on a national scale – a process in which the authorities at different levels must be involved; building the national digital infrastructure; strengthening the ICT private sector; cyber security, ensuring the protection of personal data, but also of the information space in the context of events in the immediate vicinity (Russia's war against Ukraine); boosting the digital economy by capitalizing on the opportunities offered by digitization, the substantial increase in electronic payments and online commerce (STDM, 2030)

The consistent and punctual implementation of STDM 2030 in the context of the Republic of Moldova's aspiration to full integration into the global communication system and to join the EU is crucial and therefore requires a visionary and realistic approach.

### **3 The necessity of e-Government services for citizens**

How necessary are e-Government services for the citizens from the poorest country in Europe?

In an attempt to answer these questions, we highlight that in the Republic of Moldova, the ICT sector has become the main engine of digitization and innovation, and it is growing rapidly. In 2020, the IT industry reached a share of more than 3% in GDP, the share of the ICT sector in GDP being more than 7%,

and the share of innovative enterprises represents 12.6% of the total number of enterprises. The share of ICT service exports reached 5% of total trade and surpassed traditional export fields (wines, textiles, etc.) in 2020, up 23% from 2019 and 184% from 2015; the sector employs approximately 1% of the total population of Moldova. It is little, but at the same time it is a very attractive sector for young people. (MobiSign, Strategy, 2022) With reference to the Electronic Government Agency [2], it is worth to mention that from 2011 until now, more than 100 e-Governance products have been successfully created within more than 20 e-Transformation and modernization initiatives of public administrative services, building a sustainable platform for the modernization public services and other innovations in governance. Among the most popular e-services created and managed by AGE are: Government electronic payment service MPay, Electronic signature service MSign, Government interoperability platform MConnect, Government authentication and authorization service MPass, followed by the newest platforms recently launched: MCabinet , MPower, MNotify, etc. The beneficiaries of the e-Transformation products are the citizens and visitors of the Republic of Moldova, the business environment and public institutions.

The [mpay.gov.md](http://mpay.gov.md) electronic payment platform (MPay) is the government's electronic payment service, an informational tool that can be used to pay for various online services. Although MPay is primarily aimed at public sector e-services, it can also be successfully used for commercial services. MPay makes it possible to pay for services through several payment methods such as: bank cards, payment terminals, e-banking systems and cash payments. In the case of cash payments, citizens who do not have access to the Internet can contact connected bank counters or Moldovan Post Offices.

Beneficiaries of the MPay service are primarily citizens, those who pay for public services, but also representatives of the business environment, who in their commercial activity need to receive payments for the services provided, but also to pay for the services consumed.

Cardholders can make electronic payments for public services. The payment of the consumed services can be made with any legal payment instrument available on the market in the Republic of Moldova. The payment scenario is simple. Access the e-Service on [servici.gov.md](http://servici.gov.md) and complete the online application. The service will calculate the amount to be paid and propose payment via MPay. the user will be redirected to the [mpay.gov.md](http://mpay.gov.md) site, where he will be able to select the payment method and make the payment. At the end of the operation, the service

will come with a payment confirmation. At any time, the user can check the payment status.

Offline services can also be paid through MPay, which can be ordered at the counter of public institutions. For this, access the [mpay.gov.md](http://mpay.gov.md) page, select the service and enter the number of the order, request or report, after which the payment is made in the same way as at the payment terminals.

The MPay service is carried out by the Government through the Electronic Government Agency, the Information Technology and Cyber Security Service, the Ministry of Finance in partnership with the National Bank and the private banking sector. This service is in accordance with the policies of the National Bank promoting cashless transactions.

Government e-payment service MPay has been awarded the 2022 "Digital Transformation Driver" award at "Mastercard Day 2022". [7]

MSign is the government electronic signature service, created by the Electronic Government Agency, which offers the possibility of using all types of electronic signatures in online interactions and verifying the authenticity of signatures under conditions of guaranteed security.

The Electronic Government Agency recommends the use of the MSign Service as a method of applying and verifying the authenticity of the advanced qualified electronic signature. The MSign service is hosted on the common government platform MCloud and complies with the security requirements provided by the legislation in force, including the use of electronic signatures. The informational exchange between the informational systems for the realization of the functionality of the MSign service is carried out through secure channels, using cryptographic information protection mechanisms. Through MSign it is possible to sign with the 3 tools available: Mobile Signature, Electronic Identity Card and Electronic Signature (STISC). Benefits of using:

- It offers the possibility to access electronic services remotely instead of going to the counter;
- Eliminates the need to print documents just to be signed;
- Ensures data privacy and security.

Citizens of the Republic of Moldova can receive documents and other documents requested from state institutions at their place of residence, through the Governmental Delivery Service (MDelivery), which was developed based on the Concept approved by the Government on August 25, 2021 and the

Regulation on the manner of operation and use of the MDelivery Service, approved on March 23, 2022.

The service was launched on July 29, 2022 and aims to offer authorities, public institutions and public service providers an efficient, reliable and modern technical solution, to be used as a unique mechanism for the physical delivery of the results of the provision of public services to the beneficiaries.

The MDelivery information platform ([www.mdelivery.gov.md](http://www.mdelivery.gov.md)) was developed by connecting the three subjects: the public service provider, as the sender, the public service beneficiary, as the recipient of the delivery, and the postal service provider. This platform will reduce costs for all three parties involved and will streamline the process of delivering the result of the public service to the beneficiary. People can request the delivery of the ordered document to their home address from the operator at the counter of the service provider institution, or they can access the [mdelivery.gov.md](http://mdelivery.gov.md) platform and follow the steps described to order the delivery of the document. [9]

The government electronic notification service MNotify is the way in which state institutions can notify and inform users of public services about important events in relation to the authorities, sending messages through different notification channels of the user's choice. These messages refer to debts, fines, discharges, payments, allowances, allowances, etc. that citizens have to perform to the state and/or vice versa.

Through this electronic service [mnotify.gov.md](http://mnotify.gov.md), the citizen is informed (notified) by public institutions about certain services provided by the state, without this service being requested by the beneficiary. Beneficiaries can be both natural and legal persons. The government electronic notification service MNotify was launched in November 2020 and is integrated on the Citizen's Government Portal, and users receive the electronic notification including through the [mcabinet.gov.md](http://mcabinet.gov.md) portal.

In MNotify, notifications can be generated automatically by information systems or manually by operators of service providers through the web interface. To send notifications, MNotify uses the following notification channels: electronic mail (email), the citizen's portal, push notifications, short messages (sms), instant messaging (chat) The MNotify service is provided free of charge to Senders (public authorities and institutions) as well as to Recipients.

Digital transformation is no longer a specialized, niche field. This represents an imperative of the time in all sectors of life and in all fields of activity of all states

of the world, including the Republic of Moldova. Any field can and must benefit from the advantages of modern technologies, simplifying or eliminating bureaucratic procedures, reducing dependence on the human factor, avoiding repetitive and purely technical procedures, excluding corruption factors and increasing trust in state institutions.

#### **4 Conclusions**

The results of the research paper show the positive aspects and the challenges faces by a developing country, as the Republic of Moldova is, in the process of digitalization. For sure, there are many positive elements in creating the conditions for the implementation and use of electronic services, as the development of digital skills, creation of the legal framework to improve connectivity and access to the network, the removal of critical constraints on the ICT business environment. At the same time, there have been recorded certain delays or failures in the implementation of the digitalization process, a series of challenges and problems persist, such as: insufficient material funds, insufficient qualified human resources, delays and inaction or the lack of financial resources.

### **Abstract**

Knowledge Intensive Business Services (KIBS) companies have long been recognised as key players in the modern economy since they positively affect the innovativeness of businesses and societies. Their business activities are mainly based on knowledge, which is both the input and the output of their production processes. Despite their small average size, the vast majority of KIBS companies are aware that knowledge is their most crucial competitive resource. However, they often manage their cognitive assets in a substantially informal and undeliberate way. Indeed, such companies face difficulties and obstacles typically associated with a limited size, such as, e.g., scarcity of human and financial resources, lack of time, and short-term orientation. Furthermore, KIBS SMEs face specific challenges, mainly caused by the intangible and knowledge-intensive nature of their business processes. A key issue concerns knowledge documentation and storage, which is essential to make the retrieval and reuse of possessed knowledge easier for existing and newly hired employees.

In spite of the above, research about how small and medium sized KIBS companies manage knowledge documentation and storage processes is still limited. To help fill this gap, this paper examines the main difficulties that KIBS SMEs face when documenting and storing their knowledge and how they try to face and overcome these difficulties. In particular, the paper illustrates and discusses the findings of an empirical investigation that involved 13 Italian KIBS SMEs belonging to different sectors. The decision to adopt a multiple case study approach was induced by the exploratory nature of the research. The study revealed that knowledge documentation and storage is a widespread activity among the investigated companies, which confirms the relevance of these processes. The investigated companies are aware that poor documentation generates several problems that result in late responding to client requests. Furthermore, the study allowed identifying some shared challenges that concern the entire document and storage process, as well as collecting useful indications about how companies deal with them. The study has the usual limitations of a case study methodology, and especially the difficult generalisation of the results. This paves the way for future research devoted to confirm what emerged from the present analysis, for example, by means of surveys.

## 1 Introduction

Knowledge Intensive Business Services (KIBS) companies are unanimously recognised as key players in modern economies (Kamp and de Apodaca, 2017; Pina and Tether, 2016; Tuominen and Toivonen, 2011). In particular, they are deemed to exert a positive influence on the innovativeness of businesses and societies (Liu et al., 2019; Shearmur and Doloreux, 2019). As the name suggests, KIBS companies base their competitiveness on knowledge (Miles et al., 2018; Palacios-Marques et al., 2011), which is both the input and the output of the service delivery process (Strambach, 2008). The KIBS sector includes companies providing a large variety of services that the literature subdivides into three categories, i.e., technological KIBS, professional KIBS and creative KIBS (Miles et al., 2018). KIBS companies can be also distinguished according to their knowledge base (analytical, synthetic, symbolic, and interpretive; Krupskaya and Pina, 2022), i.e., the different mix of tacit and codified knowledge that denotes their cognitive processes. In addition, the large majority of KIBS companies have a small and medium size (Zieba, 2021).

Empirical evidence (Bolisani et al., 2022) proves that KIBS SMEs are aware that knowledge is their most crucial competitive resource that would be to be adequately managed. However, despite this awareness, these companies manage their cognitive assets in a substantially informal and undeliberate way (Bolisani et al., 2016; Alexandru et al., 2020). Indeed, as well underlined by the extant literature (Massaro et al., 2016; Durst et al., 2022; Shekhar and Valeri, 2023), SMEs meet with several difficulties and obstacles to managing knowledge, largely due to their limited size (e.g., scarcity of human and financial resources, lack of time, short-term orientation). KIBS SMEs face increasingly specific challenges, mainly due to the intangible and knowledge-intensive nature of their business processes and outcomes. These challenges, when not successfully identified and faced, can negatively impact firm competitiveness.

A key issue concerns the process of knowledge documentation and storage (Anand, and Singh, 2011; Zbucnea et al., 2023). To build and manage the “organisational memory” efficiently and effectively, KIBS companies are requested to implement appropriate approaches and tools to guide employees in the memorization of information and experience acquired in previous projects and, more generally, in the business activities. This makes the retrieval and reuse of the knowledge possessed easier for existing and newly hired employees. Documented knowledge includes lessons learnt, guidelines, customer databases, project reports, procedures, and so on. Effective knowledge storage requires the continuous maintenance and updating of the knowledge repository, in order to avoid the presence of obsolete, useless, if not harmful, knowledge.

In spite of this, research about how small and medium sized KIBS companies manage their knowledge in general, and particularly the knowledge documentation and storage processes, is still limited (Bolisani et al., 2022). In light of the above, this paper poses the following research questions:

*RQ1: What are the main challenges that KIBS SMEs face when documenting and storing their knowledge?*

*RQ2: How do these companies try to face and overcome such challenges?*

To answer the research questions, in the next sections, the findings of an empirical investigation that explored the main challenges in knowledge documentation and storage processes that KIBS SMEs face are illustrated.

## **2 Knowledge documentation and storage in KIBS SMEs**

In the knowledge management (KM) literature, different taxonomies of KM processes have been published (Heisig, 2009; Andreeva and Kianto, 2011; Edwards, 2015; Costa and Monteiro, 2016). Knowledge documentation and storage is generally indicated as one of the key KM processes. Knowledge documentation, in particular, is the process of codifying knowledge into written, audio, visual, and/or video assets (APQC, 2020). Why to document and store an organisation's knowledge? The safest and most straightforward way to preserve organisational knowledge is by documenting it. Otherwise, critical knowledge is at risk when it is only stored in employees' heads. When knowledge is in the form of content, documented, and stored, it can be transferred to others at any time and is safely secured should it be needed in the future. Also, all the knowledge that has been acquired, created and shared, has to be supported by knowledge documentation and storage; otherwise, a company will be in danger of accidentally losing the gained knowledge (Andreeva and Kianto, 2011).

The special importance of knowledge storage has been earlier emphasised by many authors. Wexler (2002) argues that knowledge created within an organisation needs to be documented and stored for intellectual capital to develop and accumulate. Probst et. al., (2000) describe memory as "a system of knowledge and skills that preserves and stores perceptions and experiences beyond the moment when they occur, so that they can be retrieved at a later time." In this regard, studies highlight that an organisation's ability to store knowledge has important consequences for its performance (Olivera, 2000) and the stored knowledge can effectively safeguard the organisation from the distracting effects of turnover (Argote, et al., 1990). Thus, being knowledge as a crucial resource, companies recognize the value of knowledge storage process for present and future use as it seems to be a major building block in implementing knowledge management by re-using and facilitating knowledge creation and transfer (Jasimuddin, 2005; Zawaideh et al., 2018).

Andreeva and Kianto (2011) showed that all knowledge processes (i.e., knowledge creation, intra-firm knowledge sharing, external knowledge acquisition, and knowledge documentation) have a beneficial impact on innovation. But they especially pointed out that activities aiming at documenting and storing knowledge available within an organisation, sharing it via intra-firm interactions, and supplementing it with external knowledge acquisition provide

material for and facilitate knowledge creation processes of knowledge-intensive organisations. Another study (Ramadan et al., 2017) confirms, based on an empirical study on knowledge workers in the Knowledge intensive business services (KIBS) sector, that knowledge documentation and knowledge transfer emerged as having the strongest effects on intellectual capital (IC).

KIBS SMEs are strongly related to knowledge, since it is their most valuable resource (Zieba, 2021; Bolisani et al., 2022; Zbucnea et al., 2023). As stated by Miles et al. (1995), KIBS companies are characterised by a unique mix of knowledge associated with particular domains, applications of technology, and knowledge associated with KIBS' clients. Therefore, KIBS companies face different and various challenges related to all the diverse KM processes, and, among these, documenting and storing knowledge represent a very critical challenge (Zbucnea et al., 2023). The process of documenting and storing knowledge is a critical business activity, particularly in the case of KIBS SMEs, where there are often more tasks than people and time available to accomplish them. Also, the challenges faced by KIBS SMES, in relation with knowledge documentation and storage process, may need to be managed by adopting different KM approaches depending on the specific case and situation of a company (Zbucnea et al., 2023).

### **3 Research Method and Procedure**

Given the exploratory aim of the research, we chose to use a qualitative multiple case study method. Indeed, due to the shortage of previous research on the analysed topic, an exploratory approach was deemed essential (Eisenhardt, 1989; Yin, 2018). The object of each case study was to examine the challenges raised, and the relevant countermeasures adopted, in the knowledge documentation and storage processes carried out in the single small and medium-sized KIBS company. Data were collected by means of deep semi-structured interviews with managers and/or owners (referred to as "key informants") of a sample of KIBS SMEs located in Italy, and specifically in the Veneto region. In particular, we used a "convenience sampling" which is a popular approach (Pham and Ho, 2017; Zhang and Liu, 2021) in exploratory and descriptive research. The sample consisted of 13 KIBS SMEs belonging to different sectors (ICT services, professional services, consulting services, legal and administrative services). The interviews were carried out between May and September 2022 and were based on a semi-structured questionnaire sent in

advance to the interviewed people. The interviews were recorded and then transcribed for scrutiny and collated with field notes and information available on company websites and other media sources. All this supported the validation of the data obtained, as suggested in the literature (Suter, 2011). To perform the analysis, an Excel file was created in which all answers were reported. This helped researchers compare the data, find similarities or differences, and draw conclusions (Miles and Huberman, 1994).

Table 1 shows some basic information about the companies in the case (business services sector and number of employees), whose names are disguised for confidentiality reasons. The sample includes both technological and professional KIBS companies.

Table 1: Sampled companies

Company	Sector	Size
A	ICT (software)	20
B	Business consulting	8
C	ICT (software)	60
D	Business consulting	60
E	Legal/administrative consulting	60
F	ICT (data management)	6
G	Strategic consulting	15
H	ICT (ERP systems)	150
I	Legal/fiscal consulting	60
L	ICT (business software and consulting)	35
M	ICT (software)	40
N	ICT (software)	30
O	ICT (system integrator)	86

## 4. Results and discussion

### 4.1 Identified challenges and practical solutions

Knowledge documentation and storage resulted to be widespread activity among the investigated firms since it deemed crucial for their business, as a company affirmed:

*Very crucial. Since 1998 we have established that any document produced in the company, a letter, an email, a bid, a ticket, an appointment, any activity (activity means document) must be archived.*

According to another company:

*The company "beating heart" is the company's management system, which is supported by the document management system, which collects all our knowledge.*

Knowledge documentation and storage mainly concern the services provided to individual customers (as e.g., the implementation of a business analytics platform, the provision of a fiscal advice), and particularly all the activities performed and the outcomes achieved during the service providing process; a typical example refers to all the documentation produced during the provision of a new software program to a client company, from the first contact to the final version and then the maintenance interventions.

Therefore, it is not surprising that such activities raise several challenges, as is confirmed by another company:

*The pool of documented and stored knowledge can be regarded as a library, and therefore its effective management requires answering several questions, as follows: How should the documentary material be organised? How to inform people about new material? How to induce people to contribute with new material? How to improve the readability of the material?*

The above questions can be regarded as specific challenges that KIBS companies have to face and overcome when documenting and storing their knowledge.

Organising documented knowledge is primarily a matter of classification. However, as unanimously highlighted by the companies investigated, classifying documents is an arduous task:

*Classifying documents is not easy. First of all, it requires time, especially if you want to classify old material. Second, it is not simple to interpret what it is written, given that different classification logics could be applied to the same document. In this respect, a tool that allows (or obliges) to classify the document when you save the file could be of help.*

The large majority of companies use to classify their documents by customers, and secondly according to technology (e.g., business intelligence), topic (e.g.,

merger and acquisition), industrial sector (e.g., beverage), or other specific aspects, but they are aware that this is not the best solution:

*This is a simple way of classifying documents, but it doesn't facilitate the search of a particular document. Who search for has to know for which client the problem he/she is interested in was faced and solved in the past*

This is why, several times, employees have to ask colleagues, who in the past have used/produced the knowledge they need, where to look for, before they can start to search. Almost all the companies use internal databases (also on cloud systems) where the documents are stored in different folders. The currently used systems allow searching within the whole database using keywords, but for the previously recalled reasons, such searches are not so effective.

Classification is made more arduous by the fact that companies have a lot of documents stored in different formats:

*This material can have various formats, e.g., texts, photos, videos, audios.*

and concerning different topics:

*(there are) distinct kinds of knowledge inside the same company: those produced by the company – a sort of object (as e.g. during the service delivery process, and that can usually be stored); and those concerning the service delivery process (as e.g. guidelines, tools, approaches, which can be partially stored in procedures, but is a part of the individual skills).*

The second challenge concerns how to ensure that employees will be updated on the new knowledge that has been stored and that can be of their interest. As a company indicated:

*... knowledge is like a splendid library, it has many compartments, you can hardly stay up to date on everything*

A solution, employed by a company, is to have a "librarian" who manages the system and regularly (weekly in that case) informs employees of the new available knowledge. However:

*It is very expensive to have a person who is in charge of controlling the produced documents.*

Some companies usually organise regular meetings where people are updated about the projects in progress, and this is a way to make all employees informed about the new knowledge being produced and then documented.

Another challenge that is considered critical for most companies is how to induce employees to document knowledge promptly, i.e., as soon as they have completed an activity, in order not to forget important aspects. This is affected by

the reuse (of the documented knowledge) time, i.e., how long it will take before someone needs to use such knowledge. A company affirmed:

*In case it (reuse time) is long, it is difficult to convince people to document knowledge that they will not use in the future because they probably will not still be in the company.*

and another company added:

*If there is no immediate return you don't do it.*

Furthermore, employees do not always realise the importance of documenting what they do, as well illustrated by the following:

*The main problem is that people sometimes are not so diligent in documenting their work, especially when things are done and taken for granted. I do an activity, and I do not pose myself the problem of making it common knowledge.*

Getting people to document the knowledge produced during their work is even more difficult in the case of technicians or sales agents, who normally are rather reluctant to write down and document their activity, since they prefer to devote their efforts and time to more practical and operative activities, and also because they regard knowledge as a source of power, as a company stated:

*The sales force prefers to keep information so they can manipulate it to their advantage.*

To face this challenge, several companies are resorting to procedures and tools that involve the automatic generation of documents during the work. This is the case of a company that has always resorted to advanced document management software systems by requiring their employees to use them. Other companies try to induce employees to work only online (i.e., using systems like Google Drive, Share Point) since this allows the automatic documentation of the work done. To sum up, companies agree on the fact that:

*An ideal solution would be to automatise the documentation activity to make it a "natural" part of daily work*

*and that it could be necessary:*

*... to have something that allows for the automatic generation of documents during the work.*

The last challenge concerns the ways of documenting knowledge, which has an impact on its usability. According to the companies investigated, documents are very often written in such a way that their content is difficult to read and understand. This in particular concerns new hires:

*They (young people) are "tinkerers", but (don't like) writing ... people no longer know how to write, and this is another kind of problem. Also write using words. There are people who write completely differently. They write in a "Whatsapp" style, or something like that. Vowels are missing, things are missing, they really write like this, and this is not good. A little classical education would be good for everyone.*

Furthermore, the investigated companies affirmed that it is not so easy to create a communal writing standard because everyone, regardless of their education level, has their own specific writing style. Additional problems are raised by the fact that different people use different languages, jargons. This problem worsens as the areas of specialisations inside the company (as well as the number of people) increase. It is not only a question of different educational backgrounds (as e.g., when business economists have to interact with computer engineers) but also of different application/technology areas (as e.g. systems engineers and software developers). The situation is well illustrated by a company:

*Technicians speak a different language than economists. ... Computer scientists from economists. Then the deeper you get into the knowledge, the more the glossary is different.*

Companies are adopting different approaches to face such challenges. As far as the writing style, training and checking-up the first written documents of new hires are ways get people used to writing something easily understandable, as confirmed by a company:

*To make them (the documents) readable, those produced by a new hire are corrected until he/she learns how to write them properly.*

This is quite an expensive solution, especially because it requires that a senior employee devote some of his/her precious time to this.

Another solution can be to provide people with structured formats that they have to fill in, which is generally facilitated when using a document/content management system. For example, a company introduced a standard format for email to ensure its traceability. Another sends mails only by means of their document management systems, which implies their automatic documentation. As concerns the use of different languages, terms, many companies are trying to establish a sort of (more or less formal) common vocabulary, with terms having a shared meaning, and this is done by means of meetings where people of different areas talk together.

To sum up, the solutions the companies adopt to have useful content are “ex-ante” solutions, because they don’t provide for checking the produced documents. So their effectiveness is questionable, as confirmed by what a company affirmed:

*The format of the document is not free, anyway the interpretation, or the way of writing is not unique. We cannot have people who read what has been written every day. So, we assume it is done right. We gave rules to write documentation, but not everyone reads it. In any case, it is too expensive to control the content of all the stored documents, and we would not want to take the risk of stressing employees (by strictly controlling what they write).*

Lastly, it deserves to be mentioned that the identified challenges are of different relevance for the different companies, in relation to some specific factors as e.g., managerial style, company’s story, organisational structure and size, kind of delivered service. The latter, in particular, seems to assume a decisive weight, as it defines the knowledge base of the company, and therefore affects the way its knowledge is managed. Therefore, it is not surprising that ICT companies have affirmed that they have been able to document their knowledge in a greater part compared to what law and administrative consulting companies were able to do.

#### **4.2 Discussion**

What emerged from our study confirmed that knowledge documentation and storage is a crucial activity for KIBS firms and raises a lot of difficulties in overcoming these challenges. Poor or lack of knowledge documentation is due to four key issues/challenges, as follows.

- Employees are reluctant to document knowledge, for many reasons: lack of time, individual attitudes, professional role, feeling of usefulness.
- “Knowledge libraries” are often badly organised, and documents are not well classified.
- The writing style of people and the heterogeneity of languages make documents difficult to read and understand.
- Documented knowledge must be updated and people must be kept up-to-date with new documented knowledge.

To face the above challenges, the investigated companies are resorting to various solutions involving actions on both the technological and human side, as e.g. using more sophisticated document management systems or helping people to develop a common language. Although the two dimensions are deemed both important, the empirical investigation has highlighted that the second is even more important, given the objective difficulty in changing people's personal attitudes, consolidated behaviours, and ways of thinking connected to the technical/professional background. For instance, one of the thorniest issues, i.e., the lack of time to engage in activities not directly related to the production of revenues, as those devoted to write down the work done and the knowledge used/generated, cannot be solved if people are not aware of the importance of documentation and do not feel motivated to do so, especially when they cannot derive an immediate benefit from it. In the more advanced companies, i.e. those that have been adopting sophisticated document management systems, technology plays a fundamental role, but an even more crucial role is played by the "culture of documentation" developed over the years by the employees. All of this confirms the importance of having KM- oriented HRM practices, starting with the selection and training of new hires.

## **5 Conclusion and future directions**

The study revealed that knowledge documentation and storage is a very widespread activity among the investigated companies, which confirms the relevance of these processes. In particular, the investigated companies are aware that poor documentation generates several problems that result in a not timely response to client requests. Regarding RQ1, the study allowed us to identify some shared challenges that concern the entire document and storage process. These include, especially how to motivate people to document their activity; how to organise the documented material; how to improve the readability of the documented knowledge; how to inform employees about newly available documents. Regarding RQ2, some useful indications on how companies face the above-mentioned challenges have been collected. It is worth noting that even in the case of recurring problems, the adopted solutions are context-specific, indicating that there is no one best way of approaching the same challenge.

### **5.1 Limitations and research opportunities**

The study is affected by the usual limitations of a case study methodology, and especially the difficult generalisation of the results. This paves the way for future research devoted to confirm what emerged from the present analysis, for example, by means of surveys. In addition, future research should investigate whether different kinds of KIBS companies (e.g. Professional or Technical KIBS) perceive challenges or face them differently.

### Abstract

Firms use business analytics to improve their decision making. Analytics applications are increasingly used for decision automation regarding routine processes, and business analytics models and tools have been created for supporting firms in future planning and prediction. While benefits of using analytics to monitor, develop and improve daily operations have been reported by many scholars, the role of business analytics in improving non-routine decisions has remained somewhat uncharted. Top manager role often requires making non-routine decisions. Using thematic analysis of 12 interviews conducted in large Finnish firms, this paper outlines the perceptions of top managers on using business analytics when making decisions. It contributes to the currently ongoing academic discourse on information technology business value and business analytics business value by demonstrating how firms apply business analytics in top management decision-making activities.

**Keywords** – strategy, strategic management, decision making, business analytics

**Paper type** – Academic Research Paper

## **1 Introduction**

Knowledge is in an essential role when firms make resource-related decisions to enhance their competitiveness (Spender, 1996). Firms are continuously developing their business analytics capabilities, as they expect the increased focus on data, analysis, models, and fact-based management to improve their ability to make such decisions (Davenport and Harris 2017). Supported with analytics-based outputs, decisions may become more accurate, and may require less human involvement (Kesavan and Kushwaha, 2020). Improved business processes and decision-making performance enabled by analytics may also result in improved organizational performance (Chatterjee, Rana and Dwivedi, 2021).

Many of the decisions made by top management require making future predictions of the firm's continuously evolving environmental and strategic contexts. While firms continue to invest in business analytics (BA), it remains somewhat unclear how BAC built with these investments are facilitating top management decision making. When, how, and why top managers do or do not utilize BA when making decisions?

In this paper, we respond to these questions by outlining the role of BA in top management decisions. First, we recap what has been suggested in the previous literature on managerial decision making and the role of BA in this context. Based on 12 semi-structured interviews of top managers in large Finnish firms, we outline why top managers see using BA is important for firms. Additionally, we describe different situations where top managers use BA to support their own decision making. Finally, we discuss future research opportunities on this arena.

## **2 Theoretical background**

### ***2.1 Managerial decision making in organisations***

Firms and their managers get involved with different types of decisions. The nature of these decisions varies from structured, programmable, routine-type decisions that typically have well-defined decision criteria and well-known consequences to complex and unstructured, problem-solving type decisions that require making assumptions as the context and consequences are novel, and adequate information required for decision making cannot be stated or gathered (Simon & Norton, 1960; Holsapple, 2008). According to March and Simon (1993)

these two decision types can be considered as opposite ends of a continuum. "Routine decisions" that are often repeated evoke reactionary choice and lead to an expected decision. On the other hand, "problem-solving decisions" require a thorough understanding of the novel situation, dedicated effort to search and evaluate choice alternatives and accepting the uncertainty. Many decision situations fall between these two ends, as they include both familiar and novel aspects. (March & Simon, 1993)

Regarding firm resources, decision making responsibility often lies with managers. In large organizations, managers on higher levels of the organisation typically focus on steering the strategic-level allocation of firm resources through the decisions they make, while the managers on lower levels concentrate on operative-level decisions that aim at optimising the usage of these allocated resources (Noda & Bower, 1996). In addition to decisions related to current resource allocation, top managers are also involved in strategic decision making concerning firm longer term objectives together with resource acquisition and development required to achieve these objectives (Noda & Bower, 1996; Eisenhardt, 1999).

Labelling an individual decision as "strategic" or "operative" is not often obvious, as the nature of the decision made depends on how it is viewed. The decisions made on different levels of the organisation concerning firm resources are strongly interlinked; new resource acquisition and development shapes the role and allocation of already existing resources, and the decisions made on lower levels of the organisation regarding the latter may impact top management ability to seize new strategic opportunities (Noda & Bower, 1996).

Top manager role often involves participating in management team decision making on firm or business unit level (Hambrick & Mason, 1984). As management team members, they make decisions on firm- or unit-level resource acquisition and allocation, while they also represent their own unit or function that needs to receive an allocation of these resources (Edmondson, Roberto & Watkins, 2003).

## ***2.2 The role of analytics in managerial decision making***

BA output is often considered to have more important role in operative decision making than in strategic decision making, due to different nature of these decisions (Kunc & O'Brien, 2019). While routine decision making seems to highly benefit from using analytics-based tools and models in terms of faster and

more accurate decisions, analytics models created for supporting strategic considerations often need to be specifically tailored for solving somewhat unique problems that are highly dependent on the firm's environmental and strategic contexts (Luoma, 2016). In addition to understanding past performance and intraorganizational characteristics, strategy formation requires firms to develop understanding of their uncertain and dynamic environmental and strategic contexts (Hutzschenreuter & Kleindienst, 2006).

Analytics benefits are often considered to materialize in the form of improved decision making (Davenport & Harris, 2017). BA supports decision makers to detect patterns that indicate future events based on historical data (descriptive analytics) or helps them predict whether and when the event will happen (predictive analytics). Analytics can also be used in a prescriptive manner, to proactively suggest or even to make decisions based on predictive analytics outcomes. (Lepenioti et al., 2020). Decisions of more structured and routine nature can be automated using analytics algorithms, to the extent that human role is no longer needed (Faraj et al., 2018).

In those decisions where human role remains essential, analytics is used to amplify human intelligence (Wijnhoven, 2021). Using BA in decision making may also enhance the organisations' knowledge co-creation (Acharya et al., 2018) and help them make decisions based on knowledge (Marjanovic, 2022). However, the benefits of analytics are achieved only when decision makers possess the ability to process the information provided by analytics and utilise it when making decisions (Cao, Duan and Cadden, 2019), or to turn the insights enabled by analytics into action (Marjanovic, 2022).

Our interest with this study lies in the role of BA in top management decision making; when is it utilized, how, and why? Next, we will describe the research methodology used for discovering responses for these questions, followed by the research results.

### **3 Methodology**

#### **3.1 Research design**

Qualitative research design often forms as an outcome of iterative process (Saldana, 2013) and this study is no exception. We commenced the process by familiarizing ourselves with previous literature on BA and top management

decisions. The literature review led us to consider potential research questions to be investigated and based on the nature of the research questions (why, when, and how, see Saldana et al, 2011) we decided qualitative interviews would be a suitable method for data gathering.

Another consideration we had to go through was to select who to interview. Our main research interest was top managers who would be involved with longer-term strategic decisions concerning their firm, and who were working in large Finnish firms (annual turnover >200 MEUR) that have significantly invested in digitalization initiatives during the past decade. To identify those firms that had shared their digitalization initiatives within media, we went through the news published within the main media. Among these firms, we then identified suitable contacts via our networks to propose participation in our research.

As we were agreeing on the interviews with the potential interviewees, research material confidentiality was brought up on several occasions. To adjust our research with firm confidentiality requirements, we guaranteed anonymity for the interviewees as well as the firms and industries they represent.

### **3.2 Data gathering**

Regarding data gathering approach, we decided to utilize semi-structured interviews to collect the views from potential interviewees. Semi-structured interviews include mainly open-ended questions that can be derived from existing theories, and thereby enable collecting experience-based data while maintaining the connection with theoretical premises the research will be built on (Galletta, 2013). An interview guide was drafted and tested using one interview. The planned duration for an individual interview was 60 minutes.

The amount of data required to conduct qualitative research depends on research setup. To be able to build credibility and trustworthiness for interview findings, at least ten interviews are recommended (Saldana et al, 2011). We interviewed altogether 12 top managers, and the average duration of an interview was 62 minutes (see Table 1 for individual durations for each interview). Nine interviews were conducted onsite, and three interviews were made online using Microsoft Teams application. All interviews were recorded. The interviews were transcribed from the recordings by a third party service provider, after which we used NVivo software for coding and analysing the interviews. Interviews C and D were conducted in English and all other interviews were done in Finnish. Coding

was done in English, and the quotes from Finnish interviews used in this paper were translated in English.

### **3.3 Data analysis**

Interview data analysis was conducted in three main stages suggested by Roulston (2014) and applying analysis procedures from qualitative analysis literature. First stage included first-cycle coding of the data using initial (open) coding approach (Saldana, 2013), after which the coding outcome was reviewed. During the second stage, the condensed data was reorganized under inductive, second-cycle themes emerging from initial coding (Saldana, 2013), and then reflected with previous literature described in section 2 as well as the research questions. During the third and final stage, the themes were interpreted within the research team, and this paper was written to represent the findings.

## **4 Results and discussion**

### **4.1 Decision making responsibilities of the interviewees**

Interviewees had three types of responsibilities: 1) Head of Business Unit – full profit and loss responsibility for a named business; 2) Head of Function – responsibility for a named business function, such as sales & marketing or product portfolio management; and 3) Head of Strategy – responsibility for group or business unit strategic planning and strategic projects. The responsibilities for interviewees in each organization (marked with identifier A-L) as well as the background statistics of each interview are listed in Table 1.

Table 1. Interviewee responsibilities and interview statistics.

<b>Identifier</b>	<b>Type of responsibility</b>	<b>Interview type</b>	<b>Language</b>	<b>Duration (minutes)</b>
A	Head of Business Unit	onsite	Finnish	57
B	Head of Strategy	onsite	Finnish	60
C	Head of Strategy	onsite	English	57
D	Head of Business Unit	onsite	English	77
E	Head of Business Unit	onsite	Finnish	57
F	Head of Business Unit	onsite	Finnish	68
G	Head of Function	onsite	Finnish	64
H	Head of Function	online	Finnish	48

I	Head of Business Unit	online	Finnish	57
J	Head of Function	onsite	Finnish	60
K	Head of Function	onsite	Finnish	56
L	Head of Strategy	online	Finnish	87

The interviewees either have managerial responsibilities over a business unit or function, or they are responsible for running a strategy process for the entire firm or its unit or function. Based on the interviews, top management involvement in decision making is multifaceted and depends on the organizational context, id est decision-making role of each interviewee can be viewed as unique.

The objective of this study is not to make any generalizations on top management decision making but to explore the perceptions of top managers on using analytics. From this viewpoint, we simply acknowledge these differences regarding managerial roles and accept that they impact the perceptions of the interviewees.

#### **4.2 Top management perceptions on using BA in decision making**

##### *4.2.1 Top management perceptions on reasons behind using BA*

Based on the interviews, top managers consider several reasons for using BA in decision making. Possibilities to use BA are increasing through digitalization of business processes, but use of analytics also needs to be proactively increased to maintain firm competitiveness, to facilitate holistic business monitoring and management, to justify decisions, to make decisions based on facts, to identify new perspectives and insights, and to provide a feeling of having made the right decision. Observed reasons behind using analytics are summarized in Table 2.

Table 2. Top management perceptions on reasons behind using business analytics.

<b>First-order categories</b>	<b>Second-order themes</b>
Industry is digitalizing Customers are moving to digital channels	Digitalizing business processes
Competition is already benefitting from analytics Competition can be beat with analytics	Maintaining firm competitiveness
Systematic view and follow-up of firm activities Better understanding on what should be done	Facilitating holistic business monitoring and management
Backing up decisions with data Justifying why something needs to be done	Justifying decisions
Analytics enables more accurate predictions	Making decisions based on facts

Analytics-based data enables better decisions	
More data means more insights New viewpoints through analytics	Identifying new perspectives and insights
Manager prefers to use numbers Data brings comfort and peace of mind	Getting a feeling of having made right decisions

**Digitalizing business processes.** Based on the interviews, digitalization has been fast and moving into digital business processes has directly increased opportunities to use analytics. For some service firms, the industry operations have already previously been based on intangible assets, and digitalization has directly impacted on analytics possibilities. Interviewee F describes such situation:

*Business analytics is a challenging concept in this <service industry> context, as everything is pure analytics. Our whole operations are about data, intangible assets. Now we do not have any paper prints anymore, everything is digital, immaterial services and solutions. Of course, some of this realizes concretely in a form of service and customer care models or through our business partners.*

Some interviewees also bring up the change in customer behaviour as one of the main reasons for digitalization and see this as an important driver also for increasing the use of BA. According to Interviewee L:

*Customers can contact us via phone, we have good response times and all, but people have moved more and more towards digital self-services. We are not at our strongest there and decided we cannot accept this.*

**Maintaining firm competitiveness.** Interviewees also view what competition does when they consider the need to increase BA use. Some interviewees see that competition has managed to benefit from increased analytics use. Interviewee L considers competition to drive analytics use:

*Why we need to do this <utilize analytics for pricing> is that our neighbours do this, and if they do this aggressively, we <get the worse customers> and get in trouble with our profitability.*

Regarding the development of BAC, being among the first on the market is considered to bring along competitive advantage, although some interviewees add that this would be a temporary advantage. Interviewee C discusses this kind of first-mover advantage as follows:

*But if we were the ones managing first or best to bridge that and to really integrate that and leverage our business analytics capabilities to the point*

*of, to address a problem on the business side, then that could give us a competitive edge.*

**Facilitating holistic business monitoring and management.** BA is useful as it enables systematic view and follow-up of firm activities. For some interviewees, developing analytics has strongly facilitated business management. Interviewee J shares the following example:

*<Analytics> works rather well, also when compared with others <firms>. We can get the picture one way or another. For example, product costs, we have worked a lot during my time to get better visibility on that. Earlier we got some surprises after we had already started the production process <regarding realized costs> but we have advanced this with 1-2 years, the timing when the product development project receives product cost calculations via our systems. We used to have this in Excel but now we can do it in our production systems, not of course to production but using ERP we can run the cost structure for all existing <products>, as well as prices and offers. We achieve better accuracy with this.*

BA is also seen as an essential part of running the business, as it provides a better understanding on what should be done if the business does not go into intended direction, or the planned activities do not bring the expected outcomes. Interviewee H states the following:

*<Analytics is used> because we want to understand what activities and how the activities impact <on our business> and to ensure we are on the right track, and to get fast indication on those signals that tell us we are not on the right track, and we need to do something to fix this.*

**Justifying decisions.** Analytics is also useful when decisions need to be justified. When analytics output is used for decision making, it helps explain why the decision has been made. This can also be seen to accelerate decision making. As Interviewee B expresses this:

*It is maybe the best support for business, when one feels like this and the analytics says yes, it confirms <it> and helps accelerate decision making.*

Using analytics output also helps justify why something needs to be done. In this role, analytics output is used to motivate action that is required to implement decisions. Interviewee I describes this kind of a situation:

*I of course need to get the team excited and to believe in this thing. It helps when it is justified. I work with engineers, and I am an engineer <...> Someone said engineers do not have feelings, they only have reactions.*

*<...> It needs to be somehow justified. Not precisely but in a way that one can make the team to believe in it. <...> Analytics helps <me> in this and I have noticed that doing things systematically and chopping things into suitable pieces helps get the adaptation and acceptance. When we can show that this is not in fact that bad, because <this, this and this>*

Making decisions based on facts. BA output is also described to enable making decisions based on facts. In this context, it seems to be often compared with decisions that are based on previous experience, beliefs, or opinions. Those interviewees that mention experience-based knowledge consider analytics output to either back up or challenge the previous experience, and those who discuss beliefs or opinions see that analytics role is mainly to change these. Using analytics is seen to enable more accurate predictions than relying on previous experience or even historical data. As described by Interviewee L:

*If you do not have <analytics based predictions>, your business is random <...> your price levels are random. If your perception of <price> being right or wrong is based purely on history, and you do not analyse the future, you only guess the price with your old parameters while the world might have changed so much that these are not valid anymore.*

Using analytics output in decision making is also perceived to lead into better decisions than relying extensively on previous experience or beliefs when making decisions. Analytics is considered to reduce bias and bring neutrality and facts into decision making, as described by Interviewee K:

*I do myself believe that data-driven firms that base their decisions on data will manage better and make higher quality business decisions. Then these are not opinion-based or biased, or based on wrong assumptions, but we rather aim at being a neutral, fact-based firm and make decisions this way.*

**Identifying new perspectives and insights.** Another reason for top managers to use BA is that it helps them to identify new perspectives and insights. Especially the increased amount of data and easy access to data seem to have enabled this. These enablers are also referred to by Interviewee D when they discuss the importance of having wide data and sharing it within the organization:

*<...> data helps us to start in the right angle, and we don't start at the same perspective. Therefore, data needs to be very wide and very opened, because this is about people's development. It's not about firm development, it's about people development. We develop, when the people develop, as a firm.*

Based on the interviews, BA output also helps top managers to look at things from new viewpoints, and this may also enable more options to choose from when making decisions. Interviewee L considers analytics can be used in a creative manner to enable this:

*I like it because it gives clear rationale, you can set the questions right for yourself on what you look for from analytics <...> At the end, what limits the use of analytics is the imagination, <to figure out> what we could investigate.*

**Getting a feeling of having made right decisions.** During the interviews, individual manager's personal preferences and feelings were also emerging as an important reason for using analytics. Some interviewees described themselves as number-oriented or 'engineers' and describe this as a reason for relying on analytics output in decision making. Interviewee L explains this as follows:

*First of all, I like numbers if you have not figured that out yet <...> Because numbers do not lie, they are nice in that sense, or they can of course lie but they are unambiguous, they are not necessarily opinions but based on analysing what happens when you take a move A and how it impacts the outcome B and what is the total cost C, and you can calculate what pays off and what not.*

Data was also described to bring comfort and peace of mind, resulting in a sense of control on running the business. Or as Interviewee A described this:

*I can go home at the end of the day and be more certain of having made the right decisions.*

There are various reasons for top managers to use BA and analytics output as part of their role. Next, we will describe various situations where top managers do this.

#### *4.2.2 Top management perceptions on when to use business analytics*

We identified four themes describing the situations when top managers would use analytics. These include: 1) Monitoring, following up and improving business and operations; 2) Conducting proactive analysis for planning purposes; 3) Long-term planning; and 4) Evaluating strategic options and making decisions. Summary of these second-order themes and related first-order coding can be found in Table 3. Next, we will describe these themes in more detail.

Table 3. Top management perceptions on when to use business analytics

First-order categories	Second-order themes
Monitoring and improving product- and asset-related operations Monitoring and improving sales and marketing impact Monitoring and improving customer service and management	Monitoring, following up and improving business and operations
Investment planning & timing Business planning Product planning Project planning	Conducting proactive analysis for planning purposes
Long-term plans Scenario simulations	Long-term planning
Investment/divestment decisions Product portfolio decisions	Evaluating strategic options and making decisions

**Monitoring, following up and improving business and operations.** BA appears to have an important role in monitoring the ongoing business and operations. There seem to be two reasons for this monitoring. First, top managers want to track the progress against set targets. Interviewee A gives an example of this:

*There may be certain areas where, it is obvious, I could not live without analytics. For example, performance-based management. The understanding how our performance is formed. It would not be enough for me if someone would just say that our turnover was this, costs were these and profit was this. It is so obvious, at least for me, to have the ability to go deeper and to measure both financial and operative performance indicators.*

Second, with the help of analytics, they can identify those areas that do not perform as expected and can decide on corrective actions based on these observations, as described by Interviewee I:

*If we think about the business and market areas, we have eight of them. On monthly basis, we monitor how they perform in order acquisition, sales, profitability. It also helps us see where we need to support more, where we need to push them more and so on. Where it pays off to do what, and you start to see how different products can be sold with different prices and profitability margins in different areas.*

What is exactly monitored with analytics seems to be strongly connected with the individual responsibility area of the interviewee. Besides business in general,

interviewees use analytics to monitor and improve, e.g., sales and marketing, customer service and management, and product and asset-related operations. Interviewee B shares their experience on supply chain analytics and planning:

*We are probably most advanced when it comes to supply chain analytics and planning. This is probably due to it being so complicated, it requires so many experts to make a decision that understanding this with human brain is practically impossible, we need to trust on analytics to tell us what we should do.*

**Conducting proactive analysis for planning purposes.** Besides monitoring the ongoing business and operations and identifying areas for improvement, top managers also use BA for more proactive planning. This occurs for certain planning purpose, such as project planning, product-related planning, business planning, investment planning, or longer-term planning. Proactive analysis and planning include combining data and information from different sources. Interviewee F provides an example:

*We combine our knowledge base on customer needs into customers and customer relationship. This information is our profound raw material, our own information from customer base, product base, transactions. <...> We then use these to model and plan <product features>.*

#### **Long-term planning.**

Top managers also see BA output as a basis for long-term planning. BA helps form an understanding of the current situation and thereby provides a starting point for longer term strategic plans. As described by Interviewee I:

*<Business analytics is used> to define market size and to forecast the future potential. <...> If we know where the growth comes from and what this requires from us, we then decide in the business line <...> on what to do to achieve this.*

Regarding longer-term planning, top managers also mention generating different future scenarios. This kind of scenario simulation involves BA outputs but also other types of internal and external data. Examples of the latter include governmental plans as well as different trend forecasts from research institutions and other third parties. Internal discussions also involve making assumptions as part of the analysis. Interviewees mentioned making analysis on potential growth scenarios, macro-environment development scenarios and demand scenarios. Interviewee H characterizes scenario analysis as follows:

*We do need to understand the growth scenario we have ahead of us, on longer term. In this case we were talking about looking forward some 10-15 years <...> I immediately understood we need to make a lot of assumptions, but we must start from somewhere to understand how the world would be and what has changed <...> If we want to calculate profitability potential, we need to anchor items that are critical for this. <...> Whenever you calculate something for the future, there are politics and development of population, urbanization <...> Quite a lot of external and already researched development paths to accompany own data.*

**Evaluating strategic options and making decisions.** BA also has a role in evaluating strategic options and making decisions. Similarly, to scenario simulations, BA output is combined with other data and information for this purpose. For example, evaluating options to invest/divest businesses or product lines were described to be examples of strategic decisions that require other information besides analytics output. Product portfolio decision was described by Interviewee I as follows:

*Product portfolio, in a sense that we know about our biggest customers and their plans. Let's say we have three optional ways to <serve them>. We take one and see whether they are going that way, and this indicates whether we should go to that direction. Then we also know the trends about how these products are used globally. Our R&D team has members who have long experience, they know how trends have developed over time. They can provide experience-based information and historical information on how technological trends have changed.*

#### **4.3 Discussion, limitations and future research ideas**

Top managers see many reasons for using BA, and they use it in various situations. What seems to emerge from the interviews is the different role of BA in different decision-making situations. The regular BA output does not seem to provide enough input when top management interest moves from monitoring the ongoing business into predicting what may take place in the future or evaluating what measures the firm should take on longer term perspective. This observation is in line with the previous research (Luoma, 2016; Kunc and O'Brien, 2018) that highlights the different nature of more strategic decisions that require more tailored analysis to be addressed. However, as the technological

development continues at an accelerated pace, it may bring along new opportunities for firms to increase the use of BA also in such situations.

There are some obvious limitations in this study. It was conducted in Finland involving large firms, and the empirical material consisted of 12 top manager interviews. Hence, the narrow geographical scope, the nature of the participating firms and the small number of interviews need to be considered to avoid any generalizations made based on this study.

Despite the limitations, these research findings provide useful ideas for future research. First, the material collected for this study can still be analysed further to identify those areas where top managers feel they do not benefit from using analytics. Such analysis would help identify potential measures firms could take to increase analytics usage among their top management. Second, investigating how analytics teams are currently supporting top management and how they could still increase this support may provide fruitful insight on measures to increase the use of analytics among top management. Third, launching a wider survey to collect the measures that have already been taken by the firms to increase the use of analytics would add another possibility to gain such information. Finally, to observe how the continuously evolving analytics technologies may impact BA usage in more complex, strategic decisions in firms, a longitudinal study may be a suitable solution.

## **5 Conclusions**

The objective of this study is to examine top management perceptions on using analytics in decision making. Based on our observations, opportunities to utilize analytics have increased as business operations have become more digital, and firms need to seize these opportunities to maintain their competitiveness. From managerial point of view, analytics facilitates holistic business monitoring and management, and helps justifying decisions and making them based on facts. On the other hand, it also enables top managers to identify new perspectives and insights. At the end, it also creates top managers a sense of having made right decisions.

While top managers use analytics in monitoring and managing the ongoing operations, analytics role in planning more strategic, future-oriented moves is to be one of the information sources and not the main source of information. Whereas top managers understand the potential of analytics in this area, they

experience that other sources of information are essential when it comes to strategic decision making.

This paper contributes to the currently ongoing academic discourse on BA business value by demonstrating how firms apply BA in top management decision-making activities. For scholars and other professionals interested in understanding the use of BA in top management decision making, this paper provides novel and current insights based on real-life experiences of top managers in large firms.

### Abstract

Heritage-specific intervention projects, through the use of the Building Information Modeling (BIM) methodology, are being continuously implemented at the level of data computerisation and process automation, across all BIM dimensions and project stages. In particular, through the 4D HeritageBIM (HBIM) phase, it is necessary to take into account specific classes of intervention of the asset and, specifically, to consider its phases of evolution through the different historical epochs. This is of considerable interest because it allows the reconstruction of the constructive evolution of historical assets. The geometric-informative model can be simulated and computerised to identify situations of degradation and weaknesses, caused by anthropic and non-anthropoc factors. In this regard, the present study proposes a Knowledge Management (KM) framework for the 4D HBIM domain, with focus on a bi-directional interoperability component and the "time" variable, which can be implemented through BuildingSMART's open-source IFC (Industry Foundation Classes) format and standard and, moreover, the tasks scheduling in an upstream structured Work Breakdown Structure (WBS), also considering the Critical Path Method for process optimisation. IFC format files were applied for 4D, through the Heritage-specific tasks and their timescales, in order to describe the HBIM entities and relations. Through the implementation of 4D HBIM, it is allowed to share the same model with AEC stakeholders, exporting prepared charts and technical diagrams, obtained in the open-source exchange format to allow interoperability of related data and metadata, between different information and technology systems. The combination of KM techniques and BIM methodology is growing and has enormous potential. Many authors have focused their research on the specific topics of knowledge organisation and structuring, using

ontologies, semantic networks and various types of data mining and machine learning algorithms. The work presented, and the related KM framework, is intended to provide new research insights specifically for 4D HBIM.

**Keywords** – Building Information Modeling, HBIM, BIM 4D, Knowledge Management, IFC

**Paper type** – Academic Research Paper

## 1 Introduction

Building Information Modeling (BIM) is a “a set of technologies, processes and policies enabling multiple stakeholders to collaboratively design, construct and operate (Succar & Sher, 2014) any built object (including buildings, bridges, roads, etc.)” (ISO 29481-1, 2016). BIM can be considered as an effective base to develop the necessary knowledge to operate in the Architecture Engineering and Construction sector (AEC) (Marinho et al., 2021).

A central concept of BIM is the construction of a model with multiple dimensions (nD BIM). The 4D is usually associated with construction planning, sequencing activities in space and time and the use of tools like the GANTT chart and the Critical Path Method (CPM) (Sacks et al., 2018). Construction companies traditionally rely on Enterprise Project Portfolio Management (EPPM) (Lock & Wagner, 2018) information systems which offer functionalities for CPM (critical path management), production and visualization of Gantt charts, etc. BIM 4D software tools aim at combining EPPM functionalities with the visualisation of the sequential construction of the building (BIM Handbook) (Eastman & Sacks, 2018). Even if theoretically 4D BIM should be produced automatically, there is still a need for intensive manual effort.

When it comes to 4D heritage BIM (HBIM), it is necessary to consider specific types of interventions (Guerra de Oliveira et al., 2022) and the historical evolution through different epochs (Bruno et al., 2021).

The fourth dimension (time/planning/task scheduling) of HBIM aims to provide information regarding the constructive evolution of the archaeological and historical assets. Models can be simulated and computerised in order to identify degradation and critical situations, caused by anthropogenic and non-anthropogenic factors. The process can be automated and the level of information and the structural status of the archaeological asset can be analysed through the time phases established upstream.

Combining BIM with Knowledge Management (KM) techniques is a growing research topic with great potential (Wang & Meng, 2021) (Hu et al., 2022). Many authors focused on knowledge organisation and extraction from BIM models using ontologies, semantic networks and data mining algorithms (Hu et al., 2022)

Achieving interoperability among systems through terminology and semantics is essential to make data and knowledge resources effective (NIEHS, 2018). In the BIM field, Industry Foundation Classes (IFC), a standard defined by the international body BuildingSMART, are considered an efficient instrument to enable interoperability among different information systems (Gerbino et al., 2021).

For these reasons, the present research proposes a BIM-based KM framework specific for 4D management in the HBIM context. The proposed system is then implemented as an automated link of information between HBIM models and an Engineering Project Portfolio Management System.

In order to establish the characteristics of the framework, as a first step, a literature review has been carried out on 4D BIM and HBIM and their current issues and future prospects. Secondly, available software applications for 4D BIM management and HBIM management have been analysed. This second analysis focused also on existing technologies that enable the manipulation of the open data format (IFC) in an open-source environment and, moreover, technologies that enable the exploitation of the format for collaborative work, also through web-based solutions.

Using a case study on a real heritage building and a focus group with experts in this specific field, the characteristics for knowledge definition and extraction from the HBIM model, have been exposed. A BIM model has been produced according to the results of the focus group, including time parameters and organising information in specific clusters. Finally, the framework for 4D HBIM Knowledge Management is presented.

## **2 State of the art**

### ***2.1 Knowledge organization in BIM: the role of IFC.***

One of BIM traditional aims is solving issues and costs deriving from inefficient information interoperability in the construction sector (Eastman & Sacks, 2018), where information is created *"and managed by multiple systems and multiple*

*parties through different phases of a project".* the Industry Foundation Classes (IFC) are one of the instruments for interoperability available in the BIM context.

Specified and developed by BuildingSMART, IFC is an open, vendor-neutral data repository for the semantic information of building objects, including geometry,

associated properties and relationships (Thein, 2011).

ISO 16739 describes the data schema of the IFC standard using the dedicated data modelling language EXPRESS. Using IFC it is possible to create, share and update models by putting the related information into a pre-defined and widely accepted skeleton that can be read by a number of BIM software applications.

IFC, together with system integration and the use of cloud technologies, make collaborative work on a central BIM model possible (Eastman & Sacks, 2018), enabling knowledge management (Kivits & Furneaux, 2013).

IFC follow a "quasi" object-oriented approach and describes buildings information and their relationships as a set of objects with attributes (Theiler & Smarsly, 2018).

When the need to include new, special parameters into IFC arises, IFC schemas can be "extended" using particular mechanisms (Yang et al., 2021), (Hamledari et al., 2017) and (Lauro, 2017). The first is to create new *entity types* and add them to IFCs including the necessary relationships; the second method is to instantiate the *IfcProxy*, *IfcBuildingElement* entities; and the third method is to implement Property Sets. The three methods described above have a set of *pros and cons*, and they are suitable for different application needs and professional fields.

## **2.2 4D BIM and its challenges**

The term 4D BIM refers to the nD BIM definition, in which a model of a building can go beyond the traditional three-dimensional representation with the additional dimensions used to describe a specific aspect. The fourth dimension of BIM, 4D BIM, has been traditionally associated with the description of the evolution of construction works through time and their management. Every object included in the model contains specific information about the project phase to which it belongs and when and how it will be constructed (Koutamanis, 2020). (Koutamanis, 2020) in particular, proposes an extended definition of BIM 4D as *"a sequential list of events, including all milestones in the design, construction, maintenance and usage of the symbolized object, regarding either*

*changes in its form and substance or in its relations to the environment*". One of the main applications of 4D concerns the scheduling of specific construction activities. Events and their nesting are used to divide construction activities into work packages, using the Work Breakdown Structure (WBS) (Park & Cai, 2017).

Moreover, 4D models allow representation, visualization and analysis of the variables affecting the construction phase and, when managed with dedicated software applications, they allow time, cost, quality and safety management (Ding et al., 2014).

Summing up, 4D models, when managed with specific software applications, should allow to:

- define, organize and visualize the project's WBS (Work Breakdown Structure, *i.e* the structured list of all project activities);
- associate each object of the model to the different activities in the WBS;
- visualize the GANTT diagram of the project and the Critical Path;
- simulate and visualize the evolution of the construction and its single components through time;
- identify and resolve possible conflicts (overlapping of incompatible processing, etc.), then enabling the *clash detection* over time;
- federate several 3D BIM models
- adding relevant activities to all objects, even those not directly related to the work (objects in a material storage area, etc.)
- share the 4D model with colleagues and professionals, exporting the diagrams and graphs obtained in different formats for enabling the interoperability.

Syncro Pro (Bentley software), Navisworks (Autodesk) seems to be the most popular 4D BIM modeling commercial software applications (Messi et al., 2022) but many others are available on the market (e.g. Bexel Manager (Bexel Consulting), Acca USBIM.gantt (Acca software), Vico Control (Vico-Software), etc.)

On the other hand, the commercial major applications for EPPM are: MS project, Oracle Primavera, SAP EPPM, whereas ProjectLibre or ProjeQtOr can be listed among the available open-source solutions.

### *2.2.1 Challenges for BIM 4D: organizational, standards, software*

Even if the benefits for 4D BIM are commonly recognised, a full exploitation of 4D BIM is still affected by a set of organizational and technical (software

functionalities) issues (Swallow & Zulu, 2019), (Campagna-Wilson & Boton, 2020), (Doukari et al., 2022).

Organizational issues:

- The temporary and unique nature of a project team and the related need to constantly adapt the working methodology to each new project;
- Lack of skilled and qualified staff and the cost of training;
- Industry's resistance to change;
- Poor involvement of subcontractors, manufacturers and suppliers;
- Lack of shared industry standards.

Technical issues:

- Lack of a fully collaborative environment;
- Costs of new IT tools and infrastructure;
- Limited activity scheduling functionalities;
- Difficult automation of the link between 3D objects and the schedule;
- Lack of interoperability between software applications;

(Doukari et al., 2022) also highlights:

*"the effort and skill needed to cope with the incompatibility between BIM authoring tools (e.g., Revit and ArchiCAD) and legacy scheduling tools (e.g., Primavera and MS Project) using 4D BIM management tools (e.g., Navisworks and Synchro Pro)"*

### **2.3 4D HBIM and its challenges**

When BIM concepts are applied to cultural heritage sites and buildings, the term Heritage BIM (HBIM) is used.

Producing a HBIM model usually starts from acquiring a point cloud survey of the heritage asset and entails *"the creation of a parametric library of parts and then mapping these library parts onto the point cloud"* a strategy *"required to model the more complex shapes found in historic buildings"*. HBIM includes also adding information about methods of construction, materials and surveys to the model. (Murphy et al., 2009).

Three types of 4D models can be produced for cultural heritage (Rodríguez-González et al., 2017): (i) a model representing the diachronic evolution of an asset no longer existing apart from some archaeological remains, (ii) the reconstruction of the diachronic evolution of a structure or environment based on

the historical analysis of data acquired on assets physically accessible at the present time or at an earlier time, (iii) a 4D BIM model related to the prediction of the diachronic evolution of an historical structure in the future based on the analysis of data acquired on physically accessible assets at different times.

In order to optimise the **knowledge organisation** related to a Heritage asset the **semantic description** of the architectural elements is crucially relevant. Semantic technologies like taxonomies, glossaries, knowledge graphs, and ontologies are needed to correctly produce HBIM models. (Guerra de Oliveira et al., 2022) (De Luca et al., 2006). Moreover, the formalization of knowledge into the model should consider the types of interventions specific to the heritage domain. (Guerra de Oliveira et al., 2022) for instance, lists the following types of heritage-specific interventions: conservation, maintenance, preservation, restoration, reconstruction, adaptation, demolition, rehabilitation, repair, renovation, additions, remodeling, refurbishment and retrofitting. For each type of intervention, distinct types of geometrical data (geometric, alphanumeric, documentary and operational data, supported by reliable representations, identification and definition of concepts, classes and relationships between each *cluster*) should be considered in order to obtain a valuable HBIM model.

Once the HBIM model has been produced, specific tools and software instruments are needed to perform 4D Data Management and Visualization on cultural Heritage (Rodríguez-González et al., 2017).

Organizing knowledge for heritage asset using IFC is still a challenge and the scientific research has proposed a number of solutions related to the specific project/asset. (Banfi, 2017), (Brusaporci et al., 2018), (Diara & Rinaudo, 2020).

(Bruno et al., 2021) analyse the historical evolution of Heritage BIM through the different eras. Answering to the need of a 4D for HBIM they define 4D **HBIMM** (Historic Building Information Modelling and Management) as a constantly evolving interface on which to progressively add future refurbishment and restoration interventions, allowing **interoperability** among stakeholders. It integrates the Historic Building Information Modelling (HBIM) with the **Information Management and 4D simulation** in order to achieve the above-mentioned objectives, employing the capability of BIM tools. The authors provide a framework and a case study but do not make use of IFC, still relying on a commercial proprietary platform.

In summary, the following issues for 4D HBIM were identified:

- Lack of international standards in the Heritage professional sector;

- IFC classes not yet sufficiently defined in the HBIM domain;
- Interoperability in 4D HBIM which needs different platforms and databases to be linked together;
- Need to implement tools to automate processes for 4D HBIM, especially into the *open-source sphere*.

Among the main issues, mentioned above, which serve as a concrete obstacle to be able to make the fourth dimension of Heritage (4D HBIM) possible, the most important and in need of development in the coming years is certainly the one related to the lack of interoperability of IT systems and different proprietary software platforms.

### 3 Defining the Framework

The present study proposes a new framework for scheduling, Management and Interoperability of 4D HBIM (Fig.1, below).

The framework is based on the bi-directional interoperability of two *logical levels* implemented through two different software environments: the BIM authoring tool and a BIM-based EPPM.

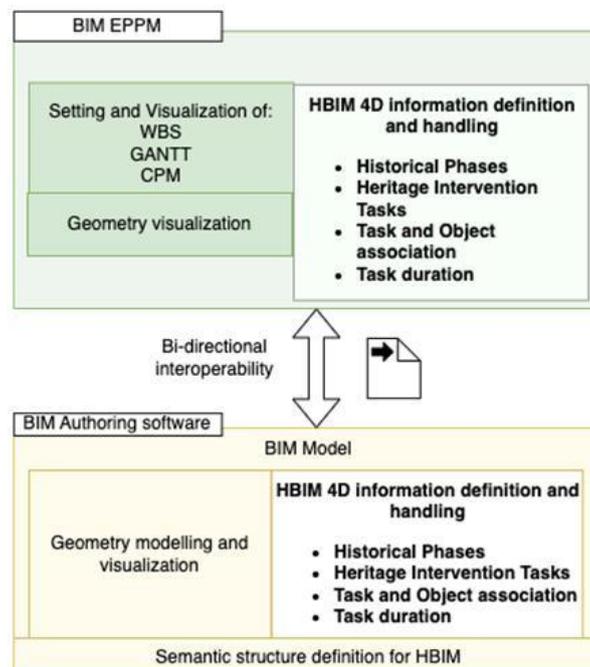

Figure 2 - KM Framework for 4D HBIM (Pt.I), two logical levels and software environments

First, the semantic structure of the HBIM asset is defined and agreed among the stakeholders, and described using the IFC classes in the specific field of Heritage, defining in advance which specific structural components of the heritage asset were going to be structured in the BIM Authoring software by predisposing the model to interoperability through the structuring of the IFC classes, also considering the different historical epochs.

In the current study, specifically, IFCs were used:

- to represent 4D (tasks and their duration)
- to describe specific entities for HBIM

The BIM Authoring software allows the generation of a high level of information in the Heritage domain (HBIM), through the asset geometric modelling and, simultaneously, its visualisation, enabling the preparation of the related Heritage intervention activities through the different historical epochs. In addition, the duration of each specific activity is also linked. In the proposed framework, the bi-directional interoperability of the proposed levels has a crucial role. From the software environment of BIM Authoring, it is possible to switch to the one of BIM EPPM (Enterprise Project Portfolio Management), in the distinctive of HBIM 4D, where, in addition to the geometric implementation and visualisation, the WBS (Work Breakdown Structure), the GANTT of the project tasks, their scheduling and the related CPM (Critical Path Method) planning, are associated.

The BIM-based EPPM level is based on two software environments where bi-directional interoperability was applied through the IFC model and classes definition, between Blender *open-source* software concerning the BIM modeling phase, and the API-extended OraclePrimavera relating to the setting and visualization of the WBS, GANTT and CPM. The sharing of information *layers* and the HBIM Model on servers and BIMviewer were involved. In reference to this, the IFC-specific extension enabled interoperability, the structuring, the scheduling visualization and, in conclusion, the phase of HBIM 4D.

In Fig.2, below, a reference image of the Paestum Temple model, created using Blender software, is included in the proposed operational framework.

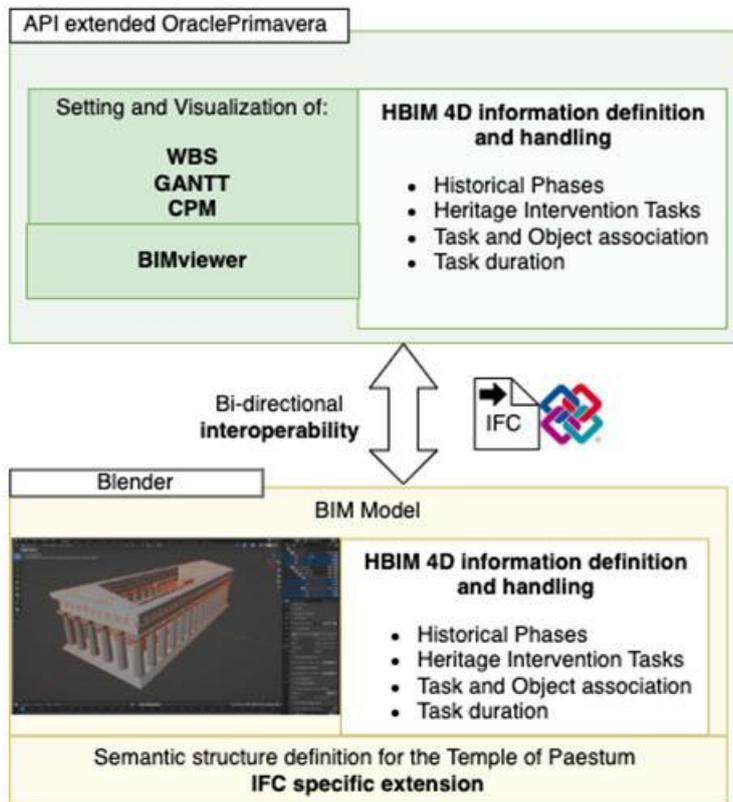

Figure 3 - KM Framework for 4D HBIM (Pt.II), open-source software and platform environments, IFC specific extension

The web-based visualization component for daily, database-supported 4D (Park et al., 2017) was considered as one of the key elements in the present work. The proposed method, taking a hint from the one of the authors (Park et al., 2017) was structured starting from the creation of the BIM model and the structuring of the tasks scheduling related to the same model, creation of the 4D HBIM model with database and automation through software platforms, database updating and scheduling, opening on web Browser/Server and importing on open-source platform for model management and visualization. These steps and specific framework, will be illustrated and explained in detail later in the current research paper. Moreover, the concept of interoperability analysis related to BIM platforms, has a distinct focus on construction management (De Gaetani et al., 2020), relating to the fourth dimension of BIM and, specifically, HBIM.

BIMserver/BIMviewer web application *tools and features* were used to implement the following features (Logothetis et al., 2018):

- 3D visualization and implementation;
- Online drawing, editing and file sharing;
- Clash Detection
- Folder hierarchy
- Support IFC files and implementation of IFC Classes
- Obj and WBS Viewer
- Enhancing BIMserver/BIMviewer tools, IFC Entities and IFC Relations
- Open-Source tools and plugins, enhanced interoperability.

### **3.1 Framework implementation: the Nettuno Temple, Paestum - Italy**

The framework has been implemented in a real case study (Fig.3).

The semantic of a temple has been defined in accordance to (Scianna et al., 2018), as a diagram relate to the structure of the doric temple (Temple of Neptune at Paestum), with the related substructures, compositional, historical and structural elements.

The new IFC classes needed, according to the semantic (*i.e., IfcColumn, IfcCapitol, IfcAbacus, IfcEchino*) have been added to the IFC schema as new entities.

The HBIM-IFC model of the Temple of Neptune at Paestum was produced using an *open-source* software (BLENDER) and a web app based on open-source software (BIMserver/BIMviewer) for the management and visualization of the classes and features of the presented model. An Add-on to the authoring software (Blender BIM plugin) was used for the implementation and the editing of the HBIM Model of the Temple.

The open-source BIMserver platform, suitable for the purposes of this study, was used for online visualization, data management and IFC classes of the Temple Model for 4D as well, through a Simplified Architecture Diagram (Beetz et al., 2010).

Using the BIMviewer application the following results were obtained: performing queries on the model, viewing IFC classes and the overall 3D geometrical HBIM model, 4D and tasks scheduling, the "tree diagram" of the project, and the ability to perform an online check of IFC Entities and IFC Relations.

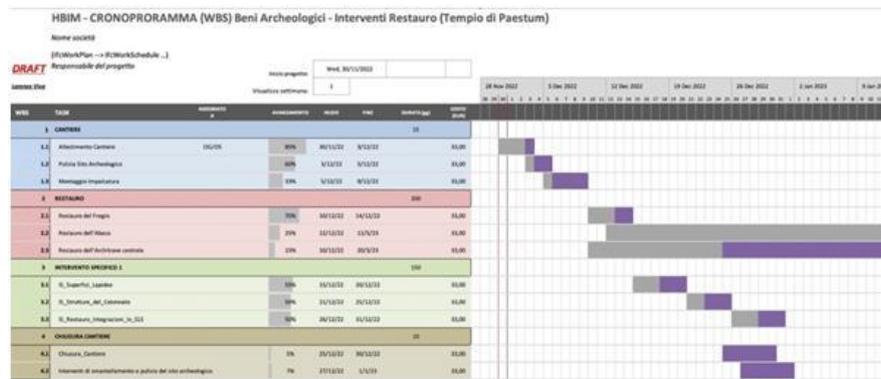

Figure 5 - Timeline/Scheduling - Project tasks, Temple restoration work - as draft. Tasks linked to IFC model and classes - Data Interoperability, 4D HBIM.

#### 4 Conclusions

This study proposes a framework for HBIM - 4D management, using mainly open-source software. The framework was implemented using a real asset, namely, the Magna Grecian temple in Paestum. The implementation needed the definition of specific IFC classes for the HBIM, especially for describing archaeological assets, not included in the official release, resulting in increased data interoperability and information definition. The IFC Model was implemented directly on Blender as an open-source software using a plugin, with which it is possible to edit the features of the model itself, increasing the information level of the IFC classes through the upstream setting of the ObjectType/UserDefined (that can also be adopted on Autodesk Revit SW). 4D functionalities could be performed on the model using EPPM Primavera software's API. Further steps on this research are to be conducted including the design and submission of questionnaire to a sample of experts in this particular field in order to receive feedbacks and validate the framework.

### **Abstract**

Following recent research calls that highlight the need for a more contextual approach to the study of intellectual capital (IC) that could provide managers with more fine-grained and actionable insights and recommendations, and considering recent concerns regarding the contribution of the marketing function to firm performance in the age of data, this paper aims at analysing how investments in marketing-specific structural capital and relational capital contribute to enhance marketers' knowledge (i.e., marketing-specific human capital) and lead to superior organizational marketing capabilities (i.e., product, price, place, and promotion) that translate into superior market performance and, ultimately, competitive advantage (i.e., superior financial performance). Based on survey data from 346 Spanish firms over 100 employees and using structural equation modelling (SEM) based on partial least squares (PLS), we find that both marketing-specific structural and relational capital are positively and strongly related to marketers' knowledge and that all marketing-specific IC categories (human, structural, and relational) are positively and significantly associated to marketing capabilities. At the same time, capabilities are strongly and positively related to market and financial performance. While marketing-specific structural capital is related to financial performance only indirectly (i.e., via human capital,

marketing capabilities, and market performance), human and relational capital are both directly and indirectly related to financial performance. Our findings also reveal what specific knowledge resources within each IC component are the most relevant, thus offering specific guidelines to improve marketing-related resource allocation decisions.

## 1 Introduction

Today's data analytics and digital revolution has completely transformed the marketing function (Sha and Murthi, 2021). The process by which companies engage customers, build strong customer relationships, and create customer value to capture value from customers in return (i.e., marketing; Kotler and Armstrong, 2018) is increasingly a data-driven process. Consistently with the above, marketing is the organizational unit where most data analytics efforts are being applied (McKinsey, 2020; The CMO Survey, 2022). However, the impact of the marketing function in the bottom line remains an open question. A recent survey found that 73% of CEOs think that marketers lack credibility and have quite a bit of work to do to earn their trust (Brenner, 2020). Indeed, since the early twenty-first century, a crisis of confidence set in (Webster et al., 2005) and a perceived lack of marketing accountability undermined marketing's credibility (Sha and Murthi, 2021). Voices emerged claiming that if marketing wanted "a seat at the table" in important business decisions, it had to link to financial performance (Lehman, 2004). This gave rise to a series of empirical studies analysing the relationship between marketing capabilities and firm financial performance— see Kamboj and Rahman (2015) for a summary—and between different types of marketing outcomes (e.g., customer satisfaction, customer value, brand awareness, etc.) and different facets of financial performance (e.g., firm value and/or stock performance; Sha and Murthi, 2021).

Despite the increasingly data-driven nature of the marketing function, these studies seldom include marketing-specific knowledge resources as a key foundation of marketing capabilities leading to superior market and financial performance. At best, market orientation is included as a complementary asset that works in conjunction with marketing capabilities (e.g., Morgan et al., 2009).

Such market orientation is conceived as “the extent to which the firm engages in the generation, dissemination, and response to market intelligence pertaining to current or future customer needs, competitor strategies and actions, channel requirements and abilities, and the broader business environment” (Morgan et al., 2009, p. 910). Thus, market orientation is a behavioural concept and the deployment of the kind of behaviour it implies should lead to the acquisition of knowledge resources (i.e., knowledge about customers, competitors, channels, and the broader business environment) that are disseminated throughout the organization to produce superior customer value (Kumar et al., 2011).

However, focusing on behaviour and omitting marketing-specific knowledge resources (i.e., marketing-specific intellectual capital—IC; Peñalba-Aguirrezabalaga et al., 2020) prevents to identify what kind of knowledge investments need to be prioritized to improve firm marketing capabilities (i.e., product, price, place, and promotion; Morgan et al., 2009; Kotler and Armstrong, 2018), increase the chances of customer attraction, retention, and cross-selling (i.e., market performance; Kotler and Armstrong, 2018) and improve financial performance.

People working at the marketing unit (i.e., marketing-specific human capital) are the ultimate decision-makers regarding marketing mix components. Therefore, hiring employees with proficient marketing knowledge and skills should translate into more effective marketing mix decisions. Nevertheless, other types of knowledge investments by the firm could contribute to enhance marketers’ knowledge and improve the quality of these decisions. According to the IC literature (Reed et al., 2006), such knowledge investments may refer to knowledge generated through and embedded in personal relationships (in this case, relationships with other people in the marketing unit, with people from other functions within the company, with customers, and with other external actors; Peñalba-Aguirrezabalaga et al., 2020) and to knowledge generated by means of information and communication technologies and/or residing in the organization’s information systems, databases, documents, routines, and/or procedures (i.e., marketing-specific structural capital; Peñalba-Aguirrezabalaga et al., 2020).

The first type of knowledge investment (i.e., investment in relational or social capital) implies a personalization knowledge management strategy (i.e., a person-to-person approach in which networks of relationships are the principal instrument for transferring tacit knowledge), while the second type of investment

(i.e., investment in structural capital) involves a codification knowledge management strategy or people-to-documents approach grounded on explicit knowledge (Hansen et al., 1999; Buenechea-Elberdin et al., 2018).

Considering the above and based on the resource-based view of the firm, this paper aims to bridge the gap between the marketing function and financial performance by showing how investments in marketing-specific structural capital and relational capital contribute to enhance marketers' knowledge (i.e., marketing-specific human capital) and lead to superior organizational marketing capabilities (i.e., product, price, place, and promotion) that translate into superior market performance and, ultimately, superior financial performance. By analysing direct and indirect relationships in the knowledge resources -> marketing capabilities -> market performance, and -> financial performance chain, this paper will offer a fine-grained picture of how the marketing unit contributes to firm competitive advantage, thus helping to restore the legitimacy and credibility of the marketing function.

## **2 Theoretical background**

According to the resource-based view, differences in firm performance are due to resource heterogeneity (Barney, 1991; Peteraf, 1993). Firms with valuable, rare, difficult-to-imitate, and non-substitutive resources (i.e., VRIN framework; Barney, 1991) are more prone to generate sustainable competitive advantages. Among the array of resources a company may have access to, knowledge resources play a prominent role. First, organizational knowledge is a complex resource (i.e., it is often made up of different interdependent components that may be held by different individuals and units; Kim and Anand, 2018); second, it can be the result of unique socio-historical conditions and accumulated set of experiences (Barney, 1991); and third, its usability and effectiveness may be highly dependent on the characteristics of the context (i.e., something that works in a particular setting may not work in another one; e.g., Kianto et al., 2020). As a result, knowledge is much more difficult-to-imitate and replicate than tangible resources.

The set of knowledge resources a company manages and has access to constitutes its intellectual capital (Youndt et al., 2004; Reed et al., 2006). Within the IC literature, knowledge resources are usually classified into three main categories, depending on where they reside (e.g., Reed et al., 2006): human capital (i.e., knowledge residing in individuals); structural or organizational capital

(i.e., knowledge residing in the organization, e.g., in its information systems, databases, documents, manuals, or other kinds of knowledge repositories); and relational or social capital (i.e., knowledge generated through and embedded in personal relationships). While structural capital is mostly related to explicit knowledge (i.e., knowledge that “can be expressed in words and numbers, and easily communicated and shared in the form of hard data, scientific formulae, codified procedures, or universal principles”— Nonaka and Takeuchi, 1995, p. 8), relational capital is mainly related to tacit knowledge (i.e., subjective insights, intuitions, and hunches, which are not easily visible and expressible, and are highly personal and hard to formalize— Nonaka and Takeuchi, 1995). According to the proponents of the IC view of the firm (which constitutes a mid-range theory dealing with a specific aspect of the more general resource-based view, i.e., knowledge resources), both types of IC (structural and relational) could be used to leverage human capital and thus improve employees’ knowledge (Reed et al., 2006).

Most of the time, IC research adopts an organization-wide perspective and studies seeking to analyse the relationship between IC and different types of performance focus on organization-wide human capital, structural capital, and relational capital. However, recent research calls highlight the need for a more contextual approach to IC that could provide managers with more fine-grained and actionable insights and recommendations (Kianto et al., 2020; Peñalba-Aguirrezabalaga et al., 2020) and that could allow to analyse the contribution of specific organizational units to overall firm performance (e.g., Sáenz et al., 2022). In this light, Peñalba-Aguirrezabalaga et al. (2020) coined the notion of marketing-specific IC. This refers to “all of the valuable marketing-specific knowledge resources than an organization manages in developing its marketing capabilities and achieving its marketing-related goals” (Peñalba-Aguirrezabalaga et al., 2020).

As for company-wide IC, marketing-specific IC is split up into three main categories: marketing-specific human capital (which includes marketers’ customer, product/service, and market knowledge, as well as employees’ marketing-related skills), marketing-specific structural capital (which encompasses knowledge generated by means of marketing-related IT solutions as well as marketing department’s “organizational memory”—i.e., other knowledge residing in the organization that does not necessarily imply data processing), and marketing-specific relational capital (which includes knowledge generated

through and embedded in the marketing department's internal and external relationships) (Peñalba-Aguirrezabalaga et al., 2020).

The above definition of marketing-specific IC highlights the role of knowledge resources as the building blocks of organizational capabilities (in this case, marketing capabilities). According to the resource-based literature, resources must work together to carry out key activities and achieve desired end results (Grant, 2021). More precisely, organizational capabilities are "complex bundles of skills and accumulated knowledge, exercised through organizational processes, that enable firms to coordinate activities and make use of their assets" (Day, 1994, p. 38). In line with the above, marketing capabilities are exercised through marketing mix processes (Morgan et al., 2009), namely, product management and development, price setting, distribution channel management—i.e., "place"—, and communication or promotion activities. By means of the right mix of the above elements, companies expect to attract and retain customers, as well as to increase their sales to them, which constitutes a firm's market performance (Kotler and Armstrong, 2018). However, to translate into positive financial performance, sales-related outcomes derived from marketing capabilities should be combined with efficient use of resources and the selection of most profitable alternatives.

### **3 Hypothesis development**

#### ***3.1 The reinforcing role of marketing-specific structural and relational capital vis-à-vis marketing-specific human capital***

Marketing department's organizational memory (i.e., any stored marketing-related knowledge that employees can access physically and/or digitally; Peñalba-Aguirrezabalaga et al., 2020) provides marketers with a useful source to improve their customer knowledge, product/service knowledge, and market knowledge, as well as to improve their marketing-related skills. In other words, organizational memory (i.e., one of the two constituents of marketing-specific structural capital) offers employees the opportunity to leverage on past experience (Walsh and Ungson, 1991). For instance, having access to customer historical data may help discover useful insights regarding customer preferences, needs, and behaviour. Likewise, documented knowledge on product development, specifications, and performance may help marketers to better understand product features, functionalities, benefits, and limitations. Similarly, stored knowledge on market

trends and competitor analysis may improve marketing employees' market knowledge. And having access to documented best practices, case studies, and success stories may provide marketers with useful insights to improve their skills.

Moreover, today's available marketing-related IT solutions (e.g., customer relationship management systems) and data analytics tools and techniques (e.g., transactional data analytics, website analytics, and social media analytics) could help improve marketers' customer knowledge by creating detailed customer profiles and identifying behavioural patterns and trends. Product analytics can also help identify what product characteristics are more appealing to customers, while competitive intelligence tools may help identify competitors' strategies and market shifts.

Therefore, the following hypothesis is formulated:

*H1: Marketing-specific structural capital is positively related to marketing-specific human capital.*

The IC literature considers knowledge generated through and embedded in personal relationships (i.e., relational or social capital) another relevant antecedent of human capital (e.g., Reed et al., 2006). Indeed, social interaction supports the assimilation of knowledge resources by allowing the exchange and combination of each other's knowledge to generate new knowledge (Tsai and Ghoshal, 1998; Peñalba et al., 2022). For instance, conversation among members of the marketing department on customer feedback and behaviour may favour the generation of new insights regarding customer needs and expectations, as well as on product use. Likewise, regular interaction with colleagues in the marketing department can provide opportunities for mutual learning and skill improvement. Furthermore, social interaction with people from other departments of the company, such as engineering and product development, can help marketers better understand the characteristics of the products and services they are marketing; and interaction with people from corporate development may help them better understand market trends and emerging opportunities and threats.

Moving now to external relational capital, listening directly to customers and interacting with them may lead to additional insights in terms of customer needs, preferences, reactions, product use, and competitor perception that registered transactions and written documents cannot capture. Moreover, interacting with customers can provide marketers the opportunity to enhance different types of skills, such as communication and problem-solving. Finally, relationships with

other external actors, such as influencers, may be a relevant source to complement customer knowledge and gain relevant insights referring to products and/or services, while interaction with distributors can provide relevant knowledge regarding consumers' buying behaviour and competitors' strategies.

Hence, we hypothesize that:

*H2: Marketing-specific relational capital is positively related to marketing-specific human capital.*

### **3.2 Marketing-specific human capital and marketing capabilities**

Marketers are the ultimate decision-makers regarding marketing mix components. Therefore, marketers' knowledge is a key aspect to guarantee the right decisions are made and satisfy customer needs better than competitors (e.g., Rapp et al., 2006; Peñalba-Aguirrezabalaga et al., 2021).

Deep knowledge regarding customer needs and preferences can help design products that better address them; understanding current products' characteristics and performance can lead to the identification of potential innovation opportunities based on detected weaknesses; and knowing competitors' offering very well can help identify existing gaps in the market. Moreover, understanding customers' reaction to price variations, knowing products' cost structure, and competitors' pricing strategies may help choose the best price options; and knowing customers' purchasing and product reception preferences, products' technical requirements in terms of delivery, and how different distribution channels work may facilitate more effective and efficient distribution decisions. Finally, good product knowledge may help develop communication messages that highlight products' unique features and benefits, while understanding the motivational levers that induce customers to buy may help stress those aspects that emotionally connect with them, and good knowledge of competitors' communication strategies may help develop messaging that differentiates company products from those of competitors and highlights the firm's unique value proposition.

Beyond customer, product, and market knowledge, an array of skills is also needed to develop an effective marketing mix strategy: e.g., analytical skills that allow to identify patterns of customer behaviour; adaptive skills to quickly address changes in the above behavioural patterns, market trends, and competitor

actions; and communication and creative skills to develop effective messaging that resonates in the target audience.

Thus, the following hypothesis is suggested:

*H3: Marketing-specific human capital is positively related to marketing capabilities.*

### **3.3 Marketing capabilities and performance**

Several studies have demonstrated the positive relationship between marketing capabilities and firm performance (e.g., Morgan et al., 2009; Ngo and O’Cass, 2012; Cacciolatti and Lee, 2016). First, developing superior products that meet or exceed customers’ expectations and deliver superior customer value may attract new customers as well as increase their loyalty. Second, effective pricing strategies may boost the chances of capturing value from customers and securing revenues by accounting for differences in customer segments and situations. Third, effective distribution helps guarantee that firm’s products are easily accessible to all customers, thus facilitating repeated sales. And fourth, effective communication strategies may help build brand awareness and create strong emotional connection with customers, hence facilitating customer attraction and retention. Therefore, we hypothesize that:

*H4: Marketing capabilities are positively related to market performance.*

Going one step further, ensuring sales by means of new customer attraction, customer retention, and increased sales to already existing customers should contribute to improving firm financial performance. Hence, the following hypothesis is formulated:

*H5: Market performance is positively related to financial performance.*

However, superior marketing capabilities are also expected to be directly related to firm financial performance. Indeed, good marketing mix decisions not only should lead to increased sales but should also promote resource efficiency and help optimize the cost-benefit ratio of the implemented strategies. Thus, it is hypothesized that:

*H6: Marketing capabilities as positively related to financial performance.*

### **3.4 Additional relationships**

The sequential set of relationships previously described implies a series of potential indirect relationships whose significance will also be tested in the research. For instance, it is expected that marketing-specific structural capital and relational capital affect marketing capabilities via their positive influence on marketing-specific human capital; that all types of marketing-specific IC components affect market performance via their positive effect on marketing capabilities; and that all marketing-specific IC categories and marketing capabilities affect financial performance via their positive impact on market performance.

Moreover, non-sequential direct relationships are also expected: marketing-specific structural and relational capital may have additional positive effects on marketing capabilities beyond the promotion of marketers' knowledge (i.e., marketing-specific human capital); all types of marketing-specific IC may also have additional positive effects on market performance beyond the promotion of marketing capabilities; and both marketing-specific IC categories and marketing capabilities may have additional positive effects on financial performance beyond their positive impact on market performance (indeed, the last linkage has already been included in hypothesis H6). These direct relationships will also be tested so as to determine whether partially or fully mediated relationships apply.

## **4 Methods**

### **4.1 Sample and data collection**

Survey data from a representative sample of Spanish companies with at least 100 employees was used to test the research hypotheses. The above employee threshold was established to guarantee that companies had a well-established marketing and sales function. The Sistema de Análisis de Balances Ibéricos (System of Iberian Balance Sheet Analysis; SABI) database was used to identify companies that met the criterion (2,436). Setting out from the above finite population, the sample size needed to carry out a representative study (342 firms) was calculated, and a stratified sampling procedure was then applied to guarantee that different proportions of company types according to industry, size, and technology level were preserved as in the population. The final sample

included 346 companies that answered the provided email or phone survey. 85.26% of the respondents held a managerial role in the marketing domain, 6.65% were marketing and sales technicians or assistants, 5.20% were CEOs, 1.45% were salespeople, and the remaining 1.45% did not specify their role.

#### **4.2 Measures**

The research model under study included two independent variables (marketing-specific structural and relational capital), three mediating variables (marketing-specific human capital, marketing capabilities, and market performance), one dependent variable (financial performance), and two control variables (size, i.e., the natural logarithm of the number of employees, and customer type, i.e., business-to-business—B2B—vs. business-to-consumer—B2C). All the independent, mediating, and dependent variables were conceived as combinations of different elements that define the conceptual variable they represent and were measured by means of 7-point Likert scales.

Regarding marketing-specific IC categories, measures used corresponded to the summary indicators suggested by Peñalba-Aguirrezabalaga et al. (2020) in their marketing-specific IC scale. In the above scale, there was a detailed list of indicators for each of the sub-components making up each IC category and one summary indicator per sub-component. The authors demonstrated that the list of indicators within each sub-component converged into the summary indicator proposed in each case. Therefore, such summary indicators could be used to represent each of the sub-components and thus analyse the relevance of marketing-specific IC as a whole by means of single and handy model (otherwise, we should have as many constructs as sub-components—i.e., 10 instead of 3—plus the remaining mediating and dependent variables, and control variables). In the case of marketing-specific human capital, there is one indicator for marketers' customer knowledge, another one for product or technical knowledge, a third one for market knowledge, and a fourth one for marketing-related skills<sup>1</sup>. In the case of marketing-specific structural capital, there is one indicator for marketing department's organizational memory and a second one for IT capital (i.e., knowledge generated by means of marketing-related IT solutions), while in the

---

<sup>1</sup> As compared to Peñalba-Aguirrezabalaga et al. (2020), marketing employees' educational background and experience have been omitted, as they work as antecedents of the remaining knowledge items.

case of marketing-specific relational capital, there is one indicator for marketing department's internal relational capital (i.e., knowledge generated through and embedded in relationships between employees of the marketing department), another one for interdepartmental relational capital, a third one for customer-related external relational capital, and a fourth one regarding other external actors (e.g., regulators, suppliers, researchers, competitors, etc.).

Moving now to marketing capabilities, here there is one indicator measuring the company's position vis-à-vis competitors per each of the capabilities corresponding to the classical components of the marketing mix (i.e., product, price, place, and promotion; Kotler and Armstrong, 2018). The same type of valuation (i.e., valuation vis-à-vis competitors) was asked for the three indicators related to market performance (i.e., customer attraction, customer retention, and increased sales to already existing customers) and to financial performance (productivity, efficiency, and profitability).

As previously explained, the indicators chosen define or shape the underlying variables, instead of being caused by them (i.e., the variables "emerge" from the indicators; Hair et al., 2022). Such underlying variables constitute purely conceptual abstractions or human-made artifacts and do not really exist in nature. When this is the case, a composite measurement model applies (Henseler, 2017). In composite measurement, latent variable scores are calculated by means of linear combinations of the indicators that make them up. To calculate indicators' weights in these linear combinations, two methods exist, which are called mode "A" and mode "B". In mode "A", weights are calculated by means of simple correlations, while in mode "B", they are calculated by means of multiple regression. This choice will depend on the degree of collinearity of the indicators within a particular construct. If collinearity is high, this could cause problems in the estimation of indicators' weights in mode "B" composites. Under these circumstances, researchers should consider using mode "A" (Henseler, 2017; Rigdon, 2016). As in our case no collinearity problems exist (see the measurement model evaluation section), mode "B" has been chosen, as this allows to assess the relative relevance of each indicator when it comes to maximizing the amount of variance explained of the mediating and dependent variables.

### **4.3 Statistical analyses**

The proposed research model was analysed with SEM based on PLS using SmartPLS 3.3.5 software (Ringle et al., 2015). This choice was made due to the "emergent" nature of the variables under study. Unlike covariance-based SEM, which adopts a common factor approach, PLS-based SEM relies only on composites (Rigdon, 2016). There are two stages of PLS-based SEM: (1) assessment of the measurement model and (2) assessment of the structural model. Conducting assessments in this order ensures that the constructs' measures are valid and reliable before drawing conclusions about the relationships among constructs (Barclay et al., 1995).

## **5 Results**

Once the quality of the measurement model was guaranteed (detailed explanations and tables have been omitted for space reasons), one-tailed 5,000 subsample BCA bootstrap was used to test the significance and strength of the proposed relationships, (Hair et al., 2022). Table 1 shows the results obtained. As can be observed, marketing-specific SC ( $\beta = 0.353$ ) and marketing-specific RC ( $\beta = 0.410$ ) are positively and significantly related to marketing-specific human capital. Therefore, hypotheses H1 and H2 are supported. Likewise, marketing-specific human capital is positively and significantly related to marketing capabilities ( $\beta = 0.224$ ), and the latter are positively and strongly associated with market performance ( $\beta = 0.447$ ). Hence, hypothesis H3 and H4 are supported. Finally, market performance ( $\beta = 0.455$ ) and marketing capabilities ( $\beta = 0.191$ ) are positively and significantly related to financial performance. Thus, hypothesis H5 and H6 are supported.

Regarding the remaining direct and indirect relationships in the marketing function -> financial performance chain, the following can be observed: Marketing-specific structural capital and marketing-specific relational capital are positively and significantly related to marketing capabilities, both directly and indirectly. In other words, both IC categories have additional benefits on marketing capabilities beyond their contribution to improving marketers' knowledge. Therefore, partial mediation applies (i.e., marketing-specific human capital partially mediates the relationship between marketing-specific structural capital and marketing capabilities, and between marketing-specific relational capital and marketing capabilities).

Moreover, although marketing-specific structural capital is positively and significantly related to market performance, both directly and indirectly, marketing-specific relational capital and human capital are only indirectly related to market performance. Put it differently, although in the case of marketing-specific structural capital partial mediation applies, in the case of the other two IC categories full mediation applies. Thus, marketing-specific structural capital has additional benefits on market performance beyond the promotion of marketing-specific human capital and marketing capabilities, while marketing-specific relational capital and human capital only contribute to market performance inasmuch they contribute to strengthening marketing capabilities.

Third, marketing capabilities are positively and significantly related to financial performance, both directly (as previously said) and indirectly. Therefore, partial mediation applies (i.e., market performance partially mediates the relationship between marketing capabilities and financial performance) or, in other words, marketing capabilities have additional benefits on financial performance beyond the promotion of market-related (i.e., sales-related) results.

Finally, although marketing-specific structural capital is only indirectly and positively related to financial performance (i.e., full mediation applies), marketing-specific relational and human capital are both directly and indirectly related to financial performance (i.e., partial mediation applies). Put it differently, marketing-specific structural capital only seems to affect financial performance from the "income" side, while marketing-specific relational capital and human capital seem to affect financial performance both from the "income" and "cost" sides.

In terms of total effects (i.e., direct + indirect effects), and regarding marketing-specific IC components, marketing-specific relational capital shows the largest effect both in marketing capabilities (0.376) and financial performance (0.366), followed by structural capital and human capital, which are virtually tied, their total effects on both variables (i.e., marketing capabilities and financial performance) being between 0.224 and 0.237. However, in terms of market performance, marketing-specific structural capital is the IC component that shows the largest total effect (0.316), followed by relational capital (0.282) and human capital (0.154). Finally, the total effect of marketing capabilities on financial performance is 0.408.

As far as the relative relevance of each of the elements making up Mode "B" composites is concerned (once more, detailed tables have been omitted for space reasons), indicators' weights show that both organisational memory and IT capital

are statistically relevant within marketing-specific structural capital, the same as all dimensions within marketing-specific relational capital. However, it can be observed that internal relational capital constituents show noticeably stronger weights than external relational capital components. In the case of marketing-specific human capital, marketing-related skills and customer knowledge constitute the most relevant items, followed by market knowledge. Conversely, knowledge about products and services is barely relevant. Moving now to marketing capabilities, communication capabilities appear to be the most important, followed by product-related capabilities, and pricing. Distribution capabilities, however, are not significant. Finally, all items' weights within market and financial performance are statistically relevant.

The coefficient of determination ( $R^2$  value) of the mediating and dependent variables was also examined, which represents a measure of in-sample predictive power that also indicates explanatory power (Benítez et al., 2020; Hair et al., 2022). As can be observed in Table 1, the amount of variance explained for marketing-specific human capital reached 48%, 33.8% for marketing capabilities, 45.1% for market performance, 54.7% for financial performance.

## 6 Conclusions

This paper offered a step-by-step view on how investments in marketing-specific knowledge resources contribute to both market and financial performance through the development of marketing capabilities. It also showed the contribution of individual items within each marketing-specific IC category, as well as within marketing capabilities. In doing so, it contributed to both the marketing and IC literatures.

On the one hand, the results obtained highlight the complementarity of marketing-specific structural and relational capital when it comes to boosting marketers' knowledge and marketing capabilities. Even though we live in the age of data, social interaction with internal and external actors still plays a substantial role and constitutes an extremely important source of knowledge. Especially, the results obtained show how relevant is to promote social interaction within the marketing department and with other departments of the company beyond doing so with customers and other external actors. Nevertheless, company investments in marketing-specific ICT-based solutions and data analytics, as well as in other forms of organizational memory, proved to be essential drivers to enhance marketers' knowledge and develop superior marketing capabilities.

Moreover, the results obtained contributed to restore the legitimacy and relevance of the marketing department since it was proven that superior marketing-specific knowledge resources and marketing capabilities were able to explain a large portion of firms' market and financial performance.

### Abstract

Visual frameworks can be essential tools for service process management and innovation as long as they succeed in representing certain key features. Firstly, they should make it possible to visualize all the steps that make up the processes. Second, they should enable representing customer interaction (i.e., the interaction between customers and service providers) and customer participation (i.e., customer contribution to service production and delivery). Third, they should help identify interacting stakeholders and assess their role in the value (co)creation process. Fourth, they should allow identifying non-value-added steps. Finally, they should provide information about the duration of process steps and the channels through which the service is delivered (e.g., face-to-face or telephone).

Several visual frameworks have been developed (Business Process Modeling Notation, Service Blueprinting, etc.), but Process Chain Network (PCN) Diagrams are the most comprehensive. Unfortunately, those diagrams have some limitations. First, PCN diagrams assume that a process begins when the customer expresses a need and ends when the need is satisfied. However, this choice may be inconvenient or impossible. In addition, they usually group stakeholders. This grouping is generally functional, but sometimes more detail is needed. In addition, the description of non-value-added steps could be refined. Finally, they do not provide an understanding of the duration of process steps or the channel through which the service is delivered. These limitations are significant in complex and lengthy processes such as health services.

Taking PCN diagrams as a reference, this paper proposes PCN 2.0 diagrams to overcome these limitations. We first conceptualized the elements a visual framework should include reviewing widely used ones. Then we refined our framework by representing actual service processes. Finally, we demonstrated the power of our framework through its application to the televisit service offered by one of the leading children's hospitals in Europe.

This study contributes to the existing literature by presenting an improved version of PCN diagrams. Our framework could support researchers and practitioners in service management and innovation for its completeness and clarity. Although we show an example drawn from the health sector, the framework is assumed to be generalizable.

## 1 Introduction

Visual frameworks can be essential tools in service process analysis and innovation because they highlight phenomena that otherwise might be difficult to conceptualize (Sampson, 2012). To do that, they should represent the following key **features**.

First, customers always participate in service delivery by providing resources essential to the process and/or participating in the actual execution of the process (Grönroos, 2006; Sampson and Froehle, 2006). Thus, customer interaction and customer participation are two key strategic factors of any service business (Chase, 1978; Sampson, 2000; Sampson and Chase, 2022). **Customer interaction** refers to the interaction between a customer and a provider (Grönroos, 2006). Initially, researchers focused only on face-to-face interaction (Chase, 1978) but then refined the concept. For instance, Sampson (2012) describes two primary types of interaction: the direct interaction, which is person-to-person interaction, either in person or mediated by technology (e.g., a phone call), and the surrogate interaction, in which an entity interacts with a resource of another entity, such as a technology (e.g., online banking). Increasing customer interaction may enhance customization potential (Sampson *et al.*, 2015). However, too much customer interaction may reduce operating efficiencies (Sampson and Chase, 2020) and negatively affect service quality (Frei, 2006). **Customer participation** is the degree to which a customer contributes to service production and delivery by providing inputs such as effort, preference, or knowledge (Dong *et al.*, 2015). Co-production is the case of customer participation under the provider's purview (Auh *et al.*, 2007). Increasing customer participation may facilitate the alignment between the operation's capabilities and its customers' needs and preferences (Lusch and Vargo, 2006), enhance customization (Xie *et al.*, 2008), and reduce

labor costs (Bowen *et al.*, 1986). However, too much customer participation may compromise quality and depersonalize service relationships (Sampson and Chase, 2022). Over the years, the interrelationships between customer participation and customer interaction and the resulting production models have been studied extensively (Grönroos, 2011; Meuter *et al.*, 2000; Moeller, 2008; Sampson and Chase, 2022). In recent years, we have seen companies increase interaction through servitization (manufacturers shift to a service focus (Raddats *et al.*, 2019)) and increase customer participation through self-service technologies (Frei, 2006; Sampson and Chase, 2022).

Technological advances have catalyzed a proliferation of service delivery **channels** (e.g., face-to-face, phone, online, mobile), allowing many more customer touchpoints. Combining multiple channels during the customer journey can improve convenience and access to information, goods, and services, boosting customer satisfaction, loyalty, and sales (Bell *et al.*, 2018; Wallace *et al.*, 2004). However, increasing the number of service delivery channels can alter how customers engage with firms (Gallino *et al.*, 2017; Gallino and Moreno, 2014) and introduce complexities that hinder the consistency of the service they experience (Field *et al.*, 2018). Each channel implies specific participation roles and responsibilities for both sides and can differently impact the service process's overall perceptions (such as perceived value, perceived quality, trust, and satisfaction) (Field *et al.*, 2018). Therefore, visual frameworks should consider the channel through which customer interaction occurs.

In service processes, networks of stakeholders (**Service Value Networks** (SVN)) interact to provide mutual value to all the stakeholders participating (Sampson, 2015). Thus, to manage and innovate a service process, we need to identify all the participants in the network (and not just consider the client-provider dichotomy) and their roles in the process (Sampson, 2015).

A process chain is a sequence of steps with an identifiable purpose (Sampson 2015). Customers and providers participate in a process chain to receive some benefit. Customers participate to benefit from the specialized competencies of the process chain. Providers participate to receive money that they will subsequently deploy to meet needs from other process chains. **Value** for the customers exists in two ways: value potential, which is the ability to satisfy the needs of the future, and value realization, which is the actual satisfaction of needs in the present. Moreover, a process step produces value if it develops the resources that customers will later use to realize value. Suppose any step of the

process does not contribute to either value potential or value realization, and it doesn't produce value. In that case, it could be eliminated unless it is necessary for accounting or regulatory reasons (Sampson, 2001). Thus, visual frameworks should show that information.

The **duration** of steps composing processes is crucial in service process analysis and innovation (Visintin *et al.*, 2014). It could be the reason why one process configuration results better than another. For instance, we could opt for a design that reduces the time to obtain the diagnosis or the one between two follow-up visits. Moreover, the customer's time in the system could be an important indicator of service quality. Finally, knowing the duration of steps composing processes may highlight how much time we spend on non-value-added steps.

Several visual frameworks have been developed over the years (Business Process Modeling Notation, Value Stream Mapping, Supply Chain Diagrams, Service Blueprinting, Customer Journey Map, Process Chain Network (PCN) Diagrams), but **PCN Diagrams** (Sampson, 2012; Sampson *et al.*, 2015) turn out to be the most comprehensive. Indeed, they show the steps making up service processes, the stakeholders in the SVN, the nature of customer interactions, and stakeholders' roles in the process. PCN has been used to improve service systems by introducing Information and Communication Technology (Rapaccini and Porcelli, 2013), to analyze the healthcare supply chain process (Sampson *et al.*, 2015), hotel facilities (Borges *et al.*, 2011) or the library services process (Suwadi and Jenal, 2019).

Unfortunately, the current version of PCN Diagrams is not without **limitations**. First, PCN Diagrams assume that a process begins when the customer expresses a need and ends when the need is satisfied. This choice may be inconvenient (if the process of achieving need satisfaction is very long or complex) or impossible (if need satisfaction is never achieved, as in the case of chronic diseases). Furthermore, although PCN Diagrams may show all the stakeholders in the SVN, stakeholders are usually grouped in practice. This grouping is generally functional, but sometimes more details are needed. Although the customer interaction types are analyzed, the service delivery channels are not: they classify all synchronous interactions as direct interactions and all the asynchronous interactions as "surrogate" interactions without considering the channel. Moreover, they do not distinguish between the process steps where customers recognize value potential, the ones where customers realize value, the ones that

produce value, and those necessary for accounting or regulatory reasons. Finally, they do not specify the duration of the steps making up service processes. These limitations are particularly significant in complex and lengthy service processes such as healthcare services (Roshanghalb *et al.*, 2018). Thus, we aimed to identify a visual framework capable of guiding practitioners and researchers in analyzing and innovating service processes.

Taking the PCN Diagrams as a reference, this paper proposes **PCN 2.0 Diagrams** that overcome these limitations. We first adopted a conceptual-to-empirical approach and then an empirical-to-conceptual one. In the conceptual-to-empirical phase, we conceptualized the elements a visual framework should include reviewing the widely used visual framework. In the empirical-to-conceptual phase, we refined our framework by representing actual service processes. Finally, we demonstrated the power of our framework through its application to a real case: the televisit service offered by one of Europe's leading children's hospitals.

This study contributes to the existing literature by presenting an improved version of the PCN Diagrams. The changes make it possible to provide all the information needed in service management and innovation without making the framework too complex. Indeed, the new framework is intuitive and rigorous. Furthermore, although we show an example in healthcare, the framework is assumed to be generalizable.

This paper is organized as follows. Section 0 reviews prior visual frameworks, discussing the strengths and weaknesses of each. Then, we focus on PCN Diagrams depicting its limitations. Section 0 describes how we envisioned PCN 2.0 Diagrams, while Section 0 illustrates PCN 2.0 Diagrams and provides an example. Section 5 depicts how the new framework may support complex service process management and innovation. Finally, Section 0 drafts this paper's main managerial and scientific contributions, limitations, and future developments.

## 2 Literature Review

Several visual frameworks have been developed over the years.

**Business Process Modeling Notation (BPMN)** (White, 2004) organizes the steps of the process into "swim lanes" that represent who is performing the steps. Each step exists within only one swim lane. Dashed lines connecting corresponding steps in different "swim lanes" depict interactions between steps

(White *et al.*, 2008). The arrows represent a state dependency (i.e., the process depends on some resource being in a state provided by another). This visual framework does not specify the type of customer interaction, the channel through which the interaction occurs (Müller and Rogge-Solti, 2011), or even the duration of the steps. Finally, value-added steps are not highlighted (Kazemzadeh *et al.*, 2015a).

**Value Stream Mapping** (VSM) (Dinis-Carvalho *et al.*, 2019; Shou *et al.*, 2017) maps processes and activities that contribute to the realization of a product, starting from the supplier to the delivery of the finished product to the customer, passing through the entire production chain. This framework aims to eliminate waste and increase the efficiency of the processes that realize product value. This type of map specifies the duration of the steps, but it is provided-centered and does not represent the activities performed by the other stakeholders in the SVN. Moreover, it omits customer interaction and customer participation.

**Supply Chain Diagrams** (SC Diagrams) show relationships between the stakeholders in a given supply chain (Sarkis, 2012). They do not show the bidirectional flows that characterize service supply chains (resources move in both directions between the provider and the customers) (Sampson, 2000). Moreover, they assume that there is some transfer of materials from one entity to the next (the arrows describe the various paths by which goods and services can flow through a supply chain) without specifying what takes place in the interactions.

**Service Blueprinting** (Shostack, 1987) is a flowchart that categorizes steps according to customer actions, visible employee actions, invisible employee actions, support processes, and managerial functions (Fließ and Kleinaltenkamp, 2004). They do not analyze the network of stakeholders involved in the process (Bitner *et al.*, 2008). Patrício *et al.* (2011) tried to address the provider-centered bias by identifying the value constellation network at one phase of analysis and then subsequently and separately designing specific dyadic service encounters with enhanced Service Blueprints. Moreover, it treats customer actions as "a black box". Eichentopf *et al.* (2011) proposed to give customers their line of visibility, line of interaction, and so forth. However, these approaches seem confusing and complex and are not widely adopted. Finally, Service Blueprinting omits the customer interaction type, but the "Physical evidence" category often characterizes the channels.

**Customer Journey Map** (Ponsignon *et al.*, 2018) is a visual storyline of every customer engagement with the service. The aim is to put the organization directly

in the consumer's mind to understand their customer's activities, needs, and perceptions. This framework analyses client-provider interactions and the channels through which they happen in-depth, but it only considers the activities that the customers perform (customer-centered), omitting the other stakeholders. This framework intuitively shows whether the steps bring value to the customer way (using emoticons or including the happiness curve).

**PCN Diagrams** combine features of SC Diagrams with features of Service Blueprinting (Kazemzadeh *et al.*, 2015b; Sampson, 2012). PCN Diagrams represent processes as sequences of steps. The steps are represented by boxes and identified by verbs in PCN Diagrams. Processes are performed by entities (all the stakeholders involved in the SVN) that act on resources (physical items, knowledge, energy, and so forth). Nouns in PCN Diagrams identify resources and entities. An entity is any process participant that makes decisions about the initiation or progress of some steps of the process (Sampson, 2015). A process domain is a set of steps that are "initiated, led, performed, and, to some degree, controlled by the process entity" (Sampson, 2015, p. 187). Indeed, each process entity has a process domain. The process domain of each entity can be divided into three regions: Independent Processing (IP), Surrogate Interaction (SI), and Direct Interaction (DI). The triangle on top of the process domain represents the degree of control of the entity over the steps: it is maximum at the center (IP region) area and decreases moving toward the sides (SI, DI regions, respectively). DI occurs when an entity person interacts with another entity person (people-with-people interaction). SI, instead, occurs when an entity person acts on/with resource(s) of another entity (belongings, information). Finally, IP occurs when an entity acts only on/with its own resources. In the PCN Diagram, there are three types of blocks: Rectangles, corresponding to "active" process steps; triangles, corresponding to waits; and rhombuses, corresponding to decision moments. Rectangles can have the outer line dotted. In this case, the step within the rectangle will only happen under certain conditions. In PCN Diagrams, the arrows that link process steps represent state dependency like in BPMN Diagrams. The symbol of money identifies costs or monetary compensations for providers. The number of emoticons represents its magnitude. Emoticons of a happy face describe value realization and value potential that customers directly perceive. Emoticons of a sad face represent non-monetary costs (such as points of inconvenience or points of pain) for customers. PCN Diagrams appear to be the most appropriate for service process management and innovation (see

Table 1). Indeed, they show the steps making up service processes, the SVN entities, the nature of their interactions, and their roles in the process.

Unfortunately, PCN Diagrams have **limitations**. First, PCN Diagrams assume that a process begins when the customer expresses a need and ends when the need is satisfied. However, this choice may be inconvenient (if achieving need satisfaction is a very long or complex process) or impossible (if need satisfaction is never achieved, as in the case of chronic diseases). Additionally, although they may represent all the entities in the SVN, they usually group entities into "macro-entity" in practice. For instance, Sampson (2012) provided the example of a restaurant. The author considered the restaurant a "macro-entity", and in its process domain, there are all the steps the entities working in the restaurant (the waiters, the owner, the pizza maker, etc.) do. This grouping is usually functional, but sometimes more details would be adequate. For instance, it may be helpful to specify who does the steps to decide how many waiters to hire. Conversely, especially if there are many entities in the SVN, generating a process domain for each of them may make the PCN Diagram unclear. Furthermore, although the customer interaction types are analyzed, the channels through which they occur are not: they classify all synchronous interactions as direct interactions and all the asynchronous as "surrogate" interactions without considering the channel. This lack can reduce diagrams' clarity and prevent identifying certain peculiarities. For instance, a face-to-face visit or a televisit (visit performed remotely) are not the same processes, although they involve several steps that are similar and that happen in direct interaction (e.g., the process step of "the doctor asks the patient to describe his symptoms"). Moving on to value, they do not specify process steps that produce value and those that are necessary for accounting or regulatory reasons. Finally, they do not show the duration of the process steps. In PCN Diagrams, dashed lines suggest a loose temporal dependency, meaning a long time passes between the connected process steps. However, the time is not quantified. These limitations are fundamental in complex and lengthy service processes such as health services.

Table 1: A comparison of the visual frameworks

Visual framework	Process steps	SVN	Duration	Customer Interaction	Channels	Customer Particip.	Value
BPMN	X	X				X	
VSM			X				X
SC Diagram		X					
Service Blueprint	X		X		X	X	
Customer Journey Map	X		X	X	X	X	X
PCN Diagram	X	X		X		X	X

### 3 Methodology

We adopted a conceptual-to-empirical approach and then an empirical-to-conceptual one.

In the **conceptual-to-empirical phase**, we first conceptualized the elements visual frameworks should include reviewing the previously defined visual frameworks. Then, we drafted PCN 2.0 Diagrams and organized a **meeting with two SOM experts** to validate our proposal and collect suggestions for improvement. Finally, at the end of this phase, we updated our draft based on the recommendations.

In the **empirical-to-conceptual** phase, we refined our visual framework by representing actual service processes and inquiring about what we would need. Thus, we were able to refine part of the elements of the visual framework from empirical data.

We demonstrated the power of our framework through its application to a **real case**: the televisit service offered by one of Europe's leading children's hospitals. Then, we verified the intuitiveness and rigor of our framework by presenting the televisit process represented through it to the healthcare manager responsible for redesigning the televisit service in the children's hospital. Moreover, in this meeting, we verified the truthfulness of the process we represented. Then, we held eight meetings with doctors working in the children's hospital and one session with a minor patient caregiver to evaluate the main issues of the current

televisit process. That way, we were able to identify opportunities for improvement. We performed that analysis in July 2022.

## 4 Results

This section illustrates the PCN 2.0 Diagrams and an example of how they can be used. The example concerns the televisit service in one of Europe's leading children's hospitals.

### 4.1 PCN 2.0 Diagrams

This paragraph describes the changes introduced within the PCN 2.0 Diagrams. Table 2 summarizes those changes, while Table 3 explains the meaning of the symbols used in PCN 2.0 Diagrams.

**Process Steps.** We suggest using the same Business Process Modelling Notation 2.0 (BPMN) formalism to report the initial and final events. The initial event starts the process's flow without incoming sequence flow. The final event ends the flow of the process and, thus, will not have any outgoing sequence flows. We propose to represent the initial event as a circle with a fine thickness and the final event as a circle with a large thickness. That way, they can be whatever type of events, not necessarily the need recognition and satisfaction. Moreover, since it could be interesting to visualize some parts of long processes with a high level of detail while leaving the others more unrefined, we suggest grouping activities. A rectangle with a grey background could be used to group a series of related activities without specifying all the process steps composing it. Moreover, a dotted rectangle could group steps inside process phases.

**Service Value Network (SVN).** To achieve a compromise between process map readability and completeness, we suggest using the "macro-entities" and specifying the acting entity by reporting the abbreviated name in brackets.

**Channels.** Specifying all the channels seemed inadequate because it could dramatically reduce the readability of the diagrams. Therefore, we suggest specifying only whether the process steps in the direct interaction area are conducted face-to-face or remotely. Letter R inside a circle may indicate remote synchronous interactions, while letter P inside a circle may indicate face-to-face interactions.

**Value.** PCN 2.0 Diagrams specify the steps where customers realize value and those where customers recognize value potential as in PCN Diagrams. The symbol

of a leaf may identify the steps that produce value, and the symbol of a brick may identify the steps necessary for accounting or regulatory reasons.

**Duration process steps.** We suggest introducing the duration of the most important and/or inconvenient process steps for stakeholders.

Table 2: Main differences between PCN Diagrams and PCN 2.0 Diagrams

Features	PCN Diagrams	PCN 2.0 Diagrams
<b>Process Steps</b>	They show all the steps making up processes. A process begins when the customer expresses a need and ends when the need is satisfied.	The initial and final steps can be whatever type of steps. A circle with a fine thickness may represent the initial event. A circle with a large thickness may represent the final event. A rectangle with a grey background could identify a group of related steps without specifying them. A dotted rectangle could be used to group steps inside the process phases.
<b>SVN</b>	They usually introduce "macro-entities"	They use the "macro-entities" and specify the acting entity by reporting the abbreviated name in brackets.
<b>Channels</b>	They do not specify the duration of the process steps	They specify if a direct interaction is carried out face-to-face or remotely.
<b>Value</b>	The symbol of money identifies costs and monetary compensations for providers. Emoticons of a happy face identify value realization and value potential that customers perceive. Emoticons of a sad face represent non-monetary costs (such as points of inconvenience or points of pain).	They specify the steps where customers realize value and those where customers recognize value potential as in the PCN Diagrams. The symbol of a leaf may identify steps that produce value. The symbol of a brick may identify steps necessary for accounting or regulatory reasons.
<b>Duration</b>	They do not specify the duration of the steps	They specify the duration of the most important and/or most inconvenient steps.

Table 3: Legend

Symbol	Meaning
	Start event
	End event
	Emoticons of a happy face describe value realization and value potential that customers directly perceive.
	Emoticons of a sad face represent non-monetary costs (such as points of inconvenience or points of pain) for customers.
	The symbol of a brick identifies steps necessary for accounting or regulatory reasons.
	The symbol of a leaf identifies steps that produce value.
	The symbol identifies costs for providers.
	The symbol identifies money compensations for providers.
	The direct interaction happens in a face-to-face mode
	The direct interaction happens remotely
(N)	A nurse oversees the process step
(D)	A doctor oversees the process step
	A dotted rectangle groups the steps inside the process phases.
	A rectangle with a grey background identifies a group of related steps without specifying them.

#### 4.2 The Example – The televisit service in a children's hospital

In Italy, patients can receive televisits via videoconferencing or telephone, and televisits can only replace follow-up visits (Ministero della Salute, 2020). Therefore, before patients can receive a televisit, they must have had at least one face-to-face visit with that doctor. The children's hospital provides the

videoconferencing televisits as described below. Figure 1 shows the televisit process using our visual framework.

Doctors choose the type of visit by assessing the patient's clinical status. If they select the televisit option, doctors email patients the form for pay the televisit and a list of required medical records to provide before the televisit. Patients must send the required medical records (photographs, results of blood tests performed outside the health facility, etc.) and the receipt of payment to a dedicated e-mail address within five days of the televised visit. A nurse is assigned to check patients have sent all the required medical records. If a patient has not sent all required medical records by the deadline, a nurse will call the patient. Once the patient has sent the required medical records, the nurse emails the doctor all of them. The doctor evaluates medical records before the televisit and enters them into the hospital's internal information system. Then, just before the televisit, the doctor may re-evaluate the medical records.

At the time of televisit, the doctor and patient log in to the regional televisit videoconferencing platform with their login credentials. If the patient does not log in to the platform at the appointed time, the doctor will contact the patient by phone.

Once the patient joins the videoconference, the televisit begins.

At the end of the televisit, the doctor communicates the identified treatment and decides whether to schedule the next visit in face-to-face mode, in televisit mode, or not to schedule a visit at all. After the televisit, the doctor completes the report, makes any prescriptions for the next visit, and books the next visit through the regional portal. Then, the doctor emails the patient the televisit report, the treatment, and the booking receipt for the next visit. If the next visit is in televisit mode, the doctor also emails the form for payment.

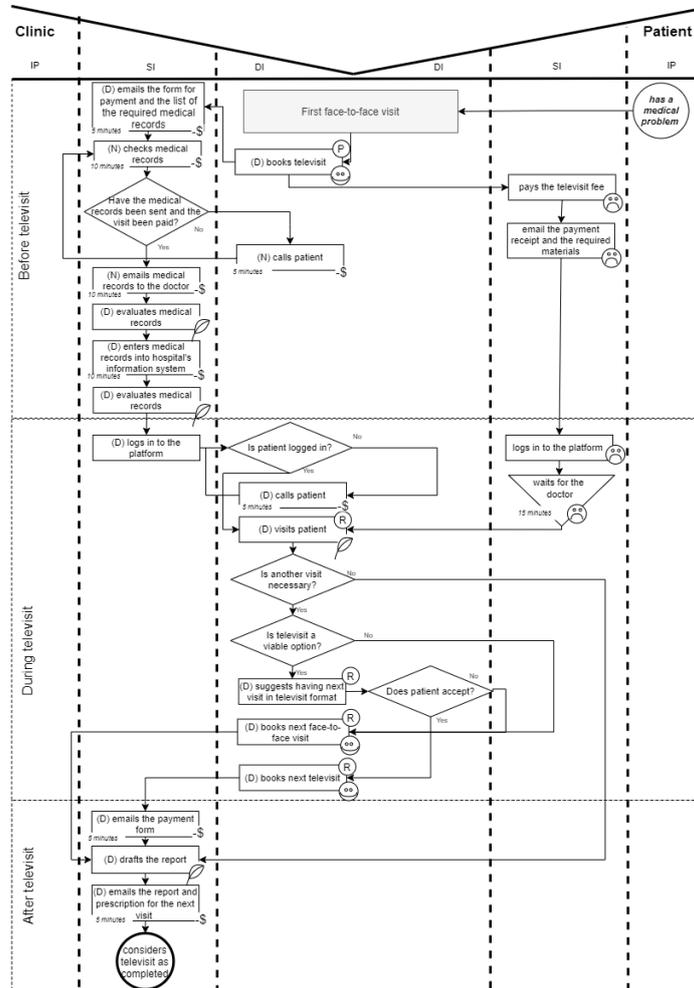

Figure 1: Televisit service in a children's hospital

## 5 PCN 2.0 Diagrams in systematic process innovation

This paragraph shows how the elements introduced to PCN 2.0 Diagrams might support process analysis and innovation. To do so, we focused on the case of the televisit service offered by a children's hospital.

The opportunity to select any start and end event and to group steps enables users to represent long and complex processes. For instance, in Figure 1, we specified that a televisit could only be a follow-up visit after a face-to-face one. Moreover, we separated the phases of "Before televisit", "During televisit", and "After televisit" improving the clearness of the representation.

Continuing using the "macro-entities" but specifying the acting entity by reporting the abbreviated name in brackets allows identifying if a doctor or a nurse performs the steps inside the process domain of the "Clinic" (which is the "macro-entity"). In addition, the distinction between steps carried out in televisit mode and those carried out in face-to-face one is clarified by specifying whether direct interactions are carried out face-to-face or remotely. Those changes improve the readability of the diagrams. Indeed, they have proven to help the manager, the eight doctors, and the caregiver we interviewed to understand the representation of the televisit process.

PCN Diagrams already allow for improving processes through changes in the position of steps (Sampson, 2015). Indeed, they represent enabling innovations (innovations that allow customers to do steps previously provided by others) and relieving innovations (innovations that correspond to a firm that starts doing steps previously customers did). The introduction of the duration of the steps and the refinements on value representation introduced in PCN 2.0 Diagrams enhance the potential of those diagrams to support service process improvement and innovation.

From the patients' perspective, the interviewed caregiver complained about the time patients wait on the platform. In face-to-face visits, patients wait at the clinic, thus, they can spend that time socializing with other patients, and they can ask the nursing staff the reasons for that wait. During televisits, patients find themselves waiting on their own, thus, the wait seems longer, and it can increase anxiety. Therefore, the regional platform may specify the reasons for the delay or may entertain patients (children in this case). Moreover, the interviewed caregiver complained about the platform login procedure. Therefore, the easefulness of use of the platform may be improved.

From the medical staff's perspective, the interviewed doctors complained about several steps that they currently oversee. For instance, they email the patient the payment form and enter the medical records on the hospital's internal information system. These steps seem easy enough to be delegated. Moreover, several steps could be automatized. For instance, we can imagine that future releases of the televisit platform will automatically check if all the medical records have been uploaded and eventually contact the patient. Additionally, the platform could automatically send patients the form to pay the televisit. Therefore, specifying the duration of the most inconvenient steps helps highlight the importance of eliminating or modifying them.

## 6 Conclusions

This study contributes to the existing literature by presenting an improved version of the PCN Diagrams. PCN 2.0 Diagrams are more elaborated and richer than the PCN Diagrams. Therefore, the proposed visual framework can support managers in identifying and analyzing the current process and depicting and selecting process design alternatives. Moreover, PCN 2.0 Diagrams are intuitive, easy to understand, and rigorous, thus, they can be easily used and understood by practitioners. Therefore, our framework is a promising candidate for healthcare process modeling, where medical staff needs to understand and discuss the process models. Although we show an example in healthcare, this methodology is assumed to be generalizable.

Finally, the feedback on the televisit experience in the pandemic years we collected in the empirical analysis can provide insights for redesigning the televisit service. For instance, Italy plans to invest much money in upgrading and improving telemedicine services (Presidenza del Consiglio dei Ministri, 2021).

In the future, researchers can improve the PCN 2.0 Diagrams. First, we could include step duration distribution (or at least the standard deviation) since it could influence service performance. Moreover, we could investigate the possibility of having other types of state dependency between steps. PCN 2.0 Diagrams consider only the Finish-to-start relationship (a step can begin once the preceding one finishes), but different dependency types can exist: Finish to Finish (a step can finish once the preceding one finishes), Start to Start (the activities must begin contemporarily), and so forth. Finally, we could develop a software tool for PCN 2.0 Diagrams representation to stimulate the use of this framework.

### Abstract

Measuring Intellectual Capital (IC) is essential for contemporary firms. To succeed in a radically changed economic environment, organizations must develop reliable measures of IC.

Yet existing studies focused on this topic missed evaluating the uncertainty sources. To our knowledge, we performed the first systematic literature review with thematic analysis to understand which IC measurement model works better in the following uncertainty areas: digital transformation, environmental impact, financial crisis, social impact and turbulent environments. We searched three databases and included quantitative peer-reviewed articles relevant to IC measurement methods in business uncertainty. This yielded 2,709 studies, of which 27 were eligible and included in the final sample.

Our study found no agreement on the best IC measurement tool for uncertain times due to varying firm characteristics, including location, industry, size, and performance dimensions. Additionally, included studies emphasized the importance of human capital in enhancing company competitiveness and profitability. However, investing in IC alone cannot ensure agility and resilience in the digital era. Firms must effectively manage intangible assets like innovation, R&D, and employee knowledge and skills to drive growth. For future research, we recommend focusing IC measurement research on under-investigated industries, such as automotive, transportation, and hospitality, which require tailored IC measurement solutions. Furthermore, to highlight the broader societal benefits of effective IC management, research should also focus on measuring IC's impact on social development goals, such as ecological sustainability, fair employment and gender parity.

**Paper type** – Academic Research Paper

## 1 Introduction

IC has enjoyed considerable attention in research and practice for over three decades. The current economy, which is highly competitive and digitized, has shifted attention towards intangible assets as companies strive to outdo each other in terms of innovation. Over the past 25 years, the investment share of intangibles has increased by 29% in the USA and ten European economies (Hazan et al., 2021). In 2018, IC made up 84% of all enterprise value on the S&P 500 (one of the most important US stock market indexes). This is a massive increase from 68% in 1995 (Aon-Ponemon, 2020).

Assessing IC provides firms with a better understanding of intangible assets' value, as traditional financial measures do not capture the value of these resources, such as knowledge, expertise, and relationships (Bontis, 1998). Evaluating IC also helps firms make more informed strategic decisions by providing insights into the organization's strengths and weaknesses and identifying areas for improvement (Edvinsson and Malone, 1997). Additionally, companies can identify and leverage their knowledge assets to improve performance, drive innovation (Sveiby, 2001), and foster knowledge sharing and collaboration (Roos et al., 2007). This makes the company more appealing to investors interested in the company's intellectual property and knowledge resources (Stewart, 1997).

While there is no universally agreed-upon definition of IC, literature widely acknowledges that IC comprises various components (Kianto et al., 2017; Asiaei et al., 2018). Here, by IC we refer to the combination of three elements, e.g., human, structural and relational capital (Edvinsson and Malone, 1997; Roos and Roos, 1997).

Previous research has suggested a need to better identify IC measurement models in the context of business uncertainty. Conventional financial measurement and reporting systems have failed to keep up with the external business environment transformations and how companies have reacted to those changes (Ashton R.H., 2005). Since entrepreneurs face numerous challenges in

turbulent and torn environments, measuring and leveraging IC has become vital to developing business resilience, thriving and surviving (Daou et al., 2019).

Given these uncertain conditions, several studies have focused on the multiple facets of IC in the past decade. For example, Jalonen's (2012) systematic review found that uncertainty is a pervasive and inevitable aspect of the innovation process, affecting various stages from idea generation to commercialization. This study gives a valuable perspective on the relationship between IC and innovation in firms. However, the author did not look at methodologies for appraisal IC. Other more recent studies (Ali et al., 2021; Lin and Edvinsson, 2021; Paoloni et al., 2023) provided a comprehensive overview of IC topics and suggested several potential gaps in IC Research. Still, this body of work has yet to consider the current inability of firms to predict any events that may lead to adverse outcomes as a result.

What are the most effective methods for measuring IC in uncertain business environments? Corporate performance goes beyond simple profit and includes social and environmental dimensions (Bititci et al., 2012). Our research question there for asks whether IC enhances social, environmental and financial firm performance. To answer these questions, we performed a systematic review with a qualitative synthesis of study findings on IC measurement in uncertain contexts.

## **2 Methods**

We conducted a systematic review under the guidelines of Tranfield et al. (2003) and following the PRISMA checklist suggested by Moher et al. (2015).

### **2.1 Search Strategy**

We searched Web of Science, Scopus, and EBSCO Business Source Ultimate on February 24, 2023.

To ensure the broadest coverage possible, we split the expression 'intellectual capital measurement' into two different keywords ('intellectual capital' and 'measurement') because several studies did not use the sentence 'intellectual capital measurement' in that exact order. Since intellectual capital is a broad concept with multiple meanings (Ramlee and Abu, 2004), we used different reference terms. Thus, we advanced on Evans et al. (2015) who suggested the following search terms: 'intellectual capital', 'intellectual asset', 'intangible asset', 'knowledge capital' and 'knowledge asset'. Finally, following (Paoloni et al., 2023),

we paired the abovementioned variations for intellectual capital with the keyword 'measurement\*' (with the '\*' wildcard to include both singular and plural versions). Table 1 represents the search strings used and the number of documents found.

Table 1: Database Source and Query Executed

Database	Search Query	No. of Documents
<b>Web of Science</b>	TS=("intellectual capital*" OR "intellectual asset*" OR "intangible asset*" OR "invisible asset*" OR "knowledge capital" OR "knowledge asset*") <b>AND</b> TS=("measurement*")	<b>870</b>
<b>Scopus</b>	TITLE-ABS-KEY ( "intellectual capital*" OR "intellectual asset*" OR "intangible asset*" OR "invisible asset*" OR "knowledge capital" OR "knowledge asset*" ) <b>AND</b> TITLE-ABS-KEY ( "measurement*" )	<b>1,127</b>
<b>EBSCO Business Source Ultimate</b>	( TI ( "intellectual capital*" OR "intellectual asset*" OR "intangible asset*" OR "invisible asset*" OR "knowledge capital" OR "knowledge asset*" ) OR AB ( "intellectual capital*" OR "intellectual asset*" OR "intangible asset*" OR "invisible asset*" OR "knowledge capital" OR "knowledge asset*" ) OR KW ( "intellectual capital*" OR "intellectual asset*" OR "intangible asset*" OR "invisible asset*" OR "knowledge capital" OR "knowledge asset*" ) ) <b>AND</b> ( TI ( "measurement*" ) OR AB ( "measurement*" ) OR KW ( "measurement*" ) )	<b>712</b>

## 2.2 Inclusion and Exclusion Criteria

We drew on the work by Shinde et al. (2022) and adapted their framework for selecting articles. In detail, we defined our inclusion and exclusion criteria using the PICOT (Population, Intervention, Context, Outcome, Time) method as outlined in Table 2.

Table 2. Inclusion/Exclusion criteria

Parameter	Inclusion	Exclusion
<b>Population</b>	<ul style="list-style-type: none"> <li>Private firms</li> <li>Micro-level analyses (organizational IC)</li> </ul>	<ul style="list-style-type: none"> <li>Education, Healthcare, Public and NPO sectors</li> <li>Meso- and macro-level analyses (global, national, regional and industry IC)</li> </ul>
<b>Intervention</b>	IC measurement methodologies	<ul style="list-style-type: none"> <li>IC conceptualization and definition</li> <li>IC reporting and disclosure</li> </ul>
<b>Context</b>	Uncertain conditions and turbulent environments	Normal operating conditionings

<b>Outcome</b>	Financial and management performance (market value, innovation, sustainability, leadership, corporate governance, organizational learning, etc.)	Reporting and disclosure performance (annual reports' relevance, reliability, readability, understandability, stakeholders' information about companies, etc.)
<b>Time</b>	Studies produced in 1985–2023	Studies published before 1985

In summary, we focused on retrieving peer-reviewed quantitative studies analyzing IC measurement methods in private firms. We focused only on papers that considered the elements of uncertainty or turbulent environments that put long-term pressure on businesses (Brende and Sternfels, 2022), such as unstable commodity markets, increasing inflation, global health crises, climate-related hazards, significant changes in consumer behavior and industrial demands, and digital transformation (Banholzer et al., 2022). Only studies in English were included and papers were excluded if they focused on the IC conceptualization and IC research in universities, education, healthcare, non-profit and public sectors, as the experiences about these topics have been examined in-depth elsewhere (Marr and Moustaghfir, 2005; Buonomo et al., 2020; Paoloni et al., 2020; Quarchioni et al., 2022).

For our purposes, where we seek to identify how to measure IC in firms and its impacts on financial and management performance, we did not include studies that focused solely on the reporting and disclosure of IC. In addition, we excluded articles focused on meso- and macro-level analyses of IC (i.e., global, regional, and national levels). Finally, we set a timespan to exclude studies published before 1985, as the main contribution to the field of IC started to be published after that year (Marr and Moustaghfir, 2005).

Unlike most structured and systematic reviews in the field, we did not perform citation impact analysis because over 40% of articles included in our review have been published in the last three years. According to Dumay (2014), recent publications should be excluded from citation analysis since they need more time to be cited. Therefore, the article's impact analysis could have reported inaccurate results in our case.

Figure 1 depicts the flowchart for the selection process of the articles. After applying inclusion/exclusion criteria, the search yielded 27 studies for inclusion in our review (Table 3).

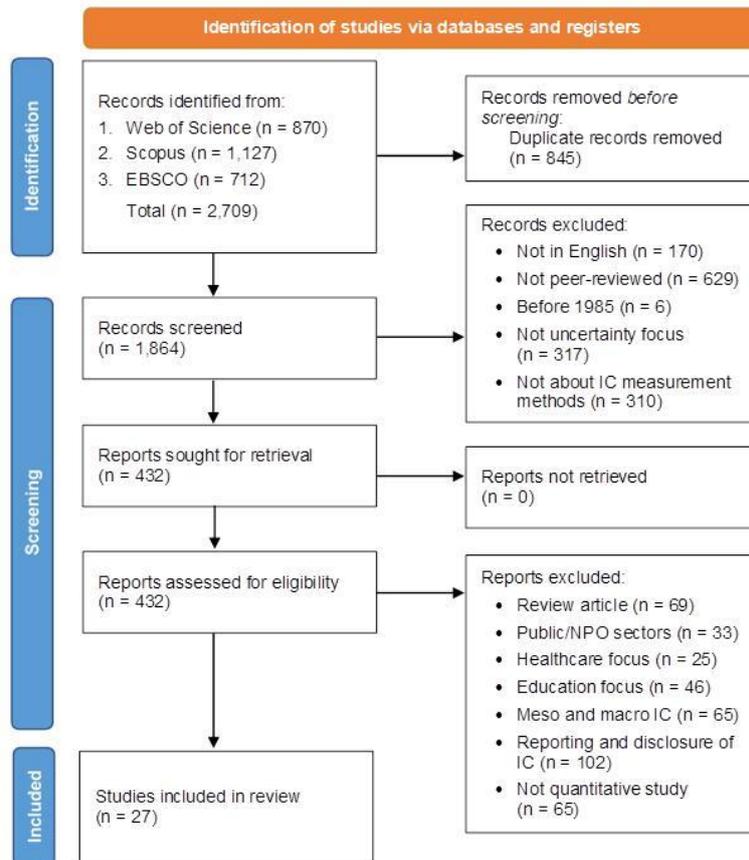

Figure 1. PRISMA flowchart for screening and inclusion

Table 3. The final sample of 27 quantitative articles included in the systematic review

Authors	Year	Journal	Main Findings
Al-Musali, M. Ismail, K.	2016	<i>International Journal of Islamic and Middle Eastern Finance and Management</i>	The impact of IC on bank financial performance indicators in Gulf Cooperation Council countries differs based on the VAIC™ components.
Asiaei, K. Jusoh, R. Barani, O. Asiaei, A.	2022	<i>Business Strategy and the Environment</i>	Green structural capital promotes environmental performance, while stakeholder relationships impact ecological performance through performance measurement.
Asiaei, K. O'Connor, N. Barani, O. Joshi, M	2023	<i>Business Strategy and the Environment</i>	Green IC is not associated with environmental performance in Iranian companies.

Bonsón, E. Escobar, T. Flores, F.	200 8	<i>Financial Markets, Institutions and Instruments</i>	The significance of intangible resources for a firm's activities does not appear to influence the development or improvement of its information technology infrastructure.
Bozburu, F. Beskese, A.	200 7	<i>International Journal of Approximate Reasoning</i>	The implementation rate of new ideas is the most important measure of organizational capital, and companies should foster a knowledge-creation culture.
Campisi, D. Costa, R.	200 8	<i>Knowledge and Process Management</i>	Effective management of intangible assets can lead to competitive advantages and business growth, as evidenced by the relationship between innovation, R&D, training investments, and increased sales through launching new products.
Edvinsson, L. Kitts, B. Beding, T.	200 0	<i>Journal of Intellectual Capital</i>	The digital landscape for IC allows for displaying the complexity of IC in a structured way, transferring knowledge, retrieving IC through exploration, planning investments and forecasting the firm future.
Iazzolino, G. Laise, D.	201 6	<i>Journal of Intellectual Capital</i>	Traditional industries prioritize outdated knowledge over human capital investment, while non-traditional industries heavily invest in human resources for economic value creation but experience lower work productivity and higher employment rates.
Ishaq, M.I.	202 1	<i>International Journal of Market Research</i>	The six-factor green brand equity scale is helpful for managers to track brand equity, allocate resources, and improve corporate image, trust, repurchase intentions, word-of-mouth communication, customer satisfaction, and brand loyalty.
Izzo, F. Tomnyuk, V. Lombardo, R.	202 2	<i>International Journal of Manpower</i>	Fintech companies' profitability is not significantly affected by VAIC™, but human capital is crucial for knowledge-intensive companies in the digital era to enhance their competitiveness and profitability.
Jain, P. Vyas, V. Roy, A.	201 7	<i>Social Responsibility Journal</i>	Corporate social responsibility (CSR) and firm performance are poorly related. The empirical data provide supportive evidence that IC profoundly impacts CSR and firm performance relationships.
Juma, N. Payne, T.	200 4	<i>International Journal of Innovation Management</i>	The EVA™ showed a significant negative relationship to ROA performance but a slight positive curvilinear relationship to ROI performance, while the MVA™ showed a modest positive relationship to ROA and ROI performance.
Kale, S.	200 9	<i>Journal of Construction Engineering and Management</i>	The Fuzzy Intellectual Capital Index (FICI) helps construction executives comprehend the connections between intangible assets and their movement within the organization.

Kozera-Kowalska, M.	2020	<i>Sustainability</i>	The Intellectual Sources of Value Added (ISVA) model is more effective than VAIC™ in Polish farms because it considers the productivity of tangible and intangible inputs that influence the value-adding process.
Liao, P.-J. Huang, C.-H. Hsu, K.-H.	2010	<i>International Journal of Services and Standards</i>	Companies in the exploitation stage prioritize employee satisfaction, turnover rate, and on-the-job training. Companies in the exploration stage prioritize engaging in strategic alliances as their most important activity.
Massingham, P. Nguyen, T.N.Q. Massingham, R.	2011	<i>Journal of Intellectual Capital</i>	The 360-degree peer review rating for human resources value measurement identifies training needs assessment, job analysis, performance appraisal, or managerial and leadership development.
Moutinho, V. Vale, J. Bertuzi, R. Bandeira, A.M. Palhares, J.	2021	<i>Economies</i>	Iberian banks' performance is largely determined by the efficiency of investing in the knowledge and skills of their human capital.
Ousama, A.A. Hammami, H. Abdulkarim, M.	2020	<i>International Journal of Islamic and Middle Eastern Finance and Management</i>	IC has a positive impact on the financial performance of Islamic banks. Among IC components, only capital employed and human capital have a significant impact, while structural capital exhibit an irrelevant effect.
Patel, P.C. Guedes, M.J.	2017	<i>International Journal of Tourism Research</i>	Higher return on intangible assets (ROIA) is linked to better performance for hospitality firms.
Peykani, P. Gheidar-Kheljani, J. Saen, R.F. Mohammadi, E.	2022	<i>Operational Research</i>	The Robust Window Data Envelopment Analysis (RWDEA) enhances decision-making reliability when dealing with data uncertainties and utilizing panel data.
Šebestová, J.D. Popescu, C.R.G.	2022	<i>Journal of Risk and Financial Management</i>	Most Czech companies invest only 20% of their profit in human resource development, which would yield a return of about 14%.
Śledzik, K.	2013	<i>Financial Internet Quarterly 'e-Finanse'</i>	Investments in human capital play a significant role in the IC of Polish banks, generating more value than investments in structural or capital employed.
Soetanto, T. Liem, P.F.	2019	<i>Journal of Asia Business Studies</i>	Both structural capital efficiency and capital employed efficiency have enhanced the Indonesian company's value creation. Although there is no significant relationship between IC and the firm's market value, in high-level knowledge industries, capital employed has a positive and significant relationship.

Soheilrad, S. Sofian, S. Mardani, A. Zavadskas, E.K. Kaklauskas, A. Darvishvand, J.M.	201 7	<i>Engineering Economics</i>	Improving IC can boost corporate performance, while perceived environmental uncertainty can influence it. The corporate performance also has a positive correlation with capital structure. Additionally, the authors developed a new IC decision-making system.
Tarnóczy, T. Kulcsár, E.	202 1	<i>Annals of the University of Oradea, Economic Science Series</i>	VAIC™ components positively influence firm profitability performance. IC has a more significant contribution to corporate value creation in Romanian companies than in Hungarian ones.
Tseng, K.A. Lan, Y.W. Lu, H.C. Chen, P.Y.	201 3	<i>Management Decision</i>	IC significantly impacts Taiwanese business strategy and firm performance, including those from before and after the 2008 financial crisis. Business strategy partially mediates the relationship between IC and firm performance.
Turovets, Y.	202 1	<i>Engineering Management in Production and Services</i>	Intangible assets effectively reduced inefficiency in various firms over time, but their impact decreased after the 2014 Russian crisis. High-tech firms benefit more from intangible assets, including research and development results, skilled personnel, and trade names.

### 2.3 Data Extraction and Analysis

We extracted the title, author, journal and year. We also extracted additional data from each article and used them to evaluate the risk of bias, including research question, quantitative methodology, sample size, time observation, industry, size of companies and main findings.

We performed a qualitative synthesis of uncertainty-related issues and findings. The 27 included studies analyzing alternative IC assessment models examined five areas of uncertainty: i) digital transformation, ii) environmental impact, iii) financial crisis, iv) social impact and v) turbulent environments. We also identified potential conflicting findings of the articles included in our final sample.

Data extraction was conducted by M.C. and then checked by D.S.

## 3 Results

We first present the overall characteristics of the 27 included studies. Next, we describe the main findings by the uncertainty context analyzed and the variations in study results.

### 3.1 Overall Characteristics of Included Studies

We reviewed four components of the organizational setting, including the location of firms, country economic development, industrial section and firm size.

Figure 2 depicts where the firms being studied were located and Figure 3 shows the number of studies by country. One study was multi-continent, involving Asia and Europe and three did not report any information about the location of their sample.

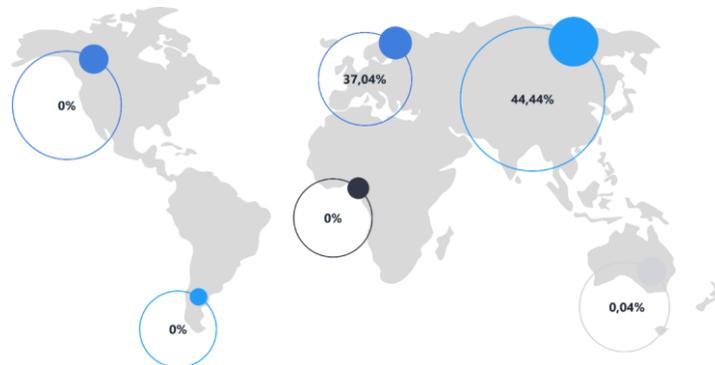

Figure 2. Continental distribution of studies

Notes: The figure shows the percentage of articles published in each continent. This graph does not include one multi-continent study and three studies that did not report geographical information.

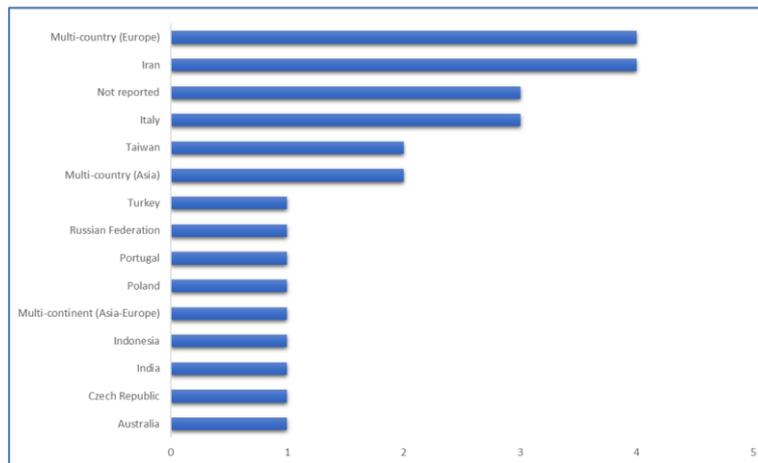

Figure 3. Number of studies by country

Following the new World Bank country classifications by income level (2022-2023), we found 14 out of 27 studies performed in high-income countries. Two studies were conducted in upper-middle-income countries and six in lower-middle-income countries. In addition, two studies analyzed countries with different income classifications. The remaining three did not report such data.

Figure 4 illustrates the industries investigated by the studies. Most articles focused on banks and financial companies (22,2%), followed by ICT firms (13,9%).

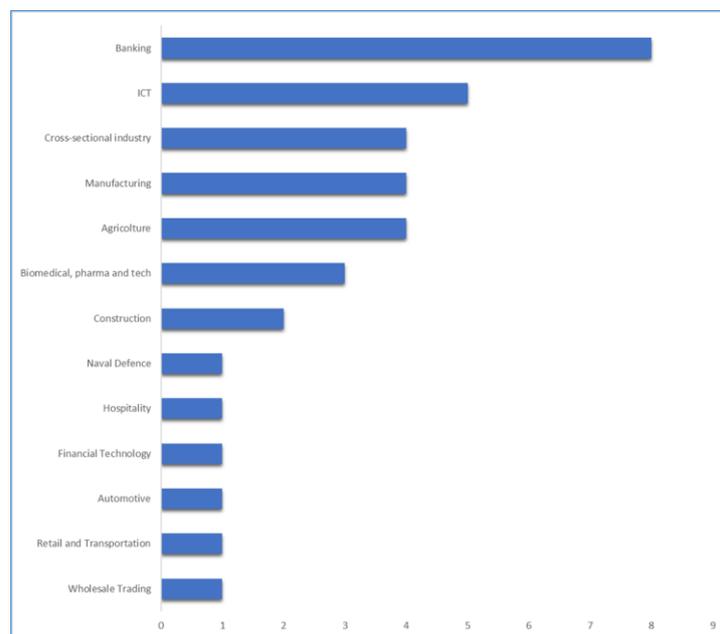

Figure 4. Industries investigated by the studies

We followed the World Bank standards to identify the size category of firms (International Finance Corporation, 2008). 21 out of 27 studies did not report the size of the companies. Two studies (Bozbura and Beskese, 2007; Ishaq, 2021) did not investigate firms, but they surveyed consumers or experts to validate their hypotheses. Of the remaining four studies that investigated firms, Campisi and Costa (2008) explored small and medium enterprises, two examined medium and large firms (Asiaei et al., 2022; Asiaei et al., 2023) and one analyzed medium firms (Kale, 2009).

## **3.2 Uncertainty Contexts**

### *3.2.1 Theme 1: Digital Transformation (n = 4)*

Four studies explored IC measurement methods in the shift from traditional organization operations to modern digital approaches.

Edvinsson et al. (2000) present and pilot a new IC measurement methodology (Digital IC-landscape) on 11 cross-sectional firms. They found that this method enhances strategic firm performance, including visually displaying the complexity of IC, transferring knowledge that affects IC, retrieving highly efficient IC through exploration, planning investments and forecasting the firm future.

Turovets (2021) analyzed the intangibles' effects on Russian manufacturing firms' efficiency from 2009-2018. Using Russian accounting standards for measuring intangibles, the author found that intangible assets robustly reduced inefficiency across different firms and over time. Still, the impact decreased after 2014, when Russia suffered a currency crisis, so investing in new technologies was more expensive. Moreover, high-tech firms receive a more significant effect on technical efficiency due to synergy between different intangible assets (research and development results, skilled personnel, trade names) and stable knowledge accumulation.

By evaluating the performance of Value Added Intellectual Coefficient (VAIC™) developed by Pulic (2000, 2004), Izzo and colleagues (2022) examined the impact of digital industrialization on human capital. The authors analyzed 10 Italian Fintech companies' financial information from 2016 to 2018. The study found that VAIC™ does not have a significant positive impact on Fintech companies' profitability. Among intellectual capital components, human capital plays a strategic role for knowledge-intensive companies looking to improve their competitiveness and profitability in the digital era.

Finally, Peykani et al. (2022) proposed a mathematical evolution of VAIC™ for assessing decision-making performance in a complex and uncertain data presence. They tested their model, Robust Window Data Envelopment Analysis (RWDEA), measuring the IC performance of 10 automotive and parts manufacturing companies from the Tehran Stock Exchange during 2013-2017. They found that the RWDEA model provides more reliable results for decision-making in the presence of large amounts of uncertain data to analyze.

### 3.2.2 Theme 2: Environmental Impact (n = 3)

Three studies examined the relationship between IC and firm environmental performance.

Asiaei et al. (2022) explored to what extent companies use environmental performance measurement to translate green IC into enhanced economic and environmental performance. The authors surveyed executives from 105 Iranian publicly listed medium-large companies. In detail, the sample included 8 IT companies, 17 banks, six agriculture firms and 74 manufacturing companies. They found that organizational resources such as technology systems, patents, and employees' knowledge enhance environmental performance and encourage performance measurement. However, stakeholder relationships impact ecological performance only when managers use environmental performance measurement.

Asiaei et al. (2023) used the same sample of firms of the previous study (2022). However, this time developed a different research question. The authors investigated whether the company's ability to innovate with green ideas (green IC) could improve its sustainable practices and environmental performance. They found no direct link between green IC and ecological performance. Therefore, Iranian companies may face challenges in establishing and maintaining green stakeholder relationships. Further, having more green resources like green human, structural, and relational capital can help promote green innovation in the company. Finally, innovative firms achieve better environmental performance.

The last study in the "Environmental impact" category proposed an original and validated scale to measure the brand green value that derives from consumer perception in a cross-cultural context (Ishaq, 2021). The author surveyed 980 consumers of telecommunication and home appliances, 452 in Italy and 528 in Pakistan, from August 2017 to February 2018. The author developed a six-factor green brand equity scale to measure the corporate image, trust, repurchase intentions, word-of-mouth communication, customer satisfaction and brand loyalty. Managers can use the scale to track brand equity and allocate resources efficiently and consistently. The ranking includes six dimensions: social influence, leadership, perceived quality, brand awareness, brand association, and sustainability. The "Green Brand Equity" worked well in both cultures as a green IC measurement method.

### 3.2.3 Theme 3: Financial Crisis (n = 7)

Seven papers evaluate the effectiveness of IC measurement methodologies in guiding firms to face the current economic downturn.

Bonsón et al. (2008) conducted a multi-country study involving 54 banking companies from Austria, Belgium, France, Germany, Greece, Italy, Ireland, Netherlands, Portugal and Spain. The study aimed to test whether the relative amount of intangibles on the entity's balance sheet implies the choice of a more advanced stage of sophistication for the banking/investment information system. The authors measured IC by Intangibles Ratio (Intangible Assets/Total Assets), analyzing annual reports dated to the 2005 year-end. They found that the importance of intangible assets in companies' operations does not seem to affect the evolution or enhancement of their information system.

Since IC assumes a strategic relevance for contemporary firms, Tseng et al. (2013) investigated how business strategy impacts the relationship between IC and financial performance. The authors analyzed 2,493 IT companies listed on the Taiwan Stock Exchange covering nine years, from 2001 to 2009. In detail, they measured IC through four metrics: i) operation profit per employee, ii) R&D intensity, iii) current capital turnover rate and iv) revenue growth rate. These metrics revealed that IC significantly impacts strategic and financial performance.

Patel and Guedes (2017) adopted the Return on Intangible Assets (ROIA) method for assessing the IC of 1,647 Portuguese hospitality firms from 2007 to 2014. The authors found that improving returns on fixed assets has the highest impact on operating profit, followed by gains from increasing returns from intangible assets.

Four papers focused on the association between IC measured by VAIC™ and firm performance in the banking industry.

Al-Musali and Ismail (2016) reported a strong positive association between VAIC™ and financial performance indicators (ROE and ROA) from 2008 to 2010 in a sample of 224 banks operating in the GCC countries. Likewise, a study by Ousama et al. (2020) used VAIC™ to assess the IC of 31 Islamic banks operating in the GCC countries from 2011 to 2013. Their results showed that IC enhances financial performance. In addition, the authors highlighted that the average IC is lower than that reported in other studies about Islamic banks operating in countries such as Pakistan and Malaysia. This may suggest that the GCC countries' Islamic banks might not fully leverage their IC. Moutinho et al. (2021) used VAIC™

to evaluate the performance of 58 Iberian banks (16 in Portugal and 42 in Spain) from 2013 to 2016. The authors reported that the effectiveness of investing in human capital's knowledge and skills mainly determines Iberian banks' global performance. Finally, Śledzik (2013) used VAIC™ to measure the IC efficiency of the 10 Polish-listed banks compared to 10 European financial institutions (Portugal, Hungary, Czech Republic, Croatia, Turkey, Romania, Denmark, Switzerland and Lithuania) from 2005 to 2009. The author reported that human capital efficiency primarily contributes to Polish and comparative banks' IC.

#### *3.2.4 Theme 4: Social Impact (n = 6)*

We identified three studies that asked whether human resource investments as a social development goal could help firms to build a more equitable and prosperous society.

Iazzolino and Laise (2016) introduced an accounting-based framework based on VAIC™ to assess the sustainability of knowledge-intensive and non-knowledge-intensive firms from a social perspective. They analyzed 1,000 Italian companies from 2010 to 2012. The authors found that traditional firms invest less in human capital than knowledge-intensive companies, which rely heavily on human resources for economic value creation. Šebestová and Popescu (2022) surveyed 278 Czech entrepreneurs through face-to-face, telephone and email interviews to explore their human capital investment strategies. The authors found that the largest group of companies (192) invests approximately 47.7% of generated profits, of which only 20% is directed toward human resources. They estimate that this human resource investment generates an annual return of about 14%. Finally, Massingham et al. (2011) performed an online survey of 118 engineering and technical workers of the Royal Australian Navy to address the subjectivity inherent in existing human capital value measurement methods. The authors proposed a new methodology that uses three data points: i) self-reporting, ii) 360-degree peer review and iii) personality ratings. Their results revealed more objectivity in human capital measurement involving quantitative and standardized techniques.

A study by Kozera-Kowalska (2020) asked whether IC promotes the shift of agricultural organizations toward sustainable development. This study aimed to demonstrate the inadequacy of VAIC™ for measuring the value creation in farms and propose a new metric called Intellectual Source of Value Added (ISVA). The author investigated numerical data from 120 Polish farms that delivered financial

reports from 2005 to 2018. Even though agriculture has been seen for years as a sector with low knowledge intensity and is skeptical about the possibility of using knowledge, the research concluded that agricultural enterprises possess IC resources and use them more efficiently than traditional ones. Therefore, ISVA is more suitable than VAIC™ because it considers the productivity of tangible and intangible inputs affecting the value-adding process in agricultural holdings.

Two studies in lower-middle-income countries analyzed the impact of IC on firm performance to achieve wealth creation and sustainability.

First, Soetanto and Liem (2019) investigated IC's influence on the market value and financial performance of 127 publicly listed firms in Indonesia from 2010 to 2017, using a modified version of VAIC™. The author reported that IC significantly and positively impacted firm performance. Specifically, intangible assets such as patents, trademarks, copyrights, databases, software, procedures, and organizational culture (structural capital) contributed to the company's value creation. Physical and financial capital (capital employed) exhibited the same results. Instead, this research found no significant relationship between IC and the firm's market value. However, when the sample was clustered into high-level and low-level knowledge industries, capital employed displayed a positive and significant relationship in the high-level industry. Second, Jain et al. (2017) surveyed 384 small and medium-sized enterprises in Rajasthan state (India) to investigate how corporate social responsibility affects a company's performance and whether this relationship is influenced by the company's IC and competitive advantage. Their findings showed that corporate social responsibility has a slightly positive effect on firm performance. The data suggested that IC plays an essential role in this relationship, but the mediating impact of competitive advantage is not significant.

### *3.2.5 Theme 5: Turbulent Environments (n = 7)*

The studies in this group examined uncertainty in general terms. They focused on how IC affects companies operating in highly unpredictable and rapidly changing market or economic conditions with much uncertainty and volatility.

Three studies focused on IC's impact on financial performance.

Juma and Payne (2004) collected financial data of publicly traded firms operating in the biotechnology, computer hardware, computer software, and telecommunications industries from 1996 through 2001. The authors used Economic Value Added (EVA™) and Market Value Added (MVA™) to assess

intangible assets. Their analysis showed contrasting results. The authors argued that the EVA™ and MVA™ methods do not appear distinct enough from conventional performance measures to be useful for predictive purposes. Although they found some evidence to support an inverse relationship between EVA™ and IC, it is not a suitable IC measurement model.

Similarly, Campisi and Costa (2008) investigated the cause-effect link between IC management and business performance improvement. The authors conducted interviews with managers of 22 Italian small and medium-sized enterprises. Through a data envelopment analysis for IC management, the study findings indicated that simply investing more in intangible assets does not necessarily lead to better business performance.

Finally, Tarnóczy and Kulcsár (2021) performed a comparative analysis of VAIC™ analyzing data collected for five years (2014-2018) from 1,340 companies (653 in Hungary and 687 in Romania). The authors found that VAIC™ positively impacts firm profitability performance. Moreover, IC's contribution to corporate value creation in Romanian companies is more significant than in Hungarian companies' case.

Four studies developed new IC measurement models to guide firms in managing their intangible assets in turbulent environments.

The study by Soheilrad et al. (2017) distributed questionnaires to 339 publicly listed Iranian manufacturing companies. The survey took almost six months period from January 2014 to June 2014. The authors found that IC enhances corporate performance in terms of productivity improvement and creativity. Additionally, their results demonstrated that the perceived environmental uncertainty did not impact capital structure because Iranian manufacturing companies operate in uncertain environments without accurate information. Based on the works by Bontis (1998) and Ismail (2005), the authors developed a new version of the IC decision-making system called the Intellectual Capital Multiple Criteria Decision Support (ICMCDS) System. This scorecard model enables the decision maker to obtain various conceptual and quantitative information on IC to analyze different strategic performance dimensions and make efficient decisions.

Liao et al. (2010) identified 49 items in three IC dimensions, including human capital, structural capital and relational capital, based on interviews with 20 CEOs or senior managers in Taiwanese biopharmaceutical companies. In the exploitation stage, companies showed more concern for employee satisfaction,

turnover rate, and on-job-training. Engaging in strategic alliances was shown to be an essential activity for companies in the exploration stage.

Kale (2009) presented a construction business case study to illustrate the proposed model's implementation and utility, called the Fuzzy Intellectual Capital Index (FICI). The author reported that the FICI model is a flexible and robust tool that enables construction executives to understand the interrelationships between intangible assets and the movement of these intangible resources within the organization, such as knowledge sharing, collaboration, innovation diffusion, and employee training. It uses linguistic variables to represent inputs and outputs, making the evaluation process easier to interpret and improving communication. FICI can be used internally by firms to assess their knowledge assets and ability to meet strategic objectives and strategy formulation, implementation, and control. By rating and weighting IC criteria, leaders can identify critical indicators and understand how they relate to the firm's long-term strategy. Overall, FICI provides valuable information for construction executives to identify strengths, weaknesses, threats, and opportunities and address improvement areas to succeed in a competitive environment.

Finally, Bozbura and Beskese (2007) developed a method for improving the process of identifying and ranking the most crucial organizational capital measurement indicators when faced with uncertainty. The authors tested their model with an independent judgment by academics and professionals. The authors determined that the "Implementation rate of new ideas" is the most critical indicator for measuring organizational capital. Therefore, companies should prioritize implementing newly generated ideas and fostering a culture of knowledge creation within their organization.

### ***3.3 Conflicting Findings***

A deeper analysis of the papers revealed conflicting findings, as shown in Table 4. Different organizational characteristics affect the choice of a measurement method to use and influence IC's impact on firm performance. For example, Tseng and colleagues (2013) demonstrated that IC plays a prominent role in high-tech firms' financial performance. However, Juma and Payne (2004) and Izzo et al. (2022) reported opposite results: they did not find a clear relationship between IC and the profitability of high-tech companies. Therefore, while organizational

settings should have some correlation with the various IC assessment models, there is no one-size-fits-all method.

Additionally, different measurement models reported a varying range of results. For example, the most investigated IC measurement method was VAIC™, but its effectiveness in assessing IC needs to be clarified. While six studies reported that VAIC™ positively impacts firm performance (Śledzik, 2013; Al-Musali and Ismail, 2016; Iazzolino and Laise, 2016; Ousama et al., 2020; Moutinho et al., 2021; Tarnóczy and Kulcsár, 2021), other three studies highlighted the inability of the VAIC™ to reliably measure companies' IC (Soetanto and Liem, 2019; Kozera-Kowalska, 2020; Izzo et al., 2022).

Our analysis also indicates that the relationship between IC and social, environmental and financial firm performance is not clear. For example, Asiaei et al. (2022) first found that green organizational resources enhance ecological performance. Then, analyzing the same firms' sample, the authors found that the overall green IC is unrelated to environmental performance (Asiaei et al., 2023). This finding might be explained by the fact that too many variables are involved and the results of the included studies are conflicting.

Table 4. Conflicting Findings

Issue	Variations in Findings
Knowledge Intensive Industry	<ul style="list-style-type: none"> <li>• IC significantly impacts information technology firms' business strategy and financial performance (Tseng et al., 2013).</li> <li>• In high-tech firms, there is no clear relationship between the measurement of IC and conventional financial indicators (Juma and Payne, 2004).</li> <li>• IC measured by VAIC™ does not have a relevant impact on the performance of the Italian Fintech companies (Izzo et al., 2022).</li> </ul>
Firm Location	<ul style="list-style-type: none"> <li>• Simply investing in IC did not improve corporate performance in the Italian biomedical industry (Campisi and Costa, 2008).</li> <li>• IC significantly and positively impacted Iranian firms' financial performance (Soheilrad et al., 2017) and Romanian and Hungarian firms' value creation (Tarnóczy and Kulcsár, 2021).</li> <li>• Despite demonstrated benefits, Czech business owners invest only 20% of their budget into human resources (Šebestová and Popescu, 2022).</li> </ul>
Environmental Impact	<ul style="list-style-type: none"> <li>• Organizational green resources enhance environmental performance (Asiaei et al., 2022).</li> <li>• Green IC and ecological performance are not correlated (Asiaei et al., 2023).</li> </ul>
Value Added Intellectual Coefficient - VAIC™	<ul style="list-style-type: none"> <li>• VAIC™ and financial performance indicators are strictly associated (Śledzik, 2013; Al-Musali and Ismail, 2016; Iazzolino and Laise, 2016; Ousama et al., 2020; Moutinho et al., 2021; Tarnóczy and Kulcsár, 2021).</li> </ul>

	<ul style="list-style-type: none"> <li>• VAIC™ does not measure relational capital that is the ability of an organization in collaborating with external stakeholders such as suppliers, customers, creditors and public administrations (Soetanto and Liem, 2019).</li> <li>• VAIC™ draws a false picture of the economic realities of firms with a high share of physical assets, like agriculture holdings (Kozera-Kowalska, 2020).</li> <li>• VAIC™ does not impact financial performance (Izzo et al., 2022).</li> </ul>
--	---

#### 4 Discussion

Our study aimed to explore how to measure IC in a climate of business uncertainty. Overall, we found no consensus about the best IC measurement tool. This lack of agreement appears to relate to considerable differences in firms' location, industry, size and performance dimensions (e.g., financial, social, environmental). Differing IC tools could yield markedly varying pictures of performance and, in some cases, contradictory patterns. Next, there is widespread recognition that human capital is a critical resource during business volatility; however, few IC tools currently incorporate human capital metrics such as employee satisfaction, turnover rate, on-job-training, and personality ratings.

As with all systematic reviews, ours has several important limitations. First, because of the heterogeneity between studies in the research questions, research setting and IC assessment methodologies examined, it was not possible to perform a meta-analysis. To address this limitation, we structured the review by uncertainty contexts, so permitting to highlight main patterns and key themes across study findings. Second, the review excluded qualitative studies because we looked for empirical applications of IC measurement methods in practice. We also excluded studies within the public or non-profit sector that could have contributed to the analysis. Third, the search focused on peer-reviewed articles. Excluding other sources may have been lost some studies. Nevertheless, we addressed this limitation by utilizing multiple databases and looking across a wide range of article focus. We did not restrict our search to journals with specific topics or rankings.

The studies themselves also had a series of weaknesses. The majority of studies focused on the IT and financial industries. There is a need in future studies to investigate other sectors, including automotive, transportation and hospitality companies, as these industries produce several social and ecological impacts. In addition, the studies did not cover all relevant locations equally; more than half of these involved high-income countries.

Notwithstanding these limitations, our study has key strengths. To our knowledge, this is the first systematic review focused on assessing IC in business uncertainty. While previous systematic reviews answered questions related to the IC, they did not specifically examine its measurement in uncertainty contexts. Similarly, other studies focused on the broader effect of uncertainty on the innovation process but did not explore methods for measuring IC in such situations.

Our research is consistent with existing IC research. First, we found that 63% of studies employed a wide range of indicators and methods for measuring IC. As Pedro et al. (2018) suggested, this highlights the importance of reaching a consensus and defining IC and its related metrics based on different analytical perspectives. Second, our geographical analysis aligns with Inkinen's (2015) observation that studies on IC did not equally encompass all relevant areas. Seven articles were multi-country despite the IC research concentration on Asia and Europe. However, the hegemony of these two continents in IC research seems quite evident. Third, although only three studies reported the sample size of firms, our findings confirm the common trend that IC research has primarily analyzed big companies (Cohen and Kaimenakis, 2007; Tovstiga and Tulugurova, 2007).

Finally, we also found that increasing investment in IC alone does not boost firms' resilience and agility in the digital era. Hence, IC measurement can help firms to face the digital transformation process only when they effectively manage their intangible assets, transforming them into competitive advantages and business growth (e.g., leverage investments in innovation, R&D and employees' knowledge and skills to increase sales by launching new products).

The systematic review highlights important research gaps. The organizational setting revealed that several industries, such as digital communication and tourism, need more investigation into IC measurement and management. Regarding Social Development Goals set by the United Nations, more research should be done on green development, decent work and gender equality to deepen the IC impacts, as reminded by Secundo et al. (2020). Future research is also needed to investigate the impact of IC assets on digital transformation performance. Importantly, two out of four studies that analyzed the digital transformation proposed innovative IC measurement models but did not evaluate or propose specific measurement instruments. It is possible to measure different performance improvements across the phases of digital transformation (Verhoef et al., 2021), yet none of the existing studies included this dimension.

Our findings have important implications for practice. The financial crisis that occurred in 2008 is still fresh in the minds of practitioners. During that time, numerous companies lost billions of euros in a single day, and the situation was deemed a crisis. Conversely, the current uncertainty could be considered a crisis of opportunity. For instance, the digital transformation market will exceed \$1,549 billion by the end of 2027, according to MarketsandMarkets Research (2023). Moreover, if firms fight inflation, they can keep their employees motivated and establish a connection with their customers.

In times of tremendous uncertainty, firms increasingly need IC measurement to maneuver and respond quickly to changing economic and social circumstances. Companies risk being unprepared for unforeseen events without adequate measurement, especially around human capital. Assessing IC means measuring the “immeasurable” and our study suggests that there is no method that works in all cases. What really matters is measuring for learning and value creation. To help businesses navigate uncertainty, we encourage more strategic use of IC measurement by mixing financial and non-financial metrics, like social impact, environmental sustainability, employees’ skills and creativity.

### **Abstract**

The Covid-19 pandemic led to a significant increase in e-commerce and digital adoption in Europe, with online consumer-to-consumer (C2C) marketplaces for second-hand goods experiencing newfold popularity. This trend is primarily driven by Gen-Zers, who are leading the way in buying and selling second-hand goods online, motivated by saving/making money, finding unique items and adopting a more sustainable lifestyle.

This research aims to investigate Gen-Zers' attitudes towards online C2C platforms and their motivations for selling second-hand clothes.

In order to investigate this phenomenon, a qualitative research method has been preferred. The study consists of two parts: the first involves a systematic collection and analysis of users' reviews of the Apps on Trustpilot and App stores in order to identify the most relevant drivers in determining the Circular Customer Experience (CCE) from the sellers' point of view, while the second part involves two focus groups to discuss the evidences emerged from the first study. The research perimeter includes the main Italian online C2C platforms for the clothing category (Vinted and Depop). The reviews were collected using web scraping software and a manual content analysis were conducted to

identify topics that emerged from the qualitative data. The focus groups were organized in light of the predominant role of the participants (sellers).

The results show that among Gen Z, the main motivation to sell is to “empty the closet” but the satisfaction of completing a transaction successfully is also important. Although sustainability is not the primary driving force behind the selling choice, some participants are concerned about sustainability and suggest that C2C platforms increase user awareness and provide solutions to be more responsible. The research highlights personal satisfaction and accomplishment as the key reason for sellers to stand out. Our findings suggest that C2C platforms can retain and attract sellers by improving the mobile experience, developing incentive systems to increase the propensity to leave reviews and equipping sellers with signalling systems to protect against buyers’ opportunistic behaviours. In conclusion, to create a positive perception of second-hand goods, marketers should emphasize their environmental and psychological benefits. If C2C platforms make it easy, rewarding and eco-friendly to sell second-hand goods, they can change people’s attitudes toward used items, so they will no longer be seen as inferior. To the best of our knowledge, this is the first study to adopt the sellers’ point of view, specifically focusing on the motivations of Gen-Z, as the main users of these platforms.

## 1 Introduction

The meteoric rise of e-commerce during the Covid-19 pandemic is a matter of fact which also boosted by 14 percent the digital adoption in Europe (Statista, 2023a), an increment that would have taken two or more years at pre-pandemic growth rates and is proving to be steady and stable as the global state of emergency recedes. In this context, B2C marketplaces such as Amazon have prospered while physical retailers struggled being slow to deliver, short on stocks or even entirely missing the online opportunity. Over the din, there has been another e-commerce history of success much less commonly told: the newfound popularity of online consumer-to-consumer (from now on, C2C) marketplaces hosting buying and selling activities of second-hand goods largely. Transaction volumes have climbed both on horizontal sites such as Facebook Marketplace and on vertical sites as well: Vinted, a Lithuanian and pan-European C2C platform for second-hand fashion and apparel items, is a prime example that have seen growth of more than 50 percent since the start of 2020 (McKinsey, 2021a).

The surge has been driven by millions of people who spent time during lockdowns selling online the unnecessary or the unwanted. It is no short-term trend and is now estimated to be worth 6 billion Euro, having doubled in 2020 and expected to grow at a double-digit rate (McKinsey, 2021b). People are buying more second-hand goods online primarily to save money but creating less waste and adopting a new sustainable lifestyle is silently driving this “behavioural shift” as well (Yeap, 2022); across Europe, fashion and apparel is the biggest second-hand category, both bought and sold on C2C platforms. Consumers of all ages are trading on C2C platforms but, behind a listing on Vinted, it is common to find a Gen Z-er: the youngest consumers, largely 15 to 24 years old, are leading the way, accounting for 43 percent of market volume today (McKinsey, 2023). According to a recent study carried out by the Spanish C2C marketplace Wallapop and Doxa, Gen-Zers are fueling growth into the online second-hand market as a smarter, cheaper and more sustainable way of shopping. On one hand, young consumers can afford higher-quality clothes and accessories without breaking the bank; on the other, they are empowered to give a second life to unwanted, unfitting or unnecessary purchases, easily listing them on a user-friendly C2C marketplace (Doxa, 2022). Money saving/making is coupled with the hunt for bargains and social interactions with peers in searching unique items that set Gen-Zers apart and showing that they are different. In the same way, buying and selling on C2C platforms give a second life to used goods and promotes responsible consumption in lengthening the life of products and avoiding over- and unsustainable production (Yeap et al., 2022).

With the notion of possession moving closer to that of sharing, the aim of this research is to dig deep into Gen-Zers attitudes towards online C2C platforms, with specific reference to those who actively use them to sell second-hand items. Our purpose (RQ) is twofold: in the first instance we identify the most relevant drivers in determining the Circular Customer Experience (CCE) from the seller's point of view; subsequently, we investigate whether and to what extent the role of sustainability was pivotal in these experiences. To do so, qualitative research methods have been preferred. The paper consists of two studies. The first provides a systematic collection and analysis (through content analysis) of users' reviews of the Apps on Trustpilot and the main App stores; the emerging evidences were then discussed in a second study that consisted of a set of focus groups with Gen-Zers where the role of sustainability was investigated in-depth.

## 2 Literature Review

Studies on second-hand shopping are limited. Existing research identifies a variety of factors that influence second-hand shopping such as economic necessity and price equity. Similarly, scholars have indicated that purchasing used goods is an efficient method for reducing waste and pollution (Khurana and Tadesse, 2019; Machado et al., 2019). As an example, in the past few years, the second-hand clothing business has grown steadily as more young buyers have become interested in vintage clothing (Su et al., 2019). This is due to the fact that environmental value is the most significant predictor of views toward used apparel (Padmavathy et al., 2019). In recent years, the market for second-hand goods has undergone a significant transformation with the rise of consumer-to-consumer (C2C) online platforms. C2C online commerce refers to online transactions between two users that involve the exchange of goods. Such transactions are carried out through various online marketplaces, including popular platforms such as eBay, Etsy, or Taobao, as well as auction websites (Statista, 2022). The proliferation of these platforms has made it easier than ever for individuals to buy and sell used items directly to one another, bypassing traditional intermediaries like thrift stores or pawn shops.

In even more recent times, there has been a shift towards mobile-based shopping platforms that encourage consumers to engage in C2C transactions without having to go through traditional business channels. The fashion industry has particularly benefited from this trend, offering new opportunities for both consumers and sellers (Johan et al., 2020) and C2C e-commerce has proven popular, especially among younger generations. Thus, social shopping platforms (e.g., Vinted and Depop) enable millions of sellers and resellers to develop their own, more or less "professional", virtual store and connect with consumers, thanks to rating, reviews and direct interactions between buyers and sellers that allow price bargaining and requesting for additional information, "social" elements far from the logic of today's retail or e-commerce. In addition, buying and selling second-hand items incorporate several elements of sustainability, both economical and environmental.

Sustainability motivations mainly indicate consumers' concern for the environment, particularly in relation to sustainability issues and beliefs (Hamari et al., 2016). Consumers who care about the environment will question the necessity and usefulness of a product before making a purchase in order to safeguard the

environment and abstain from ecologically hazardous behaviour (Parguel et al., 2017). It has been proven that sustainability-inclined beliefs (Hamari et al., 2016; Kim & Yoon, 2021) positively influence attitude towards collaborative consumption. Environmentally conscious consumers are more likely to engage in sustainable clothing consumption (Diddi et al., 2019; Parguel et al., 2017; Styvén & Mariani, 2020). Parguel et al. (2017), for instance, argued that the environmental awareness of French consumers has prompted them to purchase used goods through C2C platforms such as the local Leboncoin. Consumers believe that their actions can help to reduce waste by recycling, extending product life spans, and resulting in a decrease in indulgent, unsustainable consumption (Parguel et al., 2017; Turunen & Leipämaa-Leskinen, 2015).

Economic motivations refer to consumers' price consciousness (Padmavathy et al., 2019). In early studies on thrift store purchasing, economic motivation had been emphasised extensively (Ferraro et al., 2016). Price-conscious consumers are more likely to purchase secondhand clothing (Yan et al., 2015) and are referred to as highly economically-oriented bargain hunters (Seo & Kim, 2019). According to Edbring et al. (2016), consumers who purchase second-hand goods, especially clothing, tend to avoid purchasing first-hand goods at original prices because they may be able to purchase branded goods for a lower price or higher-quality products for a lower price on the secondary goods market.

Consumption on C2C platforms shows how users have incorporated technology into their daily lives and are progressively forming a conscience about being good for the environment. Studies on consumers' purchases of used goods have been conducted (Guiot & Roux, 2010; Mohammad et al., 2021; Seo & Kim, 2019; Yan et al., 2015), but there are fewer empirical studies on consumers' online selling and reselling behaviour for particular used goods like apparel. The study by Chu and Liao (2007) presents a taxonomy of online consumer resale behaviour and its impact on both purchase and resale decisions. The authors distinguish between planned and unplanned resale behaviours and classify online resale behaviours into four types, including resale of extra purchase, resale after temporary ownership, unplanned resale, and disposition. The study defines planned resale as consumers' intention to resell a purchased item after using it for a certain period, with the expectation of future compensation if the item is successfully resold through an online auction site. On the contrary, unplanned resale is defined as situations where consumers think about reselling a product only after its purchase. The authors also found that consumers in the second-

hand market might be driven by non-monetary reasons, such as fun or a sense of achievement, leading to increased user loyalty and promising future prospects.

Furthermore, Herrmann and Soiffer (1984) identified various types of sellers in the context of "garage sales" including (1) professional resellers, (2) dabblers, who try out the garage sale experience for the first time, (3) regulars, who regularly dispose of unneeded household items and (4) housecleaners, who dispose of unwanted items from the home. Apart from professional sellers, amateurs also began to sell excess personal goods in flea markets to clear out space at home and earn a small amount of money. Thus, consumers engage in resale for both economic and house-cleaning reasons, as well as for emotional and social motivations such as avoidance of waste, environmental protection, socialising, achievement, or simply for fun (Chu and Liao, 2007; Herrmann and Soiffer, 1984).

As consumer behaviour continues to evolve, the motivations behind the reselling of goods have become more complex. Recent research has shown that emotional motivations are becoming increasingly important factors in the consumers' decision-making process. Emotional motivations for reselling were previously identified by several studies and include avoidance of waste (Herrmann and Soiffer, 1984; Jacoby et al., 1977), environmental protection (Herrmann and Soiffer, 1984), socialising (Cameron and Galloway, 2005; Herrmann, 2006; Herrmann and Soiffer, 1984), and achievement and entertainment (Herrmann and Soiffer, 1984). These motivations may help to explain why consumers may not engage in complex financial analyses when reselling items. In short, consumers may resell for various reasons, including economic and house-cleaning purposes, as well as emotional and social reasons. Therefore, motivations that drive consumers to engage in online resale differ from those of traditional offline second-hand shops. Consumer online resale behaviour is multifaceted, composed of different motivations, and results in various impacts on consumer resale decisions. These motivations include utilitarian benefits of making a profit, satisfying other needs for consumption, maximizing shopping strategy, hedonic dimensions of enjoyment and achievement, avoidance of guilty feelings, and socializing needs (Chu, 2013).

As the world faces growing concerns over the environmental impact of fast fashion, the importance of sustainability and ethical values is becoming increasingly prominent in consumer behaviour. The study by Park (2023) highlights that consumer behaviour on C2C online platforms for second-hand fashion products is heavily influenced also by their level of environmental

consciousness. Consumers who prioritize environmental sustainability and saving tend to view second-hand trading platforms as an effective way to recycle products and purchase good quality second-hand fashion products. In contrast, consumers with low environmental consciousness tend to use the platform for hedonistic and experiential consumption. This highlights the crucial role of second-hand sellers on C2C platforms. According to Styvén & Mariani (2020), sellers should emphasize their environmental and ethical motivations for selling second-hand online, going beyond purely economic motivations. This approach has the potential to start a dialogue between buyers and sellers, and even convince buyers to choose a seller based on their real ethical and sustainability values. By promoting the environmental benefits of second-hand purchases and prioritizing ethical values, this approach could encourage a shift towards more conscious and responsible consumption. Overall, this approach has the potential to raise awareness about the benefits of purchasing second-hand products and contribute to more sustainable and responsible behaviours, which is vital for the environment.

Several studies have been conducted to examine the reasons behind consumers' purchases of second-hand products (Koay et al., 2022; Ferraro et al., 2016; Guiot & Roux, 2010; Roux & Guiot, 2008) and to investigate the purchasing behaviour of second-hand clothing on C2C platforms (Yeap et al., 2022; Moriuchi & Takahashi, 2022; Padmavathy, Swapana & Paul, 2019). However, research on consumer online resale behaviour is still scarce. Keeping in mind these under-researched issues, this study addresses a major lacuna in the literature by identifying precursors of attitude toward selling used clothing on C2C platforms. In doing so, the paper provides a deeper, more current comprehension of consumers' propensity to sell used clothing via these online platforms.

### **3 C2C online resale motivations**

Having to investigate aspects of which informants are only partially aware, also sensitive to the phenomenon of social desirability, qualitative research methods have been preferred. The paper involves two studies. The first consists in the systematic collection and analysis (through Content Analysis) of users' reviews of the Apps on Trustpilot and the main App stores. The purpose of this first study was twofold: to identify the most relevant categories/drivers in determining the Circular Customer Experience (CCE) and to investigate whether sustainability was

an element present in the ex-post evaluation of these experiences. Having collected these first set of CCE drivers, the subsequent study made it possible to discuss the evidence that emerged in a set of two focus groups, organized in the light of the predominant role of the participants (sellers).

The research perimeter included the main online C2C platforms, for the clothing category in particular (Vinted and Depop, therefore), in the Italian market (reviews and Focus Group were collected/conducted in Italian and afterward translated: transcripts are available upon request).

### **3.1 Design and Methodology: Study One**

Having identified the research perimeter (*see Table 1*), the reviews were collected using web scraping software. For our purposes, reviews were considered valid if, even separately 1) described the sales experience 2) concerned the aspects of sustainability. Unfortunately, in many reviews it has not been possible to identify whether they were written by a seller, a buyer, or both. Then, a manual content analysis has been run: as suggested by Saldana (2015), this method enables to detect, examine and present topics emerging from qualitative data, and we were looking for the CCE drivers for sellers. The CCE drivers were clustered in the light of the four touchpoints discussed by Lemon and Verhoef (2016). The classification work was carried out independently, but to ensure objectivity of the analysis, a part of the dataset (30%) was randomly extracted and analysed by all the Authors: in most cases Authors' evaluations were congruent and aligned. The content analysis has been carried out following the criterion of completeness and exhaustiveness.

Table 1: Study One perimeter (March 2023)

<b>C2C platform</b>	<b>Vinted</b>	<b>Depop</b>
Trustpilot N° reviews	4.119	5.548
Trustpilot average rate	4.4 out of 5 stars	2.2 out of 5 stars
Apple store N° reviews	439.790	34.146
Apple store average rate	4.8 out of 5 stars	4.7 out of 5 stars
Google Play store N° reviews	1,04 Mln	62.553
Google Play Store average rate	4.4 out of 5 stars	3.9 out of 5 stars

### 3.2 Design and Methodology: Study Two

Study One results were the foundation for the Study Two: Focus Group interviews (Lederman, 1990; Creswell and Creswell, 2018) were appropriate for obtaining a broad range of opinions and beliefs about the subject and experiences, pointed out in Study One. Moreover, participants were supposed to readily express themselves when they are part of a group (Kitzinger 1994).

In April 2023, 13 Italian students aged 22–27 yo (see Table 2) participated in two online focus group sessions (via Microsoft Teams). The participants were selected using Authors personal networks (opportunistic sampling) according to the following criteria: 1) confidence with main C2C platforms as sellers, 2) normal use of the Internet as Gen Z (average rate of Internet usage in 2023 has been identified by Audiweb and WeAreSocial reports). Furthermore, two more control item have been introduced to select the participants profiles, as suggested by Fischer et al. (2017): they developed a specific scale for young consumers' sustainable consumption behaviours (YCSCB) in the areas of food and clothing, that has been used to measure the informant's profile. In collecting the availability to participate in the focus group studies, no incentives have been offered for participation (Van Laer et al. 2012).

The moderator adopted a soft-empathetic style of conduction making sure that the group dynamics facilitated the emergence of reliable information: through moderation, was ensured 1) the discussion of all points highlighted by Study One and by previous literature, and 2) a friendly and neutral environment, ensuring that everyone could express their thoughts trying to soften the double social desirability bias. Participants' privacy was ensured at the beginning of the meeting, specifying that any information would have been traced anonymously and in aggregate form. Furthermore, the authorization to record the conversations has been requested and obtained.

Table 2: Focus Groups participants (April 2023)

Participant	Age (yo)	Gender	Control item 1 (I buy my clothes myself)	Control item 2 (I get clothes as presents)	Control item 3 (Internet Usage – hours in a day)
1	23	Female	Yes	No	More than 5 h
2	23	Female	No	No	More than 5 h
3	22	Female	Yes	Yes	Less than 2 h
4	24	Female	Yes	Yes	Less than 2 h

<b>5</b>	24	Female	Yes	No	3 to 5 h
<b>6</b>	24	Male	Yes	Yes	3 to 5 h
<b>7</b>	23	Female	Yes	Yes	3 to 5 h
<b>8</b>	23	Female	Yes	No	3 to 5 h
<b>9</b>	23	Female	Yes	Yes	3 to 5 h
<b>10</b>	23	Female	Yes	Yes	3 to 5 h
<b>11</b>	24	Female	Yes	Yes	3 to 5 h
<b>12</b>	27	Male	Yes	Yes	3 to 5 h
<b>13</b>	25	Female	Yes	Yes	3 to 5 h

The focus group protocol was designed on literature review and Study One results, and included the following key questions: 1) CCE drivers from a seller point of view through the different touchpoints 2) buying/consuming/selling behaviours 3) the role of sustainability in the seller CCE. Even if this is a small-scale study based on two focus groups, the results can be considered reliable, because the differences that emerge from the two moments of analysis are few and small. Focus Groups participants didn't take part in the online platforms analysed in Study One.

## 4 Findings

### *Study One*

The objective of the first study was to highlight the different components of the seller-side CCE. The main points raised are listed below (Table 3). Brand-owned and Customer-owned touch points were the most discussed, especially in negative reviews.

Table 3: CCE drivers

<b>Touchpoints (Lemon &amp; Verhoef, 2016)</b>	<b>Drivers</b>
Brand-owned touch points	platform operation and mobile app functioning, customer service assistance, pricing and payment system, advertising on the platform, loyalty programme
Partner-owned touch points	couriers, delivery/pick up points
Customer-owned touch points	request for pre-purchase support, false requests/non-purchases/rudeness, unplanned request (hand delivery, other platform with less fees)
Social/external touch points	customer word of mouth, platform and customer reviews

As far as the theme of sustainability is concerned, it does not appear often, but when present it is always linked to packaging.

### *Study Two*

1) CCE drivers from a seller point of view through the different touchpoints.

With great clarity it emerged that selling is important, but even more is the experience sellers live in the meantime. In order of importance, there are three aspects that determine sellers' CCE: the feedback obtained from the buyer, which guarantees how excellent the seller has been (social/external touchpoint), the quality of the negotiation defined by the requests and behaviour of the buyer (customer-owned touchpoint) and the functioning of the platform (brand-owned touchpoint). The real boost of the sale is the satisfaction sellers bring home in managing, governing and concluding the negotiation.

2) Buying/consuming/selling behaviours.

Through moderation, the conversation covered the different stages of the customer journey. In particular, some confirmations of the literature have emerged but also some interesting new suggestions. Since the decision to sell clothes comes later than the one to buy, there is not any particular changes in the consumption behaviours. Only in the case of garments linked to events (ceremonies, for example) has it happened to use the garment with greater care so as not to preclude its sale after the usage. The reselling intention does not lead people to buy more or "better" (with reference to higher and durable quality, to have a longer life) nor to treat better what they buy.

Among the most interesting elements of this phase of the discussion there is certainly evidence of the reasons for which they sell. If the main motivation declared is to "empty the closet", the request to go deeper into the sensations associated reveals aspects that are not entirely foreseen. "Emptying the closets" for Gen Z means feeling less guilty about previous purchases, but also feeling smart. The ability to carry out a transaction in the best way, receiving gratifying reviews, the possibility of starting to become economically independent are the essence for using these platforms. All motivations that find their pivot in the characters of Gen Z. Being sustainable is a positive side effect, but certainly not the driving force behind the selling choice. A more functional reason that emerged side by side, but still linked to the age of the cluster considered, is that of no longer recognizing oneself in what is in own wardrobes: because one has grown up, and certain items no longer fit. Or because they have changed their

taste compared to when they were “little”, or because of life changes (residence, lifestyle, broken relationships). What is obtained from the sales does not have a precise destination: in some cases, it is deposited into the current account, in others it is used to buy something else, both inside and outside the platform.

Finally, with reference to sales behaviour, sustainability concern appears in the use of recycled and/or easily recyclable packaging. In terms of timing, it clearly emerges that there is no rush to sell: the items remain on sale for a long time, without evaluating other solutions (such as charitable gift or elimination in the garbage).

### 3) The role of sustainability in the seller CCE.

During the focus groups, the topic of sustainability came up inconsistently. Some participants have immediately shown that they consider it, describing their shipping solutions, but it does not represent a priority. The shared feeling is that platforms should increase user awareness and equip sellers with tools and solutions to be more sustainable. It also emerged that during the transaction, one generally feels secure: the greatest perceived risks come from requests to leave the platform and/or the platform rules, which sometimes come from certain buyers. As commented in the previous point, the use of C2C platforms is not perceived as a behaviour mainly inspired by sustainability.

## 5 Conclusions and Implications

What makes a C2C platform appreciated by sellers is certainly its ease of use, mostly conveyed by a positive and user-friendly mobile experience. Sellers, regardless of their degree of experience on the platform, are aware of not being retail professionals and they do not want to be treated as such at any stage of the sale, from listing the object to identifying the most convenient shipping method. The research highlighted some features that can be enhanced to retain sellers and encourage a “buying and selling behaviour” to buying-only users; in particular, to improve Gen-Zers’ Circular Customer Experience, C2C platforms are suggested to: (i) develop incentive systems to increase the propensity to leave reviews, indicated by interviewees as the key indicator of reliability for both sellers and buyers, as well as an “element of social gratification”; (ii) equip sellers with signalling systems or alerts against opportunistic buyers, fake profiles, and bogus requests that may discourage sellers from actively using the platform; (iii) push for greater awareness of what might be the most sustainable solution, for example,

by suggesting a donation to charity of long-unsold garments or proposing a local delivery solution for low-value items; (iv) suggest assisted saving systems with the proceeds of the sale to avoid overconsumption and promote a saving culture among younger sellers. In the same way, our research highlights personal satisfaction and accomplishment as the key reason-why to sell on C2C platforms. With this in mind, marketers may introduce forms of social recognition for best sellers to stand out as Airbnb did with "superhosts" to identify experienced and trustworthy hosts.

In the end, to create positive views of second-hand among buyers and sellers, marketers must emphasise the environmental and psychological advantages of used goods (Koay et al., 2022). However, it takes time to change people's perceptions of buying second-hand; working upstream, if directly selling the unwanted online via C2C platforms turns out to be easy, rewarding and environmentally sustainable, once a sufficient number of people will adopt this mentality, second-hand will no longer be regarded as second best.

### **Abstract**

Global warming, pollution and the rapid absorption of natural resources require swift and immediate action to limit and reverse their impact on the environment. Circular economy offers a clear solution to addressing these global challenges. Therefore, measuring the circularity of one's organization should be the fundamental objective of all companies intending to apply circular economy. Otherwise, the effort made cannot be evaluated and the results achieved cannot be quantified.

The agri-food sector is considered one of the main challenges related to the achievement and application of Circular Economy (CE) strategies, therefore this study is aimed at developing a multilevel framework for assessing circularity in agri-food industries, by providing the user with a step-by-step approach. The framework is composed of four stages. In the first stage, a circular economy theoretical model, based on four criteria, was implemented and adapted to agri-food sector. In the second stage, a set of indicators

capable of measuring each criterion was collected. In the third stage, a weight is assigned to each indicator using the Analytical Hierarchy Process (AHP). Lastly, an Axial Distance-based Aggregated Measurement (ADAM) model is used to normalize, assess, and aggregate the results and produce final circularity scores. The model can be a useful tool to support corporate decisions concerning the circular economy, making entrepreneurs aware of their starting level. It indicates the extent to which companies are implementing circular business models across different dimensions, and thus where they are still lacking.

**Paper type** – Academic Research Paper

## 1 Introduction

There is growing consensus on the need for a gradual transition to a more sustainable economic growth. Global warming, pollution and the rapid absorption of natural resources require swift and immediate action to limit and reverse their impact on the environment. Circular economy (CE), when applied to various business models across a variety of sectors and at different levels, offers a clear solution to addressing these global challenges (United Nations, 2019).

In recent decades, CE has emerged as a prominent topic in both natural science and management literature (Alhawari, et al., 2021). The CE concept came to the fore in 2010 thanks to the popular activity of the Ellen MacArthur Foundation (2015), which revived, among others, the most recent cradle-to-cradle approach (McDonough and Braungart, 2002). Since then, CE insights have never stopped going forward. However, since there is no single theoretical definition of CE, the originality and scope of new contributions on the subject have not always been clear, often making the concept confusing (Borrello et al., 2020).

Based on several scientific contributions, CE can today be defined as a regenerative system in which resource and waste inputs, emissions and energy losses are minimized by slowing down, closing and narrowing of material and energy loops (Boulding, 1966). Seen as a new business model, CE reconciles the relationship between economic development and environment protection, which is achieved through seven main actions: long life design, maintenance, repair, reuse, remanufacturing, reconditioning and recycling (Afuah and Tucci, 2003; Zott and Amit, 2010).

A growing interest in CE can be also highlighted in the EU policy looking for developing guidelines to support CE organizational strategies on the national level. In 2015, the European Commission launched a Circular Economy Action Plan (European Commission, 2015) to stimulate Europe's transition towards a more circular economy, to boost global competitiveness and to foster sustainable economic growth. Beginning with a limited focus on waste recycling, CE has steadily shifted to broad efficiency-oriented operations through an increase in the effectiveness of resource allocation, resource utilization and productivity, in a variety of areas, including agri-food (Su et al., 2013).

The application of CE principles in the agri-food sector appears to be an important and necessary change to transform society and face future challenges (European Commission, 2020).

The increasing global food demand, in fact, is forcing the agri-food companies to identify effective new strategies for production, distribution and consumption (Accorsi et al., 2019).

The agri-food value chain has many aspects to invest in to make production systems more sustainable and circular and resource recovery is only one of the most relevant aspects (Kyriakopoulos et al., 2019). CE, in fact, is a concept that is not limited to improving the sustainability of production processes, but enters into the organizational logic of the company, becoming a long-term goal whose progress must be monitored.

Therefore, measuring the circularity of a product or a process should be the fundamental objective of all companies intending to apply circular economy. Otherwise, the "profuse" commitment cannot be evaluated, and the results achieved are not quantifiable and, above all, comparable.

Measurement allows the entrepreneur to understand which actions to implement to improve circularity performance and which to avoid. It gives a contextualized dimension, in which to set improvement objectives.

## **2 Circular economy in agri-food companies**

The agri-food sector is considered as one of the main challenges related to the achievement and application of CE strategies (Muscio and Sisto 2020). The agri-food sector includes activities of other industrial sectors and it is defined as a syneresis of several economic activities, such as natural processes managed by anthropic actions and industrial processes, fully under human control. This sector

is creating unsustainable resource consumption and waste creation, which has environmental, economic and social consequences (Agnusdei and Coluccia, 2022). The concept of CE within agri-food sector is becoming a challenge for researchers and practitioners and it is declined in the objectives of Sustainable Development Goals (SDGs) as it plays a key role in the transition to a sustainable food system. Responsible Consumption and Production is the key objective of SDGs in which sustainability strategies are applied to the agri-food sector. The interest in this field is also highlighted by the European Commission which is addressing the shift from a linear model to a circular model. Therefore, reducing food loss and waste along the whole supply chain can be considered the main action to achieving sustainability in the sector. Practitioners, scientists and policymakers are working toward food loss and waste reduction strategies adopting sustainable production and consumption approaches (Shafiee-Jood and Cai, 2016). However, circular economy can be applied to all stages of the agri-food chain: from the cultivation and processing of food to packaging, up to the management of waste and by-products. The latter represent a unique resource to produce biomaterials with several applications (Esposito et al., 2020). In addition to the important environmental benefits, applying a circular economy approach to the food sector makes it possible to obtain concrete industrial and economic advantages, such as an increase in capital inflow, the attraction of talents and aware consumers, the increase in brand value and the adaptation to constantly evolving European regulations (Mehmood et al., 2021). A circular economy approach in agri-food allows for the recovering of resources by significantly reducing the negative externalities of the production cycles. Among the applications proposed in the literature, actions aimed at reducing food waste throughout the supply chain receive the greatest attention (Agnusdei et al., 2022; Principato et al., 2019). Other authors have focused on reducing packaging, on its recycling and on preferring biodegradable materials (Meys et al., 2020; Silva and Pålsson, 2022; Guillard et al., 2018). An important trend has dealt with the improvement of efficiency along the entire supply and distribution chain (Cravero et al., 2021; Pagotto and Halog, 2016), giving new life to production waste, through recycling or revaluation of materials (La Scalia et al., 2021; Kapoor et al., 2020). Finally, many authors have valued the downstream stages of the supply chain, promoting the consumption of eco-sustainable foods and favoring a plant-based diet (Coluccia et al., 2021; Cappelozza et al., 2019).

### **3 Literature review and scope**

There are no commonly accepted methods to measure circularity (Kristensena and Mosgaard, 2020). An increasing number of scholars and practitioners have focused on the assessment of the progress of CE initiatives and, accordingly, on the development of performance measurement tools (Vinante et al., 2019). However, literature shows that advanced research and data availability on CE assessment tools and indicators are lacking (Yazdani et al., 2021). Quite simply, developing a framework for assessing circular economy is a challenge that must be coupled with the collection of framework, metrics and indicators. This is because, developing the right framework and selecting the correct indicators that capture different CE practices is the essential starting point for measuring circularity (Kumar et al., 2019). The number of CE frameworks is relatively small, and most of them are missing some important CE oriented strategies (European Commission, 2015; Rainville, 2019). The available frameworks tend to focus primarily on physical parameters and materials circularity without considering other CE aspects such as policies and regulations, customers contribution, organizational aspects, and technological advancement (Chauhan et al., 2022). From the literature analysis, it emerged that many of the reviewed frameworks are not intended to assess the circularity, but rather focus on a very specific stage(s) or area(s) of a selected product or process, such as end-of-life and waste generation.

There are numerous studies using the Life Cycle Approach to measure circularity (Laso et al., 2016; Thakker and Bakshi, 2021; Ferreira and Fuso-Nerini, 2019; Avdiushchenko and Zajac, 2019; Coluccia et al., 2022).

Other authors have combined LCA with MCDM, which allows greater flexibility, allowing the user to choose his own set of indicators based on his measurement needs (Rocchi et al., 2021; Alamerew and Brissaud, 2019; Ahmed et al., 2022).

To date, it is very challenging to achieve a predefined set of standard indicators for CE at the micro level. This is mainly due to the unlimited variety of goals, objectives, characteristics and challenges that different companies, businesses and products have. Different sets of indicators have been developed by different organizations to capture the circularity of different products and processes (European Commission, 2021). However, even the different taxonomies only focus on the operational aspects of the circular economy, such as material flow and waste generation. It is therefore difficult to find a single complete set of indicators

that takes into account the environmental, organizational, economic, social and technological factors of the model that implements a circular business model (de Arroyabe et al., 2019).

At the institutional level, the best-known model is Circulytics (Ellen MacArthur Foundation, 2017). This tool measures the CE performance of companies' materials and water flow and other services provided along with energy use. However, the focus of the model is on the balance of the materials, without considering that circular economy is a process that includes governance and organizational aspects. Another assessment tool is the Cradle to Cradle Certified by Cradle-to-Cradle Products Innovation Institute (MBDC, 2021). The tool lacks flexibility even on the product level as it does not assess products that operate on non-renewable energy sources.

Most of the approaches proposed to assess circularity provide only partial information, mainly focusing on the analysis of environmental sustainability performance. In general, the available frameworks have recurring weaknesses, mainly revolving around their limited selection of indicators that fail to capture different aspects and phases of CE. Furthermore, a lack of assessment of circularity in the agri-food sector is evident, despite its complexity and its strategic role in the circular transition.

Beyond the attempts of measuring the firm's performance circularity, what is lacking is an approach that can assess the circularity status of a company in a holistic vision, considering the complexity and disruption of all circular economy principles.

In this context, this work is primarily aimed at developing a novel comprehensive circular economy assessment framework that is flexible, easy to use, and accurate when determining the best business organization choices that fit the circular economy model in agri-food companies. The developed model can be applied to the transformation and industrial processes, thus excluding the agricultural and consumption phases. The literature gaps are addressed by providing the user with a step-by-step approach, leading up to the selection, weight and use of a customized set of indicators that are capable of accurately assessing the level of CE.

#### 4 Theoretical model

This section describes the approach for the evaluation of agri-food firms in terms of circularity using a novel assessment framework. As shown in Figure 1, the framework is composed of four stages. In the first stage, through the analysis of the literature, a theoretical model which provides a holistic vision of the circular economy was implemented and adapted to the agri-food sector, as presented in Section 4.1. In the second stage, users are required to collect a set of indicators capable of measuring each sub-criterion, as presented in Section 4.2. In third stage, a weight is assigned to each indicator using the Analytical Hierarchy Process (AHP), which is a pairwise comparison methodology (Section 4.3).

Lastly, a geometric Multi Criteria Decision Making (MCDM) method, called the Axial Distance-based Aggregated Measurement (ADAM) model is used to normalize, assess and aggregate the results and produce final scores for the different alternatives to be ranked based on their final circularity scores (Section 4.4).

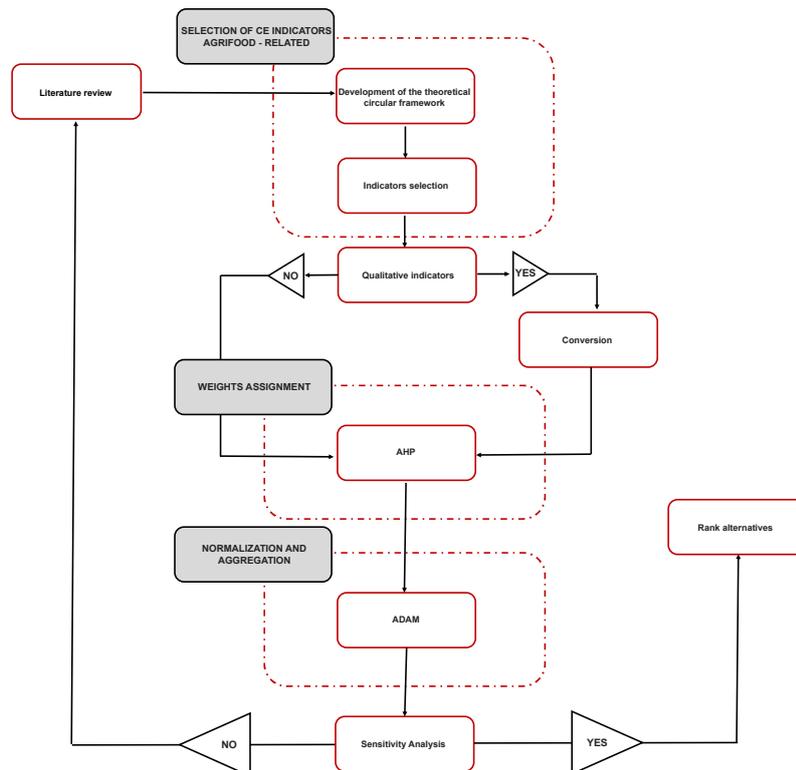

Figure 1- Circular Economy Assessment procedure

#### **4.1 Development of a theoretical circular framework**

In this first phase a theoretical framework was developed, thus providing the basis for the selection of criteria and sub-criteria of the general model. Through the analysis of the literature, the methodological framework of Lacy et al. (2020) was selected. It provides a holistic vision of circular economy, indicating the strategic areas that need to be considered to assess the level of circular maturity of companies, in order to ensure a reliable assessment:

- *Operations (OP)*: evaluating the value lost through the operations and by-products of business processes across energy, emissions, water and waste.
- *Products and services (PS)*: rethinking the design, lifecycle, and end of use of a product or service to optimize usage, eliminate waste and close product loops.
- *Culture and organization (CO)*: embedding circular principles into the fabric of an organization through redefined working practices, policies, and procedures.
- *Ecosystem (EC)*: collaborating and partnering with public and private sector actors to create an enabling environment for collective transformation.

In the present study, each of the above four dimensions was used as criteria for the evaluation of circular economy in agri-food firms. All these criteria are composed of sub-criteria (Table I), which can be measured using a set of indicators that are thought to be important for a valid evaluation of the circularity of agri-food firms.

The *operations* criterion was investigated taking into account four main sub-criteria in which companies typically focus their circular operational initiatives: energy (OP<sub>1</sub>), emissions (OP<sub>2</sub>), water (OP<sub>3</sub>) and waste (OP<sub>4</sub>).

Circularity in terms of *products and services* (PS) was evaluated by considering the four key stages of a product's lifecycle as sub-criteria: design (PS<sub>1</sub>), use (PS<sub>2</sub>), use extension (PS<sub>3</sub>) and end of use (PS<sub>4</sub>).

In order to evaluate the circular *culture and organization* (CO), we focused on the following four sub-criteria: vision (CO<sub>1</sub>), innovation (CO<sub>2</sub>), people (CO<sub>3</sub>) and governance (CO<sub>4</sub>).

Finally, we define a circular *ecosystem* as the network of organizations collaborating and partnering to create an enabling environment for collective

transformation. Therefore, in order to capture the potential of the ecosystem, we selected four key sub-criteria: sharing (EC<sub>1</sub>), collaboration (EC<sub>2</sub>), investment (EC<sub>3</sub>) and policy (EC<sub>4</sub>).

Table I. Description of criteria and sub-criteria

Criteria	Sub-criteria	Description
Operations (OP)	Energy - OP <sub>1</sub>	Implementing measures that reduce energy consumption, increase operational energy efficiency, and start to shift from fossil fuels to renewable sources.
	Emissions - OP <sub>2</sub>	Identifying emission points within the direct scope of core operations as well as throughout the supply chain and then making suitable interventions to reduce those emissions.
	Water - OP <sub>3</sub>	Reducing a company's water dependence by minimizing water abstraction, prioritizing water-saving opportunities and increasing water reuse to improve efficiency and reduce costs.
	Waste - OP <sub>4</sub>	Reaching zero waste by eliminating waste leakage throughout company operations and reducing waste capacity by maximizing asset utilization.
Product and Services (PS)	Design - PS <sub>1</sub>	Conductive assessment of the current lifecycles of materials and their resource footprints.
	Use - PS <sub>2</sub>	Maximizing the value delivered through the single use of a circular product or service in its original form. The aim is to leverage a product as a service or sharing platform model to maximize product utilization.
	Use extension - PS <sub>3</sub>	Maximizing the value delivered through multiple uses of a circular product or service in its original form.
	End of use - PS <sub>4</sub>	Maximizing the value delivered through multiple uses of a circular product or service in any form. This might include identifying circular uses for waste at end of use and repurposing it by recycling.
Culture and Organization (CO)	Vision - CO <sub>1</sub>	Setting a long-term goal with milestones and supporting targets to become a circular organization over time.
	Innovation - CO <sub>2</sub>	Breaking down research and development silos to encourage innovation across the organization, instilling a "laboratory" mindset to drive innovative circular thinking, sharing best practices and relevant use cases, conducting learning expeditions to embed circular principles and design in organizational centers of innovation and encouraging the operational and product/service pivot to circularity.
	People - CO <sub>3</sub>	Engaging employees with circular projects sponsored from the top of the organization, providing training and internal support systems for those workers by identifying and empowering the people who can drive the journey of change and incentivizing circular

		performance at all levels against clear and challenging KPIs.
	<b>Governance - CO<sub>4</sub></b>	Making the circular economy a core element in the company's ways of working and structure by embedding circularity in policies, processes and procedures.
<b>Ecosystem (EC)</b>	<b>Sharing - EC<sub>1</sub></b>	Non-competitive, transparent sharing of knowledge, information, and learning to support circular thinking and performance. Initiatives in this area center around sharing insight and expertise with peers to address shared challenges.
	<b>Collaboration - EC<sub>2</sub></b>	Bilateral and multilateral partnerships to deliver practical circular solutions, Initiatives in this area focus on establishing bilateral partnerships and working with multilateral public-private stakeholders to bring to market circular solutions that benefit all.
	<b>Investment - EC<sub>3</sub></b>	Financial support to drive circular innovation. The investments can be in innovative start-ups, products, and business-model development, thought leadership, R&D, and non-commercial third parties such as NGOs or academia.
	<b>Policy - EC<sub>4</sub></b>	Support of an enabling regulatory environment for circularity. Initiatives in this area include engaging in local and national discussions as well as international forums to inform and/or influence relevant policy measures and regulations that would foster a regional and global circular economy.

According to Lacy et al. (2020), through these dimensions it is possible to detect the degree of circularity of a firm, understood as the extent to which it is implementing circular business models for all four dimensions. Necessarily, to reach an advanced level of transformation, companies should not dwell on just one dimension but will have to implement the new models on all of them in parallel.

#### **4.2 Indicators selection**

In this phase, indicators that are suitable for assessing the level of circularity achieved in each criterion and sub-criterion (non-existent, emerging, consolidated, lead and last) were identified. Table II summarizes the different indicators that users of the proposed framework should consider to be able to obtain a comprehensive choice of indicator set, consistent with the objectives of the circular economy in agri-food companies. To end up with a reliable set of indicators, the set should be targeted, measurable (even qualitative indicators

should have defined qualities using words like “successful, appropriate, effective”), reliable, feasible and utile in decision making (Church and Rogers, 2005).

Table II - Indicators to be selected for the circular economy assessment in agri-food firms

Criteria	Sub - criteria	Indicators
OP	OP <sub>1</sub>	1. Energy consumption
		1. Energy renewable sources / Total Energy Consumption
	OP <sub>2</sub>	2. Water consumption
		3. Blue Water footprint
		4. Green Water footprint
		5. Grey Water footprint
		6. Waste production
	OP <sub>3</sub>	7. Food waste production
		8. Recycling rate
		9. Recycling rate of overall packaging
		10. Recycling rate of plastic packaging
		11. Recycling rate of wooden packaging
		12. Recycling rate of paper packaging
		13. Recycling rate of glass packaging
		14. Recycling rate of bio-waste
		15. Recycling rate of e-waste
		OP <sub>4</sub>
17. Imported raw materials		
PS	PS <sub>1</sub>	18. Use of software/management to process data to support business decisions
		19. Energy class of electronic equipment
		20. Food loss
		21. Packaging quality
		22. Quality of equipment
	PS <sub>2</sub>	23. Percentage of exploitation of agricultural raw material
		24. Throughput time
		25. Supply chain certifications
	PS <sub>3</sub>	26. Use of recycled materials for primary or secondary packaging
		27. Use of biodegradable materials for primary or secondary packaging
	PS <sub>4</sub>	28. Food waste or by-products disposed of
		29. Food waste or recycled by-products
		30. Food waste or by-products processed by other industries to obtain new products

		31. Food waste or by-products used for energy production
CO	CO <sub>1</sub>	32. Goals of circularity in the company's long-term planning
	CO <sub>2</sub>	33. Investments in innovation
		34. Use of digital technologies for process efficiency
		35. Use of digital technologies for process traceability
	CO <sub>3</sub>	36. Performance monitoring system through KPIs
		37. Capacity building: organization of courses, events and campaigns to educate employees on circularity
	CO <sub>4</sub>	38. Circular orientation: the circular economy is a component of the company's sustainability policy
		39. Ownership of environmental quality and sustainability brands for products and services
EC	EC <sub>1</sub>	40. Sharing of environmental performance results with competitors through platforms, calling of forums, consortia, hubs
		41. Sharing of equipment/machinery with other neighboring producers
	EC <sub>2</sub>	42. Activities, involving all actions related to co-operation among different actors for synergies, projects, and workshops to boost a circular economy
		43. Participation in panels for the construction of sector policies
	EC <sub>3</sub>	44. Funding of initiatives to drive circular innovation of start-ups, research centers or universities
	EC <sub>4</sub>	45. Membership in trade associations
		46. Membership in business networks
		47. Belonging to public or private partnerships for research and identification of circular economy measures

### 4.3 Conversion of qualitative indicators

The normalization process is applied to the previously gathered data to convert qualitative indicators to scores. Other quantitative indicators pass directly to the fourth stage where the assigning of weights to indicators takes place through AHP methods. In this stage, for each qualitative indicator five scores are defined which correspond to the five levels of circular maturity identified in the literature: non-existent, emerging, established, leading and ultimate, as shown in Table III (Lacy et al., 2020). These levels present a progression associated with the stage of consolidation of the circular economy practices adopted by the organization. The more professional the management, the more consolidated the practices adopted

tend to be. Each level of circularity demands the formalization of a set of practices that contribute positively to making the agri-food firms circular.

Table III – Conversion to score

<b>Linguistic term</b>	<b>Score</b>
Non-existent	1
Emerging	2
Established	3
Leading	4
Ultimate	5

#### **4.4 Assigning weights to indicators through AHP**

The AHP method was developed by Thomas Saaty for analyzing complex problems in different decision-making scenarios. The AHP generally consists of three main steps namely, decomposition of the problem, comparative judgment and generation of priorities (Janic and Reggiani, 2002). The main aim of the AHP method is to develop a hierarchical structure with the main goal at the top level, the criteria, or attributes (Indicators), are placed at the second level and the alternatives at the bottom level. For this framework, no priorities are generated since the AHP method can only be used to define weights. Therefore, the first step in the AHP is aimed at constructing a pairwise comparison matrix  $P_{AHP}$  ( $w \times w$ ) with the indicators aligned in the first row and the first column in the same order, as seen in Table IV.

Table IV – Pairwise comparison matrix

	<b>Indicator 1</b>	<b>Indicator 2</b>	<b>Indicator w</b>
<b>Indicator 1</b>	1	1/a	1/b
<b>Indicator 2</b>	a	1	1/c
<b>Indicator w</b>	b	c	1

The same procedure is applied to the indicators belonging to each sub-criterion and to the sub-criteria belonging to each criterion. In the second step, a group of experts decide the comparative relative importance of among indicators, sub-criteria and criteria, in order to perform judgement for pairwise comparisons. The group of experts should be composed of a variable number of individuals

who know the circular economy, but who are external to the organization, in order to provide a competent but not biased view.

Same indicators will have a relative importance of 1 as illustrated in Table 4. Other indicators are given a number from 2 to 9 and reciprocals are given to same indicators when the order is switched as seen in Table V.

Table V – AHP intensity of importance table

Linguistic term	Intensity scale
Equal importance	1
Very Low	2
Low	3
Fairly Low	4
Medium	5
Fairly High	6
High	7
Very High	8
Extremely High	9

These values represent the relative importance of one alternative when compared to other keeping one indicator fixed (Singh and Malik, 2014). A normalized element is then obtained using Eq. (1).

$$r_{ij} = \frac{p_{ij}}{\sum_{i=1}^w e_{ij}} \quad (1)$$

where  $p_{ij}$  is an element of the original matrix PAHP ( $w \times w$ ) and the denominator is the summation of all the elements in the respective column. Finally, the weight vector is obtained using Eq. (2).

$$w = \frac{1}{N \sum_{i=1}^N r_{ij}} \quad (2)$$

where  $N$  is the number of alternatives (Singh and Malik, 2014).

Subsequently, the weights obtained from the comparison between the indicators must be multiplied by the weights of the respective sub-criteria and criteria, thus obtaining the final evaluations.

#### 4.5 Normalization, aggregation, and final rank using the ADAM method

ADAM method represents a new class of MCDM techniques, known as geometric MCDM (Krstić et al., 2023). This approach rates alternatives by computing the volumes of complex polyhedra made up of points (vertices) in a three-dimensional coordinate system as an aggregate measurement. Each point belongs to one of three classes: coordinate origin (O), reference points (R), weighted reference points (P). The coordinate origin is a coordinate point (0,0,0). Reference points in the x-y plane are points with the coordinates (x,y,0) that establish the value of the alternatives based on the four different CE orientations, such the point's axial distance from the coordinate origin. The weighted reference points have coordinates (x,y,z), where the coordinate z is used to obtain the axial distance of the weighted reference point from the x-y plane. These distances correspond to the weights of the indicators. A complex polyhedron volume can be calculated by summarizing the volumes of the m polyhedral (where m is the number of alternatives), by defining all the points that define it. According to the decreasing values of the obtained volumes of complex polyhedra, the final order of alternatives is determined. The step-procedure of this approach is given as follows.

**Step 1:** Define the decision matrix  $E$ , elements of which are evaluations  $e_{ij}$  of the alternatives  $i$  ( $A_1, \dots, A_m$ ) in relation to indicators  $j$  ( $S_1, \dots, S_n, W_1, \dots, W_n, O_1, \dots, O_n, T_1, \dots, T_n$ ), i.e., vector magnitudes which correspond to the evaluations of the alternatives in relation to the indicators:

$$E = [e_{ij}]_{m \times n},$$

where  $m$  is the total number of alternatives and  $n$  is the total number of indicators.

**Step 2:** Define the sorted decision matrix  $S$ , in which the evaluations  $e_{ij}$  are sorted in the descending order according to the importance (weight) of the indicators:

$$S = [s_{ij}]_{m \times n},$$

**Step 3:** Definition of the normalized sorted matrix  $N$ , in which the elements  $n_{ij}$  are normalized as:

$$n_{ij} = \begin{cases} \frac{s_{ij}}{\max_i s_{ij}}, & \text{for } j \in B \\ \frac{\min_i s_{ij}}{s_{ij}}, & \text{for } j \in C \end{cases}$$

where  $B$  is the set of benefit, and  $C$  is the set of cost criteria.

**Step 4:** Find the coordinates  $(x, y, z)$  of the reference  $(R_{ij})$  and weighted reference  $(P_{ij})$  points that define the complex polyhedron in the following way:

$$\begin{aligned} x_{ij} &= n_{ij} \times \sin \alpha_j, \forall j = 1, \dots, n; \forall i = 1, \dots, m, \\ y_{ij} &= n_{ij} \times \cos \alpha_j, \forall j = 1, \dots, n; \forall i = 1, \dots, m, \\ z_{ij} &= \begin{cases} 0, & \text{for } R_{ij} \\ w_j, & \text{for } P_{ij} \end{cases}, \forall j = 1, \dots, n; \forall i = 1, \dots, m, \end{aligned}$$

where  $w_j$  is the indicators weight and  $\alpha_j$  is the angle that determines the direction of the vector that defines the value of the alternative.

**Step 5:** Find the volumes of complex polyhedra  $V_i^C$  as the sum of the volumes of the pyramids of which it is composed using the following equation:

$$V_i^C = \sum_{k=1}^{n-1} V_k, \forall i = 1, \dots, m \quad (9)$$

**Step 6:** Rank the alternatives according to the decreasing values of the volumes of complex polyhedra  $V_i^C$  ( $i = 1, \dots, m$ ). The best alternative is the one with the highest volume value.

## 5 Example of the implementation of the framework

This section presents an example intended to present briefly how the assessment procedure is to be used. It is also intended to help users understand the results they obtain from the assessment framework, and accordingly, draw conclusions on the circularity and point out possible areas of improvement within processes or products assessed.

In this example, four agri-food industries with four different circular orientations were compared: Operation orientation ( $A_1$ ), Product and Services orientation ( $A_2$ ), Culture and organization orientation ( $A_3$ ), Ecosystem orientation ( $A_4$ ). Each of the four companies has decided to implement circular economy actions by focusing on one of the four dimensions. The first step in assessing

circularity consisted in collecting the information needed to calculate the 48 indicators. The information was obtained through direct interviews with the operators of the four companies. Immediately after the calculation, since it is a mix of qualitative and quantitative indicators, they were subjected to the conversion process in the five levels of circularity, with the respective scores indicated in Table 4. Subsequently the indicators were normalized in the sorted matrix, as indicated in Equation 5.

The next step is assigning weights to the indicators through AHP method, as illustrated in Section 4.4. The weight obtained for each indicator, based on each criterion and sub-criterion, is presented in Table VI.

Table VI – Weighted obtained used AHP method

<b>Indicators</b>	<b>Weights</b>
1. Energy consumption	0.0227
2. Energy renewable sources / Total Energy Consumption	0.0202
3. Water consumption	0.0031
4. Blue Water footprint	0.0061
5. Green Water footprint	0.0019
6. Grey Water footprint	0.0192
7. Waste production	0.0083
8. Food waste production	0.0047
9. Recycling rate	0.0098
10. Recycling rate of overall packaging	0.0107
11. Recycling rate of plastic packaging	0.0191
12. Recycling rate of wooden packaging	0.0066
13. Recycling rate of paper packaging	0.0088
14. Recycling rate of glass packaging	0.0155
15. Recycling rate of bio-waste	0.0062
16. Recycling rate of e-waste	0.0155
17. Carbon footprint	0.0800
18. Imported raw materials	0.0160
19. Use of software/management to process data to support business decisions	0.0049
20. Energy class of electronic equipment	0.0034
21. Food loss	0.0043
22. Packaging quality	0.0093
23. Quality of equipment	0.0093
24. Percentage of exploitation of agricultural raw material	0.0130
25. Throughput time	0.0022
26. Supply chain certifications	0.0043
27. Use of recycled materials for primary or secondary packaging	0.0383
28. Use of biodegradable materials for primary or secondary packaging	0.0383
29. Food waste or by-products disposed of	0.0269

30. Food waste or recycled by-products	0.0122
31. Food waste or by-products processed by other industries to obtain new products	0.0300
32. Food waste or by-products used for energy production	0.0539
33. Goals of circularity in the company's long-term planning	0.1293
34. Investments in innovation	0.0155
35. Use of digital technologies for process efficiency	0.0406
36. Use of digital technologies for process traceability	0.0089
37. Performance monitoring system through KPIs	0.0135
38. Capacity building: organization of courses, events and campaigns to educate employees on circularity	0.0067
39. Circular orientation: the circular economy is a component of the company's sustainability policy	0.0178
40. Ownership of environmental quality and sustainability brands for products and services	0.0178
41. Sharing of environmental performance results with competitors through platforms, calling of forums, consortia, hubs	0.0243
42. Sharing of equipment/machinery with other neighboring producers	0.0728
43. Activities, involving all actions related to co-operation among different actors for synergies, projects, and workshops to boost a circular economy	0.0323
44. Participation in panels for the construction of sector policies	0.0162
45. Funding of initiatives to drive circular innovation of start-ups, research centers or universities	0.0668
46. Membership in trade associations	0.0076
47. Membership in business networks	0.0076
48. Belonging to public or private partnerships for research and identification of circular economy measures	0.0227

After obtaining the weight of each indicator, the ADAM method was used to aggregate and rank the data obtained from the indicators and present a final circularity score for each circular orientation, as highlighted in Section 4.5. Results are shown in Table VII.

Table VII – Final ranking

Alternatives	Volume	Rank
A1	0.003871236	2
A2	0.003410277	4
A3	0.003986811	1
A4	0.003795765	3

The results showed that the "circular and organization" orientation is the one with the best score in terms of circularity, also expressed in graphic form in Figure 2. This emphasizes the importance of considering the circular economy as part of the corporate organizational strategy and not to relegate it to the sustainability of processes. The company that sets long-term circularity goals manages to be a circular organization over time. Initiatives in this area aim to develop time targets to support the circular vision and mobilize the necessary resources that can help business units prioritize and implement circular initiatives. Recognizing that established internal ways of doing business are likely to impede circular decision-making and at speed and be a barrier for further uptake, it is important to make the circular economy a central element in the ways of working and in the structure of the company, by incorporating the circularity in policies and processes.

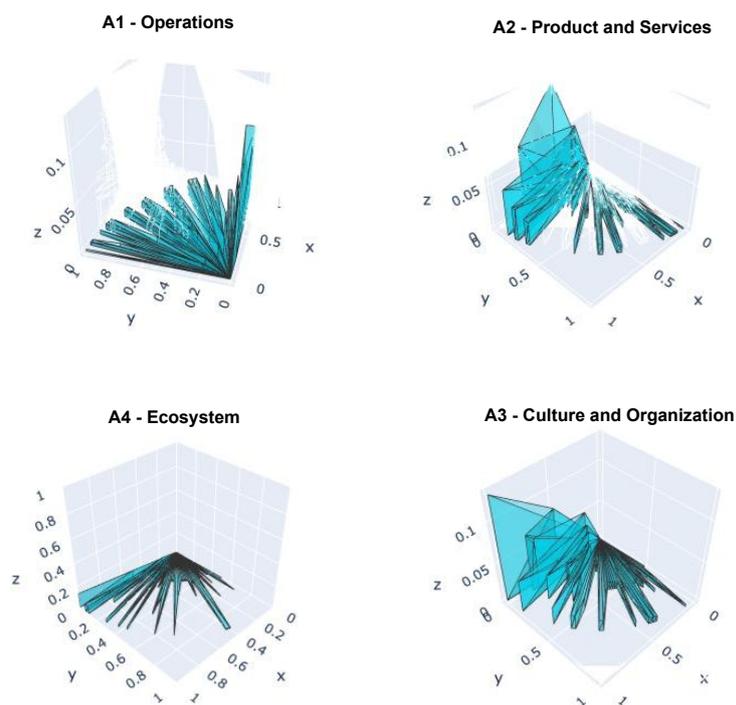

Figure 2 – Graphic representation of the application of the ADAM method to four different circular orientations

## 6 Conclusion

The need to move from linear to circular production and consumption systems has now been established by both scholars and practitioners. Measuring circularity should, therefore, be a primary objective of all companies intending to apply the circular economy. Otherwise, the efforts made would be untargeted and could lead to non-quantifiable and non-comparable results.

The measurement tool allows the company to understand if, with respect to its business model, by applying the concepts of the circular economy and taking certain actions, it is improving or worsening its performance. Measurement serves to give a contextualized dimension and to inevitably set improvement objectives. To progress successfully, companies must look inward and outward across the value chain and external ecosystem. Organizations need to understand where they fall within the stages of the circular maturity and the extent to which they are implementing circular business models across different dimensions, and thus where they are still lacking. While companies might tend to focus on areas within their immediate control, it is crucial to consider all dimensions holistically due to their interdependencies. The model developed in the study and based on the MCDM method, can be a useful tool to support corporate decisions of agri-food companies on the circular economy, making entrepreneurs aware of their level. This methodology is increasingly being used in management studies (Yalcin et al., 2022).

The applicability of the framework was tested by comparing the circularity of four different circular strategies. The results showed a higher circularity score for "Culture and Organization".

To further improve the demonstrated CE assessment framework, engaged governments, organizations and policymakers are urged to standardize further sets of indicators based on agri-food industries and to involve sectorial expertise. Moreover, to facilitate the evaluation processes, there should be a variety of platforms for data sharing that can be used to create global sets of indicators. This would help expand the capabilities of the framework enabling it to assess circularity on larger scales. Finally, this tool can be useful to channel financial resources towards actions that can effectively enhance circularity.

### Abstract

Sustainability-oriented open innovation (SOI) has gained significant attention in recent years. However, there is a lack of evidence on the actual outcomes of this paradigm across enterprises. Thus, this study aims to investigate the implementation of SOI in the energy sector. A thematic analysis (TA) approach was adopted to analyse 64 sustainability reports from energy sector enterprises worldwide. The findings of this study identified five key themes, with three related to the sustainability outcomes of SOI, including "Empowering Business and Increasing Economic Prosperity", "Environmental Stewardship and Conservation", and "Building Sustainable Communities." The remaining two themes focused on how these outcomes were achieved, including "SOI Advancing Measures" and "SOI Facilitating Measures". By providing practical insights, this study aims to bridge the gap in the current body of knowledge on SOI.

## 1 Introduction

The indispensable role of the energy sector in shaping every aspect of human existence is undeniable. Indeed, this vital sector serves countless functions, ranging from manufacturing goods to creating emotional connections (DeCotis, 2020). From a financial perspective, the energy sector is also considered a strength for national economies and a driver of economic growth worldwide since it significantly impacts the functioning of other important industries (e.g., construction and transport) (Kowal and Kustra, 2016). Nevertheless, despite all the economic benefits of the energy sector, it generates detrimental environmental and social consequences as well. The ever-increasing emissions of greenhouse gases (Bogdanov et al., 2021) and delivering energy at unaffordable prices (Afshari et al., 2022) demonstrate that the energy sector can be an example of an unsustainable industry (Howell, 2022).

Approved by the United Nations (UN) in 2015, the Agenda for Sustainable Development offers a framework including 17 goals and 169 targets, which aims to accomplish sustainable development globally by the end of 2030 (Wu et al., 2018). Ever since the introduction of Agenda 2030, sustainability has become a prominent feature and a standard practice in every business activity, including those in the energy sector. Since sustainability is of utmost importance and the energy sector is historically unsustainable, enterprises in this sector must continue prioritising sustainability by any means necessary. There are numerous methods to achieve sustainability in the energy sector, such as adopting renewable energy sources (Wang and Zhan, 2019), improving energy efficiency (Meng et al., 2018), and reducing waste (Chong et al., 2016), innovation being at the core of all these methods.

Innovation and sustainability were often regarded as the opposite of each other in the past since industrial innovation was the main cause for using natural resources. However, nowadays sustainability is vital in innovation paths (Bigliardi and Filippelli, 2022). Previous studies also reinforced that the innovation capabilities of enterprises are related to corporate sustainability in a positive and

significant manner (Sempere-Ripoll et al., 2020; Behnam and Cagliano, 2016). Furthermore, according to Kennedy et al. (2017), sustainability and innovation now are regarded as two significant business drivers that when adopted together, have the ability to enhance performance and provide competitive advantage. Nevertheless, because of the ever-increasing uncertainty and complexity of the globalised business environments, it is almost impossible for enterprises to innovate on their own (Payán-Sánchez et al. 2021). Therefore, they need to collaborate with others forging alliances to achieve their sustainability goals as well as, in the long term, for their very survival.

The above-mentioned trend resulted in a paradigm shift in knowledge management and the inception of a novel concept named Open Innovation (OI). OI was first introduced by Chesbrough (2003), and its definition has evolved thenceforth. The very first definition of OI was *"Valuable ideas can come from inside or outside the company and can go to market from inside or outside the company as well. This approach places external ideas and external paths to market on the same level of importance as that reserved for internal ideas and paths"* (Chesbrough, 2003, p. 43). But, more recently, in 2014, Chesbrough suggested an update on the definition of OI according to the concept of business models: *"We define open innovation as a distributed innovation process based on purposively managed knowledge flows across organisational boundaries, using pecuniary and non-pecuniary mechanisms in line with the organisation's business model"* (Chesbrough and Bogers, 2014, p. 17). Broadly, the core concept of OI is the flow of knowledge across the boundaries of organisations (Behnam et al., 2018).

The benefits of OI in addressing sustainability issues have prompted the development of sustainability-oriented open innovation (SOI) (Behnam et al., 2018). Over the past decades, SOI has become an important topic among practitioners and academics. So far, several studies have tried to concentrate on this topic from different perspectives, including identifying its future trends and research trajectories (Bigliardi and Filippelli, 2022; Payán-Sánchez et al., 2021), investigating factors regarding its successful implementation in large organisations (Behnam et al., 2018; Lopes et al., 2017) as well as in small and medium-sized enterprises (SMEs) (Kurniawati et al., 2022). SOI is also adopted in various sectors, including the tourism industry (Del Vecchio et al., 2018), food industry (Troise et al., 2021; Jeong et al., 2020), and even creative industries (Errichiello and Micera, 2018).

In the energy sector, however, SOI can contribute to increase the efficiency of energy (Shinkevich et al., 2019), to create new renewable energy sources (Lacerda and van den Bergh, 2020), and to develop novel transportation systems (Qu and Li, 2019). Nevertheless, despite the increasing emphasis on SOI in enterprises, there is a lack of evidence demonstrating its actual outcomes in the energy sector, as none of the previous studies provided a comprehensive overview of SOI's impact. Therefore, the present study aims to address this research gap by exploring the implementation of SOI in the energy sector. Accordingly, the primary objective of this study is to identify and analyse the outcomes of SOI in the energy sector.

The study aims to achieve the mentioned objective by addressing two research questions. The former is to explore the outcomes of SOI in enterprises operating in the energy sector (RQ1), and the latter is to investigate how these outcomes are achieved (RQ2). To answer the two RQs, this study analysed 64 sustainability reports from enterprises in the energy sector across different countries. The analysis was realised using a combination of computer programming by Python and human critical thinking (See the methodology section). Then, a thematic analysis (TA) approach (Braun and Clarke, 2006) was adopted to determine the themes relevant to the two research questions. This study makes two major contributions: (a) it provides practical insights regarding the sustainability outcomes of the enterprises in the energy sector and how these outcomes were achieved through OI, (b) the findings of this study seek to address a gap in the emerging body of knowledge on SOI.

The remainder of this study is structured as follows. In the next section, the relevant literature on SOI is reviewed. Then, in Section 3, the adopted methodology is explained. Then, in Section 4, findings are provided, and results are discussed. Finally, Section 5 draws the conclusion.

## **2 Literature Review**

### ***2.1 Sustainability-Oriented Open Innovation (SOI)***

Herzog (2011) explored two main approaches toward innovation, namely open innovation (OI) and closed innovation (CI). Herzog (2011) also argues that companies must choose the appropriate strategy by considering factors such as their industry, competition, and available resources. CI may benefit some

companies in certain situations, such as when they have proprietary technologies and expertise they want to protect or when they have a solid internal R&D department. Nevertheless, as the uncertainty and complexity of the business environments increased today, the predominance of OI is more established in companies (Bigliardi et al., 2021), especially to address sustainability challenges (Bigliardi and Filippelli, 2022; Payán-Sánchez et al., 2021) and radical innovation (Kennedy et al., 2017).

As previously described, OI is a novel approach to managing knowledge that entails innovation procedures that are distinguished by a willingness to engage with the external environment. This approach contrasts with the traditional CI model that has been embraced by companies in the past. Moreover, as the notion of OI gained prominence in the academic literature, it was referred to using various terms that overlap, although the nuances of their meanings may differ slightly, such as co-creation (Frow et al., 2015), crowdsourcing (Majchrzak and Malhotra, 2013), and user innovation (von Hippel and Euchner, 2013). In addition to the different notions of OI, two distinct forms can be identified: inside-out (inbound) OI and outside-in (outbound) OI. According to Chesbrough (2012), the inside-out process entails converting internally generated innovations into external business opportunities through licensing, spin-offs, patent sales, and commercial joint ventures. The second process, outside-in, facilitates the exploitation of externally generated innovations from traditional suppliers and new alternative sources.

Furthermore, in the sustainability context, it is also apparent that diverse terminologies have been employed to explore the potential of (open) innovation in promoting sustainable development. Fussler and James (1996) were the pioneers in SOI literature. They introduced the concept of eco-innovation, which pertains to creating and implementing novel products, processes, services, and business models that support environmental protection and sustainability. Eco-innovation involves incorporating ecological considerations at every stage of the innovation process. Other comparable phrases have arisen, such as environmental innovation (Dias Angelo et al., 2012), green innovation (Schiederig et al., 2012), and sustainable innovations (Bos-Brouwers, 2010), all of which aim to capture the essence of innovation for sustainable development. Some studies have concentrated specifically on environmental concerns, mainly regarding new product development, resulting in the term environmental or green product development, which has been extensively investigated in prior research (de

Medeiros et al., 2022; Khan et al., 2021). However, the present study employs the term "Sustainability-Oriented Open Innovation" to examine its outcomes based on the three pillars of sustainability (environmental, social, and economic) (Purvis et al., 2019). This way, the findings can be more comprehensive according to the Agenda for Sustainable Development. This term is also more commonly used in the innovation management literature (Behnam et al., 2018).

## ***2.2 Sustainability-Oriented Open Innovation (SOI) in the Energy Sector***

There is a dearth of research specifically mentioning SOI within the energy sector. Still, several studies in this sector have explored the concept of OI and considered sustainability simultaneously.

Arnold and Barth (2012) investigated how OI can increase energy efficiency in urban energy systems through a real case study. The findings of this study provided insights into how OI tools can be beneficial in driving innovation and sustainability in urban energy systems. Although various businesses employ OI tools like innovation workshops or ideas competitions to discover and create novel designs and products, there is limited familiarity with using such methods for energy efficiency concepts. In the same vein, Ramirez-Portilla et al. (2013) explored the potential of OI practices to improve industrial energy efficiency by investigating case studies of companies that have implemented OI to achieve energy efficiency gains. Results suggested that an inbound approach toward OI can be more advantageous for decreasing technology-related barriers to energy efficiency. Also, in another study, Ramírez-Portilla et al. (2014) investigated the relationship between indicators of energy efficiency and OI practices in SMEs. The findings showed inbound open innovation is quite used to improve energy efficiency, while outbound open innovation is not a common and, therefore, relevant practice. There are also other studies by Jalal et al. (2019) and Shinkevich et al. (2019), both of which focused on the role of OI in energy efficiency initiatives. Closely related to the energy efficiency domain, Stanisławski (2022) explored the characteristics of OI practices in the rational use of energy resources to achieve sustainable development goals (SDGs) amongst SMEs. The survey results in this study revealed the key factors that drive the adoption of OI practices and their impact on innovation and sustainability performance.

Furthermore, other studies on OI pursue renewable energy sources as a sustainable outcome. Analysing the existing literature, González et al. (2012)

explored OI practices' adoption, including collaboration and co-creation with suppliers, customers, and other stakeholders, in developing wind energy supply chains. This study showed that OI could contribute to developing the wind energy supply chain by increasing knowledge sharing and reducing costs. Also, Chiaroni et al. (2015) analysed the implementation process of OI practices in a specific renewable energy project and assessed their impacts on innovation and project outcomes. This study identified key success factors and challenges of OI implementation in this context, including the need for effective communication and collaboration with external partners.

Moreover, de Paulo and Porto (2017) explored the development of solar energy technologies through OI by reviewing the available literature on this subject and adopting a social network analysis (SNA) approach. This paper determined indirect evidence of OI regarding solar energy development since the literature on solar energy technologies did not explicitly mention it. In another study, Lacerda and van den Bergh (2020) investigated the knowledge-sourcing strategies for innovation in two technology fields of the renewable energy sector: solar and wind power. According to the findings of this paper, solar power innovation benefits from a broad search strategy drawing on a large number of external knowledge sources. In contrast, wind power innovation tends to thrive intensively using a more limited number of external sources. Finally, Alam and Ansari (2020) explored the role of OI in decreasing the cost of wind energy projects in energy-poor countries. Through case studies of wind energy start-ups, they explored the characteristics and benefits of OI ecosystems. They concluded that these start-ups could leverage OI ecosystems to reduce costs and improve competitiveness.

In addition to focusing on renewable energy sources, Qu and Li (2019) also concentrated on new energy vehicles as a sustainability outcome of OI. They used case studies of firms active in the new energy vehicle industry to analyse leveraged demand-side OI. They proposed industrial policies, including the need for policies that promote collaboration and knowledge sharing among firms and other stakeholders. Table 1 summarises previous studies that have explored the concept of SOI in the energy sector.

Table 1. Previous Studies on SOI in the Energy Sector

<b>Sustainability Outcome</b>	<b>Study</b>	<b>Objective</b>

	de Paulo and Porto (2017)	Exploring the development of solar energy technologies through OI
	Lacerda and van den Bergh (2020)	Investigating the knowledge sourcing strategies for innovation in the renewable energy sector
	Alam and Ansari (2020)	Exploring the role of OI in decreasing the cost of wind energy projects
New Transportation Systems Development	Qu and Li (2019)	Analysing leveraged demand-side OI

Table 1 presents a summary of previous studies' findings and highlights four possible outcomes of SOI in the energy sector: energy efficiency initiatives, conservation of energy resources, promotion of renewable energy, and development of new transportation systems. However, these outcomes have predominantly focused on the environmental aspect of sustainability, with little attention given to the social and economic dimensions. Despite existing research in this field, no comprehensive study has investigated the outcomes of SOI in the energy sector based on all three dimensions of sustainability simultaneously. Additionally, no studies have explored the measures employed to achieve these outcomes. As such, this study aims to address this research gap.

### 3 Methodology

As stated earlier, the main aim of this study is to investigate the implementation of SOI in the energy sector. A qualitative research approach was used to achieve this goal, which involved four steps, as shown in Figure 1. The necessary data for analysis were sourced from the Global Reporting Initiative (GRI) Sustainability Disclosure Database, that until December 2020 was open and accessible to the public. The database contained sustainability reports from companies worldwide, including GRI-based and non-GRI-based. The sampled reports had to meet four main criteria. Specifically, they had to be written in English, comply with the GRI standard, be verified by third parties, and be related to 2018. By applying these selection criteria, the data become more consistent, leading to an enhanced quality of analysis. Ultimately, 64 GRI-based sustainability reports from the energy sector companies were selected for the study. The subsequent paragraphs provide a comprehensive overview of each step.

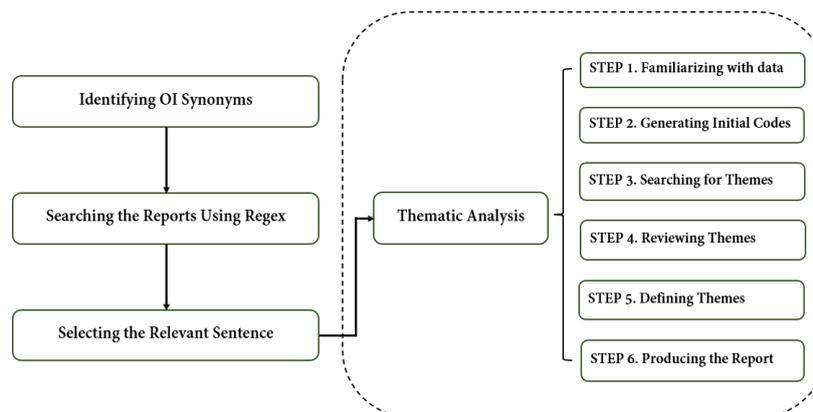

Figure 1. Research Process

#### STEP 1. Identifying OI Synonyms

As previously mentioned, the existing literature on OI comprises various overlapping terminologies, each with its subtle nuances in meaning. To avoid overlooking any relevant reference to OI in sustainability reports, all possible synonyms of OI should be included. To accomplish this, a search of the Scopus database was conducted using the keyword "Open Innovation" combined with "Review".. Then, to ensure that all relevant references to OI in sustainability

reports were captured, 30 synonyms were selected based on the 45 literature reviews found.

#### *STEP 2. Searching the Reports Using Regular Expressions*

To automatically detect within sustainability reports the various OI synonyms identified in the previous step, it was necessary to account for their different phrasings. To achieve this, regular expressions (regexes) were employed. Regexes are snippets of code used in computational analysis to identify patterns within text strings. For instance, to recognise the term "Start Up" in the reports, the following regex was utilised with Python's re library:

```
(r"start[\s\W]?up|start[\s\W]?\Wsup", re.IGNORECASE)
```

This regex identifies all variations of the term, such as "startup" , "Start-Up" , and "Start Up" , among others. It is essential to apply this step because the same OI synonym can be expressed in different ways in various reports while maintaining the same meaning. Failure to address this issue can negatively impact subsequent analysis. The same procedure was applied to identify other OI synonyms. Upon request, the corresponding author can provide the complete list of regexes and the Python code used in the analysis.

#### *STEP 3. Selecting the Relevant sentence*

Although all of the identified synonyms have a common meaning of OI, not all of the selected sentences necessarily relate to OI. Hence, an additional screening process was conducted, according to the OI definitions established by Chesbrough (2003) and Chesbrough and Bogers (2014). This screening process was based on human perception to verify that the selected sentences were relevant to OI. The outcomes of this step serve as the input for the main analysis, which is explained in the subsequent step.

#### *STEP 4. Thematic Analysis (TA)*

The analysis of the sustainability reports was conducted using the TA approach proposed by Braun and Clarke (2006). TA is a qualitative research method used to identify, analyse, and report patterns or themes within data in various fields. This qualitative method is flexible and iterative and can be tailored to suit the research question, data type, and analytical approach. Braun and Clarke (2006) outline six phases of TA:

1. familiarising yourself with the data: the researcher reads and re-reads the data repeatedly to obtain a comprehensive understanding of the content;
2. generating initial codes: the researcher recognises intriguing aspects of the data that may be germane to the research question and assigns them a short phrase;
3. searching for themes: the researcher investigates the preliminary codes to determine patterns, resemblances, and disparities that can be combined into possible themes;
4. reviewing themes: the researcher evaluates the themes to ensure they are consistent, meaningful, and accurately depict the data. The researcher may also modify or merge themes, if necessary;
5. defining themes: the researcher defines each theme, providing a clear description of its significance and supporting evidence from the data. Each theme is also given a name that encapsulates its essence,
6. producing the report: the researcher documents the findings, utilising quotations and examples from the data to clarify the themes and their connotation.

Furthermore, since demonstrating rigour in qualitative research relies heavily on exhibiting precisely how the researcher progressed from unprocessed data to final themes (Tracy, 2010), the TA utilised the data structure proposed by Gioia et al. (2013). According to Gioia et al. (2013), a data structure is the favoured way to capture the evolution of themes from primary coding to aggregated or theoretical themes. The data structure not only facilitates the arrangement of data into a logical visual aid, but also delivers a graphic representation of the theme development process (Mishra and Dey, 2022).

#### **4 Results and Discussion**

The concept of OI has gained significant attention in recent years as a means of increasing competitiveness (Gao et al., 2020; Huizingh, 2011), particularly for addressing sustainability challenges (SOI) (Bigliardi and Filippelli, 2022). However, an analysis of sustainability reports from 64 energy sector enterprises worldwide suggests that OI adoption is lacking, as only 28 companies mentioned OI or its synonyms in their sustainability reports. This result suggests that most energy companies are not using OI to enhance their sustainability efforts. Additionally,

the analysis reveals that OI is more prevalent among large, privately owned energy companies, with only one instance of OI mentioned by an SME. However, this may be due to the challenges that SMEs face when initiating sustainability reporting (Arena and Azzone, 2012). Geographically, 18 of the companies mentioning OI were located in Europe, followed by six in Asia, three in Oceania, and one in North America. This result indicates significant regional differences in the awareness and adoption of OI practices within the energy sector. This trend is similar to other emerging paradigms, such as Industry 4.0 (Calabrese et al., 2023).

As outlined in the methodology section, TA (Braun and Clarke, 2006) was used to address the two research questions. Also, according to the data structure mentioned in the Gioia method (Gioia et al., 2013), relevant sentences related to OI were selected, and 1<sup>st</sup> order concepts were extracted from each sentence. These concepts were then aggregated to develop 2<sup>nd</sup> order themes, which were grouped to form aggregate dimensions or main themes. To clarify this process, Table 2 and Table 3 provide examples. To ensure transparency, the corresponding author can provide the data structure for all the sentences upon request.

Table 2. Identifying 1st Order Concepts through OI Sentences

<b>OI Synonym</b>	<b>Sentence</b>	<b>1<sup>st</sup> Order Concept</b>
Venture	Through our venture capital arm, Bangchak Initiative and Innovation Center (biic), we developed the Green Community Energy Management System (GEMS) to leverage our investments in renewable energy and lithium mining to support the growth of electric vehicles and lithium-ion battery (Bangchak Petroleum, 2019, p. 4).	<ul style="list-style-type: none"> <li>• Innovating through venture capital arm</li> <li>• Supporting green energy management</li> <li>• Developing renewable energy</li> <li>• Developing lithium mining</li> <li>• Supporting electric transportation</li> <li>• Investing in lithium-ion battery</li> </ul>
Start-Up	Shell Foundation has provided support to start-up business Aceleron which is exploring, among other things, how to use waste car batteries in the off-grid sector as storage or a power source (Shell, 2019, p.60).	<ul style="list-style-type: none"> <li>• Supporting start-ups</li> <li>• Reusing waste car batteries</li> </ul>
Co-Creation	By co-creating and collaborating with our ecosystem, we are able to significantly decrease the span of time from innovation to market, and to respond faster to new market needs with the development of holistic solutions (Wärtsilä Corporation, 2019, p. 34).	<ul style="list-style-type: none"> <li>• Co-creating with ecosystem</li> <li>• Decreasing the span of time from innovation to market</li> <li>• Responding faster to new market needs</li> </ul>

Table 3. Main Themes Development Process

1 <sup>st</sup> Order Concept	2 <sup>nd</sup> Order Themes	Aggregate Dimensions (Main Themes)
<ul style="list-style-type: none"> <li>Developing novel recyclable products</li> <li>Supporting and Encouraging plastic waste reduction</li> <li>focusing on reusing waste car batteries</li> </ul>	Promoting Circular Economy Concept	Environmental Stewardship and Conservation
<ul style="list-style-type: none"> <li>Developing co-creation events to solve industry challenges</li> <li>Co-creating new products and solutions</li> <li>Promoting co-creation activities for innovation</li> </ul>	Advancing Open Innovation by Co-Creation	SOI Advancing Measures

The TA of sustainability reports revealed five main themes, three of which relate to the outcomes of SOI (RQ1), while the remaining two address how these outcomes were achieved (RQ2). The three main themes developed to answer (RQ1) are “Empowering Business and Increasing Economic Prosperity”, “Environmental Stewardship and Conservation”, and “Building Sustainable Communities”. The two main themes developed to address (RQ2) are “SOI Advancing Measures” and “SOI Facilitating Measures”. Figure 2 depicts the sub-themes for each theme.

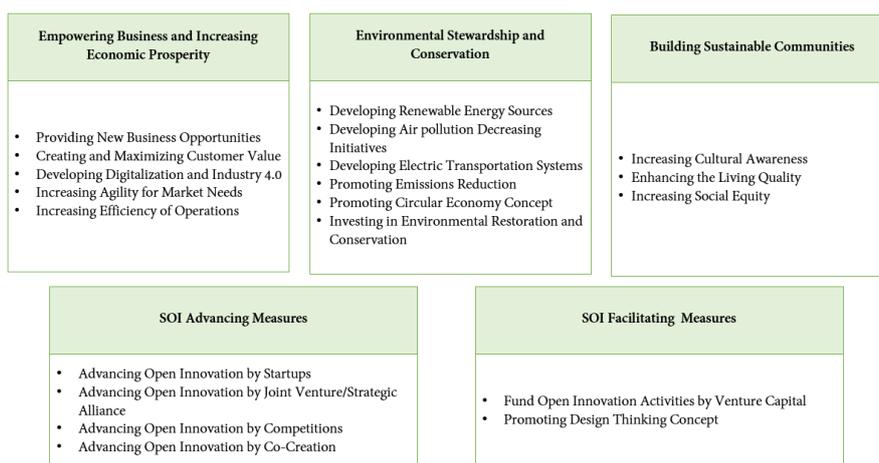

Figure 2. Final Themes of SOI in the Energy Sector

As shown in Figure 2, "Empowering Business and Increasing Economic Prosperity" consists of five sub-themes, including "Providing New Business Opportunities", "Creating and Maximising Customer Value", "Developing Digitalization and Industry 4.0", "Increasing Agility for Market Needs", and "Increasing Efficiency of Operations". These sub-themes include various concepts aimed at empowering businesses and increasing economic prosperity through OI, which is identical to the outcomes of conventional OI (compared to sustainability-oriented ones) (Rauter et al., 2019). For instance, in the sub-theme of "Developing Digitalization and Industry 4.0", the focus is on promoting digitisation (e.g., for the health and safety of human resources) and using technology such as digital twins and cyber security to generate new S-curves. Moreover, some of the sub-themes, including "Creating and Maximising Customer Value" which aims to identify potential customer values and maximise the value of new products and solutions, or "Increasing the Efficiency of Operations" which concentrates on developing novel operational tools and solutions, are identified in other novel revolutions like industry 4.0 (Calabrese et al., 2023)

As one of the most important themes for the outcomes of SOI, "Environmental Stewardship and Conservation" includes six sub-themes, each addressing different aspects of environmental protection and sustainability. These sub-themes are "Developing Renewable Energy Sources", "Developing Air Pollution Decreasing Initiatives", "Developing Electric Transportation Systems", "Promoting Emissions Reduction", "Promoting Circular Economy Concept", and "Investing in Environmental Restoration and Conservation". These sub-themes aim to promote sustainability and a greener future. Amongst them, the sub-theme of "Developing Renewable Energy Sources" was paid the most attention in the previous literature (Alam and Ansari, 2020; Lacerda and van den Bergh, 2020; de Paulo and Porto, 2017). Of course, other subthemes, such as "Developing Electric Transportation Systems" and "Investing in Environmental Restoration and Conservation" were also mentioned in the previous studies (Stanisławski, 2022; Qu and Li, 2019)

Furthermore, only three sub-themes related to "Building Sustainable Communities", associated with the social SDG11 (Sustainable cities and communities) , were identified. This result demonstrates that social outcomes and social enterprises have not received significant attention from academics and practitioners (Harsanto et al., 2022). The three identified sub-themes in the social theme include "Increasing Cultural Awareness", "Enhancing the Living Quality", and "Increasing Social Equity". "Increasing Cultural Awareness" focuses on

promoting the responsible use and conservation of natural resources and community well-being. Also, "Enhancing the Living Quality" aims to improve the quality of life in urban areas by developing new lighting solutions, implementing smart city technologies, and improving the quality of drinking water. Moreover, "Increasing Social Equity" addresses inequality by supporting local and small-scale producers and providing energy access to low-income communities.

On the other hand, in response to the second research question, two main themes were determined: SOI Advancing Measures and SOI Facilitating Measures. Advancing measures generally refer to actions that actively move SOI objectives toward completion or achievement. These measures are typically more direct and specific. Facilitating measures, however, refer to activities that make it easier to achieve SOI objectives, and they may not directly contribute to the achievement of the objectives. According to the findings of this study, there are four "SOI Advancing Measures", i.e., "Start-ups", "Joint Venture/Strategic Alliance", "Competitions", and "Co-Creation". "SOI Facilitating Measures" consist of two sub-themes. The first sub-theme, "Fund Open Innovation Activities by Venture Capital", emphasises the importance of venture capital in funding open innovation activities and supporting the growth of start-ups and new ventures. The second sub-theme, "Promoting Design Thinking Concept", highlights the significance of design thinking in facilitating OI by promoting user-centricity and collaboration.

It is worth noting that this study has two significant contributions. Firstly, it provides practical insights into how enterprises in the energy sector achieve the outcomes of SOI and how these outcomes are achieved. Secondly, the study aims to fill a gap in the current body of knowledge on SOI. However, the study has limitations to consider. Specifically, the findings are only based on the analysis of 64 sustainability reports from the energy sector in 2019. Future studies can improve upon this by examining more sustainability reports from the energy sector, adding additional years to compare themes, which could be particularly valuable in light of the COVID-19 pandemic and the Russia-Ukraine conflict. Alternatively, future researchers can broaden their scope to include other sectors.

## 5 Conclusions

In the past, innovation and sustainability were viewed as conflicting concepts. However, sustainability has now become an essential component of innovation. Nevertheless, due to the complex and uncertain global business environment, enterprises cannot innovate alone, and they must form alliances to achieve their sustainability goals and ensure their survival. This has resulted in a paradigm shift, leading to the emergence of SOI, which has gained attention in academia and practice in all industries and sectors. The primary objective of this study was to explore the implementation of SOI in the energy sector. To achieve this, the study analysed 64 sustainability reports from energy enterprises worldwide, using a combination of Python programming and human critical thinking. The study employed TA to identify relevant themes. The findings of this study revealed five main themes, three of which relate to the outcomes of SOI, while the remaining two address how these outcomes were achieved. The themes developed to determine the outcomes of SOI are "Empowering Business and Increasing Economic Prosperity", "Environmental Stewardship and Conservation", and "Building Sustainable Communities". On the other hand, the themes developed to address how the outcomes of SOI are achieved are "SOI Advancing Measures" and "SOI Facilitating Measures". By offering practical insights regarding this novel paradigm, the study aimed to address the gap in the current body of knowledge on SOI.

## Abstract

This paper analyses the tension field between digitalisation, sustainability and knowledge management in the water sector, particularly, in the context of climate change and water stress. The importance of sustainable hybrid drinking water supply and simultaneous flood protection is outlined by a practical case study within a German water association with a total volume of around 100 Mio. EUR. An ongoing evolutionary digitalisation project is presented and research propositions are stated, which are centred on the questions of deployment of sustainable critical success factors (CSFs) based AI-solutions paired with knowledge management systems (KMS) in the context of climate change and water stress. The application of CSFs and the creation of digital and rational decision-making models based on KMS are elaborated on. Additionally, it is elucidated, whether digitalisation, knowledge and sustainability are to be seen as CSFs in themselves, which thereafter is confirmed. Finally, the possibility of integrating Kingdon's multiple stream model into an AI-based KMS to provide management decision support is explained. In conclusion, knowledge is seen as a binding key for achieving a sustainable digitalisation strategy within a critical infrastructure organisation.

**Keywords** – flood protection; drinking water supply; data-driven knowledge management; evolutionary digitalisation IT project; sustainable public water sector

**Paper type** – Practical Paper

## 1 Introduction

Following Ntuli and Abu-Mahfouz (2016) and Debele et al. (2019), water scarcity and water stress issues have rendered themselves to be an imminent threat to the global society. Simultaneously, climate-change induces stronger and more frequently occurring natural hazards, which will threaten the totality of human existence without human intervention. Future global water demand is projected to exceed the availability of existing water resources by approx. 40%. (Hake et al., 2016). Therefore, by 2040, various countries in Europe will face drastic water stress, i.e., low groundwater and river water levels, heavy rainfall, or flooding, which may affect supply security as well as water transport routes and, thus, will cause (critical) system failures (Scheffler, 2020; Hake et al., 2016). Guerreiro et al. (2018) similarly demonstrate these increasing trends of flooding in European cities through the elaboration on the influence of floods in over 570 cities in Europe. One of the most recent, drastic and largest examples of flooding and its consequences can be seen in the German Ahrtal-catastrophe 2021, with 134 dead and damages ranging around 33 Bn. EUR (Scheffler, 2022). Referring to drinking water security, Mondejar et al. (2021), state that existing variability in drinking water quality represents a morbid threat to the broad population and encourages smart city solutions to strive for the highest possible quality of water for all respective citizens.

Therefore, this paper, which is based on a case study, addresses any person, entity or organisation concerned with the adaptation of digitalisation, sustainability and knowledge management in the context of drinking water supply and flood protection. In the following, the paper elaborates on the scientific and practical implications of these three main focal points for practitioners and knowledge researchers in the domain:

1. How to implement holistic or system-wide climate-proof and sustainable drinking water supply through hybrid solutions, which are applied to classic flood protection facilities (e.g. dams)?
2. How to realise projects faster through the application of identified critical success factors (CSFs) at the political and planning level?
3. In which frame is the creation of digital and rational decision support models based on a synergy of knowledge management systems (KMS) and artificial intelligence (AI) solutions achievable?

The paper is based upon the results of a larger research study, which started in 2010 as a case study in a German water association, encompassing six research papers; its scientific insights are directly and practically implemented. The concerned association incorporates one of Europe's exemplary hybrid solution pilot-projects for technical flood protection and drinking water supply and the planning of a (semi-autarkic) surface water plant including a multi-barrier system (MBS) with a total volume of around 65 Mio. EUR. In the course of the research study, Scheffler (2022) and Scheffler and Vogl (2022) determined the successful implementation of a knowledge management system (KMS) based on empirically derived CSFs. Moreover, an evolutionary digitalisation project has been initiated within the association, which serves the purpose of engaging in the human-water-data nexus (see Poch et al., 2020) as well as exploiting the existing, yet, not utilised data-pools to further optimise the existing KMS and enhance predictive disaster management processes, among others. Further intention is to secure the flood protection systems as well as to guarantee the highest drinking water quality from a technical and economical point of view. To explicate the latter supposition further, the past research study enables the knowledge-driven planning on a political and policy level, while the ongoing evolutionary digitalisation project reflects these insights on an organisational and technical process level.

Thus, to be more detailed, the ultimate goal of the project is to enable an integration of Kingdon's multiple stream model (see A.1) into an AI based KMS, which is expected to serve as a management decision support system in the future (Appio et al., 2021; Ardito et al., 2018; Herweg, 2015). The combination of AI and policy models in the given context is currently seen as a gap in the existing literature. The Kingdon's multiple stream model represents an analysis model, which is distinguished into three streams, namely, the problem stream (i.e. delta between current and intended state), the political stream (i.e. content aspect of the political dimension) and the policy streams (i.e. processual aspect of the political dimension) (Herweg, 2015). Given a corresponding degree of maturity of the streams, overlaps arise that with the support of policy entrepreneurs, create a "policy window" and, thus, elevate the referring subject to the decision-making level of the political agenda (Herweg, 2015). Concerning AI-based solutions, that are capable of gaining insights from big data, the aim is to provide decision supports for the political and policy processes, leading to integrated data and

knowledge-based political decisions to cope with the challenges of climate change in the water sector.

Hence, following current research, AI is proposed to enable transfers between passive data into knowledge-driven decision-making systems (Al Aani et al., 2019). With this a pure rational and fact-based identification and exploitation of the “policy window” is expected to be possible within an acceptable period.

The denoted surface water plant (see A.2) represents a part of the mentioned case study and is one result of the successful practical implementation of the derived CSFs on a policy level (Scheffler, 2020). The surface water plant is part of a hybrid solution, which enables to repurpose and enhance existing dams (as representations of MBS) for drinking water supply, energy generation, low-water enrichment and other tasks. As previously mentioned, climate change will lead to severe event chains effecting the water sector in general (Scheffler & Vogl, 2022; Debele et al., 2019). These cause-effect relationships result from the increase in heavy rainfall and flood events in interaction with longer and more severe drought periods (Scheffler & Vogl, 2022). In addition, future snowmelt will be absent or more irregular, leading to a negative effect in groundwater recharge in the years ahead (Scheffler & Vogl, 2022). Furthermore, hotter summers with severe droughts are predicted, leading to parched soils on which heavy rainfall events then run off on the surface (Olmstead, 2014). Moreover, possible damages may occur and seepage with groundwater level rise fails to happen (Olmstead, 2014). This negative combination of too little precipitation, declining groundwater levels, and extreme heavy rainfall results in a continuous stress test for the water sector (Scheffler & Vogl, 2022).

The evolutionary digitalisation project has been initiated to face climate change and enable the according water association with the technological capabilities to implement, adapt and exploit the possibilities granted by real-time big data, data science, AI and other technological conceptions with the goal to provide efficient flood protection and secure drinking water supply in a hybrid setting. To enable the association with the latter capabilities, it has been deemed unavoidable to restructure the complete organisational structure, business processes and underlying informational architecture as well as the technical infrastructure. Thereinafter, it is intended to implement various layers of technical applications, deploying data scientific and AI-driven algorithms to aid in the given task of flood protection and drinking water supply. In particular, as already denoted, the creation of an AI-driven KMS for management decision support is intended.

Nevertheless, as viable core member of the critical infrastructure of Germany, the association has to comply with various regulations and other dimensions in parallel to ensure a legally compliant and a state-of-the-art project realisation (see A.3). Nonetheless, the remainder of the paper will focus on the tension field between digitalisation, sustainability and KMS, while aiming to close the stated research gaps.

## **2 Research Presuppositions**

Based on the introductory elucidated insights and aims of the evolutionary digitalisation project, several research propositions can be derived, which are the basis of this paper. Scheffler (2022) states that the multiple stream model of Kingdon reveals itself in practical policy matters successfully, while “policy windows” opened after the Ahrtal catastrophe. Furthermore, the derived CSFs have been practically applied as binding element in the context of the “policy window” to enable the planning of said surface water plant, translating theory into practical policy politics. Within the evolutionary digitalisation project, these insights are required to be implemented on an operative or organisational level. Thereto, the first research presupposition can be stated as the question, whether it is possible based on the denoted CSFs in the context of climate change induced water stress to determine and implement an AI-based KMS to support management decisions, which also respects the dimensions of sustainability and digitalisation at the same time. Building upon this supposition, the second research conjecture arises, namely, whether in the context of sustainability and digitalisation, AI and related applications as well as knowledge in itself are to be treated as CSFs. Finally, it must be clarified if such an AI-based KMS decision model can be trusted, is reliable and can be scaled and standardised as a template for future projects. All these supposition are additionally to be set into perspective of resilience and ethics, since the water sector is part of the critical infrastructure and decisions based on AI need to be ethically validated since human lives are directly at stake with its decisions.

## **3 Scientific Insights**

### ***3.1 Digitalisation***

The global economy is shifting through an extended period of digitalisation, encircling the majority of daily live activities, which are highly dependent on innovation and contemporary technology (Mondejar et al., 2021). Furthermore, digitalised applications are inherently interwoven in socio-economic, environmental, sustainable and climate research activities among productive or information systems (Balogun et al., 2020; Ceipek et al., 2020). This holistic perspective states digitalisation as advantageous in terms of solving problems such as biodiversity and climate change (Mondejar et al., 2021). To define digitalisation, Brenner and Hartl (2021) are regarded, who contrastingly state digitisation as the process of conversion between physical and analogous information into its digital counterpart, which then can be processed, stored or manipulated (Dougherty & Dunne, 2012; Loebbecke & Picot, 2015). Digitisation in itself is driven by technological progression, focussed on enhancing efficiency through process automatization (e.g. by means of organisational reconstruction) (Brenner & Hartl, 2021). Notwithstanding, digitalisation centres around the disposition of information and communication technologies to transform a given organisation's business model (Li et al., 2018; Ramaswamy & Ozcan, 2016). However, with the presented project, a unison between digitisation and digitalisation is required, thus, digitalisation and a restructuring is conducted simultaneously.

Notwithstanding, the aim of AI-based KMS is not a singularity within the academic literature and in terms of digitalisation, several publications build the foundation of the presented insights. Following Metta et al. (2022) assess the contribution of digitalisation and its responsible usage as case study with a socio-cyber-physical system concept applied to US agricultural deployments framed by the context of innovation and responsible research. Metta et al. (2022) state the elucidation of relationships between digital and sustainable development intensions, optimising assessments and avoid emotionally biased dichotomies related to digitalisation by specifying effects and referring trade-offs successfully. However, drawbacks are stated in terms of complexity of multiple topic dimensions, leading to the requirement of conceptual and operational knowledge as basis of responsible digitalisation evaluations (Metta et al., 2022).

The results are additionally cornered by stated concerns about the socio-technological and environmental requirements, direct and side effects of given digital transformations at a micro- or macro level of social inequalities, climate justice and ethical debates (Metta et al., 2022). Moreover, top-down frameworks and pre-defined quantitative metrics can be negatively affect reflexivity and limit the understanding gathered of denoted interrelations between digitalisation and stakeholders within a sustainability dimension, considered a gap as of now (Metta et al., 2022).

Referring to more practical applications, Du et al. (2022) state the possibility of sustainable management of global water resources as critical to achieve productivity and maintaining ecological security, thus, provide an exploration of virtual water trade, elevating water sustainability, to cope with water scarcity, which renders itself visible as a global risk. The resulting water conservation is deemed to enable national economies and inherent sectors to adapt to climate change more efficiently (Du et al., 2022). To elaborate on the denoted possibility, Du et al. (2022) propose an integrated framework of meta-coupling, including human-nature interactions across space- within a place (intra-coupling), between adjacent places (peri-coupling) and between distant places (tele-coupling), validated as advantageous tool with unique systematic viewpoint to depict human interactions. Furthermore, by introduction of feedbacks and trade-offs of multiple systems, the framework is able to improve policy effectiveness in terms of global trade, knowledge dissemination and others capable to evaluate water sustainability over various systems (e.g. groundwater systems) (Du et al., 2022).

Analogously to the human-water-data nexus depicted in Poch et al. (2020), Bhandari et al. (2023) suggest transformations of water utilities as cyber-physical-human systems with increasing interconnections and interdependencies between physical assets, cyber systems and human interactions. The provided review includes existing methodologies to model the changes and arising knowledge gaps (Bhandari et al., 2023). Furthermore, the scientific consensus states that technological, social, environmental, economic, regulatory and operational factors influence water utilities, which is reflected in the evolutionary digitalisation project from a practical point of view (see A.3) (Bhandari et al., 2023). Moreover, challenges emerge in terms of legacy IT systems, outdated infrastructure, environmental influence and sustainability, data management and analytics as well as cyber security knowledge and regulatory compliance, among others (Bhandari et al., 2023).

A notable gap exists in the identification and evaluation of multiple impact factors, their interconnections and evolving risks for decision-making, which, however, has been addressed in the meanwhile in Scheffler (2022) by stated CSFs. Finally, the stated gap encompasses topics such as strategic planning for technological adoption and data management, which is covered by the presented digitalisation project (see A.3).

Since one aim of the digitalisation project is to enable an AI-based KMS decision model, it is relevant to elaborate on the state-of-the-art in context of AI and water management applications. Following Fu et al. (2022), propose a review of deep learning applications within the water sector for e.g. planning, forecasting and assessments as well as monitoring of flooding. As a result, Fu et al. (2022) state that the applicability of AI within the water sector is still in an early stage, as most studies applied benchmark networks, synthetic data, laboratory or pilot systems to evaluate performance of deep learning applications with no practical adoption being reported.

Hence, the application of AI within the presented digitalisation project will pioneer the implementation of AI-based solutions based on real-time water monitoring data within a real-world scenario. Fu et al. (2022) further denote five critical challenges, namely, data privacy, algorithmic development, explainability, trustworthiness and multi-agent as well as digital twin systems, which are seen as key areas to advance frontiers of research and practical applications in the water sector. The successful implementation of AI within the water sector is seen as the key driver of urban water systems towards autonomy and high intelligence (Fu et al., 2022).

Building upon AI deployment, AI itself necessitates big data lakes to be efficiently implemented and trained, thus, an efficient water management system requires thousands of constraint devices (e.g. sensors) to be deployed across the water distribution network to enable almost real-time monitoring and control of water grid components (Ntuli & Abu-Mahfouz, 2016). Given this presupposition, a high level of security at both the device and network level is critical to the operation of such systems (Ntuli & Abu-Mahfouz, 2016). It has become imminent that a technological world, elevated and enhanced by information and communication systems, has become crucial in terms of sustainable development and digitalisation, in particular, water management is such a targeted area (e.g. leakage detection, dynamical optimisation of performance), however, is simultaneously prone to cyber-attacks (Ntuli & Abu-Mahfouz, 2016).

Notwithstanding, these algorithms emphasise the requirement of in-depth future research activities to enable (critical infrastructure) organisations to cope with cyber threats by network monitoring at runtime, avoiding false alarms or keeping the algorithms updated in the context of novel cyber threat technologies (Cascavilla et al., 2021). The attempt to prevent cybercrimes requires the according organisations to yield a better understanding of the functioning and nature of the cyberspace and data, among other aspects of expertise in computer sciences (Maimon & Louderback, 2019). Henceforth, the digitalisation project presented in this paper is given the crucial challenge of cybersecurity, since a drinking water and flood protection organisation must neither collapse nor cease functioning under any given terroristic nor cyber-attack of any kind. Please note that due to classified security details, no details of the practical nor academic implementation of the cybersecurity aspect are granted.

On the other hand, regarding the drawbacks of digitalisation, following Ågerfalk et al. (2022), debate that digital technologies can also be deemed harmful for the environment, which contrasts the preservation intention of these technologies and propose pathways towards potential green information system solutions. More specifically, a biological baseline has to be established to evaluate the influence of climate change and other impacts on the global biodiversity (Hedrick et al., 2020). Further, following Lopez et al. (2016), point out that the sole existence of data itself is not a guarantee for best practices referring to the dimension of data quality dependencies. Moreover, major principles and components have to be complied with to utilize big data in such crisis-induced scenarios, i.e. strong technical infrastructures, local skill deployment, context-specific and ethical applied data incorporated in an experimental learning based KMS (Sarker et al., 2020; Scheffler, 2020; Scheffler & Vogl, 2022). Finally, in terms of the flood protection and drinking water supply function of the water association under regard in this study, the digitalisation project has to adhere to hybrid technological solutions as well. To be more detailed, a pure analogue process of handling all the technical equipment is a minimum requirement in case of a total blackout, under which digital processes would cease to function. Therefore, a fully digitalised approach in the project must always have a full analogue mirroring in the context of catastrophe scenarios, leading to the relevance of resilient structures in both the digital and physical world.

### **3.2 Sustainability and Ethics**

The implicitly denoted proficiency of conducting well-informed decisions to employ resources and respective services more efficiently, directly influences sustainability, yet, requires solutions to various challenges (Appio et al., 2021; Ardito et al., 2018). Referring to water, Wu et al. (2020) state it as one of the pivotal components for the definition of smart cities in the context of smart water and the underlying holistic approach to water resource management, water infrastructure, respective water treatments and subsequent water supply. Hand in hand with digitalisation, following de Albuquerque et al. (2021), denote that the role of digital technologies such as big data and citizen-generated data enables transformation to sustainability. To succeed, systemic multidimensional prospects in terms of innovations for smart and sustainable city solutions are required (Tura & Ojanen, 2022). Nonetheless, following Tura and Ojanen (2022), state that sustainable evolutions presuppose innovations directed at organisational transformation and system creation, thus, reflecting the requirement for innovations as catalyst of institutional change on a large scale. Regarding the role of policymakers and the ongoing rapid development of AI, it is stressed that the promotion of AI can be seen as a 'double-edged sword', which according to Stahl (2022) may strengthen the AI industry, yet, may likewise lead to fatal consequences if ethics are neglected in the process. A summary of the ethical debate on forecasting procedures and AI implementations can be found in Vogl et al. (2022), which ought to be considered during the digitalisation projects final phase, namely, the implementation of advanced flood predictive algorithms and AI-based KMS solutions.

### **3.3 Knowledge Management Systems**

Following, Kuang and Liao (2020) flood events are assumed to trigger learning processes in stakeholders, which if enabled with knowledge management can lead to successful learning processes and, thus, may insinuate flood resilience. However, the problem discussed in this paper and the problem of sharing knowledge to provide for more efficient environmental policy progress (as demonstrated in Scheffler, 2020) has already been established in Freeman (1977), yet, is still dominant today. Henceforth, the need for sustainability transitions has

widely been accepted in the scientific community, alongside the requirement of evolution of KMS to lead to more effective policy actions (Oliver et al., 2021).

It is relevant to identify specific knowledge and competency requirements for governing sustainability transitions related to the interconnected phases of envisioning, implementing and evaluating (Oliver et al., 2021). Furthermore, the process has to provide further knowledge development in terms of an iterative and holistic process (Oliver et al., 2021). Nonetheless, such deep-rooting changes in policy KMS will be considered disruptive and present challenges for, especially, traditional organisational models of knowledge delivery, however, is deemed essential to successfully enable sustainability transformations (Oliver et al., 2021). Furthermore, a knowledge architecture consists of monitoring, data, information, assessment and knowledge, named MDIAK process (see A.4), which can support the policy processes as proposed by the European Environment Agency in hindsight of knowledge development processes (Oliver et al., 2021). However, Oliver et al. (2021) state limitations within the funding and cycle times due to long lasting planning periods, which are addressed in Scheffler (2022).

Building upon the previously denoted dilemma, Landriani et al. (2022) provide a systematic review about the critical role of knowledge in water service coproduction and referring policy implications. Finally, regarding disaster management, KMS play a critical role owing to certain practices, which are displayed in Oktari et al. (2020). Notwithstanding, following Oktari et al. (2020) state the practical implementation or realisation of such concepts as a current gap.

## **4 Practical Insights**

As demonstrated within the previous section, the practical application of AI-solutions, KMS or AI-based KMS decision support systems based upon vast amounts of data is currently seen as a clear gap in science and practical applications. With the presented digitalisation project (see A.3) it is intended to a) close the gap and b) pioneer the practical implementation of such solutions.

### **4.1 Surface Water Plant**

The introductory mentioned hybrid solution incorporated within the water association is realised by the combination of the pillars technical flood protection (TFP) and drinking water supply. An optimal TFP is ensured by means of the dam,

which has an ordinary high water retention volume of 4.5 Mio. m<sup>3</sup> to 5.77 Mio. m<sup>3</sup> at damming.

A minimum discharge of 500 l/s supports the water flow of the according river and, thus, the survival of the biotopes in case of drought. A hydroelectric power plant is operated via the bottom outlet, which covers the electrical requirements of the entire plant with up to 300 kWh in a climate-neutral manner and, additionally, supplies the future surface water plant with clean electricity on a pro-rata basis. Furthermore, the coating of said surface water plant will consist of a PV façade and roof and is expected to generate approx. 1.3 Mio. kWh/a. The surface water plant with an investment volume of approx. 65 Mio. EUR is expected to supply approx. 13.5 Mio. m<sup>3</sup> drinking water in combination with the groundwater production wells (+4.5 Mio. m<sup>3</sup>) per year for the conurbation (see A.2). The quality of the surface water will be monitored by a consequent monitoring with automated analytics of the intakes and the reservoir and the treatment will be ensured by a parameter specific adapted MBS developed by IWW Mühlheim (Germany). This MBS is equipped with an ultrafiltration and functions in conjunction with the automated monitoring even under "worst-case" conditions. In summary, this represents an important step towards adaptation to climate change and building resilience in the event of a disaster as well as provide a sustainable solution coping with water stress in the future. Furthermore, it is planned to automatize all sensors and measurement stations to enable future real-time monitoring and big data collection.

#### **4.2 Structure of AI-based KMS Decision Model**

Following the existing literature, a combination of AI-based KMS decision models is seen as a scientific as well as a practical gap. Within the digitalisation project it is planned to implement an AI algorithm-based variant of Kingdon's multiple stream model (see A.1). To do so, the three streams have to be algorithmically deployed and encoded. For the problem stream, the MDIAK framework (see Oliver et al., 2021, A.4) will be automatized and recurrently elucidated. The politics stream, however, consists of human interactions, which are triggered, once a negative event enforces a political reaction (Herweg, 2015). Thus, (we reasoned) a potential solution may be to apply natural language processing (NLP) procedures paired with catastrophe prediction models to

anticipate political actions as well as to evaluate pre-defined potential solutions availabilities.

Finally, the policy stream can be anticipated via application of macroeconomic data, sentiment indicators for economical regimes as well as with profitability-cost calculations in combination with Behavioral Finance or psychological human pattern recognitions. The overall goal in this context is the AI-optimized anticipation of the maturity of the “window of opportunity” based on the combination of CSFs and big data. In addition, feedback loops will be performed and scenario-based reality models will influence decisions.

#### ***4.3 Evolutionary Digitalisation Project***

Finally, it is of importance to briefly outline the contents of the evolutionary digitalisation project (see A.3.). As depicted in Section 3.1, it is vital that to enable a successful digitalisation procedure, in particular, at the extent of a critical infrastructure organisation, proper planning steps are to be adhered to. Therefore, the state-of-the-art in IT project management practises as well as information system and enterprise architecture management (EAM) guidelines are regarded. To be able to plan, structure and realise an IT project of the proposed scale and level of inherent and exogenous complexity, the best practices of the field of IT and architectural planning are deemed important to comply. Moreover, several frameworks and guidelines are consolidated in the given framework such as EAM, TOGAF-9, SLC, ConOps or evolutionary architecture designs and subsequently abstracted from pure software applications to business process design (see A.3). Furthermore, to plan the operative implementation thoroughly, the PRINCE II project management standard has been selected, since it is mostly suitable for projects that are more complex.

Following the set guidelines, the whole organisation is digitized and restructured, i.e. the current state is critically elaborated on, and business processes are optimized and prepared for digitalisation, among many other steps. This is done within a regulatory frame of critical infrastructure and IT laws and regulations in Germany and Europe. Finally, pre-defined goals will be evolutionarily (i.e. dynamically) implemented to meet the set goals of rendering technological capabilities to implement, adapt and exploit the technological possibilities granted by real-time big data, data science, AI and other

technological conceptions with the goal to provide efficient flood protection and drinking water supply in a hybrid setting.

Thereinafter, it is intended to implement various layers of technical applications, deploying data scientific and AI-driven algorithms to aid in the given tasks. Finally, it is planned to deploy advanced predictive algorithms as well as the presented AI-based KMS decision model in a phase plan based manner.

## **5 Conclusion**

To conclude, within the water association's hybrid pilot project, a surface water plant has been realized with application of CSFs and a given KMS, which will provide means to digitalisation and sustainability in terms of coping with climate change. Moreover, the digitalisation project is presented, goals outlined and the aim to create a data-driven AI-based KMS decision model has been elaborated on as one final goal next to the enablement of technological solutions such as advanced predictions and digital knowledge transformations with regard to sustainability. Finally, it is seen during the practical realisation of the project that knowledge in itself is a binding key, allowing to respect all relevant factors and multidimensional features required to achieve a sustainable digitalisation strategy within a critical infrastructure organisation. Overall, the proposed evolutionary digitalisation project within the hybrid pilot project of the water association in Germany is seen as template for future project realisations and a first definite step towards coping with climate change and solving water stress in the future.

Finally, it is relevant to elucidate the research propositions given in Section 2. As depicted in Section 4.2, it is possible to deploy a CSF and AI-based KMS, automatizing the Kingdon's multiple stream model for management decision support in context of climate change and water stress in hindsight of digitalisation and sustainability. Given the stated importance of sustainability and digitalisation in the water sector, these factors should definitely be considered alongside the other CSFs presented in Scheffler (2022). Furthermore, given the clear lack of ethical guidance and practical implementations, as displayed in the literature, it is not possible yet, to discern, whether the presented AI-based KMS decision model is reliable and standardisable at scale, which is seen as current gap.

### Abstract

Sustainability has been extensively studied in different disciplines especially since the publication of the Brundtland commission's report in 1987. However, in public management as well as knowledge management literature sustainability has gained limited scholarly attention. Especially, there is a lack of understanding of sustainability as an issue that needs managing. Therefore, article approaches sustainability in organizational context and is interested in how sustainability is managed in local government and what knowledge is used to support management. While sustainability can be regarded as a pressing societal challenge, relatively little is known on how sustainability policies and strategies are implemented and managed in public organizations. In order to understand how public managers perceive sustainability as a management issue and define sustainability information, an interview study was carried out. The article analyses the data of 25 semi-structured interviews from branch and financial directors in Finnish municipalities to provide an in-depth knowledge-based view to the practice of managing sustainability in local government. The article contributes by developing new understanding about the different roles knowledge management can have in supporting public organizations and public officials to grasp the complex phenomenon of sustainability.

## 1 Introduction

This article aims to understand how sustainability is managed in the public sector and analyses how public managers understand sustainability information, its role in public management, and how they use it in their management tasks specifically in local government context. Sustainability has been extensively studied in different disciplines, especially since the publication of the Brundtland commission's report (WCED, 1987). While sustainability can be regarded as a pressing societal challenge that requires action in all sectors of society, relatively little is known about how sustainability is implemented and managed in public organizations. Previous knowledge management (KM) research has been scant (Martins et al., 2019), and especially for KM scholars, there is a need to better understand how KM can help public organizations foster sustainability.

In public management literature, research on sustainability is still at an early stage (Fusco & Ricci, 2019). There is a lack of understanding of sustainability in the context of management (e.g., Fiorino, 2010; Zeemering, 2018) because the main emphasis of previous research has been on policy tools and in developing indicators. Instead of this external view, this study approaches sustainability in the organizational setting of local governments. This article asks how sustainability is managed by the local government and the role of knowledge management in fostering sustainability. Most of the literature on KM and sustainability focuses on private organizations (e.g., Hörisch et al., 2015; Martins et al., 2019; Shiroyama et al., 2012), and one aim of this study is to learn from this literature and develop ideas for promoting KM in the local government. There is also an urgent need in practice to better understand how public officials take sustainability in their everyday decision-making and learn what management practices lead to improved sustainability (cf. Zeemering, 2018). Prior research has not thoroughly scrutinized the implementation of sustainability, that is, how sustainability policies and strategies are executed and managed in public organizations. Indeed, a key factor in working towards sustainability is the implementation of sustainability in practices and managerial processes. The article contributes by developing a new understanding of the different roles KM can play in supporting public organizations and public officials to grasp the complex phenomenon of sustainability.

The remainder of this paper is organized as follows. In the next section, we briefly review the KM and sustainability literature. The third section presents the

empirical methods used in this study. Section 4 presents the results of the interviews. In section five, we discuss the results, and section six draws some conclusions.

## **2 Literature on knowledge management and sustainability**

The academic literature linking KM and sustainability in the context of local government or the public sector is still scarce. Therefore, this section provides a more general view of KM and sustainability. We briefly review the selection of studies that connect these two research streams. These studies have focused on the corporate context, which is typical in studies combining sustainability with managerial activities (e.g., Thomson 2014).

Martins et al. (2019) carried out a systematic review of the literature on KM and sustainability. According to the authors, the literature considers KM as “a new paradigm of development that aims to enhance compliance with the guidelines of economic, environmental, and social sustainability” (ibid., 490). The authors considered KM as a management mechanism for information sharing and recognized research gaps regarding KM in the context of sustainability. According to the authors, further research is needed regarding sustainability in small and medium enterprises and the role of universities as knowledge generators. The authors also highlighted the need for specific models, tools, and systems to facilitate the sharing of information and guidelines for KM implementation. Finally, they also pointed out that quantitative studies are lacking.

The analysis by Hörisch et al. (2015) reveals that larger companies apply significantly more sustainability management tools, even though these tools are also applicable to small- and medium-sized enterprises. The authors provide three different theoretical explanations for this finding. First, based on the resource-based view, it is argued that large companies possess more financial and human resources that enable them to gather information, develop expertise in sustainability management tools, and unlock the potential benefits associated with them. Second, legitimacy theory explains this finding by arguing that large organizations are far more publicly exposed. Third, absorptive capacity states that larger firms have more extensive knowledge bases for sustainability management and thus know more about the available options in this area. Hörisch et al. (2015) find also that knowledge about sustainability management tools is a crucial factor between strategy and implementation. These results are also relevant for public

organizations that are typically large and have a wide range of resources both in terms of human and financial resources. They are also exposed to public opinion, and the legitimacy of their decisions is evaluated externally. Moreover, public organizations are constantly evaluated in terms of the transparency of their actions and are held accountable to various stakeholders. In addition, big cities are regarded as points of reference to smaller ones as well as for private sector entities.

Alvino et al. (2019) discuss whether IC, through the implementation of KM processes, can influence the entrepreneurial orientation towards the creation of sustainable business models. Their bibliographic analysis identified that research published on IC and sustainability focuses mainly on the measurement of results in terms of increased business performance. The results also show that IC is linked to long-term value, but less attention has been paid to the use of IC in relation to the goals set by the 2030 agenda and established guidelines for companies. This finding resonates well with the public sector literature (cf., Zeemering, 2018). In this regard, there is a growing body of literature on smart cities in the context of sustainability (Karppi & Vakkuri 2020).

Shiroyama et al. (2012) propose an analytical framework for risk-related governance for sustainability. The authors note that different actors within society hold different viewpoints on sustainability; thus, there is a need for sustainability governance. This is especially true in the public sector, where different values and expectations must be reconciled (Laihonen et al., 2023). According to Shiroyama et al. (2012), governance for sustainability requires knowledge integration to address multiple dimensions of sustainability and uncertainty. They state that multi-actor governance involves public–private and multi-level interactions, which are needed to obtain agreement on sustainable actions among actors for designing and establishing resilient systems. The authors emphasized the importance of a reflexive approach and learning that necessitates knowledge integration among experts in various academic fields and stakeholders. Regarding sustainability management, Hu et al. (2018) highlighted the importance of KM, organizational learning, and data-mining systems adopted to capture the best practices of sustainability initiatives.

Several studies have been conducted in the construction industry, in which knowledge transfer is considered a critical success factor for sustainability management. Robinson et al. (2006) suggest a maturity roadmap to facilitate the implementation of a KM strategy. They found that KM is inextricably linked to

corporate sustainability and suggested a mechanism for organizations to benchmark KM activities and to develop a KM strategy that would improve their activities. The authors argue that bringing knowledge or intangible assets to the forefront of an organization's business strategy will have a significant impact on the future wealth of organizations, and that developing a KM strategy enables an organization to unlock and leverage the different types of knowledge, to identify competencies required to become a forward thinking and learning organization with the ability to put sustainability principles into practice. Schröpfer et al. (2016) examined knowledge transfer (KT) practices in construction projects. In general, the authors suggest that enhancing KT between all project participants could help secure a certain standard of green building quality in the long run. According to Schröpfer et al. (2016), many actors involved in the construction process claim to strive for sustainability, but the ways in which different stakeholders perceive and translate it into practice vary. The concluding argument is that enhanced KT between project participants offers a solution to achieve a certain quality of the built result.

Preuss and Cordoba-Pachon (2009) aimed to determine how KM processes can foster (or impede) progress towards corporate social responsibility (CSR). They reviewed KM literature to identify areas that are particularly relevant to managing a company's social and environmental externalities toward sustainability. The authors note that KM is predominantly internally focused, whereas CSR is mainly concerned with external stakeholders' and companies' responsibilities to society. This excessive internal focus of KM is something that Laihonon et al. (2023) also pinpoint when discussing criticisms levelled at knowledge management. Evangelista and Durst (2015) provided a structured literature review of KM and KM strategies in the environmental sustainability practices of logistics service providers. The authors identified three basic elements of appropriate KM approaches and strategies: customer relationship management, quality of human resources, and the adoption of information and communication technology tools and systems. These three areas of sustainability management are relevant for all organizations, whether public or private.

### **3 Methodology**

To understand how public managers perceive sustainability as a management issue and to define sustainability information, an interview study was chosen as

the most suitable method. Empirical data were collected using semi-structured interviews. Interviews are an efficient method for gathering rich empirical data (Eisenhardt & Graebner, 2007). This article analyzes the data of 25 semi-structured interviews with branch and financial directors in Finnish municipalities to provide an in-depth view of the practice of managing sustainability in local governments. Data were collected during October-November 2022, when Finnish municipalities were at the edge of a historical social and welfare service reform. Interviewees were selected to represent the service branches that remained in the responsibilities of municipalities after the reform: education, environmental, technical, development, and city planning services. Interviews were conducted in teams, video-recorded, and transcribed verbatim. All interviews lasted approximately an hour.

The interviews dealt with the following six themes: 1) sustainability as a phenomenon and part of your work, 2) sustainability and municipal strategy work, 3) management of sustainability, 4) sustainability knowledge base, 5) sustainability reporting, and 6) external steering mechanisms for sustainability. In this article, we focus on Themes 1 and 4 and first show how the interviewees perceive the phenomenon. Second, we provide preliminary results on the role of sustainability information and KM. During the analysis, the interview transcripts were first carefully analyzed line by line to recognize different interpretations and definitions. In the second phase, the focus was on sustainability information and the underlying knowledge processes. Through this two-step analysis, the researchers gained an understanding of the different roles and impacts of KM on sustainability management.

## **4 Results**

### ***4.1. What is sustainability – different views and definitions***

The interview data showed how different interpretations and definitions of public managers affect sustainability, depending on their position and tasks. Therefore, it is important to understand that the definition of sustainability depends on several factors.

The financial directors approached sustainability from the viewpoint of financial sustainability. Financial sustainability was also highlighted by most of the directors, which was less obvious because of their strategic position and role in

resource allocation decisions. Financial directors defined financial sustainability for example in the following ways:

*"Financial sustainability means that you do not live beyond the resources, not make the type of settlements that burden the city's future or the future of the economy so that you do not basically eat its base or other. It is a durability." [Financial Director]*

Like all interviewees, the directors of the education branch approached the phenomenon as a major societal change and emphasized the multifaceted nature of sustainability management. However, for them, social sustainability played a special role in how they approached the questions regarding the definition of the phenomenon and how it is reflected in their work.

*"All four dimensions of sustainable development, economic, social, cultural and ecological, are important to us. All of this is very strongly reflected in our operations, the aim is that our operations are financially sustainable so that we have resources going forward as well, we take into account what is happening in the operating environment." [Director of Education]*

Infrastructure and development directors pretty much continued the same agenda but an emphasis on ecological and environmental sustainability could be recognized.

*"Well, the first three things that come to mind in terms of sustainability are ecological sustainability, then the economic perspective, economic sustainability, sustainable municipal economy. And perhaps the third point of view in urban structure services, which is emphasized, is this kind of social sustainability or sustainable urban structure." [Director of Urban Planning and City Infrastructure].*

It is also worth noticing that local government has an important role in fostering the vitality of the area. This viewpoint is well captured in the following quote from an interview with a Director of Development.

*"For me, that sustainability is how this city remains a growing and developing city in terms of both attraction and holding power. In other words, the kind of continuous, permanent development of the city in such a way that all the time it is ensured that the conditions for development exist and the requirements of the environment are taken into account in that development." [Director of Development]*

From the KM viewpoint, especially concerning decision-making information, it is critical to understand how organizational objectives affect the priorities and

emphasis of KM. The strategic KM literature has highlighted that “business objectives” should drive all knowledge initiatives (e.g., Zack, 1999; Hansen et al., 1999; Laihonen & Mäntylä, 2018) and this concerns also defining, gathering, and use of sustainability information.

#### **4.2. Sustainability information – what is it and how is it used in public management?**

Following their different positions and roles in the organization, the interviewees also defined sustainability information differently. Discussions with directors did not really go into detail; directors only gave some overall direction on the concrete metrics and data used for evaluating their services. In general, all directors linked the discussion to city strategy and, in some cases, to the legislative task of the city. The following quote from the Director of Technical Services illustrates the ambiguity of sustainability management in the public sector:

*“Yes, of course, I think about this point in relation to sustainability in that way, a bit like a tripod, you probably can't think of it specifically from the point of view of sustainable development, environmental legislation and environmental protection, the ecological point of view, that of course it is important from the point of view of my own industry. Since I am in the role of a leader, of course the economy also comes into question as a whole, that the economy is also on a sustainable basis, and this balances out certain choices. [...] there are also very strong values in this field of activity, and through that the social perspective also comes into play, i.e. issues of equality and equality. Inclusion is also very strongly included as a legislative program here. Such a diverse field, I see these things from the point of view of the ecological field, the economic field and the social field. Such a mixed fruit soup, and of course, from time to time, one is emphasized more than the other.” [Director Of Technical Services]*

Financial directors emphasize the role of financial information. They work with budgets, investments, and tax revenues, and this information is critical to their role.

*“At the whole city level, I would say that from the point of view of monitoring, the top should be the income statement. Of course, investments in relation to the targeted amount. it says a lot about the*

*activity as well, about the ability to promote what has been planned. [...] From a monitoring point of view, if we are thinking about the government level, then we need to pay attention to two different things. There is the development of operating expenses and income in relation to the budget. [...] And operating margin is of course important in the sense that then we respect the things that happen in our core tasks. [...] At the government level, it is natural to always assess the outlook for tax revenues at a fairly precise level.” [Financial Director]*

For educational directors, important decision-making information relates, for example, to the well-being of both teachers and students as well as the social environment provided by the education services area.

*“In the entire strategy work, we have taken these SDG indicators. We chose ten, those that we felt were the most relevant for us in. And then, of course, there are others besides these SDG indicators that we consider, for example, school health surveys, it is a really important document for us, and on the basis of that we draw up well-being plans, and which in turn affect that well-being. [...] In terms own service production, there are different metrics that are then monitored, related to meals, energy use and things like that. And, of course, also social sustainability and how you do it, how people work and so on, so these types of metrics exist.” [Director of Education].*

It was already evidenced in the previous section that, because the definition of social sustainability covers many aspects, the required information cannot be easily defined and is ambiguous.

*“There is a lot of variety. For us, student absences, the amount of support needed, etc. New needs are emerging [...] Then, service processes and service network. How much with different calculations, how much, for example, students from different schools cost us per student.” [Director of Education]*

One of the main points of sustainability management and the needed information and knowledge is the overwhelming amount of data.

*“I would say that the main question related to information is not that we should have more of it, but that existing information should be simplified and bundled, and we are currently working on such reporting that would bring together the essential information to support management.” [Director of Education]*

The question related to sustainability information also challenged the infrastructure and development directors.

*"Well, financial information of course. Continuously, as far as the finances of one's own operations are concerned. We make a lot of use of data related to demographic development. That is public information. And population, migration, all of this is of course the same basic thing, we already use it in connection with planning. We use not only information on resources but also various information that is collected. Our 'resource wise program' has about 180 separate measures. Also, location information is very important." [Director of Urban Planning and City Infrastructure].*

*"We compile an ecological road map and the data of the related meters, from which we can see whether our actions are sufficient. We are thinking about how many solar panel sites we need to put into use every year, we have an energy saving working group that monitors the energy consumption of our buildings on a property-by-property basis, and of course, the financial monitoring systems are part of where we monitor how our operations for that year are progressing." [Director of Environmental and Technical Department]*

One interviewee nicely summarized that it is not only directors that know it all, but their role is more in a team building that is able to efficiently gather and use various information and knowledge.

*"I don't need to know everything myself, but I have a good orchestra with very good experts, and they are experts in their field and do their work with a certain passion and manage that knowledge reserve better I could. I trust them. For me the main thing is to ask the right questions." [Director Of Technical Services]*

## **5 Discussion**

The aim of this study was to investigate sustainability management in local governments. Special attention was paid to sustainability information and the knowledge base of sustainability management. Local governments are a fruitful and relevant research object for sustainability management research, as their role in promoting and creating sustainable practices has been recognized (e.g., Krause et al., 2016). Local governments carry out local activities for the local people, and they inevitably play a special role in promoting sustainability. This study

demonstrated that sustainability can be managed in many ways and at many levels.

It has been noted that sustainability is at the heart of public administration as a starting point, main aim, and desired outcome (e.g., Fiorino 2010) and that there is an urgent need to better understand how public officials implement sustainability (cf. Zeemering, 2018). This adds public sector sustainability management to Martins et al. (2013) list on the important and highly relevant areas of future research. Cities and public organizations more generally are big organizations with multiple resources, and it is therefore of great importance to prioritize sustainability, allocate resources, share information, develop expertise, and encourage the use of various tools to support sustainability management (cf. Hörisch et al., 2015). In addition, the publicness of their activities necessitates a careful analysis of the sustainability of all services. It is also critical that sustainability management is not considered only as a transfer of sustainability information (Schröpfer et al., 2016), but also its strategic implications need to be considered (Robinson et al., 2006), which also relate to the management of intellectual capital, which poses a critical success factor for any knowledge-intensive organization (cf. Alvino et al., 2019). Sustainability management must consider both short- and long-term strategic objectives.

Based on our data, sustainability is a well-known phenomenon, but its interpretation involves caution, uncertainty, and a lack of awareness. Sustainability appears as a phenomenon recognized as important in strategy work; however, in terms of implementation, the responsibilities and tasks are not clear. Therefore, it can be stated that there should be space, time and opportunities in the municipal organization for the interpretation of sustainability and the building of a common understanding. This clarifies the responsibilities of sustainability management. Knowledge integration and multi-actor governance are required, as highlighted by Shiroyama et al. (2012), to agree on sustainable actions among actors in designing and establishing resilient systems. Sustainability management necessitates continuous dialogue between different actors and levels of society about what is acceptable and the assessments of what to aim for as well as with what means to build the desired future (Laihonen & Mäntylä, 2018). This type of joint knowledge formation (Laihonen et al., 2023) is a prerequisite for structuring multifaceted and wicked problems such as sustainability.

It has become evident that learning from sustainability information is a key mechanism in sustainability management. This was highlighted by Hu et al.

(2018), who stressed the importance of KM, organizational learning, and data mining systems in capturing the best practices of sustainability initiatives. Preuss and Cordoba-Pachon (2009) discussed the different standpoints of KM and CSR and stated that it is not enough in sustainability management to focus only on the internal efficiency of operations (see also Laihonon et al. 2023). Thus, there is a need for a balanced measurement of the success of sustainability management. This was also highlighted by Evangelista and Durst (2015), who recognized customer relationship management, quality of human resources, and the adoption of information and communication technology tools and systems as the three basic elements of KM in environmental sustainability practices. This finding has important implications for the perception of sustainability information. In our interview data, financial information emerged as the most frequently used information from the local government. In addition to financial information, various expert information, analyses, publications, and statistical information form the information base public managers use to support their decision-making. The information provided by national institutions and actors (e.g., central government actors and ministries) was also perceived as useful in sustainability management. It was somewhat surprising that managers were quite satisfied with the available sustainability information. Sustainability information is used for budgeting, goal setting, operations management, strategy implementation, procurement, and investment. The interviews also evidenced the multidimensionality of sustainability information. The data showed that information is available from different sources; however, information on sustainability is not always identified. In addition, sustainability information often remains siloed into individual service branches or areas of responsibility. Despite this, no specific wishes regarding sustainability information came up in the interviews. It appears from the data that it would be hoped that the information would be as comparable as possible, in which case the interpretation of the information could be done between different municipalities. National and inter-municipal statistics and numerical data are particularly useful. Overall, based on the data, it can be interpreted that the role of information, and thus its management, is perceived as an important element in managing sustainability, but identifying sustainability information needs is still perceived as difficult.

## 6 Conclusions

Sustainability management should not be approached from a single perspective. It is necessary to consider the different starting points and capabilities of local governments to deal with such multifaceted phenomena. This research has revealed the versatility of conversation and provides tools to conceptualize the phenomenon. In this regard, our key message is that managing sustainability requires a comprehensive review of local government organizations and consideration of different sustainability perspectives. Based on our findings, sustainability management seems to focus primarily on quantifying and making the phenomenon visible. This is important, but from a management viewpoint, even a slightly imperfect metric can sometimes be useful in indicating the direction of development. In recent years, the use of sustainability information has been strongly emphasized in performance management literature. We call for this, also in terms of sustainability management. A more structured discussion on how sustainability is positioned in other areas of performance is needed. According to our understanding, it is not a new performance goal per se but a phenomenon that forces us to redefine the traditional ways of conceptualizing performance in the public sector. This finding has clear implications for KM and requires further investigation.

## UNESCO Buffer Zones and Territorial Identity: Design as a Potential Tool for Context-Heritage Integration

---

Sara Ghirardini

Politecnico di Milano  
via Edoardo Bonardi 3, Milano

### Abstract

In the last thirty years the notion of heritage has deeply changed, and the attention has shifted from the materiality of monuments, as bearers of intrinsic values, to a wider recognition of cultural heritage as a process that increasingly involves the territorial context and its dynamics. UNESCO official preservation tools include the definition of a buffer area surrounding an enlisted property as a non-compulsory added layer of protection to the heritage core, but, without further specific criteria and purpose, this remains as a mere generic “defensive shield” instead of becoming a contact point between heritage and territory. The contribution critically investigates how the implementation of UNESCO *buffer zones* is conflictual with the more recent compulsory *management plans*, theoretically fostering the inclusion of local dynamics in valorisation policies. Design and spatial transformations, that are fundamental components of a living cultural environment, are mostly excluded from the development of strategic interconnections between heritage sites and their surroundings, and they are mainly seen as threats to the heritage integrity and authenticity.

In this framework, the analysis of case studies highlights the potential of design actions in the heritage-context reconnection. The selected examples – both in and out of the UNESCO system –, are projects able to conjugate the territorial transformation processes with the heritage preservation priorities in a tentative to encompass the idea of architecture as a practice of care of heritage-related territorial fragility. Starting from these examples, the study of how design actions can be integrated both in the process of definition of buffer areas (*cognitive framework*) and in the drafting of the management plans (*interpretation framework*), defines a methodology that could activate new forms of preservation policies, that take into account the need for a renewed and shared knowledge of local traditions and for a valorisation that goes beyond the heritage site boundaries. The narrative and activating potential of architectural transformation cannot be excluded from the valorisation policies, and rethinking the role of UNESCO *buffer zones* can be crucial in a new balancing between preservation instances and territorial development.

**Paper type** – Academic Research Paper

## **1 Introduction: a change of perspective in heritage vision**

In the definition of what heritage is, the last thirty years have seen a shift in focus from the materiality of objects, considered as witnesses of a past to be preserved, to the concept of the value these witnesses carry, widening the vision to immaterial and contextual aspects. The "static" idea of heritage, typical of 19th century western culture, linked to the physicality of artefacts to be preserved and/or restored, has gradually been overtaken on a theoretical level by a dynamic vision, in which cultural value is recognised in terms of significance rather than signifier; conservation and enhancement policies, though slowly and with difficulty, are embracing this change, widening their scope to involve territorial systems. On the one hand, the international scientific and academic debate is increasingly focused on an inclusive idea of heritage as cultural practice (Smith, 2006); on the other hand, this change of perspective has been slowly taken up by national and international institutions committed to the preservation of cultural heritage. First of all, UNESCO, which established the list of intangible cultural heritage in 2003 and has seen an increasing presence in the World Heritage List (WHL) of inscriptions of properties with a broad territorial scope, such as cultural landscapes or serial sites.

## **2 Heritage-territory relationship in the UNESCO system: management plan and buffer zone**

The change of perspective on cultural heritage is a phenomenon of an interdisciplinary nature, which from an architectural point of view leads to a new consideration of the relationship between a site or monument and its context, linked to an active process of constant construction of a living place, bearer of recognised cultural values, to be protected and enhanced as a whole. This inevitably influences cultural heritage protection systems and practices, traditionally focused on safeguarding the physical qualities of circumscribed sites or places with clearly defined perimeters. For properties listed in the WHL - or in the tentative list - UNESCO guidelines do not provide direct legal constraints related to property protection: however, through the *Operational guidelines for the implementation of the Heritage Convention*, some specific tools are defined that must be implemented for all sites, and that influence and address the relationship between a property and its surrounding territory. Since 2005, the

drafting of a management plan has been mandatory for each WHL-enlisted or candidate site; this strategic management tool aims not only at organising and monitoring activities to protect the heritage in its physical component, but especially at safeguarding and promoting the values linked to it, through the involvement of stakeholders and local communities. The role of management processes in the connection between cultural heritage and the territorial context is made explicit in the Resource Manual *Managing Cultural World Heritage*:

«Heritage place cannot be protected in isolation or as museum pieces, isolated from natural and man-made disasters or from land-use planning considerations. Nor can they be separated from development activities, isolated from social changes that are occurring, or separated from the concerns of the communities.» (UNESCO, 2013, p.13)

The system of heritage management influence should therefore extend well beyond the geographical boundaries of the properties listed in the WHL, and involve portions of the territory of different sizes according to the strategies adopted, which however fall under different regulatory and administrative types, thus making the implementation of effective projects very difficult.

Among the UNESCO promoted tools, there is a possible delimitation of settings and areas of influence - the so-called *buffer zones* - which could take charge of structuring the relationship between heritage and territory, acting as a connective tissue, but is most often relegated to an anachronistic role of a defensive shield for heritage against external "threats". A world heritage buffer zone is the non-compulsory delimitation of an area outside the core property, and therefore not included in the WHL, but which can be established as an added level of protection for the site's preservation. Envisaged by the *Operational Guidelines* since the establishment of the WHL in 1977, buffer zones are currently included in the "Protection and management" section of the UNESCO regulations, and defined in Art. 104:

«For the purposes of effective protection of the nominated property, a buffer zone is an area surrounding the nominated property which has complementary legal and/or customary restrictions placed on its use and development to give an added layer of protection to the property. This should include the immediate setting of the nominated property, important views and other areas or attributes that are functionally important as a support to the property and its protection. The area constituting the buffer zone should be determined in each case through appropriate mechanisms. Details on the size, characteristics and authorized uses

of a buffer zone, as well as a map indicating the precise boundaries of the property and its buffer zone, should be provided in the nomination.»

Despite the changes made over the years to the official definition of world heritage buffer zone, its role is still very uncertain and difficult to be grasped by the managing bodies of both heritage and the surrounding territory. In 2008, an expert meeting held in Davos explored in depth the issues related to the definition and use of buffer zones, trying to highlight, also through the presentation of "best practice" cases, their potential as a connective fabric for the relationship between heritage protection and territorial development; however, what emerged above all were the criticalities linked to a superficial interpretation of their role, often limited to the forced tracing of a perimeter on a map (Martin and Piatti, 2009). The Davos expert meeting represents a key moment for the theoretical change of the role of UNESCO buffer zones, from a passive tool of exclusion and defence to a connective fabric for the interaction of heritage and territory. The key to the innovative interpretation of the role of buffer zones lies in the recognition of the need to address, at a wider scale than the perimeter of the monument, both threats and opportunities, adding a connective function to the defensive nature of buffer zones. It is identified as a potentially effective tool for heritage protection, but sometimes not sufficient to respond to different territorial demands and opportunities. A more nuanced concept with respect to the rigid geographic perimeter of buffer zones is the "area of influence", which is indicated in the Davos report as a possible alternative terminology to identify territorial contexts that are not so strictly defined by boundaries and limits. The possibility of using an alternative vocabulary to the term "buffer zone" is also outlined, which State Parties can define according to the management needs and cultural and linguistic characteristics of each country, to be able to communicate their value more clearly to local stakeholders. The expert meeting, in an attempt to update the concept of world heritage buffer zone and make it more comprehensible at local level through an articulated and more varied nomenclature, highlights the difficulty - or perhaps the impossibility - of giving a clear and univocal definition, and the need to broaden the matter of the relationship between heritage and territory by adding further levels of interpretation. In fact, the buffer zone delimitation strategy promoted by UNESCO responds on the one hand to the need of applying protective regulations with respect to heritage, while on the other hand it refers to an original political-military principle - namely that of the buffer zone - which is often an area "cut

out" from the active territorial fabric that becomes a passive element, in order to fulfil its role as a "neutral place". It is easy to see how such use of a buffer zone clashes with the contemporary idea of heritage as a cultural practice that draws substance from a living context, active in the production of place value, in which the setting cannot be reduced to the crystallisation of a static and passive image. Fifteen years have now passed since the Davos expert meeting, but the practical implementation of world heritage buffer zones has not yet fully absorbed - except in rare cases - the potential of this tool. Although their use as protective perimeters is now widespread, and their geographical scope extended, buffer zones remain mainly passive areas of application of restrictive regulations (Valentino, 2018) - often poorly coordinated and overlapping with each other - which generate stalemates in territorial development, in the name of an alleged safeguard of cultural heritage that contradicts the very contemporary meaning of heritage as part of a living cultural fabric. Buffer zones and management plans, instead of working in a complementary and coordinated way on the exchange between heritage and the contemporary context, often travel on parallel tracks, with little interrelation and with different objectives, causing a disconnection between the management systems of the World Heritage site and the local territorial reality. The valorisation strategies promoted by management plans, in fact, aim at involving the different stakeholders through intangible and episodic actions - such as temporary events, educational activities and workshops, communication and digital attractiveness - but rarely contemplate actions of transformation of places that structure - in the short and long term - a potential development of local communities in correlation with the valorisation of cultural heritage. Buffer zones, on the other hand, instead of being understood as a framework for deploying the potential deriving from the contact between universal heritage and the sustainability of local development, are left on the margins of management and transformation strategies, and become fragile parts of the territorial fabric due to the numerous constraints imposed by heritage conservation. In both cases there is a lack of design, understood as the practice of care for space, which structures the transformative strategies of places.

### **3 The project as a practice of care and significance reconnection between heritage and territorial identity**

It is unthinkable to prevent a living territory from transforming itself in accordance with the social, economic and cultural changes of its contemporaneity. This consideration is also well recognised in the field of cultural heritage, and is witnessed by the growing attention paid to the category of cultural landscapes, established in the WHL since 1992 and since then increasingly at the centre of studies on the values of a widespread and living heritage, inextricably woven into the fabric of the territory (Carta, 2002). In addressing a type of heritage so different from the traditional nineteenth- and twentieth-century monument, the fundamental conceptual shift in preservation policies aims at balancing conservation and valorisation, where the former loses the connotation of static crystallisation of a supposedly original and authentic state, to allow the latter to promote heritage values in synergy with ongoing socio-economic processes. However, what is excluded from the current safeguarding and valorisation instruments - UNESCO and others - is precisely the more concrete aspect of the reality of places. In order to ensure that the transformations implemented are compatible with heritage values, the imposition of constraints and prohibitions is not the solution; it is rather necessary to define a proactive and project-based vision, which channels the transformative thrusts towards sustainable and beneficial objectives both for the valorisation of cultural heritage and for local development. As Emery emphasises, understanding architecture as therapy of the space means *first* putting into practice a design of an essentially relational type, focusing on the qualitative implications of the transformations brought about through the planned works.

«To cure means to manifest relationships and to preserve them, to relate to natural otherness and to the fabric of pre-existences in a different way than the colonising way of overcoming and almost unconditionally denying the other. » (Emery, 2007).

From this point of view, architecture is not to be seen as a demiurgic and totalising gesture, boasting a self-referential protagonism, but rather as a discipline that studies and structures in a holistic manner the relationship between human activity and the space in which it takes place.

In the last decade, a number of valorisation project experiences have been realised that are particularly significant for the heritage-context integration; they

are mainly outside the UNESCO sphere, in places where the incumbent constraints are less limiting, and at the same time where the construction of an effective heritage valorisation system is fundamental for territorial development. In the present contribution, two international case studies not belonging to the WHL are briefly presented, which are illustrative of the role that architectural design can play in the reconnection of significance between heritage and the territorial context. They deliberately refer to different heritage types and cultural contexts, but reveal some common features in terms of design approach: the Chengtoushan Archaeological Park, located in the heart of rural China, has found in the architectural and landscape enhancement project the key to reconnecting the archaeological site with the living agricultural culture that generated it millennia ago; in Alsace, a French region known above all for its wine production, the design of the Chemin des Carrierès has returned the ancient quarry railway route to local life as a new slow infrastructure, reconnecting the different identity assets of the territory.

### ***3.1 Chengtoushan Archaeological Park***

Discovered in the 1980s in the poor rural countryside of Hunan Province, the archaeological site of Chengtoushan turned out to be the oldest city in China, and the oldest trace of rice cultivation ever. The cultural site, which has been immediately protected at the national level, has, however, over time created several problems for the development of local activities: initially, the protection system provided for the expropriation of large agricultural areas in the surroundings of the archaeological area as limits to preserve its authenticity and integrity, exacerbating an extremely widespread condition of poverty among the local population; later, in order to promote the site's tourist attractiveness, expensive monumentalisation works were financed and partially carried out on the access roads and surroundings, consisting of large museum buildings and wide avenues with an urban imprint, lacking any relation to the context and strongly impacting on the structure of the territory. When the landscape design studio Turenscape was called upon to rethink the relationship between the site and the surrounding landscape in 2015, the situation was of neglect and decay, with poor attractiveness and no connection between the local communities and the archaeological area. The project was aimed at structuring the vast area around the site (approximately 20 hectares) as an agricultural and archaeological

park, returning part of the land to the local communities to be used for visitable rice crops, where tourists can understand the contextual reality that supports the values of the archaeological heritage and take part in it. The design strategies implemented refer to three scopes: the strictly archaeological one, constituted by the circular site of the ancient city, surrounded by a ring-shaped pond; the landscape one, reconstituting a vegetal system composed of both cultivated fields and plantings to restore the local ecosystems; the architectural one, identified by the structuring of the paths and centred on the glass bridge suspended over the fields that allows access to the heart of the site. In the first scope, intervention was minimal: the archaeological area was interpreted as a place for silence and contemplation of the past, and only the minimum interventions were carried out to guarantee accessibility. Design efforts were concentrated on the second and third areas, which are deeply interconnected. The land returned to cultivation, supplemented by a vegetation project that designs its structure and regulates water management, is configured as an open-air rice museum, thanks to the alternation of cultivated species and the use of traditional agricultural techniques. Placing itself at the same time in continuity with the surrounding extensive cultivation and as an interpretative threshold of the archaeological site, the park acts as a filter to protect the heritage authenticity, and adds an important reading level for visitors, who, thanks to the glass walkway suspended four metres above the fields, can approach the heart of the site in a slow and interesting way, crossing space and time and adding interpretation layers of the history and characteristics of the place. The glass bridge becomes the true landmark, and offers a panoramic view of the archaeological area, set in its contemporary landscape context. The other paths, built as wooden footbridges at ground level, allow the visitor to explore the park in its different aspects: not only the cultivated areas, but also the marshy ecological areas and the different pavilions, newly built and already existing, which implement the knowledge of the area. The realisation of the project, completed in one year, has had an immediate feedback in terms of tourist attractiveness, particularly of short and medium proximity, increasing the local populations' awareness of their own origins and cultural traditions; a broader level of notoriety, both national and international, has been achieved thanks to the recognition of the World Landscape of The Year award at the 2017 World Architecture Festival, while the local communities benefit from an economic development linked to tourist flows and their induced activities.

### **3.2 Chemin des Carrières**

The case of Chemin des Carrières addresses a less obvious cultural heritage, which may appear irrelevant in terms of material assets, but plays an important role in local history: it is in fact the recovery of a short railway line, created at the beginning of the 20th century to carry stones and quarry materials from the hilly area of Saint-Nabor to the plain towards Strasbourg, and used until 2002 to transport goods and passengers along an 11 km route, linking a number of villages in the Alsatian Bas-Rhin region. The transformation of this route into a pedestrian and bicycle path, promoted by the local community association, exploited the infrastructure's potential for the valorisation of the area's complex cultural heritage and landscape system, made up of the intertwining of historical events, production activities and natural treasures.

*Fig.1: two of the architectural landmarks along the 11 km Chemin des Carrières path. Photos by the author*

The valorisation project, designed by Reiulf Ramstad Architects and completed in 2019, takes concrete shape in the redefinition of the pedestrian and bicycle path that incorporates the traces of the old tracks, bringing out at times the reminiscences of the railway structures - stop barriers, crossroads, station points, water pumps - as the fil rouge of a narrative that, starting from the "pretext" of

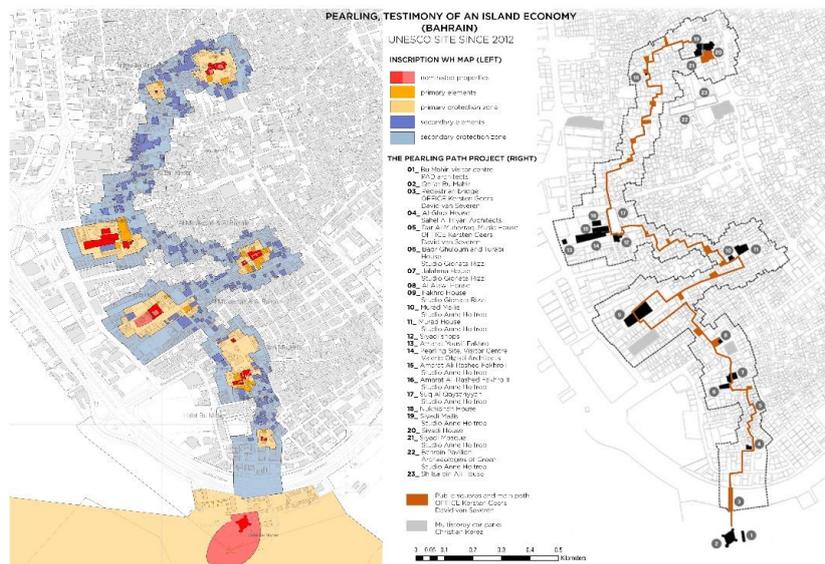

the quarry's productive past, becomes a trace for the grafting of other stories. Along the route, in fact, at the tangential points with the main towns, five thresholds are designed, identified both graphically in the paving and through the presence of pavilions and architectural-sculptural installations. Each of them represents a narrative stage, a 'chapter', emphasising the different landscape sequences and notable sites. The form of each pavilion is linked to a specific theme: the *past*, as an element to be discovered through the glimpses and stopping points of the labyrinth structure in Rosheim, starting point of the route; *water*, the subtle structuring element of the landscape, which is frequently encountered but is highlighted by the resting steps along the watercourse at the village of Boersch; the *cultivated land*, which opens up to view at the end of a forest tunnel in Leonardsau, framed by a high portal consisting of two large corten plates; the *journey*, symbolised by the former Ottrott station, where the signs left by the railway are embedded in the urbanised fabric, in a square reminding visitors and locals of past activities; finally, the theme of *luck*, which has given its nickname to the entire route - now known as 'portes bonheur' - represented by the sculptural belvedere positioned in the old Saint-Nabor quarry, where a process of renaturalisation is gradually restoring the mountain's productive wound, but the presence of the pavilion and the associated resting facilities allows visitors to experience the richness of the area, unfolding before their eyes in an impressive panoramic view of the landscape. In addition to these five main stations, the route is dotted with signposts and small rest facilities, which provide information on the visible and invisible features of the area and stimulate its slow rediscovery, made up of moments of contemplation and detours to nearby roads. The enhancement project, which has won several international awards, has above all been a success at the local level: community identity has been consolidated around this green infrastructure used both in daily life and to promote cultural activities and sustainable tourism systems. The Chemin des Carrières is a true project of local dynamism that embodies the ambition of its territory: to open up to the world, to allow safe and pleasant circulation in the heart of the communes, to promote a common history.

#### **4 The inclusion of design in UNESCO tools for a new contextual valorisation methodology: the example of the Pearling Path project**

The two cases described above show how an effective heritage valorisation system can be based on the design of the relationship with its context, working concretely on the structure of the territory and guiding its transformation.

At an institutional level the role of the project is still ignored by official UNESCO instruments, even if in practice it is present in some innovative practices of heritage management system, which can give useful indications for a more structured insertion of design/architectural tools. In fact, a design approach in relation to the UNESCO instruments previously analysed, in the definition of respect areas and to integrate the management systems of sites registered in the WHL (not only in the sphere of cultural landscapes, but more in general in the relationship between a cultural heritage and its context), would imply the structuring of a methodology that uses the tools of architecture both in the cognitive phase of the territory and in the planning of its transformations. An exemplary case in this regard is represented by the *Pearling Path*, a project with a strongly architectural imprint directly associated with the WHL inscription of the serial site "Pearling, testimony of an Island economy", which involves the entire historic centre of Muharraq, in Bahrain. Since the nomination dossier of 2009, the site has presented itself with innovative characteristics: the proposed Outstanding Universal Value integrates elements of the local material and immaterial culture, in the construction of a narrative of the place and its history that makes it more comparable to a cultural landscape than to an historic centre, in full agreement with the idea of heritage as a cultural practice linked to the local community. The narrative aspect is also dominant in the proposal of safeguard measures, which explicitly aims at the recovery and valorisation of specific elements within the urban fabric and the marine environment (*core zone*), connected by the shared fabric of the *buffer zone*, articulated in a dual sphere, which winds through the city and reconnects the pieces of a common narrative through public spaces and community life. The definition of these ambits is linked from the very start to a design intent, which is made explicit in the management plan and becomes operational following the obtaining of UNESCO recognition in 2012, through the study of a project for the curatorship and coordination of targeted transformative actions, planned to be implemented in different phases. These concern the core

zones, with restoration work on buildings of historical relevance, but above all the buffer zones, through projects for the urban redevelopment of public spaces and the construction of new facilities to benefit visitors and the local community - such as the Centre for Traditional Music - and are entrusted to designers with renowned experience in their respective fields. The project to revitalise the city, which after the heyday of its economy had been in an ever-increasing state of decay since the 1930s, is proving successful both in recovering a heritage in danger of oblivion and in triggering new dynamics of involvement of the inhabitants.

*fig.2: mapping of core and buffer zone of the UNESCO site "Pearling, Testimony of an island economy (left) and design interventions program in the area (right).  
Elaboration of the author on official UNESCO maps*

The particular political, regulatory and economic conditions of Bahrain, which is implementing a decisive, solidly financed cultural valorisation policy, are certainly factors that condition the implementation of such ambitious projects; however, the case of the Pearlling Path is of particular relevance for an attempt at a programmatic definition of the contribution of design disciplines in the structuring and management of UNESCO sites in relation to their context.

## 5 Conclusions: a new key for heritage valorisation tools

The case of the Pearling Path helps clarifying the potential of a new design-based methodological approach: two application phases can be identified, which are interrelated and consequent. The first, which can be defined as a *cognitive framework*, is linked to the territorial knowledge project, through holistic and direct investigations that integrate historical, morphological and constraining research in order to concretely define the territorial assets that contribute to the definition of the value of the cultural heritage, and can positively or negatively influence its preservation and transmission. The aim of this first phase is the identification of the territorial areas of influence, which comes together in the definition of the *buffer zones* (at one or more levels); these are understood as complex and active territorial areas, subject to particular attention both from the point of view of control and of the promoted transformations. The buffer zones thus identified are in fact the preliminary cognitive step of a territorial development project based on the sharing of cultural heritage values and the construction of local identity. The second phase is therefore linked to the management of heritage over time, and is constituted as a multi-scalar and multi-phase project definable as *interpretation framework*, which defines in a coordinated and hierarchical manner the transformative actions to be promoted in the territory, whether of a public or private incentive nature. This type of strategic architectural design is concretely linked to the reality of places and constitutes the backbone of land management in relation to heritage, helping to reduce the dispersion of resources in fragmentary and extemporaneous projects, and also rooting intangible activities in the reality of places.

In an increasing focus on cultural heritage values, the change in the approaches to safeguarding and valorisation practices entails opening up to different fields and disciplines that look at the relationship with the contextual fabric as a resource. The institutional instruments implemented in the UNESCO framework acknowledge this evolution, but struggle to consider the physical transformations of places as a positive element in the construction of a relational fabric between heritage and territory; The introduction of a methodology that integrates the design tools with the management structure of the sites, involving both the definition of the buffer zones and the design of their transformation in a coordinated manner, can be effective in establishing a concrete dialogue between the sites registered in the WHL and the surrounding areas, unblocking the

stalemate mechanisms given by the purely constraining use of the buffer zones, which can thus become a place for the exchange of values with the local communities and an element for the construction of a shared identity, triggering a virtuous circle of mutual enhancement.

### **Abstract**

The EU Strategy for Sustainable and Circular Textiles outlines a comprehensive approach to promoting sustainability in the industry, including the use of recycled and renewable materials, circular business models, the uptake of sustainable innovations, and the reliability of sustainability knowledge. Literature suggests that promotion of sustainability knowledge spillover within the textile industry can have an impact on the overall textile

business in terms of social, financial, and environmental sustainability and its overall competitive advantage. This paper aims to provide a comprehensive overview of the current research on sustainability knowledge spillover in the textile industry. The research method is a systematic literature review of articles published in the leading KM journals.

**Keywords** – Knowledge Management, sustainability, textile industry, knowledge spillover

**Paper type** – Academic Research Paper

## 1 Introduction

In 2022, European Commission released the EU Strategy for Sustainable and Circular Textiles, which aims to promote sustainability in the fashion, textiles, clothing, leather, footwear, and carpet industries. This strategy emphasizes the importance of transparent communication, the promotion of circular business models, and the uptake of sustainable innovations. Furthermore, it outlines a comprehensive approach to promoting sustainability in the industry, including the use of recycled and renewable materials, circular business models, the uptake of sustainable innovations, and the reliability of sustainability knowledge. (EU Strategy for Sustainable and Circular Textiles, 2022)

According to the World Bank (2005), textile manufacturing was responsible for up to a fifth of industrial water pollution (Kant, 2012). In 2015, textile production contributed to 1.2 billion tons of CO<sub>2</sub>, which was “more than those of all international flights and maritime shipping combined”. Since, the growth of the industry has been strong, alone in 2021 the “[g]lobal industry revenues grew 21 per cent year on year” (Amed et al., 2022). In terms of waste, it has been estimated that up to a fifth of materials are wasted during the clothing manufacturing process. (Ellen MacArthur Foundation, 2017) Furthermore, Europeans send 87 % of their clothes into landfills or post-use waste incinerated which equals 11 kg per person (The Impact of Textile Production and Waste on the Environment (Infographic) | News | European Parliament, 2020). Thirdly, Siegle (2011) writes that the textile industry employs 40 million employees worldwide, and the industry is known to have its challenge with “low wages and poor working conditions” (Bick et al., 2018).

Thus it is not a surprise that existing literature indicates that alone in the fashion industry, which is only one part of the overall textile industry (see Figure

1), "sustainability presents the biggest opportunity" (Amed et al., 2022; Amed et al., 2016).

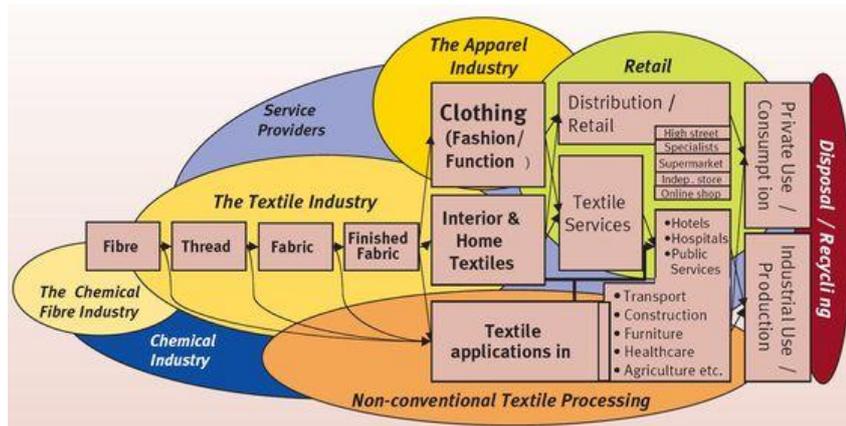

Figure 1: Textile production value chain and included businesses as presented by the Tex-Map project (adapted from Fontell & Heikkilä, 2017)

The preliminary findings on sustainability knowledge spillover in the textile industry show that knowledge management strategies and knowledge-based development can promote sustainability and competitiveness in the sector (Heisig et al., 2016; Kumar & Ganesh., 2011). Promotion of sustainability knowledge spillover within the textile industry can have an impact on the overall textile business in terms of social, financial, and environmental sustainability and its overall competitive advantage.

The paper aims to provide a comprehensive overview of the current research on sustainability knowledge spillover in the textile industry. The research question of this paper is: What is the state of the art of sustainability knowledge spillover in the textile industry among KM literature? The research method is a systematic literature review of articles published in the leading KM journals.

## 2 Background on Sustainable Development

The concept of sustainable development is defined by World Commission on Environment and Development (1987) in the so-called Brundtland Commission's report, *Our Common Future*, as a "development that meets the needs of the present without compromising the ability of future generations to meet their own

needs." One of the objectives of sustainable development is to balance economic growth with environmental and social concerns while eliminating poverty.

Desore & Narula (2018) suggest that sustainability in the textile industry is aligned with environmental sustainability. In practice for the company, sustainability may mean process engineering approaches like re-engineering wastewater systems to reduce water and energy consumption and adding up-to-date machinery and chemistry to the different process phases. In addition, companies may utilize recycled material as part of their production or use renewable energy sources . Secondly, from a business perspective, companies may enter new environmental business segments, launch new 100 % organic cotton products or redesign existing products to have more organic components, upcycle and have eco-labels as a marketing aid or use reusable packages . (Desore & Narula, 2018)

At the start of 1990s, the spillover theory was mentioned in the textile context within the KM discipline when Romer (1992) pointed out that the generation of big "(for example, how to make high-temperature superconductors)" and an enormous number of small ideas "(better ways to sew a shirt)" enables sustained economic growth. Coming to the concept of spillover, the core idea of spillover lies on causality, meaning that a specific action causes some other, not intended action or effect. Thus, spillover is something unintended and this is the starting point also in knowledge spillovers. For example, Breschi & Lissoni (2001) discuss the concept of localized knowledge spillovers and define them as knowledge externalities bounded in space. Furthermore, knowledge spillover refers to the unintentional transmission of knowledge to others beyond the intended ones. To be more specific in knowledge management terms, if knowledge is exchanged with the intended actors (person or organization), it is understood as knowledge transfer. Whereas any other knowledge that is exchanged outside the intended boundary, it could be argued as spillover. (Fallah & Ibrahim, 2004)

### **3 Methodology**

We employed a systematic literature review (SLR) as a guiding framework to identify valid papers and provide an overview of sustainability knowledge spillover in the textile industry within the field of knowledge management. The use of SLR is selected to minimize potential researcher biases (Tranfield et al., 2003), while the selection of seven leading KM publications aimed to reduce

publication biases (Moher, 2009). According to Snyder (2019), SLR is a valuable methodology for gaining a comprehensive understanding of research questions, providing an audit trail, and ensuring the repeatability of the study. Also, Tranfield et al. (2003) highlight the significance of SLR as “a key tool” for managing the diversity of knowledge in academic research.

We performed SRL in two phases to map the state of the general literature in the sustainability knowledge spillover in the textile industry. The 1st phase consisted of scoping search of the literature of published papers in one of the leading KM journals to reveal what has already been studied on the topic within the KM discipline (ref. Atkinson & Cipriani, 2018), and the 2nd phase involved an in-depth systematic review of leading KM journals based on the (Serenko and Bontis, 2022) study of KM/IC journals ranking. In the 1st phase a researcher analyzed the papers and in the 2nd phase study investigator triangulation (Denzin & Lincoln 2000) among three researchers was used to analyze the papers to ensure the reliability of the findings.

In the 1st phase, we conducted a keyword search in the Journal of Knowledge Management using the keywords "sustainability textile knowledge" on September 6th, 2022 to ensure that textiles and sustainability are in the scope of the KM discipline. The search resulted in 32 articles, of which 17 were relevant after using the find command (ctrl F) to identify instances of the keywords "textile" and "sustainability" in the main text. An additional three articles were found during a keyword search on December 7th, and two were deemed relevant for the literature review. A second keyword search using the keywords "sustainable textile knowledge" on December 13th, 2022, resulted in 50 articles. After importing both ris-files into a reference management software program (Zotero) and removing duplicates, 23 articles remained. The find command was used to identify instances of the keywords "textile" and "sustainable" in the main text. We applied the practical screening criteria to include only the papers, which mentioned Textile industr\* and Spillover\*. Table 1. below outlines the resulting papers after applying the practical screening criteria.

33	(Wen & Wang, 2022)	Does knowledge structure matter? Key factors influencing formal and informal knowledge sharing in manufacturing

In the 2nd phase, to ensure a thorough sample of covering the most important papers in relation to our research question in the field of KM, we covered the following academic journals: Journal of Knowledge Management, Journal of Intellectual Capital, The Learning Organization, VINE Journal of Information and Knowledge Management Systems, The Journal of Knowledge Management Research and Practice, Knowledge and Process Management, International Journal of Knowledge Management. The time frame for the academic journal selection was the last ten years (2012 – 2022), which we used to ensure that articles are relevant and current.

We used search string (“circular economy” OR degrowth OR “environment\* protection” OR “green economy” OR “green transition” OR “integrated production” OR “natural resources” OR “organic production”) OR (sustain\* OR cultural OR ecological OR economical OR economic OR social OR agriculture OR consumption OR “forest management” OR living OR tourism OR use OR development) AND “textile industry\*” AND spillover\* as the aim was to especially understand the concepts related sustainability and their intersections with the textile industry in the context of knowledge spillover. We selected the search

string so that the overall concept of sustainable development and its related concepts were covered, and therefore we built the search string based on the Finnish Thesaurus and Ontology Service Finto. We chose FINTO, since the overall concept of sustainable development and its related concepts have been created 25th of March 1992 and the Ontology has been regularly updated, the latest update is from the 18th of February, 2023. The Service is developed by the National Library of Finland, and then international users of the service include UNESCO and BARTOC. Therefore, we considered the search string current and valid. With the search string, 76 articles we identified related to this study all the results are documented in the spreadsheet.

We used a systematic approach to identify each search string keyword in the paper. We used the "ctrl+f" function to search for search string keywords within the text of each paper, and we logged the results into an Excel spreadsheet. We marked x into a spreadsheet when we found the keyword in the paper, and on occasions where the keyword was not found in the paper, we marked N/A. This way, we could identify the specific concepts related to sustainability based on the search string. We applied the practical screening criteria to include only the papers, which mentioned Textile industr\* and Spillover\*. Table 2 outlines the resulting papers.

Table 2. The overview of Papers containing Textile industr\* and Spillover\* in the leading KM journals 2012 – 2022.

No.	Author	Title	Publication
1	(Marques et al., 2021)	Technological transfer and spillovers within the RIS3 entrepreneurial ecosystems: a quadruple helix approach	Knowledge Management Research & Practice
2	(Zhang et al., 2021)	Knowledge spillover driven by institutions: evidence from the big science project in China	Journal of Knowledge Management
3	(Sun et al., 2022)	The contingent roles of market turbulence and organizational innovativeness on the relationships among interfirm trust, formal contracts, interfirm knowledge sharing and firm performance	Journal of Knowledge Management

#### 4 Research findings

Based on the reviewed papers during the 1st phase, the preliminary findings suggested that sustainability knowledge spillover in the textile industry shows that knowledge management strategies and knowledge-based development can promote sustainability and competitiveness in the sector (Heisig et al., 2016, Kumar & Ganesh., 2011).

As the table above shows, we found a limited number of papers, totally there are three papers, which mention the textile industry\* and spillover\* and had a sustainability-related concept mentioned, the earliest paper is in 2021 and the latest is from 2022 (ahead-of-print). Considering our aim is to understand the sustainability knowledge spillover literature landscape, we compiled table 3 by the selection of papers based on the knowledge spillover type, sustainability concept and chosen research method.

Table 3. The overview of the paper knowledge spillover type, sustainability concept and research methodology applied.

	<b>Knowledge Spillover</b>	<b>Sustainability Concept</b>	<b>Research Method</b>
(Marques et al., 2021)	positive spillover effect	sustain*development	qualitative
(Zhang et al., 2021)	positive spillover effect	sustain*development	qualitative
(Sun et al., 2022)	negative spillover effect	not in content, referred to in references	qualitative and quantitative/mixed method

Marques et al. (2021) studied the implementation of smart specialization and technology transfer in a quadruple helix in Portugal. In this article, the textile industry is referred to as one of the university's collaborations partners, and one of the informants refers to Inditex as an example. The sustainability concept of the 'circular economy' is used as one of the suggestions to indicate collaboration possibilities between the society's actors and higher education. In addition, 'Sustainable development' is found in the references. In the article, the authors highlight the knowledge spillover perspective where the knowledge spillover is seen as a building block for innovations towards sustainable competitive advantage. (Marques et al. 2021; Ramadani et al., 2017). Furthermore, the authors suggest that regulations should be placed to encourage the knowledge spillover between higher education and SMEs to foster local economic growth, zero-waste

behavior and optimizations of resources (Davies et al., 2021; Dimitropoulos et al., 2019; Marques et al. 2021).

Zhang et al. (2021) explored “the knowledge spillover mechanism in big science projects” in China. The textiles were referred to as cite notes to mention that a specific city used to be well-known “for its wool textile industry”. In this article, sustainability is seen as an outcome of the big science projects to help the government draw different policies and funding (Zhang et al., 2021).

Sun et al. (2022) explored trust and contract governance mechanisms and their influence on knowledge sharing in connection with company performance, market conditions and organizational innovativeness. I study data was also collected from the textiles/clothing industry among other industries. In the paper, sustainability is only referred to in the reference section. In the terms of knowledge spillover, the authors pointed out that knowledge spillover can have two effects on firms’ performance it can either harm (negative spillover effect) or influence positively.

From the SLT review above, the key preliminary finding is that that there is a limited amount of literature available on sustainability knowledge spillover in the textile industry among knowledge management disciplines.

## **5 Discussion and conclusions**

As knowledge spillover is seen as one of the contributors to innovation ability, we suggest that sustainable knowledge spillover research in the context of fashion, textiles, clothing, leather, footwear, and carpet industries may have a positive impact by fostering new eco-innovations leading to the long-term competitive advantages for the sector.

Regarding the practical/managerial implications: In general, a previous study showed that knowledge spillover has a favorable influence on businesses’ innovation ability (Montoro-Sánchez et al., 2011). At the same time, European Commission (2012) promotes that eco-innovations are “[t]he key to Europe's future competitiveness”, and the Commission expects that eco-innovations among other things decrease the expense and boost the businesses’ image in the eyes of the consumers. Studies also suggest that businesses, which have implemented green practices seem to have greater profitability, better relationships with stakeholders, and lower overall costs (Wu et al. 2012; Baskaran et al., 2012; Caniato et al., 2012; Hansen and Schaltegger 2013).

## Abstract

In this paper we explore: What are definitions for legal innovation and regulatory innovation? in the context of the whole lifecycle of regulation. We use systematic literature review (SLR) method. The lifecycle of regulation consists of law drafting, law implementation, monitoring, and sanction of law in act. Definitions of legal/regulatory innovations (LRIs) are interpreted and applied in the field of public regulation as well as private regulation. Our paper has two objectives:

- Provide a holistic account of the literature on legal/regulatory innovations based on current knowledge about a set of key research themes;
- Identifying an agenda addressing new research directions in this field of study.

We found out that only few writers in the selected articles clearly define, what do they mean with the terms legal or regulatory innovation. SLR analyses provided an overview of the topics of legal and regulatory innovations: Topic 1: LRIs in the context of Complex Adaptive Systems; Topic 2: LRIs for social welfare and Topic 3: LRIs in the different levels, networks of actors and phases of the regulatory life cycle.

LRIs develop in complex adaptive systems which means that there is a continuous relationship between legal system and society.

New kind of LRIs were discussed in the context of public and private regulation: Default design, Sandboxes and Nudge are possible tools of new governance approaches to regulation developed by governments. Process standards compared to traditional product standards are seen more innovative as they allow regulates develop most innovative way to comply the standards. Process-based standards and other standards developed by private actors have a lot to offer for the development of new LRIs. Regulatory knowledge is needed in the dynamic, complex society, in order to understand how LRIs can promote the change towards desired goals.

**Paper type** – Academic Research Paper

## 1 Introduction

In this paper, we explore with systematic literature review (SLR) method research questions: What are definitions for legal innovation and regulatory innovation? in the context of the whole lifecycle of regulation. The lifecycle of regulation consists of law drafting, law implementation, monitoring, and sanction of law in act. Definitions of legal/regulatory innovations are interpreted and applied in the field of public regulation as well as private regulation.

In order to explore the phenomena of legal/regulatory innovations we carried out a Systematic Literature Review, by analyzing a set of papers through a text

mining approach based on the Latent Dirichlet Allocation (LDA) in order to find what are the relevant topics in the investigated research domain (Denyer and Tranfield, 2009). This activity was performed through MySLR software (Ammirato et al., 2022). To our best knowledge, no systematic studies on the explored phenomena are present in literature, as such, our work aims to fill this gap, by having the following objectives:

- Provide a holistic account of the literature on legal/regulatory innovations based on current knowledge about a set of key research themes;
- identifying an agenda addressing new research directions in this field of study.

## **2 Key definitions**

Regulation in a wide sense is, the sustained and focused attempt to alter the behaviour of others according to standards or goals with the intention of producing a broadly identified outcome or outcomes, which may involve mechanisms of standard-setting, information-gathering and behaviour-modification (Black et al. 2005, 11.)

Law is defined to mean publicly-made regulation, incorporating both mandatory and enabling methods, which individual or collective private actors can specify and modify for their own needs. Regulation contains—especially from a European perspective— “the idea of control by a superior; it has a directive function” (Ogus 1994). According to Ogus (2009, p. 333) regulation refers to obligations imposed by public law designed to induce individuals and firms toward outcomes that they would not voluntarily reach, mainly enforced by public officials. Compliance is aided by deterrence or imposition of some sanction.

Rules and other regulatory measures can also be enacted and developed by private actors. Private rule-making is the process during which private actors use their regulative power both in areas where there is enabling legislation and where public law-making has not emerged or cannot operate due to constitutional limitations. Private regulation takes the form of codes of conduct, codes of ethics, codes of good practice, guidelines, and voluntary agreements. (Sorsa 2011).

In the literature regulatory innovation is defined to be the use of new solutions to address old problems, or new solutions to address ‘new’ or newly constructed problems, but not old solutions to address old problems (Black 2005, p.4). This

means that regulatory innovation is time and place specific; old measures in one country can be innovative in another country. According to Duffy (2007), "True innovation here means not any change (like a change in social values or a mere change in fashion) but rather a change that is an intellectual advance and is objectively better in accomplishing the purposes of the law".

Innovation of regulatory technique and diffusion of LRIs are two different things – they are innovations in the different place of the regulatory lifecycle (Fromond, Similä & Suvantola 2009, 4). Understanding, how legal innovations diffuse, is needed, in order to understand law's impact on society and the way society and law interact (Rubin (2015, 365).

### **3 Methodology**

#### ***3.1 Paper location and selection***

We conducted an SLR to provide an overview of scientific literature on the topic of legal and regulatory innovation. In line with the SLR principles provided by Tranfield, Denyer, and Smart (2003), the research protocol we adopted consists of three main steps: paper location and selection, paper analysis, and results presentation/analysis.

##### *3.1.1 Search string*

Our research is aimed at analyzing works related to regulatory innovation or legal innovation. Therefore the search string was structured so that the results contained papers with at least one term between "legal innovation" or "regulatory innovation" in the title, abstract, and keywords. We selected Elsevier's Scopus and Web of Science (WoS) as scientific databases in which to perform our search which are widely recognized as relevant and comprehensive scientific databases in the managerial field of study (Bhimani, Mention, & Barlatier, 2019).

We performed the search in January 2023, finding 556 papers from Scopus and 323 papers from WoS. The following selection criteria were then introduced to ensure the quality and relevance of the papers to be analyzed:

- papers are written in English;
- papers are published in scientific journals;

- papers are indexed at least in one of the following subject areas: Business, Management, and Accounting; Social Sciences; Engineering; Economics, Econometrics, and Finance; and Decision Sciences.

At the end of this step, 406 journal articles from Scopus and 276 articles from WoS were extracted. We then merged results from the two scientific databases, finding 521 unique papers. We manually analyzed the title and abstract of each paper to decide whether they matched the focus of our study. At the end of this process, a total of 448 papers to be analyzed has been found.

### 3.1.2. Paper analysis

We utilized a text-mining approach based on latent Dirichlet allocation (LDA) to reveal the research topics in the context of legal and regulatory innovation. The LDA technique gives as output  $k$  sets of relevant keywords (where each set represents a topic) and the document-term matrix, i.e. a matrix describing how much each paper is devoted to a specific topic (i.e. topic proportion).

To perform this activity, we utilized MySLR software (Ammirato, Felicetti, Rògano, Linzalone, & Corvello, 2022), which is a semi-automated tool supporting researchers in performing SLRs.

Following Blei (2012), we selected  $k$ , i.e. the number of topics to be extracted, by evaluating multiple LDA results with  $k$  ranging from 2 to 20. We chose  $k$  and the LDA algorithm to guarantee a sufficiently high value of topic coherence (Chen & Liu, 2014) and, at the same time, a simple interpretation of the results for a human reader. The most meaningful set of topics was achieved with  $k = 3$ .

### 3.1.3 Results synthesis

Three topics were identified through the LDA procedure, each of which is related to a different perspective: Legal and regulatory innovations in the context of Complex Adaptive Systems for topic 1; Legal and regulatory innovations for social welfare for topic 2; and Legal and regulatory innovations (e.g. nudge) in the different levels and networks of actors and phases of the regulatory life cycle for topic 3.

The LDA procedure assigned 151 papers to topic 1, 110 papers to topic 2, and 187 papers to topic 3. In fig 1. the intertopic distance map, a visualization of the topics in a two-dimensional space, is provided. The area of these topic circles is proportional to the number of words that belong to each topic across the dictionary. The map would seem to suggest a strong polarization of the

documents on the individual topics; in other words, the papers that are assigned to a topic have little to do with the other topics.

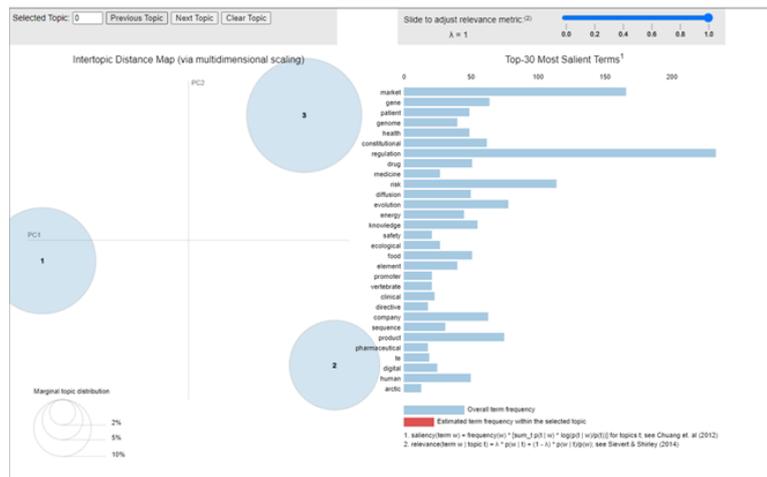

Fig 1. The inter topic distance map with three topics.

What emerges when analyzing the evolution of the publications within topics over time (see Figure 2) is that the number of papers is rapidly increasing, both overall and in each topic; therefore, all the topics represent both present and future research themes.

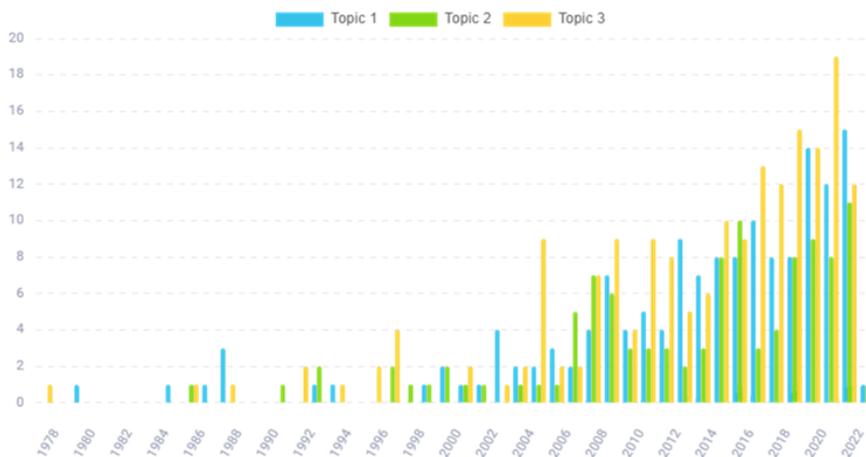

Fig. 2: distribution of the sampled papers per year and per topic

In what follows, the three topics identified through the LDA procedure are presented and discussed.

**Topic 1: LRIs in the context of Complex Adaptive Systems (CAS)**

Topic one is combination of articles from two different areas: those focusing on legal doctrine and those focusing on regulatory innovation in the biology. In the latter, regulatory innovation words have different meaning compared to what we were expecting. 'Regulatory innovation' is understood in genome evolution context as an innovation which emerges regularly.

Articles representing legal doctrine focus on the field of international trade law, criminal law and intellectual property law all representing the field of complex, adaptive systems (CAS), in which law coevolves with other complex social and natural systems as well as how legal systems grow and sustain themselves (Morin, Paywelyn and Hollway 2017, 378). Innovations always derive from existing elements. Similar to biological reproduction and genetic recombination, social innovations are the product of recombining existing ideas. Applied to trade agreements negotiations, trade negotiators invent new legal norms by combining or refining existing norms (Morin et al. 2017, 378).

Two other examples represent criminal law: Beckett and Herbert (2008) describe new social control techniques, which fuse criminal and civil legal authority and are touted as 'alternatives' to arrest and incarceration. Examples come from U.S. Suk's article (2006) discusses LRIs in the domestic violence enforcement context. Traditionally home was considered as private space in which the criminal law did not enter. Suk discusses the protection order that excludes a person accused of domestic violence from the home.

Rubin's (2015) article clarifies the diffusion of LRIs. She distinguishes between the prison's innovation and early adoption in the South and frontier states in U.S. LRI was driven by the desire to conform to increasingly widespread practices. Her study illustrates the importance of distinguishing between the motivations that initiate criminal law innovations and the varied reasons behind their diffusion.

Duffy's (2007) article analysed the development of patent law. "True innovation here means not any change (like a change in social values or a mere change in fashion) but rather a change that is an intellectual advance and is objectively better in accomplishing the purposes of the law". Patentable inventions must be new, useful, and *nonobvious*. Nonobvious criteria was a real innovation as it is most important in the context where technology and society change rapidly. (Duffy 2007, 2, 70-71; See also Alaassar et al. 2020).

In the CAS social interactions are continuous. Alaassar, Mention and Aas (2020) focus on the social interaction element. Their findings indicate many positive issues which regulator-regulatees' social interactions increase: the legitimacy, risk management capabilities, and knowledge of regulatory frameworks. These interactions and knowledge exchange are promoted in the context of regulatory sandboxes between regulators and market participants by increasing regulators' understanding of regulatory constraints and potential risks in enabling technologies. Regulators will be better informed of regulatees' support needs. Therefore they can offer them early access to regulatory innovations.

The second part of topic 1 describes 'regulatory innovation' in the biological evolution context. However, regulatory innovation was used in the following articles in genome evolution context as an innovation which emerges regularly: Lowe, Craig B., Clarke, Julia A. Baker, Allan J., Haussler, David and Edward, Scott V. (2015); Lowe, CB Kellis, M Siepel, A Raney, BJ Clamp, M Salama, SR Kingsley, DM Lindblad-Toh, K Haussler, D (2011); Gerdes, P Richardson, SR Mager, DL Faulkner, GJ (2016); de Mendoza, A Hatleberg, WL Pang, K Leininger, S Bogdanovic, O Pflueger, J Buckberry, S Technau, U Hejnol, A Adamska, M Degnan, BM Degnan, SM Lister, R (2019) and Carelli, FN Liechti, A Halbert, J Warnefors, M Kaessmann, H (2018).

***Topic 2: LRIs for social welfare.***

This topic has articles from law journals from researchers, who present the field of legal or policy research.

Burris (2008) investigates how the human subjects who are target of the research should be protected and how their rights are protected. He analyses different legal instruments and strategies and evolution of them in U.S. Burris argues: "the system was in key respects a departure from traditional top-down regulation and hard law, but through flaws in its mission, structure and implementation, has ended up reproducing the sort of self-referential legalism."

Faulkner and Poort (2017) discuss what kind of strategies of law-making - commensuration, an analogical legislative strategy, including new provisions in an existing legal framework or development of new legal frameworks - are needed and what kind of knowledge should be used in law-making process. They specifically addressed the question of adaptation of existing regulatory frameworks in the face of innovation in biotechnologies, and specifically the role of expert knowledge. They demonstrated in their article how different modes of regulatory knowledge can shape regulatory innovations either by maintenance of

regimes through commensuration and stretching, or through differentiation and separation creating new frameworks practices. Article focuses to the beginning of the regulatory lifecycle, to the law-making and implementation. It sheds light on to a broader understanding of the concept of regulatory knowledge and its role in the construction and re-construction of law: Regulatory knowledge encompasses more than scientific knowledge only. Their analyses is based on combination of a legal and Science and Technology Studies (STS) perspectives. They point out to the need to use expert committees and the workings of other expert knowledge actors as vehicles or channels of regulatory knowledge.

Need for the change of regulatory instruments has risen as a consequence of dynamic change in the different parts of the social life. Van Alstine (2002) has found out that the progress in the law has come to be characterized more by large legislative initiatives than by slow accretions of common law experience<sup>1</sup>. His article emphasized the role of transaction costs analysis for lawmakers. Available drafting and implementation techniques can mitigate transitional friction before it arises and facilitate both the acceptance and effectiveness of legal reforms. For achieving the ultimate goal of regulations - how a proposed change can correct some perceived problem or otherwise improve the substance of the law (Id, p. 853) - and finally to improve social welfare, it is useful to consider also the costs of change in legal environment. A minimal and flexible enabling approach over comprehensive regulation (Id, p. 859; 869) should be preferred.

In addition to transaction costs, the limits of human rationality (Amir & Lobel 2008 and Burgess 2012) and should be taken into account in the law-making. The nudges are designed to improve individual welfare, well-being, and happiness in accordance with an individual's own preferences. The law maker's role is to offer defaults by simply facilitating a fuller expression of individuals' desires by choosing welfare-enhancing defaults rather than remaining neglectfully default neutral. Nudging is based on the behavioral economics. Burgess argues that nudging provides the modern and cheaper means of dealing with social problems to policy maker with a fresh and practical perspective on a range of problems in society (Burgess 2012, 5; see also Van Alstine 2002).

---

<sup>1</sup> He mentions as examples the fields of law which steadily gained momentum for transition throughout the twentieth century, matters as diverse as labor relations, securities trading, racial and gender discrimination, consumer protection, and environmental rights were removed from the province of contract, tort, and property law and newly regulated by public legislation (Van Alstine 2002, 805)

Camacho's (2007) discusses LRIs in the context of Endangered Species Act's ("ESA") Habitat Conservation Plan ("HCP") program. According to Camacho, the HCP plan was the earliest of a number of experimental innovations, which transformed administrative law from its traditionally static and inflexible "command-and-control" regulatory model into a negotiated process that balances public goals through both collaborative and adaptive decision-making. Fromond, Similä & Suvantola (2009) highlights the same issue in the biodiversity context.

Robinson's (2016) article brings a new perspective on social welfare topic discussing how technological innovation and regulatory innovation interacted and (see also Faulkner and Poort 2017) and enabled the pregnancy tests to bring home.

***Topic 3: LRIs (e.g. nudge) in the different levels and networks of actors and phases of the regulatory life cycle.***

Topic three is presented in several international journals of management, economics and policy.

Chaisse (2012) discusses the time when EU Member States ratified the Treaty of Lisbon, which amended the Treaty on European Union and the Treaty establishing the European Community. By this ratification EU acquired a wide legal competence for external economic matters extending the scope of external trade policy on issues of investment. Chaisse considers these changes as "essential innovations in EU international treaty-making powers, both on the international stage and in the EU bilateral relations, are significant", (Chaisse 2012, 52). By extending 'trade' policy to include investment changed the conditions of future negotiations between EU and other countries: Any regulatory innovation in the EU policy, may systematically affect regional and global Foreign Direct Investment flows (Chaisse 2012, 52). Alschner & Skougarevskiy (2016,) also investigated LRIs on global level analysing 2100 international investment agreements using content analysis methods. They were able to trace consistency and legal innovation in national treaty networks on the country-level.

Simmons (2001) and Flannery and Rangan's (2004) discuss harmonization of laws as a LRI in the international financial markets focusing on the interactions between a dominant "regulatory innovator" and the rest of the financial world. Explanations for how harmonization unfolds fall into two dimensions: (1) the incentives other regulators face to emulate or diverge from the regulatory innovation of the dominant financial center, and (2) the nature and extent of the

externalities produced by this reaction, as experienced in or anticipated by the dominant center (Simmons 2001).

From financial world to food industry, Lee's (2009) article focuses on collective action and policy content diffusion in the field of organic food industry in U.S. Lee (2009) investigated how local and federated certification organizations, which he calls Standards Based Certification Organizations (SBCO), within a state, are associated with policy outcomes. Three important policy outcomes were found: content innovation, content variation, and content elaboration. (Lee 2009, 1251). Lee's article aims to fill the research gap, how public and private regulation interacts in the legal innovation diffusion.

Unnevehr's and Jensen's article (1996) about Hazard Analysis Critical Control Point (HACCP) system is also from food industry and self-regulation. HACCP was a new approach for food safety, which relies on science-based risk assessment and prevention rather than on detection of hazards. Therefore, it is considered as a regulatory innovation in the food safety regulation. Another connecting issue with these two articles is that both discuss the relationship of private regulation and instruments created by private sector actors, either by companies or non-governmental organisations, and relationship of these regulatory instruments with the state-made-laws.

Pomeraz et al. (2009) discuss different regulatory innovations to address obesity. Obesity is a huge problem in U.S. but as well in other countries. Pomeraz et al. (2009, 187-197) analyse different regulatory options for reducing risks for obesity. Considering performance-based regulation (PBR) as an alternative to typical regulatory actions, sounds most interesting approach. Traditional "command and control" regulation tells businesses what to do, whereas PBR tells businesses what to achieve but leaves it to them to get there. Callard's and Collishaw's article (2013) also discuss health issues from tobacco industry viewpoint. tobacco industry on "Supply-side options for an endgame for the tobacco industry". They discuss six different approaches to regulate tobacco markets in order to reduce harms for health. Proposals differ in two way: One difference is whether those who supply tobacco should be set accountable primarily for their achievement of financial or health goal. Another different regulatory approach to use input- or outcome-based regulation. Input-based regulation assumes that if enterprises make the ordered behavioural changes, then improved public health performances (Sugarman 2009,) will follow. Outcome-based regulation instead

would mean that tobacco suppliers should meet the regulatory objectives, such as a reduction in overall tobacco use.

Under topic three a lot of discussion was focused on different regulatory tools and strategies.

#### **4 Conclusions**

We found a lack of clear definitions for legal and regulatory innovations. The articles analysed in this paper cover broad variety of issues under the umbrella concept 'legal and regulatory innovation'. One connecting issue between topics was the idea of evolution of law and regulations in the complex adaptive system (Topic 1); as the surrounding society evolves, laws and regulations need to evolve as well. Our SLR tool had selected also articles on the field of biology, from where the term complex adaptive systems come from and also in cell biology, regular evolution is central. The articles discussing cell biology does not directly answer the question of legal innovation, but perhaps some analogy can be explored, as has been done with the term ecosystem (a term borrowed from biology and the natural sciences to the social sciences).

LRIs for social welfare -topic (Topic 2) focused on strategies of law, specifically how different modes of regulatory knowledge can shape regulatory innovations. Different regulatory instruments and strategies were discussed as well. LRIs in the different levels and networks of actors and phases of the regulatory life cycle (Topic 3) covered roles and issues emerging in global and local networks.

New innovative regulative strategies and tools like default design, sandboxes and nudge were discussed as possible tools of new governance approaches to regulation. Process standards compared to traditional product standards were seen more innovative as they allow regulates develop most innovative way to comply the standards.

Further research is needed in the area of legal innovations and knowledge management research: We found out that public law-makers do not have all the expertise needed e.g. for drafting law in the context of the fast changing technology, they need to have knowledge exchange with the industry representatives which may take place e.g. by actively networking with them. Public law-makers may also deliver law-making powers to industry and actors of civil society (self- and private regulation) or combine public- and private regulation (co-regulation). Understanding the system of implementation and

diffusion of LRIs need active exchange of knowledge between the regulator and regulates – these could be topics for research in future.

### **Abstract**

Global warming and resource depletion lead ports worldwide to define new strategies for reducing their environmental impacts. The paper offers an explorative analysis of three of Europe's largest and most polluted ports - Rotterdam, Antwerp, and Hamburg - describing how those ports address the sustainable challenge. Particularly, the analysis is beneficial to decline a recurrent concept, i.e., green port. The concept has been developed to increase environmental awareness and refers to a set of actions describing how the port balances the ecological footprint by economic benefits. Key actions to be sustainable often are mainly attributable to green technology adoption. Instead, the paper focuses on how ports act to be green. Is a green port a port that adopts green solutions for improving operational performance, or does it develop green solutions and guide the green strategy

with and for the entire local area? Results show that ports, in addition to adopting intelligent and digital solutions that improve ports' activities, they act as innovation hubs, building an innovation ecosystem that leads their green transition.

**Keywords** – Green ports, ports, sustainability, innovation ecosystem, innovation

**Paper type** – Academic Research Paper

## 1 Introduction

A green port results from a sustainable long-term strategy adopted by an entire port infrastructure, therefore, by the set of actors involved in port activities (Chang and Wang 2012; Ng et al. 2013; Li et al. 2011). The strategy aims to realize the development of sustainable port infrastructure focused on reducing negative environmental impacts (Pavlic et al. 2014). A green port is a valuable strategy, as ports must counter the adverse effects of pollution from the ship and cargo handling operations, congestion from using the hinterland transport network, and the negative effects of infrastructure developments (Lam and Van de Voorde 2012). Due to the emission control policy, ports must find a way to adapt and modernize port facilities; otherwise, they will lose their cargo, business volume and competitive position in the market. For instance, during shipping, ports operators emit pollutants such as CO<sub>2</sub>, SO<sub>2</sub>, and NO<sub>2</sub>, to reduce their value new advanced technology should be applied to transport equipment to increase fuel efficiency and reduce fuel consumption (Zhen, Zhuge and Wang 2020) on the condition that also new investment in technology and modernization must comply with the new "green" standards. Green technology represents the core tool for implementing ports' sustainable solutions. The more the port adopts technology labeled as green, the more it is aligned with environmental practices, regulations and recognized as green. However, green technology is not a magic bullet to transform a port into a green port. Technologies should be integrated with the local territory, adopted by stakeholders involved, and sometimes ad hoc developed since they affect the environment in and out of the ports' boundaries. In this term, adopting a sustainable strategy means knowing how to involve and engage a wide stakeholder network (industries, production, markets, citizens, and public authority). A green port is not only a deal of port authority and users that should "develop and operate proactively and responsibly, based on the economic green growth strategy" (European Commission, 2014; Twrdy and Zanne, 2020) it

should involve as many stakeholders as possible. Acciaro (2015) offers an avant-garde definition of green ports, integrated with a much more systemic view of ports: "green ports are those ports engaging in the proactive development, implementation, and monitoring of practices aiming at reducing the environmental impacts of the port at local, regional and global levels beyond regulatory compliance. They engage in innovation and research intending to balance environmental challenges with economic performance". This definition is not far from the view of ports as ecosystems. More and more academic contributions look in fact, at the port no longer as a silos infrastructure but as a sort of system well integrated with the surrounding environment that acts as a link among the social, economic, environmental, and spatial matrix of a region (Chen et al. 2010; Jansen et al. 2021). According to Bichou (2009), a port acts as an economic strategist since it participates in regional economic policy and planning initiatives in the region; it creates links among the social, economic, and environmental of a region, and actively engages and provides the rationale for other local stakeholders to contribute to regional development efforts. Verhoeven (2010) also stresses the port's ability to augment regional opportunity in terms of innovation, technology, and idea, considering the port an enabler of economic dynamism. In this way, considering modern environmental and digital transition challenges, the port might be a lighthouse for local innovation development and not just an adopter. More precisely, recent papers refer to innovation ecosystem concepts to explain how ports develop digital systems to exchange information and knowledge (Kapkaeva et al. 2021; Gerlitz and Meyer 2021) or facilitate start-up creation (Witte et al. 2018). What has been theorized, suggests that rather than adopting green technology and green practices ports may be fully engaged in the sustainable mission creating an innovation ecosystem around sustainability. To test this hypothesis, we conduct an explorative analysis investigating three of Europe's ten most polluting ports (Rotterdam, Antwerp, Hamburg) according to the T&E (2022), analyzing how they react to be green. Our research questions are how do ports address the sustainability challenges? How are they engaged in green solutions: do they adopt or develop green innovation? A multiple case study methodology (Yin, 2009) supports our purpose. We plan to obtain primary data through interviews with ports and local stakeholders; however, currently, we collect secondary data through the official websites of ports, articles, and papers in academic databases and social media such as youtube and Twitter. Preliminary results confirm ports may act as green port ecosystems, developing green

innovation to address the sustainability challenges. They play the role of innovation hubs that lead the sustainable transition of the local area and their global networks.

This paper provides an examination of green ports adopting the lens of the innovation ecosystem. It discusses best practices that may be extended to other traditional industries that are forced to be engaged in sustainability, illustrating how they can do and which benefits gain in adopting the innovation ecosystem approaches. Furthermore, the paper enlarges the ecosystem perspective in evaluating the sustainability behaviors applied by networks of organizations.

## **2 Theoretical Background**

### **2.1 Green Ports**

With the development of environmental legislation accompanied by increased public awareness of environmental issues such as global warming and resource depletion, the port's sustainability concept (Woo et al., 2018) is becoming more critical. The main reason the greening of the maritime transport sector and ports has a vital impact on the environment is that more than 80% of global trade volume is carried out by sea (UNCTAD, 2021). In addition to being the center of an important economic activity, ports attract attention due to their environmental impacts, and new strategies are developing to reduce these environmental impacts. These vital requirements have led to the emergence of the "green port" concept. Thus, the "green port" concept was developed to increase environmental awareness. When the idea of green port first emerged, it was defined as "a new ideology for the sustainable development of the port sector and referred only to the ports themselves, which balance their environmental footprint with economic benefits" (Żukowska, 2020). Subsequently, the organic combination of port development, resource utilization, and environmental protection, the green port began to refer to the port, which is characterized by a healthy ecological environment, reasonable use of resources, low energy consumption, and low pollution (Wan et al. 2018; Chen, 2009). Therefore, with all these definitions and concepts, it can be deduced that the roots of the green port concept are based on the triple bottom line principle, which includes social, economic, and environmental goals from a microeconomic standpoint (Elkington,1997). By its broadest definition, "green ports" can be defined as ports concerned with the

proactive development, implementation, and monitoring of practices aimed at reducing the environmental impacts of the port at local, regional, and global levels (Acciaro, 2015). This definition states that ports can be associated with ecosystems. Haralambides stated (1997) that a port provides a vibrant networking platform for regional development where efforts to sprout innovation, cluster formation, community engagement, environmental protection, and social capital increase, contributing to regional and national economies (Sakalayan, Chen, and Cahoon, 2017). In addition to environmental issues, the world's ports have to cope with technological, economic, and social problems and developments (Ravesteijn, Liu and Yan, 2015). Ports are inherently complex systems that require integrating and balancing technological, environmental, economic, institutional, and political considerations to achieve desired goals and meet many community needs (Abood, 2007). Therefore, it is inevitable to include all stakeholders of the ecosystem. It has been determined that different approaches have been used to analyze green ports in the literature. In the past, port development and operations took a regulatory-oriented approach. However, today, ever-increasing growth trends have raised concerns about declining consumption of resources, rising costs, and environmental and quality of life impacts. These concerns have required a more holistic approach and adaptive management built around a self-sustainability framework (Abood, 2007). Abood (2007) proposed a sustainable green port development and operations method. LEED (Leadership in Energy and Environmental Design) covers six categories; Sustainable Site, Water Efficiency, Energy & Atmosphere, Materials & Resources, Indoor Environmental Quality, and Innovation. If a project scores up to 26 (category scores range from 5-17) is certified. In another study, green ports were categorized into resource management, environmental construction, and environmental quality. The former includes material selection, waste management, water resources, energy use, and transportation. At the same time, the latter covers environmental quality in ports, carbon dioxide emissions, water quality, land use, and ecological management (Maritz, Shieh, and Yeh, 2014). The researcher used an analytic hierarchy process for crucial success factors in Green Port. A hierarchy process performed with the geometric mean of relative importance between paired elements presented the consistency ratio revealing the consistency of the expert's decision. According to these metrics, the focus on being green is on solutions and technology that enable port to reduce its impact on the environment and not on how it reaches these goals regarding network and strategies. Furthermore, the attention is on

the responsibility of the green strategy and consequently of green performance is to port authorities that design, develop and monitor the sustainable plan (Lirn, Jim Wu and Chen, 2013), neglecting the behaviors of other actors.

## **2.2 Port as innovation ecosystems**

During the last two decades scholars are looking at the port no longer as a silos infrastructure but as a sort of system well integrated with the surrounding environment that acts as a link among the social, economic, environmental, and spatial matrix of a region (Chen et al. 2010; Jansen et al. 2021). According to Bichou (2009), a port acts as an economic strategist since it participates in regional economic policy and planning initiatives in a region. It creates links among an area's social, economic, and environmental and actively engages and provides the rationale for other local stakeholders to contribute to regional development efforts. Verhoeven (2010) also stresses the port's ability to augment regional opportunity in terms of innovation, technology, and idea, considering the port an enabler of economic dynamism. According to Acciaro (2015), ports are engaged in innovation and research to balance environmental challenges with financial performance. Recent papers refer to ecosystem concepts to explain how ports should change how to collaborate and involve stakeholders to cause economic and environmental benefits for all actors involved and for the local area (Carpenter and Lozano, 2020). An ecosystem creates, integrates, and expands the value involving different stakeholders. The broader involvement ensures the inclusion of several dimensions, such as environmental, technological, legal, economic, governance, and social, enabling the ensemble of actors to address interdisciplinary issues and solve problems (Audretsch et al., 2019). Since ports are called upon to manage multiple and interdisciplinary issues to address sustainability challenges, the ecosystem approach may help them adopt a wider vision, align different economic agents (ports and their hinterlands), and impact the local area (Gerlitz and Meyer, 2021). Literature that merges the ecosystems approach with ports management proposes different ecosystems; each has the purpose of bringing together actors as well as information and knowledge to reach the port's sustainable goal. De Langen, Sornn-Friese, and Hallworth (2020) suggest the business ecosystem configuration. They propose a view of "*ports as localized business ecosystems in which individual companies strongly depend on the development of the ecosystem as a whole.*" Their idea of the ecosystem is

focused on creating customer value and involving all actors involved in delivering a specific product or services linked to the port's activities - cargo handling, ships consignment, passenger transport, stowing, and dredging. Gerlitz and Meyer (2021) propose a service ecosystem configuration. They suggest ports (mainly small and medium ports) should have service-centric offers to lead the environmental and digital transition. Ports should systematize the port's network resources and satisfy the multilevel needs of their customers. Clients that are at the same time resource providers refer to four domains: institutional, technological, social-environment, and market; therefore, those clients may require services related to norms and code of conduct, technology, environmental monitoring, and access to investment. These listed are an example of a set of services offered by a port service ecosystem that enables the development of a coordinated port community. Kapkaeva et al. (2021) describe the port of Hamburg as a (maritime) integrated system service supported by an IT and digital system that enables the transparent exchange of information between all stakeholders in the supply chain. The ecosystem concept expressed by Kapkaeva et al. (2021) is closer to the digital ecosystem since the authors focus on a digital platform for exchanging information between agents involved in the port supply chain. The platform aims to create a network of actors for a safe, efficient, and sustainable door-to-door supply chain. Witte et al. (2018) envision port as an innovative and entrepreneurial ecosystem. The interaction among stakeholders is not based on industry relationships but on cooperation between port and city. The authors explore the conditions for successful collaboration between the port and city by looking at the potential of start-ups and innovation ecosystems in port cities. They neglect the sustainability purpose of ports but discuss the innovation opportunity that ports may seize if they integrate innovation start-up into their network.

### **2.3 Analytical framework**

The literature on green port and ports as ecosystems suggests that ports may follow two approaches to be a green port: adopting green technology and green practices within operational activities and/or being involved in the co-development and co-diffusion of sustainable innovation to apply in their own activities and in with o all the port stakeholders comprehended stakeholders of local port area (ecosystems actors). The last approach transforms a port into a

green innovation ecosystem. Drawing from the same literature, we propose a framework to analyze the port strategy toward sustainability. We identify three units of analysis: a) the port intended as a port authority, b) the port supply chain, c) the city and the hinterland. The coherence and the integration of sustainable purposes at the three levels confirm the ecosystem nature of the port. The objectives of their linkages may establish their common innovation purpose. To comprehend the role of the port and its key actors in adopting or developing innovations, we identify three dimensions for the analysis: operational, organizational, and strategic. The operational dimension identifies for each level green solutions implemented or developed; the organizational dimension describes how resources are allocated and organized to implement the sustainable strategy (e.g., green department or green manager); and the strategic level identifies sustainable plans and objectives fixed by the top (e.g., sustainable report, sustainable strategic plan). The more dimensions are integrated at all three levels, the more the port and its network behaviors as an ecosystem. The table describes in detail the subdimensions for each level of analysis.

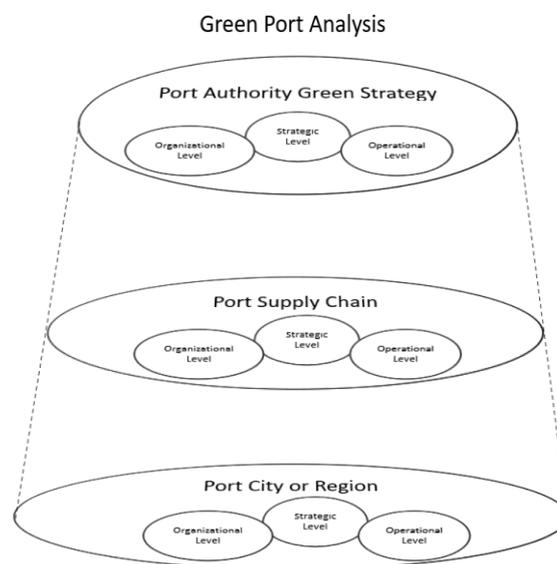

Figure 1. The analytical framework

### **3 Methodology**

We conduct multiple case study methodologies to explore how ports address sustainability challenges (Yin, 2009). The paper intends to observe replications across the cases to investigate the same phenomena concerning the adoption or development of innovation (Patnaik and Pandey, 2019). Multiple case studies are characterized by different design situations (e.g., different context settings) where the same units of analysis are examined. According to Yin's (2009) theorization, we conduct a descriptive case study design since we present a complete description of a phenomenon within its context. The goal set by the researcher is to describe the data as they occur. Shanahan, Jones, and McBeth (2018) suggest that descriptive case studies may be in a narrative form, we offer narratives covering each of the cases singly and then a cross-case analysis is shown in the discussion section (Stake, 2013).

The study aims to guide the selection of cases. We select the three most polluted North European ports to describe how ports address the sustainable challenges and if they co-develop innovation within the port ecosystems or adopt green technology. Selected cases are Rotterdam, Antwerp, and Hamburg. Collected data derived from multiple sources of information, i.e., observations, indirect interviews, audiovisual material and documents, and official reports. Various sources of information support the triangulation process and increase the quality of the findings (Eisenhardt, 1989; Yin, 2009).

### **4 Results and Discussions**

The Port of Rotterdam is Europe's largest seaport and most polluted port. It emits 13.7 million tonnes of carbon dioxide annually (T&E, 2022). Emissions are due to ships departing and entering and emissions from loading, unloading, and refueling activities. The port and the industrial area are managed by the Port Authority of Rotterdam, an unlisted public limited company, held by the Municipality of Rotterdam (approx 70%) and the Dutch government (approx 30%). The authority is fully engaged in maintaining safe and smooth shipping handling and limiting the impact of port activities on the climate and nature. At the operational level, it is directly involved in the development of several green projects: the largest green hydrogen plant; the longest Green and Digital Corridor; Nature 2000 to transform Rotterdam into the Wild Port of Europe, Porthos for the collection and transport of CO<sub>2</sub> in the Rotterdam port; moreover

it supports and host relevant green project such as the Neste biorefinery; and it applies various technologies to improve their activities such as the Data Safe House, the acoustic monitoring sensors. The executive board affirms:

*"We act as an entrepreneurial developer, matchmaker, facilitator, driver, director, investor, and initiator. The Port of Rotterdam Authority acts as the initiator for the development of the expansion of energy infrastructure for hydrogen, heat and CO2 . We establish connections with partners, provide room for business locations and, where necessary, initiate investments. In addition, we are working with partners to expand our position as a production location in the value chain of future-resilient, sustainable activities".*

At the organizational level the port of Rotterdam has a dedicated department to the "Strategic Environment Management" following these projects and maintain contact with key stakeholders which are port clients, employees, local residents, the public and suppliers. The Executive Board affirms:

*"Engaging in enduring relationships with parties in our environment is widespread practice at the Port of Rotterdam Authority. [...] We talk to our stakeholders about our long-term strategy, policies, goals, and priorities. Engaging in dialogue, with a genuine interest in stakeholder interests and a commitment to achieving a win-win situation [...] We worked with our stakeholders on goals linked to the three focal points of our strategy: Climate and Energy; Safe and Healthy Environment; People and Work".*

At a strategic level, the port has a clear strategy for transforming the port of Rotterdam into a sustainable and green port. The strategy is based on four pillars: efficiency and infrastructure, a new energy system, a new commodity and fuel system, and making logistics chains more sustainable. Efforts in these areas are reflected in three focal points of the strategy: a) accelerating sustainability in the port (e.g., science-based targets initiative; concrete project and partnership); b) smart partner in logistic chains; c) entrepreneurial and effective organization (e.g., multidisciplinary teams). Two of the focal points of the strategy extended the sustainable vision across port boundaries, i.e., the entire port supply chain and the local and regional area: " We are collaborating successfully with many regional and supply chain partners to develop new, circular value chains." Concerning the supply chain, the port of Rotterdam is working to build a green corridor in collaboration with Singapore Port Authority for sustainable and efficient shipping, establishing a broad coalition of shippers, fuel suppliers, and other companies to

develop solutions for the use of low-and zero-carbon fuels. Furthermore, it is leading the digitalization of the supply chain, requiring the adoption of specific tools that monitor emissions and shipping traffic. Portbase is the Maritime Single Window to which ships report their arrival and departure information; Routescanner is the routing function for global container transport. Both suggest transportation choices that are based in part on emissions. Concerning the local and regional area, between lines of the latest annual report is written:

*"The Port of Rotterdam Authority is a socially committed organisation that wants to make a contribution across the spectrum to the port and industrial complex, and to the liveable city of Rotterdam and its residents".*

The Port of Rotterdam, Rotterdam City Council, Erasmus University Rotterdam, Rotterdam Partners, Rotterdam Festivals, Rotterdam Topsport and Erasmus MC work together for a collective city brand: "Rotterdam Make it Happen", since 2014. The port of Rotterdam is one of the main actors who provides substance to the city brand "with innovation and entrepreneurship; by collaborating and connecting; by moving ahead of the crowd and having the courage to explore new avenues; by thinking about sustainable solutions; by discovery and action". It contribute to three city mission: Smart city; Healthy city and Circular city and it is involved in common project with the city municipality such as "Bluecity", projects on material reuse, the realisation of the biofuel cluster and the implementation of the project "Hydrogen watertaxi". Furthermore, the port plays a key role in increasing the innovation rate of the area. The port hosts one of the major specialized accelerators, "PortXL," and contributes to testing innovation, implementing new technologies, and linking established firms to up-and-coming players.

The Port of Antwerp-Bruges is the second largest port in Europe and the second most polluting in Europe, emitting 7.4 million tonnes of CO<sub>2</sub> annually (T&E, 2022). The port is managed by the Antwerp-Bruges Port Authority, a public law limited liability company with the City of Antwerp and the City of Bruges as its shareholders. Even though it is criticized due to the damage it causes to the environment, it develops and implements essential strategies to contribute to the environment, humanity, and the economy. The mission is *"a home port that acts as a lever to create a sustainable future."* The Port of Antwerp is working to be the major green energy hub and support a sustainable future. At the operational level, the port is involved in several projects, and all are managed in collaboration

with the area's largest private companies. As the CEO of Port of Antwerp reported:

*"We are joining forces with seven leading players from the energy and chemical sectors. Together with Air Liquide, BASF, Borealis, ExxonMobil, INEOS, Fluxys, and Total Energies, we are working on innovative CO2 reduction. The project Antwerp@C can potentially reduce the CO2 emissions in Antwerp by half between now and 2030".*

For instance, Antwerp@C is one of the most important projects transforming the port into an innovative energy hub. However, the port is longtime engaged in climate and energy transition. It leverages the residual flows of the Antwerp chemical companies to commercialize energy and supply it to buildings in the city and the port, through the project named "Antwerp-North Heat Network." The project is again led in collaboration with industry, the government, and other social actors. Its sustainable strategy is also supported by incorporating the most environment-friendly technologies available on the market for executing their ordinary tasks, e.g., a tug powered by hydrogen "Hydrotug"; "Hydroville" shuttle used for sustainable commuter transport within the port area; shore power to mooring ships. At the organizational level, the port has dedicated managers who deal with the sustainable mission: a sustainable transition manager, a program manager hydrogen and a program manager fuel transition. The organization, as planned, is coherent with the port strategy to be *"an active pioneer of the sustainable hydrogen economy, [...] an Europe's leading import hub for green hydrogen"*. The port supply chain is managed to spread a sustainable vision and practices. Several smart technologies are used to detect what is happening in the port: a digital twin to control which ships are in which locks and docks, how much energy are our wind turbines producing, smart sensors, and cameras. Jacques Vandermeiren, CEO Port of Antwerp-Bruges, stated:

*"Port of Antwerp-Bruges is aiming to build a digital nervous system to manage the port remotely fully. By working with innovative partners and opening up the port as an innovation platform, we are making our port smarter, safer, and more efficient."*

The port is well connected to the city of Antwerp and helps to contribute to the screening, start-up and scale-up of innovative start-ups. The port hosts the port area Next Gen District, an incubator for innovative, sustainable, and circular chemistry. Piet Opstaele, innovation manager at the Port of Antwerp affirmed:

*"The Port of Antwerp is an open innovation platform where unprecedented opportunities are offered to test and implement innovative solutions. If it works here, you can roll it out all over the world."*

The port offers in fact a space to test new technologies and circular demo projects that have outgrown the lab on a larger scale and in an industrial environment before proceeding to commercialization.

The Port of Hamburg is Europe's second-largest container port and the most important transit seaport (Shakeel, Kirichek, and Chassagne, 2020). Parallel to this, the Port of Hamburg is the third most polluting in Europe, and it is associated with 4.7 million tonnes of CO<sub>2</sub> each year (T&E, 2022). The Hamburg Port Authority owns most port properties and deals with the operation and development of the port. Its mission is *"ensure maximum efficiency, safety and economy in all areas of the port infrastructure, looking for innovative approaches to allow us to sustainably exploit the growth potential of the port"*. At the operational level, the port is involved in applying intelligent solutions to guarantee a smooth, efficient port operation and protect the environment. Many innovation and digitalization projects are implemented by the Hamburg Port Authority to support green strategies. With the smartPORT philosophy, the Hamburg Port Authority promotes sustainable economic growth and the best possible benefit for customers and people in Hamburg while minimizing environmental impact. The SmartPort Philosophy comprehends that SmartEnergy is composed of actions on renewable energies and shore power from renewable energies. The port exploits quantities of biomass accumulated in and around the harbor area and has a transformer station of energies used to shore power. Differently from the previously analyzed ports, Differently from the previously analyzed ports, the port authority does not have a dedicated department with green responsibilities at the organizational level. The engagement in the improvement of the port supply chain is massive. The port authority explicitly recognizes its responsibility for environmental protection through environmental guidelines involving port clients and providers.

Furthermore, it provides several tools and intelligent solutions (drones, AI, VR, AR) for monitoring the flow of traffic and goods. chainPORT is a global network of logistics hubs that enables maritime players to create secure, efficient, and sustainable supply chains through innovation and digitalization. Hamburg Port Authority's chainPORT initiative creates an international community and aims to bring together port authorities, their partners, and customers to share

experiences and develop joint strategies. The Hamburg Port Authority believes that only the sharing of intelligent data systems and an open exchange will enable sustainable growth. By focusing on innovative technologies, the Authority is adopting a pioneering role in Germany on the issue of a turnaround in energy policy. The link between the port, the city, and the federal government is strong. The city is funding the expansion of the shore power infrastructure for both large seagoing and inland waterway vessels. The port authority affirmed:

*"The aim is to ensure a sustainably better quality of life in our city and is based on emission reduction."*

Furthermore, the port contributes to the city's economic development and leverages innovation and start-ups. The port host homePORT aims to give innovative and ambitious port players, science, technology companies, and start-ups the freedom to try, experiment, and collaborate with other partners and actors. For guiding the start-ups, the port collaborates with several actors such as the Authority for Economy and Innovation, Helmut Schmidt University, Technical University of Braunschweig, Hamburg Innovation, 3DStrong, DroneMasters Academy, ALFRED Maritime, Bionic Production, and so on. Start-ups are satisfied by the service offered; the CEO of 3DStrong company stated:

*"Ports enable the provision and develop important innovation infrastructure acting as innovation centers."*

Results show ports may act as green port ecosystems, developing and promoting green solutions to address the sustainable challenges. Furthermore, they play the role of innovation hubs that lead the sustainable transition of the local area and their global networks. Comparing the three case studies, we demonstrate the green port strategy reflects on two levels: the supply chain and the local area. The supply chain level means ensuring the port diffuses sustainable practices through a monitoring system of client activities. Adopting and promoting sustainable and digital value chain solutions focuses on customer value and supports clients to reach sustainable goals, guiding and digitizing their operational actions. As de Langen and Soronn-Friese and Hallworth (2020) describe, the port represents a business ecosystem at this level. Maintaining a sustainable strategy at the local level and generating a sustainable effect on a large scale transforms its role in the innovation hub. It increases its commitment to innovation projects such as big projects on the energy transition or small projects financing and hosting innovation start-ups. At this level, the port brings together the local development strategy with that of the port and those of key

private companies located in the area (Witte et al., 2018). The port leverages its existing network of actors and their respective knowledge and competencies to re-design the network for developing sustainable innovations and attract young talents and innovators to accelerate the sustainable transition. In this sense, the concept of the green port is much closer to that of an innovation ecosystem since it focuses on developing green solutions and guides the green strategy within and for the entire local area.

## **5 Conclusion**

This paper examines green ports by adopting the lens of the innovation ecosystem and discusses best practices that may be extended to other traditional industries that are forced to be engaged in sustainability, illustrating how they can do it and which benefits gain in adopting the innovation ecosystem approaches. Although definitions of green ports are frequently included in previous studies, most are often described superficially without providing much detail. In this study, we tried to explain how the green port concept evolved from past to present beyond the general definitions in the literature. The theoretical contribution of the study is not only for the development of this concept but also to reveal what sustainable green port strategies are, both in theory and in practice, with three selected case studies. From a theoretical point of view, the study presented a unique conceptual framework by interpreting the ports in light of the innovation ecosystem under the concept of the green port. Despite its valuable contribution, this study presents some inherent limitations that should be addressed in further research. First, the case study is limited to three cases. Therefore, the scope should be expanded with more case study examples. Second, only the case study was chosen as the research method; therefore, substantial secondary data were used. In future studies, using the interview method and case studies can improve research the addition of quantitative methods can strengthen studies.

## **Abstract**

The project manager must possess various skills in order to achieve the goals set in the project for which he is responsible. According to the existing literature, these managerial skills possessed by the project manager can be not only of the hard type (technical), but also of the soft type (behavioural or transversal). In order to better understand these dynamics, the aim of this research is to present the discussion about how project managers learn soft skills according to the scientific literature. The purpose, specifically, is to map and group the various articles published, from 2003 to 2022, to have an overall representation of the studies carried out.

The methodological approach used was quantitative through a literature review that took place in three phases. The main results showed that the most prominent research areas are knowledge management, the typologies of skills and the learning method and style.

**Keywords** – Management education, experiential learning, literature review

**Paper type** – Academic Research Paper

## **1 Introduction**

The way of working in organizational contexts, both public and private, is becoming more and more based on the "project" which requires the figure of the project manager within it (Cheng, al., 2005; Magano, et al., 2020). Specifically, the project manager (PM) is the person in charge of leading the group he is responsible for in achieving the project objectives (PMI, 2017) who must possess different skills (Jena and Satpathy, 2017; Liikamaa, 2015).

Thus, if on the one hand according to Boyatzis (1982) competence constitutes "*an intrinsic characteristic of an individual that leads to effective performance*", on the other according to Jałocha, et al. (2014), the project manager should possess specific managerial skills and generic skills. But while the specific skills would be those of a technical type (hard skills) essential for project management and those for working towards the achievement of the project objectives (Jałocha, et al., 2014; Ribeiro et al., 2021).

The so-called soft skills would be those concerning the behavioral or transversal aspect and which would be common to all managers, regardless of the sector in which they work (Grugulis, and Vincent, 2009; Jałocha, et al., 2014).

Thus project managers should possess behavioral skills attributable to leadership skills regarding the ability to lead, motivate and direct a team, studying

people: their behaviors and motivations (Jena and Satpathy, 2017; Moradi, et al., 2020; PMI, 2017), helping to have self-awareness and teamwork. The idea would be to work together like a basketball team, where each team member is given a specific role to play in order to successfully complete the job (Jena and Satpathy, 2017).

But the issue of soft skills that project managers should possess opens the debate on learning, i.e. on how project managers should acquire these soft skills, perhaps by following appropriate training courses that allow for a change in skills, knowledge, attitudes or behaviors (Magano, et al., 2020; Treven, 2003): focusing, for example, on improving job performance in the areas of human relations, self-awareness, problem solving and decision-making, motivation/values and general management (Burke and Day, 1986). Furthermore, questions are asked about their real value in certain working contexts and about how, specifically, the project manager's personality traits and dimensions (soft skills) can allow the projects to be carried out effectively and successfully (Creasy, and Anantatmula, 2013).

In the field of project management this theme is significant and therefore the objective of the research is to verify how the literature examines and discusses the learning of soft skills by the project manager. The purpose, specifically, is to map and group the various articles published on the relationship between learning and soft skills of project managers, in the last twenty years (from 2003 to 2022), in order to have an overall representation of the current trend of the studies carried out.

The article has been organized as follows. The adopted methodology will be presented in the next section. Subsequently, the paragraph on the main results achieved will be shown. Finally, in one section we will present the discussions and conclusions.

## **2 Methodology**

The methodological approach adopted was quantitative. The work took place in two different phases.

(1) The articles were found through the inclusion of some keywords in the Web of Science (WoS) and Scopus platforms covering a period ranging from 2003 to 2022. We queried on March 2023 the two main indexing databases (WoS and Scopus) to retrieve the main references of the literature concerning learning and project management. We employed in particular a search string including the

term "project manag\*" AND "learning" AND ("soft skill\*" OR "competenc\*"). In recent years there was an intense debate concerning which database is better (e.g., de Winter et al., 2014; Harzing and Alakangas, 2016; Prancutè, 2021). Each database has strengths and weakness, and the choice should be guided by the different research goals and the reference sphere (Falagas et al., 2008). WoS covers a wide range of disciplines, including science, social sciences and humanities. It is known for its strong coverage of high-impact, peer-reviewed academic journals and conference proceedings, but has limited coverage of non-English language publications. Scopus, on the other hand, covers a wider range of sources than WoS and includes more open access publications and more publications written in languages other than English. Since it is impossible to generate a completely exhaustive query, there are always false positive and false negative results. Scopus, for example, considers a wider time-span than WoS but with a higher rate of duplicated citation records, mainly caused by a certain lack of standardisation (Valderrama-Zuriàn et al., 2015; van Eck and Waltman, 2017). The joint use of the two sources allowed leveraging the different features they hold, widening the coverage of the surveyed research domain.

(2) The selection of articles was done through Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) by Moher et al. (2009). Figure 1 depicts schematically the different steps used in the construction of the dataset. The analyses were focused on the last 20-year literature produced in English and published on journals, books, and conference proceedings. After cleaning and filtering the two datasets obtained by WoS and Scopus separately, we merged them in one dataset and removed duplications. The result is a set of 864 bibliographic records used both for *performance analysis* and *thematic analysis*.

*Performance analysis* (e.g., Peters and van Raan, 1991; White and McCain, 1998) aim at evaluating through bibliographic data the productivity and the impact of different actors involved in a research domain (authors, institutions, countries).

*Thematic analysis*, as an approach to science mapping (Börner et al., 2003), tries instead to depict the cognitive patterns of the analysed domain, visualising the major topics in a synchronic (Callon et al. 1983) or a diachronic perspective (Cobo et al., 2011). Thus, we were able to explore the conceptual structure of the publications through thematic analysis. The textual content of publications' abstracts has been algebraically represented by using the Vector Space Model (Salton et al., 1975). After pre-processing the collection to filter not informative terms, a abstracts x terms binary matrix  $X$  with  $n$  rows and  $p$  columns is built. Each

generic element  $x_{ij}$  ( $i = 1, \dots, n; j = 1, \dots, p$ ) assumes 1 or 0 depending if a term  $j$  appeared or not in a publication's abstract  $i$ . From  $X$ , it is then possible to derive a  $p$ -dimensional terms  $\times$  terms matrix  $C$ , whose generic element  $c_{jj'}$  ( $j \cdot j'$ ) represents the number of abstracts in which terms  $j$  and  $j'$  co-occur (i.e., they are both present in an abstract). This matrix can be graphically depicted as a network, where each node represents a term, whereas each link between two terms expresses their connection (for a more detailed description see Misuraca and Spano, 2020).

Performing on this network a community detection – a method similar to clustering that group nodes in highly cohesive sub-networks – allows identifying groups of terms representing different themes/topics embodied in the collection. In particular, the walktrap algorithm proposed by Pons and Latapy (2005) showed high effectiveness in comparison with other competing proposals. The topics obtained through the community detection can be visualized in a thematic diagram, according to centrality and density measures for each topic. The measures express the participation of a topic in the organization of the domain's conceptual structure, with the centrality expressing the importance of the topic in the entire research domain and the density expressing the theme's development.

The thematic diagram can be interpreted looking at the four quadrants present in the map:

- *motor topics (I)* have higher values of centrality and density, representing the issued necessary for structuring the research domain;
- *basic topics (II)* have higher values of centrality but lower values of density, representing the issues essential for the domain and transversal to its different research areas;
- *emerging or declining topics (III)* have lower values of centrality and density, representing weakly developed or marginal issues in the domain;
- *niche topics (IV)* have lower centrality values but higher values of density, representing strongly developed but marginal issues in the domain.

All the analyses reported have been carried out by using the library *bibliometrix* (Aria and Cuccurullo, 2017) in the R environment.

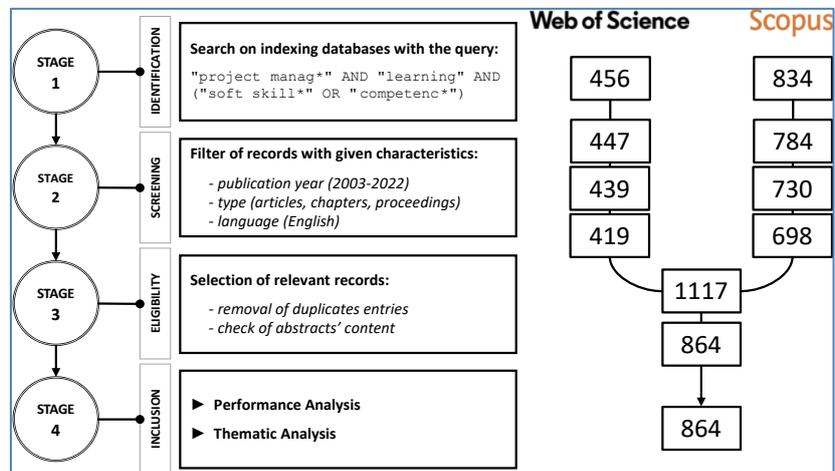

Figure 1: PRISMA flowchart with the data searching and selection steps

### 3 First results

The first results on the *performance analysis* and the *thematic analysis* revealed the following situation.

**Performance analysis.** Regarding *performance analysis* in terms of bibliographic contributions on learning and project management based on the number of authors, their nationality and the institutions involved, some significant graphs are shown below.

In particular, the scientific production of publications concerning learning and project management increased across time (Figure 2), with a growth rate of 4.84% per year. Each publication included in the collection received, on average 7.14 citation. We observed a quite low share of single-authored publications (16.97%), a very low share of publications produced by international co-authors (6.25%), revealing in this domain a strong cooperation among scholars but at a national level.

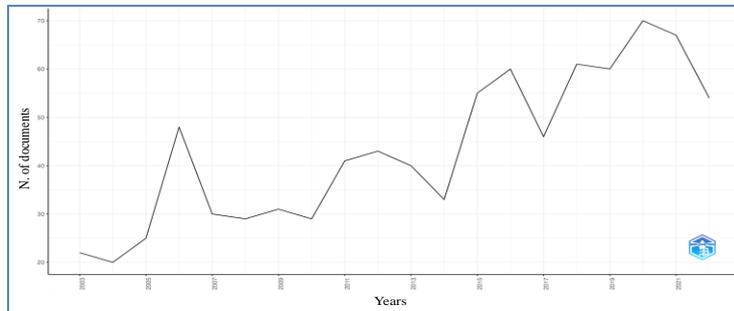

Figure 2: year-wise distribution (2003-2022) of publications included in the collection

As concern the scientific production per country, in the absence of a clear indication of the geographical localisation of publications in the indexing databases, we considered as a proxy the corresponding author’s country. In Figure 3, it is possible to see how U.S. produced the greater share of publication in the field across years. Nevertheless, it is interesting to note how Spain increased the scientific production after 2013, with a growth rate greater than other leading countries like United Kingdom, Germany, and Australia.

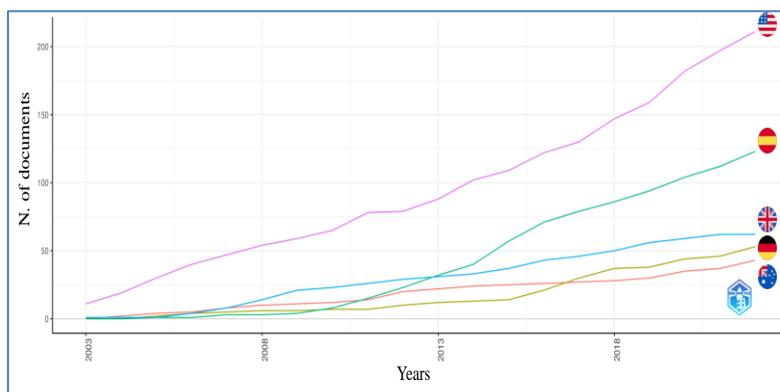

Figure 3: year-wise distribution (2003-2022) of publications for the top-5 countries

Observing more in-depth the social structure of the research domain, we can highlight which were the top-5 leading institutions in the last 20 years. As previously stated, we had to consider the corresponding authors’ affiliations as a proxy of the institutions. In accordance with the findings reported above, we found in the first positions four U.S. universities and one Spanish university (as depicted in Figure 4). Interestingly, both DeVry University and Illinois Tech (3rd and 4th position, respectively) are located in the U.S. State of Illinois.

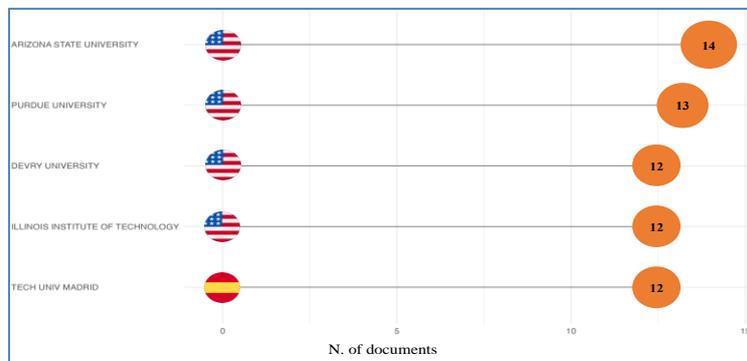

Figure 4: top-5 leading institutions in the analysed collection (2003-2022)

At an individual level, surprisingly, the most productive authors were not located in the top-5 leading countries neither in the top-5 leading institution. As showed in Figure 5, we found two authors from Romania (C.N. Bodea and M.-I. Descalu (2010), from the Bucharest University of Economic Studies and the Polytechnic University of Bucharest, respectively), two authors from Portugal (R.M. Lima and D. Mesquita (2020), both from the University of Minho), and one author from Norway (B. Hussein (2021) from the Norwegian University of Science and Technology). The presence of authors from the same country and/or institution confirm, as claimed above, the strong cooperation among authors at a national level. This aspect can be also highlighted looking at the collaboration networks of the authors (Figure 6), in which some research groups more frequently occurrent can be noted.

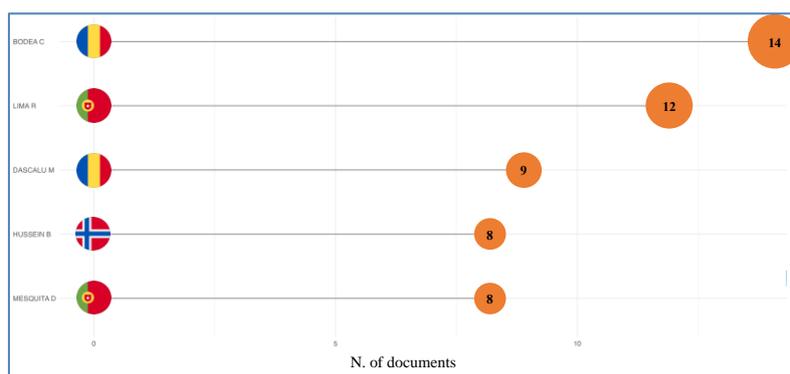

Figure 5: top-5 leading authors in the analysed collection (2003-2022)

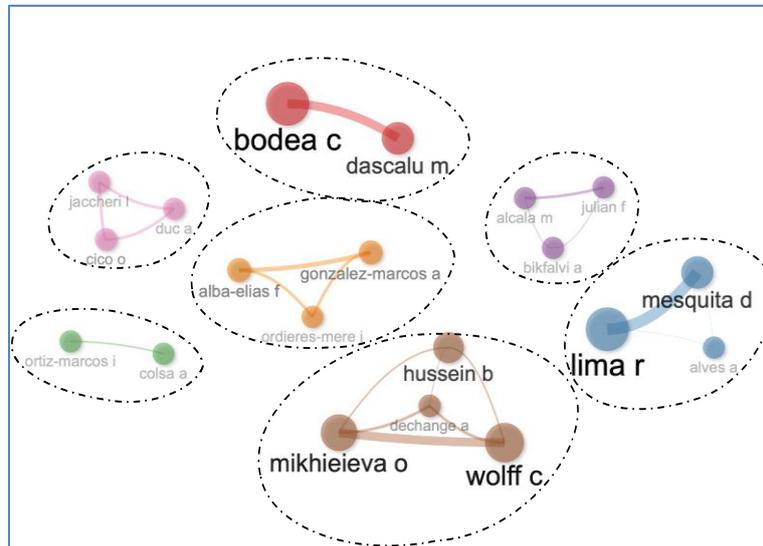

Figure 6: authors' collaboration in the analysed collection (2003-2022)

The impact of the scientific production in the field of learning and project management may be evaluated by considering the most important sources (also considering the *h*-index and the other metrics used in the indexing databases to quantify the relevance of a journal or of a conference) and the most important publications in terms of total number of citations. In Figure 7, the top-10 sources appearing in the analysed collection are graphically represented.

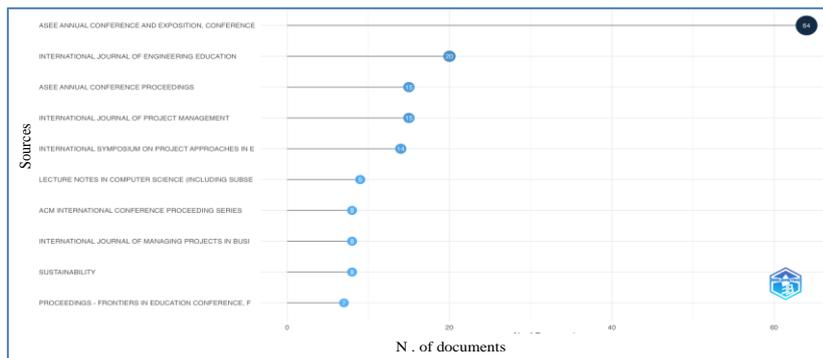

Figure 7: top-10 sources in the analysed collection (2003-2022)

As concern the most relevant publications included in the collection, it is possible to consider the total number of citations (Figure 8) as a measure of the impact of each contribution in the surveyed literature.

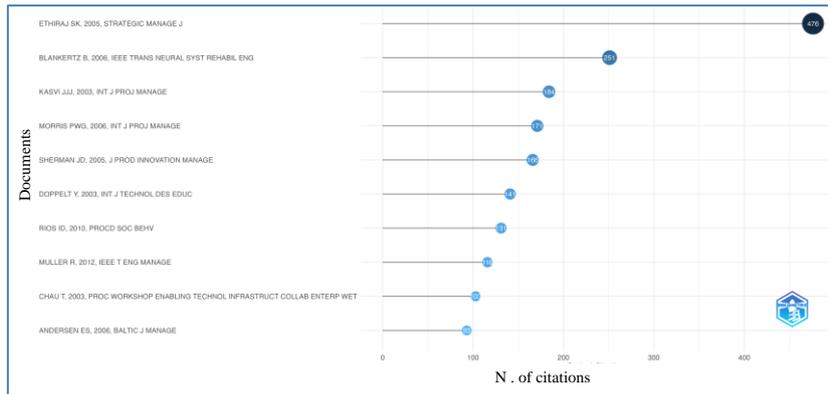

Figure 8: top-10 most relevant references in the analysed collection (2003-2022)

**Thematic analysis.** Figure 9 graphically represents the topics debated in the learning and project management literature under investigation, highlighting the different kind of issues.

The following paragraph highlights some observations regarding the main topics raised.

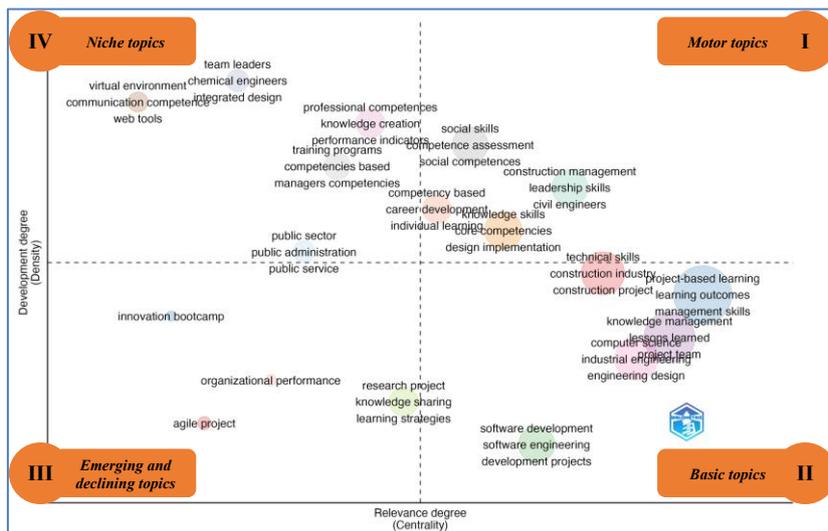

Figure 9: thematic diagram of the topics debated in the analysed collection (2003-2022)

#### **4 Discussion and conclusions**

Analysing the relationship between soft skills project manager and the learning process is quite useful to discuss how literature was focused on this important issues and to understand which are the main issues that emerge around this topic.

Specifically, three main research areas emerge from the literature review: 1) knowledge management; 2) the typologies of skills; 3) the learning method and style.

Concerning the first research area, surprisingly in many articles is possible to find studies or implications related to the knowledge management field. Beyond the label "knowledge management" there are other expressions such as knowledge creation, knowledge sharing, lesson learned that could be easily associated with the complex KM area. What is particularly interested from our point of view is the idea that acquiring soft skills is part of more complex and broader strategy that affects the entire organization. Referring to knowledge management, in fact, implies reasoning about all the strategic choices organizations make, in order to facilitate the different goals to guarantee a better and structured way to use knowledge inside the organization. If this is true, then, the learning process of soft skills project managers, become a complex process that involves the most important part of the organizations.

The typologies of skills are another central category that emerges from the data analysis, in different ways and forms. First of all, there are some general categories such as managerial competence, or social skills that refer to all the behavioural competences that are more and more important for project managers. Then it is possible to individuate some specific competences that could be considered particularly relevant. For example, team management competencies (such as leadership) or communication skills. While the first group is team specific, the second one reminds us that the role of project manager is not just about managing people in a team, but also dialoguing with other external stakeholders. And maybe this implies a more responsible role for project manager, that following a more strict project management language, becomes project sponsor or project coordinator. In this sense it would be very interesting discussing about a possible role's evolution maybe due also to the spread of project management or projectification in general. The last research area is related to the learning style and method and data show how the issue of learning

is considered at a general level, finding expressions such as learning strategies and learning outcomes. Surprisingly there is not any reference to the concept of experiential learning that could be considered as one of the prominent methods to reflect on behavioural competences. The only concept that could be associated to the behavioural dimension is the competence assessment. This is clearly an important issue that involves the role of assessment both in the selection and in the education process. It would be interesting to discuss how the assessment is investigated and if there are some examples of outdoor training or other original forms to work on soft skills. This is really a key point because many consultants are suggesting to adopt this kind of learning program to give project managers the possibility to experiment different soft skills in situations outside of the job contest.

Our paper is a first attempt to open up a debate on the relationship between learning and soft skills for the project manager, identifying the research areas to develop in order to contribute to a critical managerial debate.

## Abstract

This article investigates the link between technology, digitalization, and knowledge management using digitalization and knowledge management to achieve sustainable development. In addition to the increased interest in knowledge management for implementing sustainability, technology, digitization, and knowledge management have an important influence on promoting sustainable economic systems. Knowledge resources must be exploited and managed, and a knowledge management system must be created to solve sustainability issues. Digital technologies such as Big Data are particularly significant in the context of sustainability since they provide improved decision-making processes. Furthermore, using digital platforms facilitates inter-organizational communication and information exchange by facilitating the exchange of best practices and collaboration. Using bibliometric network data analysis methodologies, we propose exploring the links between technical development, digitalization, and innovation in knowledge management for sustainable growth. The "core" themes covered in the literature will be determined using bibliometric analysis based on network-based methodologies, specifically community-detection algorithms. This information will be optimized using ensemble methods, and any possible bias from the many algorithms will be eliminated.

The relevant results of this work emphasize the role of new technology, innovation, and digitalization, all playing a vital role in the applicability of these findings to sustainability. Organizational reforms and internal strategic approaches are required to apply these technologies effectively and sustainably. This study adds to the expanding body of research on sustainability, knowledge management, and digitalization by shedding light on

---

<sup>1</sup> We thank two anonymous referee for their comments and suggestions.

the interrelationships between these factors and emphasizing the significance of adequately managing knowledge resources to address sustainability concerns. Five essential organizational performance and sustainable growth principles have emerged: knowledge management, sustainability, innovation, intellectual capital, and corporate social responsibility.

Additionally, the analysis emphasized the significance of leadership in knowledge management processes. Several clusters also highlighted the significance of promoting sustainable growth through collaboration, innovation, and knowledge transfer. Small and medium-sized firms (SMEs) may benefit from intellectual capital and open innovation initiatives to better their knowledge management procedures and support sustainable growth. Growth and competitive advantage can be attained if these concepts are managed effectively. A firm's success depends on its leadership and ability to share and transfer information. Therefore, the sustainable growth of a business needs a knowledge management process that is backed by a strategic approach and incorporates knowledge exchange and transfer in its design.

## 1 Introduction

While sustainability has become increasingly complex over the last few years, there is a growing interest in knowledge management to implement sustainability (Martins et al., 2022). Technology, digitalization, and knowledge management significantly promote sustainable economic systems (Castagna et al., 2020; Fortuna et al., 2023; Fortuna et al., 2022). Furthermore, to meet sustainability challenges, organizations may benefit from utilizing and managing their knowledge resources more effectively to find solutions to those challenges properly (Awan et al. 2020, Vartanova et al. 2021). Therefore, implementing a knowledge management system is crucial (Ray 2008). In order to do that, collecting, storing, and analyzing vast amounts of relevant data is essential, for example, in promoting sustainable process innovations (Nwankpa et al. 2021). So, the advent of Big Data and other digital technologies can be considered powerfully relevant to knowledge management processes. After all, they allow an improvement in decision-making in a context of sustainability because they also promote the rise of new analytic approaches critical to the discovery of relevant data patterns (Schmelzer, 2023, Kibria et al., 2018, Allam & Dhunny, 2019, see also Siddiqa et al. 2017 for a survey of big data storage technologies).

In addition, the new digital platforms also facilitate communication and information sharing between different organizations (Möhlman & Jarvenpaa 2019), which can also positively impact sustainability by enabling the sharing of best practices and collaboration (e.g., to implement processes and products better). It is also possible to better monitor sustainability practices and promote accountability and transparency in processes. Sustainability is in some ways more strongly impacted by knowledge management technologies (Hossain et al. 2022).

The purpose of this article is to explore at an exploratory level the relationship between technology, digitalization, and innovation in knowledge management for sustainability (see also Sanchez Ramirez et al. 2022). This is done by using bibliometric data analysis techniques of the relevant literature in order to examine the different relationships between these elements (see Donthu et al. 2021, Drago et al. 2021). There is increasing use of bibliometric analysis techniques to review the existing literature and identify key topics and relevant results published in the literature (see, for instance, Naciti et al. 2022). In addition, bibliometric analysis is increasingly applied to examine any significant gap found within the literature to identify the most relevant topics and results.

More specifically, we will consider network-based approaches to bibliometric analysis (see, for instance, Abdullah & Mahmood 2020) to identify most specifically the "cores" of the literature in terms of topics by using relevant techniques and algorithms community-detection-based (Fortunato 2010). The communities are groups of co-occurring keywords on the articles, strongly connected. In this way, there is a clear indication of relevant "core" concepts discussed in some papers which are part of the literature. The keyword members of these communities, however, are not strongly connected to each other different member of other communities (Fortunato, 2010; Drago et al. 2021). Community detection algorithms aim to extract these basic data patterns from the literature. Nevertheless, the results can depend on the algorithm considered, which can be biased by existing data structures (Leskovec et al. 2010). The advantage of using an ensemble methodology (see Dahlin & Svenson 2013, Drago 2018; Drago & Balzanella 2015) is the possibility to optimize the information, which is possible to obtain from these techniques in terms of relevant, robust groups to eventual occurring biases of themes and relationships that emerge from the different topics.

The practical relevance of these results is high due to the importance of new technologies, innovation, and, at the same time, digitalization in knowledge

management, and it should not be underestimated. In addition, these results demonstrate how knowledge management contributes to sustainability (Ochoa-Jiménez et al. 2021, Martins et al. 2022, Hossain et al. 2022, Weina & Yanling 2022, Tajpour et al. 2022).

However, these technologies require adequate organizational changes and internal strategic approaches, so it is necessary to simultaneously develop adequate changes in organizational issues in the company and new business models (Parida et al., 2019, Ruggieri et al., 2022). These changes may or may not lead to a successful implementation of these technologies in a sustainable manner. The article's organization is as follows: in the second section, we will present and discuss the dataset used. In the third section, we will present the results in the first paragraph. Then we discuss the practical implications. Finally, in the fourth section, there are the conclusions.

## **2 Data and Methodology**

Quantifying the amount and quality of academic publications using bibliometric analyses of bibliographic data is possible (Donthu et al. 2021, Drago & Aliberti 2019, Gatto et al. 2022). Using these analytics, authors, institutions, and publications may better comprehend their place among reference research disciplines (Li et al., 2021). Furthermore, bibliometric data may be used to identify the key trends in a particular area of study or assess the influence of a particular author on the academic community (Kiyomi et al., 2022). In this respect for academics, publishers, research funders, and government organizations, bibliometric studies are beneficial for objectively assessing the quality and effect of research. Also, it is crucial to conduct bibliometric studies in economics since they may reveal whether economic variables (for instance, economic activity and innovation) can have an impact on other relevant variables and so the existence of robust economic relationships in a good or negative way (Kumar et al. 2022). Bibliometric analysis may be considered to assess research publications in scientific and technology domains, such as start-ups and successful corporations (see, for instance (Damayanti et. 2023). Information like this may also assess whether policies supporting innovation and research produce the expected results, such as rising productivity and competitiveness (Akbari et al., 2020). Moreover, bibliometric evaluations may pinpoint high-priority research topics and chances for corporate and academic institutions to collaborate, allowing the

knowledge economy to reach its full potential. So the research question explores the relationships between technology, digitization, and innovation in sustainable knowledge management.

The data used comes from the following query:

```
TITLE-ABS-KEY ( technology OR digitization OR innovation AND "Sustainable Knowledge Management" OR "Sustainability" AND "Knowledge Management" )
```

The query was performed the 14\3\2023 using Scopus obtaining 787 publications which are the bibliometric database considered in the analysis. In the context of bibliometric analysis of publications, Scopus is often used to retrieve data for bibliometric analyses of journals and books to perform those analyses (Al-Khoury et al., 2022). Scopus, one of the most popular databases owing to its broad coverage of academic publications, provides scholars with access to a comprehensive database of scholarly publications. This makes Scopus the database of choice for researchers (Ismail et al., 2022). The methodology considered in this work focuses on network analysis based on the co-occurrences of the specific keywords identified (see Drago et al. 2021). In this respect, the analysis is based on a community detection approach in which we can identify some relevant communities of keywords that are maximally connected in the considered literature covered by the bibliometric dataset.

Furthermore, the ensemble approach using multiple correspondence analysis proposed by Drago (2018) allows for robustifying the different results considering different relevant approaches and algorithms. Finally, a comparison with a methodology based on multiple correspondence analysis to visualize the different keywords in a conceptual structure map is proposed to analyze the sensitivity of the results considering different methods. The approach based on multiple correspondence analysis (Greenacre & Blasius eds. 2006) is also based on a hierarchical clustering helpful approach to identify the most relevant groups of concepts which can be extracted from the literature (Aggarwal & Reddy 2016).

R is the programming language used to perform the analysis where the packages used are *bibliometrix* (Aria & Cuccurullo 2017), *igraph* (Csardi & Nepusz 2006) and *clValid* (Brock et al. 2008).

### 3 Results

#### 3.1 The Network-based ensemble community detection analysis

Based on the bibliometric analysis, the results: can be described as follows: first of all, we have computed the network of the key co-occurrences (figure 1). Then, we can observe the relevance of five relevant concepts from the network of crucial co-occurrences. The first relevant group of linked concepts is based on the core relationships between knowledge management, sustainability, innovation, and intellectual capital (Salehi et al., 2022).

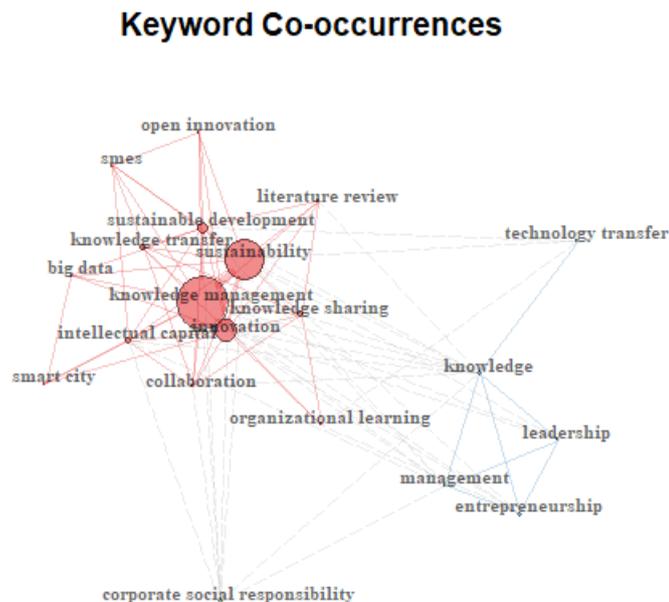

Figure 1. Network visualization of the keyword Co-occurrences

A second important concept is related to corporate social responsibility, where a third is related to technology transfer, and finally, a fourth to organizational one: knowledge management, leadership, and entrepreneurship (see in this sense, for instance, Suri Babu et al. 2008, Politis 2001). These different relevant concepts (or network communities) extracted are assessed considering a more specific community detection analysis based on the ensemble of different methodologies, and the results are visualized in figure 2. First, the different economic concepts

are expressed more clearly after a formal cluster analysis considering the coordinates of a multiple correspondence analysis. In this respect, we identified 4 clusters based on a group of relevant keywords and 6 clusters on single (important) keywords considered singularly. Next, we clarify the original network's relevant concepts, observing that a first cluster based on group keywords shows important relationships in the literature on knowledge management, innovation, sustainability, and collaboration (see Johannessen et al.; An et al. 2014). Then the second cluster can be observed based on knowledge transfer and sharing. In this sense, we can identify knowledge management's relevance in sustainability, collaboration, and innovation based on knowledge transfer and sharing (see also Widyasari & Nasution 2022).

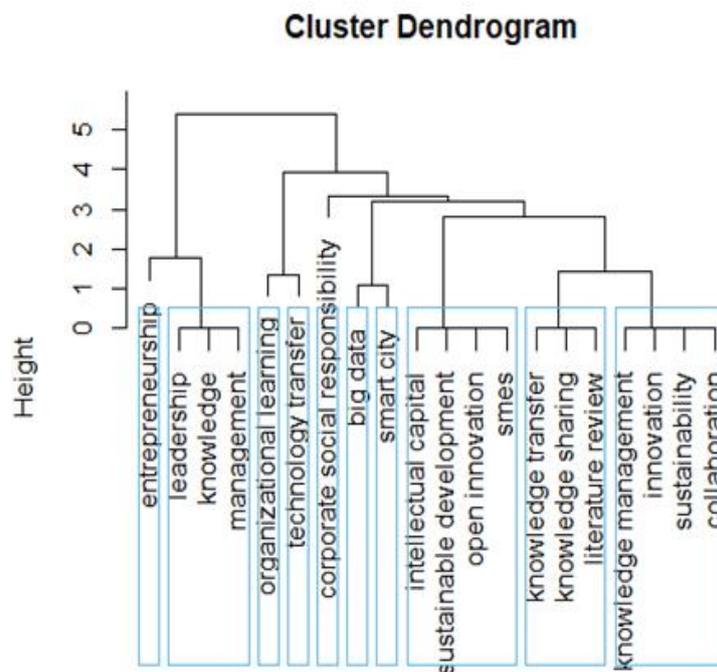

Figure 2. Dendrogram of the ensemble community detection approach

Then small and medium-sized businesses (SMEs) cannot overstate the significance of intellectual capital and open innovation. These two concepts boost the knowledge management processes of small and medium-sized enterprises and encourage sustainable development. Moreover, by efficiently managing intellectual capital and embracing open innovation strategies, SMEs can generate

new opportunities for development and competitive advantage (Millers & Gaile-Sarkane 2021).

In addition, the analysis of the overall network and specific clusters reveals the significance of leadership in knowledge management. By providing the necessary guidance and support, leadership can facilitate knowledge sharing, transfer, and innovation among employees and enhance organizational performance (for instance, Muhammed & Zaim, 2020, Arunga & Kilika 2023). Furthermore, the leadership of SMEs fosters sustainable development and improves knowledge management procedures, which are crucial SME elements.

Intellectual capital, open innovation, and leadership are assets that leaders of SMEs cannot undervalue. In addition, knowledge management processes can enhance organizational effectiveness and promote sustainable development. In this respect, leadership can be relevant in innovative processes which can be considered toward a firm's sustainable growth.

Finally, in figure 3, we can compare the results obtained by observing the multiple correspondence analysis. The results obtained from the ensemble community detection of the literature network are substantially confirmed. The axis can be interpreted as follows: on the left, we have the managerial and strategic issues related to knowledge management in action for innovation and sustainability, whereas, at the bottom, we have the technological impact on the environmental issues (in the middle, we have as a relevant topics environmental management). This axis confirms our previous analysis showing the importance of leadership and management strategy. Implementing solutions to environmental, social, and economic challenges through effective leadership and strategic management drives innovation and sustainable business practices (see also Mrusek et al. 2022).

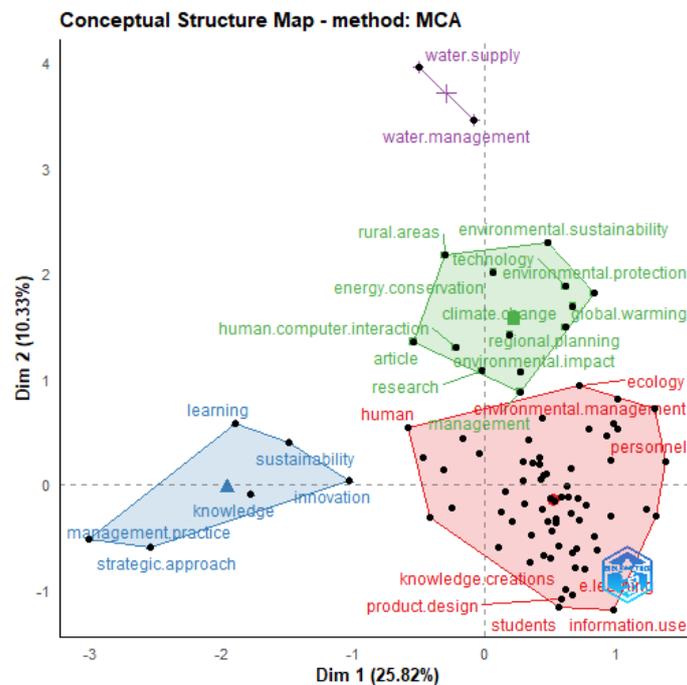

Figure 3. Conceptual Structure Map: method multiple correspondence analysis.

At the same time, we can identify two large clusters indicating relevant topics in the literature. A first cluster related to knowledge management and its importance on the firm's sustainable growth (including relevant topics such as knowledge transfer and knowledge sharing) can be identified. So, in the first axis on the opposite side (on the left), we also see another relevant cluster based on the firm's managerial practice and style but also on the different strategic issues that can be relevant. Finally, a third relevant cluster is related to essential concepts such as environmental impact, sustainability, and energy conservation, so it is related to the literature concepts that consider technology in the context of sustainability. This concept allows one to understand better that relevant concepts in a firm toward long-term sustainability are good knowledge management processes that need to be empowered while considering knowledge sharing and knowledge transfer.

In these contexts, processes of change leading to innovative new technologies (digitization, big data, for instance) should be sustained by considering good management practices and strategic approaches toward a higher capacity for the business to grow in an environmentally sustainable context also externally

communicating their outcomes (in this respect see Testarmata 2018). So in this way, leadership and corporate social responsibility (see Fortuna et al. 2020) are significant. Finally, stakeholder approaches to business are supported by leadership, strategic management, innovation, and sustainable business practices (see Suriyankietkaew & Avery 2014). Therefore, in order to achieve long-term success and create shared value for all stakeholders, it is essential to consider stakeholder interests when developing and implementing sustainable business practices (Freeman et al., 2010).

### ***3.2 Implications for Business Practice***

The link between knowledge management, corporate social responsibility, sustainability, leadership, and knowledge transfer has a variety of practical ramifications. Given this setting, we may make the following practical conclusions:

A knowledge management approach that encourages information sharing, supports learning and enables innovation may enhance corporate social responsibility and sustainability. Organizations should encourage staff to share their best practices and lessons gained on sustainability efforts to foster continual progress.

Organizations may inspire and encourage staff to participate in sustainable activities to improve sustainability and corporate social responsibility. Leaders may set a good example by leading and discussing sustainability with their staff.

Knowledge transfer may improve an organization's capacity to manage knowledge successfully and build sustainable processes. For instance, firms might build communities of practice that allow the exchange of information and cooperation amongst personnel working on sustainability projects. In addition, by establishing a pool of knowledge and expertise that can be used for sustainable business operations, it is possible to increase a company's intellectual capital.

Using sustainable practices promotes sustainable growth for organizations. In addition, organizations may minimize their carbon footprint via energy-efficient technology, diversity, and inclusion in the workforce.

Sustainability may be incorporated into an organization's overall strategy to guarantee that sustainability and corporate social responsibility are wholly integrated into its operations. For example, the United Nation's Sustainable Development Goals can be matched with business practices, and sustainability indicators might be devised to track progress toward sustainability objectives.

In conclusion, technology, innovation, corporate social responsibility, and knowledge management are interconnected in several practical ways. In addition to improving competitiveness, fulfilling social duties, and fostering sustainable development, companies may gain from implementing these principles and strategies.

#### **4 Conclusions**

This study concludes by emphasizing the significance of technology, digitalization, and knowledge management in promoting sustainable economic systems. Organizations may solve sustainability concerns and foster sustainable process innovation by exploiting and managing knowledge resources more efficiently.

Big Data and other digital technologies are very relevant to knowledge management procedures from a sustainability perspective. With the exchange of best practices and cooperation, digital platforms allow inter-organizational communication and information sharing, positively affecting sustainability.

Bibliometric network data analysis methodologies have been used to explore and understand the link between technology, digitization, and innovation in knowledge management for sustainable development. By identifying the "core" ideas covered in the literature, our results shed light on the significance of effectively managing knowledge resources to arrive at sustainable solutions.

Overall, this study contributes to the expanding body of research on sustainability, knowledge management, and digitalization by shedding light on the interrelationships between these factors and highlighting the necessity to manage knowledge resources to promote sustainability effectively. Notably, successfully applying these technologies necessitates organizational adjustments and internal strategic approaches. Therefore, future studies should concentrate on establishing sustainable knowledge management and practical technology implementation solutions.

Network-based bibliometric analysis in this research examined the link between corporate social responsibility, sustainability, leadership, and knowledge transfer. Some fundamental ideas are crucial to organizational effectiveness and sustainable growth. The network analysis highlights the significance of five essential concepts: knowledge management, sustainability, innovation, intellectual capital, and corporate social responsibility, via a network of significant co-

occurrences. In addition to technology transfer, organizational concepts such as knowledge, management, leadership, and entrepreneurship play a significant part in the study. Identifying particular clusters is facilitated by ensemble community detection and cluster analysis of related topics. Based on group keywords, two clusters of knowledge management procedures promote sustainable development. An additional cluster relates to the firm's management techniques and style and the many strategic concerns that may be pertinent to the organization. The environmental effect and sustainability cluster emphasizes incorporating technology while evaluating sustainability.

According to the report, a solid knowledge management approach incorporating knowledge exchange and transfer is vital for sustained development. Furthermore, leadership and corporate social responsibility programs should encourage collaboration, creativity, and sustainability. In addition to emphasizing the need to integrate technology into sustainable development initiatives, the research highlights the necessity for effective management practices and strategic approaches to support new technologies.

## Abstract

This work provides evidence of the impact that Recovery Plans (RPs) have had on the productivity growth of Italian hospitals from 2010 - 2019. Using the Malmquist TFP index, we decompose the hospital's productivity into technological and efficiency changes. We find that the RPs have resulted in an increase in efficiency change, i.e. hospitals use their resources (physicians, nurses, other hospitals' employees and the number of beds) more efficiently. In contrast, technological change has dramatically declined because hospitals are not using financial resources to buy innovative tools and learn new techniques that could improve healthcare processes. So, austerity measures have certainly reduced healthcare expenditure by optimising inputs capital, but they have contained investment in Information and Communication Technology (ICT). These results confirm that a lack of innovation and development has a severe longer-term impact on productivity.

**Keywords** – TFP, productivity, health policy, health technology, Italy

**Paper type** – Academic Research Paper

## 1 Introduction

The rapid increase in healthcare costs has drawn the attention of managers and policymakers on containing health expenditures. Several efforts have been made to improve providers' efficiency: increase hospital competition, change the payment system, change the organizational model, and others. Policymakers may include productivity gains in hospital payment systems by providing premiums or penalties for those organizations that improve or worsen their performance over time. Managers may find useful to compare their organization with others, assess their relative position and implement corrections for improvements (Colombi et al., 2017).

Recent studies in different countries have argued that the growth in Total Factor Productivity (TFP) is due to a quality improvement rather than an increase in output volumes and to the reduction in hospital stays and the critical role played by health policies (Karmann and Roesel, 2017; Atella et al., 2019).

Karmann and Roesel (2017) argued that, in German federal states, the effect of such policies on TFP growth depends on the types of cost reimbursement: fixed daily rates or Diagnosis-related groups (DRG) funding. In each case, hospital size and specialization are the variables that are the essential sources of TFP growth. When the type of reimbursement is fixed daily rates, hospital size is positively correlated with hospital efficiency in terms of quality and quantity but is not associated with technological progress. The increase in capacity is inversely proportional to technological innovations: in other words, huge hospitals are less likely to innovate. The level of specialization, on the other hand, when the type of reimbursement is of the DRG type, leads to a productivity gain.

Atella et al. (2019) compare the productivity growth of the English and Italian healthcare systems. They find that the English productivity growth index increased by 10%, while the Italian National Health System (SSN) productivity increased by 5%. The authors suggest that different policy objectives are reflected in differential growth rates for the two countries. The attention paid to specific disciplines is directly proportional to the perceived quality in those disciplines. The more specialized a hospital is in treating a particular disease, the higher the likelihood of offering the best solution to the patient.

Many European governments have designed policies and reforms to reduce public spending, optimise and reallocate resources and raise funds. The impact of these reforms and policies on productivity has been evaluated in many studies.

Blank and Egging (2014) examined the role of the Dutch government and the policies it has implemented in the health sector. Using econometric time series analysis, they aim to understand whether adopting new laws and regulations has positively impacted Dutch hospitals' productivity from 1972-2010. Introducing a budget system to control healthcare expenditure significantly increased productivity but resulted in long waiting lists. In contrast, the subsequent liberalisation of the healthcare market, with the resulting abolition of budget restrictions and the associated rise in financial resources, decreased productivity, probably due to adaptation lags.

Using Total Factor Productivity (TFP), Aragón Aragón et al. (2019) tried to understand whether some hospitals in the UK's national health system (NHS) are more productive than others. The sample used for the analysis consists of 151 hospitals that have not undergone organisational change, merged with other existing hospitals, or ceased to function during the period analysed (2008 - 2013). They conclude that each hospital in the set follows a trend that indicates productivity increases in one year and decreases in the next, or vice versa. In other words, it is impossible to cluster the hospitals into good and bad performers.

Always considering the NHS, Valdmanis et al. (2017) focused their analysis on hospitals in Scotland, where several measures, such as better resource allocation and continuous reduction of waiting times and production costs, have been introduced since 2004 to improve patient care. They used a bootstrapped Malmquist approach to assess the differences in productivity (efficiency and technology change) in 43 general acute hospitals from 2003 to 2007. The main findings relate to technical change: if there are significant changes in one period, these will cause negative changes in the following period. In other words, a time lag exists between introducing a new technology and its total absorption in a hospital.

Among European countries, Italy has experienced wide-ranging changes in its healthcare sector as the Italian government has attempted to reduce the negative impact of healthcare expenditures on its budget deficit and public debt (De Nicola et al., 2014). Starting from these results, this paper assesses, through the use of the Malmquist Index, how healthcare policies and technological change influence the Italian healthcare systems. Malmquist index is calculated using efficiency scores obtained from non-parametric Data Envelopment Analysis.

For this reason, productivity change can be decomposed into technological change and efficiency change, underscoring that productivity depends upon the

state of technology and the efficacy with which technology is applied. The expected results would help investigate whether productivity in the hospital sector is growing and whether government policies and technological endowments can influence this productivity growth. In fact, we aim to have further insights into whether there is a direct proportionality relationship between hospitals' technological endowments and productivity growth.

## **2 The Italian National Health System**

The Italian National Health System (SSN), established by Law n.833 of 1978, belongs to organizations that have alternatively adopted different corporate structures. Universality, equity, and legality are the fundamental principles, which require strengthening the capacity to operate as a community-based system designed for and with people. Until 2001, the Italian Government distributed funds for health care to individual regions based on the size and age of the local population. The reform adopted in 2001 allowed the Italian regions and the autonomous provinces to be administrative and fiscal independent in the health decisions and expenses with the constraint of guaranteeing a package of standard health services (the so-called *Livelli essenziali di assistenza*). However, this decentralization and exceptional funding emanated by the central government to reduce social and economic disparities, may encourage an opportunistic behaviour of management, which quickly needed to balance their budgets due to their limited health service performance and severe deficit (Ricciardi and Tarricone, 2021). In 2006 the cumulative deficit from healthcare spending reached six billion euro (Depalo, 2019). The central government was forced to impose specific Recovery Plans (RPs), which are still active in about 8 of 21 regions with a considerable health budget deficit (Guccio et al., 2022). The RPs are agreements between the Italian Government and the regions with significant deficits in the health accounts. They were introduced by the national budget law for 2007 and were compulsory for regions with a deficit greater than 5% (Bordignon et al., 2019). The RPs aim to curb the growth of health expenditures and deficits and have a duration of three years. Regions must therefore be able to protect the health of their citizens while maintaining a balanced budget by rationalising expenditure.

However, if the regions fail to meet the plan's objectives, the plan is automatically renewed for three years. Moreover, in the case of a large deficit, the

central government can appoint a commissioner, who is made responsible for the effective implementation of the plan. Until now, ten Italian regions have experimented with RPs. Some of them (*Sardegna* and *Liguria*) came out almost immediately, others (*Piemonte*) came out after a more extended period, and others were (and still are) commissariats for the entire period. Table 2 shows the evolution of the RPs in the Italian regions; many have resorted to the Commissioner's intervention.

Table 1 Evolution of RPs in Italian regions

Region	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019

Note: RP = standard recovery plan; RPC = presence of the commissioner; X = no recovery plan in force

Since our dataset covers a period between 2010 to 2019, this work assesses whether the recovery plans promoted by the Government have stimulated regional health productivity growth.

The Italian National Health System began an extensive reorganization process for local and hospital health services to rationalize healthcare expenditures by reducing healthcare staff and beds, especially for the regions under RPs (Ferrè, 2012). While many studies suggest that the primary financial objective has been achieved without negative effects (Bordignon et al., 2019; Giaccotti et al., 2020), others argue that cost reduction has decreased specific efficiency indicators (Depalo, 2019; Arcà et al., 2020; Guccio et al., 2022). More than ten years after the introduction of the plans, we want to analyze their impact on hospital productivity contributing to the debate in the literature.

Using an econometric approach, Bordignon et al. (2019) suggest a good performance of RPs, at least from the financial point of view. The public health expenditure decreased significantly by about 28 euros per capita in regions subject to RPs and 92 euros in regions under RPCs without any significant effects on health services utilization and health outcomes. However, they argue that there is a lag period of two years before experiencing the RP's positive effects. As a confirmation of this, Giaccotti et al. (2020), analyzing a sample of 41 Italian public hospitals from 2010 to 2013, affirm that reforms reached their aim of decreasing public health spending without weakening hospital efficiency. In the regions subjected to RPs, total deficit spending was reduced to 0.3 billion euros in 2016 from 4.1 billion euros in 2007. In addition, using Data envelopment analysis (DEA) and the Malmquist index, they show that RPs produced positive effects on technological change, scale efficiency, and overall productivity. Conversely, Depalo (2019) provides strong evidence for a positive correlation between reduced healthcare expenditure and mortality rates. A counterfactual analysis confirms that between 2007 and 2009, austerity measures caused a slight increase in mortality rates. He also shows that the reduction in health expenditure is inversely proportional to the reduction in hospital admissions, i.e., the more significant the cost reduction, the lower the volume of hospital admissions. These findings are confirmed by Arcà et al. (2020), who collected and analyzed a panel dataset for 21 Italian regions, from 2004 to 2014. They argue that the health expenditure cuts resulted, on average, in a 3% rise in avoidable deaths among men and women. Finally, Guccio et al. (2022), using a panel of 547 hospitals over the period 2003-2010, find that RPs increased the technical inefficiency of hospitals in the regions covered by the policy. They also conclude that the policy has affected the public sector more than the private sector. The rest of the paper

is organized as follows. Sections 3 and 4 describe the empirical strategy and data, respectively. Section 5 discusses the results. Section 6 provides a brief conclusion.

### 3 Methodology

In this study, we calculate the variation in productivity using the Malmquist productivity index. This index is constructed as ratio of distance functions. Let  $x = (x_1, \dots, x_N) \in R_+^N$  denote a vector of inputs and  $y = (y_1, \dots, y_M) \in R_+^M$  be an output vector. The production technology  $T$  consists of all feasible  $(x, y)$  and is defined by:

$$T = \{(x, y) : x \text{ can produce } y\} \quad \#(1)$$

Here we define the output distance function directly on the technology as in Shepard (1970). The output distance function is defined on the technology  $T$  as:

$$D(x, y) = \inf\{\theta : (x, \frac{y}{\theta}) \in T\}, \quad \#(2)$$

i.e., as the "minimal" feasible contraction of the output vector, given an input vector.

Let  $t$  and  $t + 1$  denote two time periods and let  $D_o^t(x^t, y^t)$  be the value of the output distance function related to the technology in the period  $t$  and the input-output vector in the same period. Let  $D_o^t(x^{t+1}, y^{t+1})$  be the value of the distance function for the input-output vector of period  $t + 1$  and the technology at time  $t$ . The output-oriented Malmquist productivity index considering the  $t$ -period as reference technology is defined as:

$$M_o^t = \frac{D_o^t(x^{t+1}, y^{t+1})}{D_o^t(x^t, y^t)}, \quad \#(3)$$

Since we want to assess whether the reduction in health expenditure due to RPs still hurts productivity, we calculate the output-oriented Malmquist index. The latter allows us to measure how much output quantities can be proportionally expanded without altering the input quantities used. Inspired by Caves et al. (1982) we define the output-oriented Malmquist index as the geometric mean of (3) at period  $t$  and  $t + 1$ ; i.e.,

$$M_o(x^t, y^t, x^{t+1}, y^{t+1}) = \left( \frac{D_o^t(x^{t+1}, y^{t+1})}{D_o^t(x^t, y^t)} \frac{D_o^{t+1}(x^{t+1}, y^{t+1})}{D_o^{t+1}(x^t, y^t)} \right)^{\frac{1}{2}} \cdot \#(4)$$

We use the data envelopment analysis (DEA) to compute Malmquist productivity indices. This allows to exhaustively partition the Malmquist productivity index into useful component measures. In particular, the index can be decomposed into a technological change and an efficiency change component (Färe et al., 1998). The first source of productivity results from a shift in production technology and measures the hospital's ability to produce more (or less) with a given vector of input quantities. The second source of productivity results from a movement towards production technology and measures the hospital's ability to make a more efficient use of its inputs and exploit the available technology.

#### 4 Data and Variables

The data used for the analysis were obtained from the Italian Ministry of Health. The period is from 2010 to 2019. We analyse the productivity of Italian hospitals during the years they benefited from the bailout and evaluate the efficiency of the region that opted out of the bailout. The sample is constituted by 429 hospitals in 2010 and 346 hospitals in 2019. Table 3 shows, for each of the Italian regions, the numbers of hospitals in each of the five management types represented in our sample for 2010 and 2019: Aziende Ospedaliere (AOs), teaching hospitals (THs), non-profit hospitals (NPs), Ospedali a Gestione Diretta (OGDs) and institutes for scientific research and treatment (IRCSSs).

<b>TOTAL</b>	35	27	26	313	28	<b>429</b>	25	28	26	238	29	<b>346</b>

Note: Aziende Ospedaliere (AOs), teaching hospitals (THs), non-profit hospitals (NPs), Ospedali a Gestione Diretta (OGDs) and institutes for scientific research and treatment (IRCSSs).

Table 2 shows that the number of AOs and OGDs decreased significantly from 2010 to 2019. This reduction, as argued by Guccio et al. (2022), is due to the strict cost containment strategy, which resulted in institutional reorganisation through hospital mergers, particularly a 40% reduction in the number of AOs (OASI, 2021). Giaccotti et al. (2020) assert that from 2010 to 2013, to reduce public expenditure, many hospitals were subject to aggregation processes and mergers. Except for *Basilicata* and *Sardegna*, all the regions in the South area are subject to recovery plans and the number of AOs and OGDs has fallen by 15.8% and 31.2%, respectively. The other regions covered by the plans are *Piemonte*, and *Lazio*. *Piemonte*, which left the plan in 2017, confirms the reduction of AOs and OGDs, by 40% and 10%, respectively. *Lazio*, still subject to the recovery plan, exhibits a reduction of 33.3% in AOs and IRCSSs and 22.2% in OGDs.

After eliminating the observations with missing values, the final sample consists of a balanced panel of 271 observations. We specify four inputs (physicians,

nurses, other employees, and number of beds) and three outputs (number of inpatients, number of outpatients and number of surgical procedures). The inputs and outputs are expressed in terms of physical quantities because no reliable data are available. The physician input is measured by the number of salaried physicians in each hospital. Similarly, the nursing input is given by the number of nurses; other employees are measured as the total number of employees in a hospital, minus numbers of physicians and nurses. The number of beds is the sum of outpatient and inpatient beds. Outpatient beds consists of the number of beds for outpatients, while inpatient beds number of beds available for treatment of inpatients. The number of beds provides a proxy measure for capital, which is otherwise difficult to measure. Using beds as a proxy for capital is typical in hospital studies (Grosskopf et al., 2004; Aletras et al., 2007; De Nicola et al., 2014): (i) the reduction in beds means the cut in healthcare costs; (ii) the reduction of this capital input implies inefficient use of resources.

The included outputs are inpatients, outpatients, and surgical procedures. In the hospital sector, the main output is inpatients, but not all inpatients who arrive at the hospital require the same attention and service. That is why it is necessary to adjust the hospital production in terms of complexity, using the case mix index (CMI) (Ferreira and Marques, 2014). For this reason, the number of inpatients and the number of surgical procedures are adjusted by multiplying them by a hospital case-mix index (CMI) to weigh output quantities by the intensity of treatment received.

Table 3: Description and role of variables

<b>Variable</b>	<b>Description</b>	<b>Role of variables</b>
Physicians	Total number of hospital physicians	Input
Nurses	Total number of hospital nurses	Input
Other employees	Total number of employees in a hospital, minus numbers of physicians and nurses	Input
Number of beds	Total number of hospital beds, obtained as the sum of outpatient and inpatient beds	Input
Number of inpatients	Total number of patients admitted to hospital	Output
Number of outpatients	Total number of patients not admitted to hospital	Output
Number of surgical procedures	Total number of hospital surgical procedures	Output

Table 4 provides summary statistics for our dataset of Italian hospitals. We calculated the median and the mean for each input and output variable. The median is a more robust estimator of the central value. If an outlier is present, the mean changes drastically, while the median remains close to the central value of the original statistical distribution (de Nijs and Klausen, 2013). In the regions subject to recovery plans, the medians of physicians and nurses increased slightly by 13.5% and 12.33%, respectively. Instead, the median for other employees and beds, decreased by 4.44% and 9.54%, respectively. The slight increase in physicians and nurses may be because many years have passed since the signing of the RPs, and the regions have improved their deficit condition, starting to unfreeze staff turnover. However, a minimal reduction in the number of beds is still evident. In the regions not subject to recovery plans (NRP regions), the median of inputs increased between 2010 and 2019. Those for physicians increased by 37.3%, nurses by 28.1%, other healthcare staff by 35.7% and beds by 3.9%. Concerning RP regions, the medians of the inpatients and outpatients have decreased by 2.15% and 16.7%, respectively; conversely, the median of surgical procedures has increased by 35.5%. Therefore, austerity measures are still visible in the lack of growth of beds and the reduction of the number of hospital admissions. In the NRP regions, all the medians' outputs have increased significantly. The median with the highest increase was for surgical procedures (27.1%).

## 5 Results

### 5.1 Malmquist TFP's results

We analyse the evolution of hospital productivity during the period 2010-2019 to evaluate if the regions subject to recovery plans have improved their hospital performance. In Table 5 we distinguish between hospitals located in regions involved in RPs and those in regions that were not involved. In addition, we observe the evolution of *Piemonte* to understand the effects of this region that has left RP during the period of analysis. They show that the slight growth in TFP was due to an increase in the efficiency change (EC) component. Overall, there is a decreasing in productivity between 2010-2019, but RP regions show an improvement in the efficiency change component. This means that during the period 2010-2019, hospitals used their inputs (physicians, nurses, medical staff, and beds) and available technologies more efficiently. By contrary, there is a decreasing in the technological change, that results in a worse overall productivity. Regress in technology could be considered abnormal, but it is consistent with the system's pressure to reduce costs, which does not allow for the introduction of innovation and new technologies into the healthcare system in the long period. Information and Communication Technologies (ICT) are

valuable tools to support the traceability of healthcare processes and the exchange of information between the different actors involved in the patient care pathway. Different information systems can help healthcare providers in their daily activities, but the austerity measures have limited the vision of challenging ICT solutions based on cloud computing, mobile health, and innovative ICT digital solutions. Even if, as shown by Ciaschini et al. (2016), a strict ICT investment policy can significantly improve care ability and cost containment expenditure without worsening the quality and efficiency of health services.

Moreover, previous studies underline that a close alignment between the technology introduced by the hospital and technological needs raised by physicians and nurses hospital administrators are necessary (Ancarani et al., 2016). However, organizations take time to absorb newly developed technologies and become confident with innovative processes (Liao et al., 2016). In addition, complementary investment in learning and reorganizations are needed to exploit all the opportunities from ICT. Our result suggests that finding a trade-off between reducing health expenditure and improving the technologies employed may be complicated.

Our findings are in line with the aim of the recovery plans, i.e. to reduce healthcare expenditure and optimise resources. But as a consequence, the hospitals are losing productivity in the long period. Therefore, cost-cutting has optimised and made resource use more efficient, but it is not a sustainable strategy over the years. According to Giancotti et al. (2020) and using a smaller sample, austerity measures caused an increase in technological change and productivity up to 2013. Using a larger and updated sample, we obtain different results: the technological change worsens productivity in the long run. Instead, we confirm that RP and NRP regions have yet to recover the technical inefficiency also described by Guccio et al. (2022). On the other hand, considering the regions that have left their recovery plans, hospitals in *Piemonte* continue to make more efficient use of resources and increase productivity.

Table 5 Descriptive statistics of the Malmquist (M), efficiency change (EC) and technological change (TC)

		2010 - 2019				
		Median	Mean	S.D.	Min	Max
<i>RP regions</i>	M	0.937	0.958	0.216	0.542	1.530
	EC	1.001	1.048	0.252	0.561	1.777

	TC	0.932	0.934	0.114	0.643	1.292
<i>Piemonte</i>	M	1.003	1.037	0.162	0.823	1.542
	EC	1.016	1.077	0.291	0.820	2.089
	TC	1.020	0.985	0.097	0.732	1.104

## 6 Conclusions

In this paper, we analyze the productivity of Italian hospitals after the introduction of recovery plans. Using the Malmquist TFP index, we have conducted an analysis to assess the impact of recovery plans to the productivity growth of the Italian regions from 2010 to 2019. Our findings confirm that the average Malmquist TFP has decreased in both groups of regions (RPs and NRPs). However, in RP regions, a significant improvement is visible in the efficient change components. In other words, hospitals under recovery plans use resources more efficiently. Moreover, we find that the decline in productivity is attributable to technological change. Then, reducing health expenditure and improving technology are trade-off because the introduction and the adoption of new technologies requires significant time and complementary investments in learning and reorganization. This paradox causes significant productivity losses in the long run. A new idea to support policy decisions is understanding from which year productivity worsens to find the right trade-off between efficient use of resources and hospital productivity.

### Abstract

The increasing connectivity and digitization of organizations have made cybersecurity a top priority. Organizations have become highly dependent on integrated systems and data, exposing them to cyber threats that can lead to economic and reputational losses. The COVID-19 pandemic has further highlighted vulnerabilities in cybersecurity systems across sectors. In particular, there has been a recent focus on the role humans play in this scenario by turning out to be both a possible source of vulnerability and a mitigating factor. To manage this, organizations must focus on establishing a culture of cyber security awareness by promoting policies, standards, and users' behaviors from an organizational learning perspective.

Employees' education is one of the components needed to create such a culture, hence training programs on cybersecurity have a crucial role.

However, the effectiveness and sustainability of training programs depend on including a variety of stakeholder groups to identify and mitigate cost and efficacy concerns, adopt accessible training techniques, employ trainers with relevant expertise, and address psychological obstacles like trainee guilt and shame. A balanced human-machine approach is needed to maximize the benefits of connectivity while minimizing cyber risks. Overall, cybersecurity training requires an ongoing, collaborative, and flexible process tailored to

each organization's context. Today, there is no consensus on the most effective and appropriate cybersecurity training methods. This research investigates available cybersecurity awareness types of training and provides guidelines for developing good organizational training programs in increasingly digital environments.

**Keywords** – digitalization, cyber resilience, human factor, training 4.0, innovation

**Paper type** – Academic Research Paper

## 1 Introduction

Today hyper-connected environment has resulted on one side in an appreciable increase in productivity, efficiency, and system integration, on the other side it has raised the number of possible hazards. Organizations are now highly dependent on data and information from their integrated systems (Corallo et al., 2022). This has exposed not only company secrets but also the personal information of millions of consumers resulting in both economic and reputational loss for organizations. For these reasons, cybersecurity has become a top priority for organizations that find themselves working in an increasingly dynamic and real-time optimized system (Colabianchi et al., 2021).

Furthermore, the fast and global spread of the coronavirus pandemic exposed the vulnerabilities of existing cybersecurity systems (Ramadan et al., 2021). IT has played an important part in all activities, serving as the focal point of operations in healthcare, business, education, industry, and other fields (Weil & Murugesan, 2020). However, there are several disadvantages, including increased cybersecurity threats and hazards, performance issues due to a significant rise in workload, and business continuity.

These considerations fit into a context in which the debate is developing as to which is the human role in cybersecurity. Specifically, the increasing complexity and interconnectedness of these systems are forcing researchers to investigate in which part humans are a threat or an opportunity for organizational cybersecurity (Zimmermann & Renaud, 2019). On one side human error is the weakest link in security. On the other side, recent studies addressed humans as flexible and able to rapidly judge and attack, stressing the importance of a continuous synergy among humans and machines to pursue cybersecurity effectiveness. Especially, in the context of small-medium organizations focusing on what employees do, what they need, and how they react to cybersecurity tools can be the first line of

defence. With education, awareness, and reminders, humans will make informed decisions by interacting with technology (Annarelli et al., 2022). Therefore, the increase of support people, training, and documentation are the most obvious options. There is a need to invest in programs that increase cybersecurity awareness and the ability to identify and manage a cyber threat (Chowdhury, Katsikas, et al., 2022).

However, the added costs associated with staff, software, building space, and so on make this option unfeasible for many organizations (Zhang et al., 2021). In addition, when talking about cybersecurity, shame, and reticence can have a strong impact. When workers realize that they have caused a cybersecurity incident they often feel guilt and shame, trying not to communicate the error and making the consequences of the attack worse (Renaud et al., 2021). It is therefore very difficult for organizations to structure a training program that is effective, attractive, and sustainable economically.

There emerges from the literature an absence of a common line on which training methods are most effective and appropriate for the organizational context in which one operates. Organizations need to carry out considerations about the profiles of the people who will support the training, the continuing increase in the severity of social engineering attacks, the variety of 4.0 training techniques ranging from the most classic face-to-face training to gaming and platforms that make use of Virtual Reality tools (Alhashmi et al., 2021; Angafor et al., 2020). For this reason, in the present study, we aimed at reviewing the training methods available in the literature to train workers on cyber risks and to discuss the aspects that need to be explored to develop an appropriate and sustainable training program.

To accomplish our objective, we explored the literature on the topic of cybersecurity awareness training programs and detailed relevant aspects for the implementation of effective cybersecurity training programs. Finally, a discussion and conclusions are provided.

## **2 Organizational learning**

Organizational learning is defined as “the process of improving actions through better knowledge and understanding” (Fiol & Lyles, 1985) and is one of the most vital competencies of an organization. It is a dynamic process that involves the acquisition, interpretation, and application of new knowledge and skills to

improve an organization's performance and effectiveness (Argote & Miron-Spektor, 2011). It is a continuous process that involves both individual and collective learning, as well as the creation and sharing of knowledge across different levels and functions within an organization. It supports the idea of the organization as a whole learning and adapting its behavior and it is largely adopted in management sciences with the specific intent to change employee behavior (Ojha et al., 2018). The benefits of organizational learning are numerous, including improved innovation, greater adaptability to change, enhanced problem-solving capabilities, and increased employee engagement and satisfaction (Garvin et al., 2008). Moreover, organizational learning can also contribute to the development of a learning culture, where learning is seen as a core value and a source of competitive advantage.

Most of the organizational learning theories are based on the idea that people have mental processes and their reactions in situations (including planning, implementing, and reviewing their actions) depend on these processes.

Training is one of the most significant practices for the organizational learning process since a good training program makes individuals elaborate information and turns it into useful organizational knowledge (López et al., 2006)

### **3 Social engineering attack and cybersecurity awareness**

Social engineering defines a type of cyber-attack in which the attacker exploits human vulnerabilities through social interaction to breach the security goals of cyberspace elements (such as infrastructure, data, resources, users, and operations) (Wang et al., 2020). Using influence, persuasion, deception, and manipulation, the victim is induced to trust the attacker who will obtain data that were supposed to be confidential, without respecting principles of integrity, availability, controllability, and audibility (Fang, 2018).

Social engineering attack goal comprises network intrusion, gaining unauthorized access to information or systems, denial of service, data exfiltration, modification, fabrication or destruction, infrastructure sabotage, and obtaining physical access to restricted areas (Wang et al., 2021).

The key for mitigate social engineering cyber risk by making employees less vulnerable is to establish a cybersecurity awareness culture within the organization through specific cyber awareness training programs aimed at

informing what security threats are and acting responsibly to avoid potential risks (Van Niekerk & Von Solms, 2010).

One of the most famous social engineering attacks is called phishing and has the aim to obtain confidential information from a target (Bhavsar et al., 2018). It consists of sending a message or email that appears as being from a respectable administration, seems urgent, and invites the targets to open a website that is a duplicate of the original one. In the message, the victims are asked to provide personal information on the website that, unfortunately, is stolen by the attackers who can use it, for example, to enter the system to steal money or to obtain precious confidential data (Desolda et al., 2022).

Considering the specific context of cybersecurity training which embodies technological, normative (policy/standard), and behavioral aspects, and its central role in organizational learning, this study aimed at reviewing the existent cybersecurity training methods (focusing on cybersecurity awareness training) and providing direction for their improvement.

#### **4 Methodology**

Key terms such as cybersecurity awareness, social engineering, training, course program, etc. were identified to search for training programs available in the literature. The database used for the search was Scopus. Once the key articles were identified, the articles cited and those that cited them were also explored. Our focus in this study is on cybersecurity training rather than cybersecurity education. With the term cybersecurity training the authors will refer to those practices which provide employees with the specific knowledge necessary for their job responsibilities, utilizing more practical methods such as seminars, workshops, and game-based activities. To be effective, training must be designed to be relatable to employees and aligned with the business context of the organization, while also utilizing a variety of delivery methods (Chowdhury, Katsikas, et al., 2022). To classify the identified training programs, we relied on two classifications known from the literature. The first is that of (He & Zhang, 2019) that propose best practices for implementing successful cybersecurity training programs. The second is the one proposed by (Gkioulos & Chowdhury, 2021), which analyzes aspects such as the tools used and the performance of the training.

## 5 Results

The provided classification combines the aspects highlighted in the previous section and ranks the identified items providing an overview of cybersecurity training programs. It is worth specifying that this study is limited to these types of programs that focus on the human component and not on technological and network protection aspects.

The table is structured as follows:

- *Reference*: article in which we can find an outline of the training program
- *Description*: a brief description of the training program
- *Delivery method*: We divide the delivery methods into 5 categories. These identify the type of training used to transfer the training content.
  - Conventional methods: refer to on-site courses; paper-based teaching and exercises; presentations.
  - Online/Software-based: refers to online courses; cloud-based training material and software; email tests.
  - Game-based: refers to serious games and training based on competition.
  - Video-based: refers to educational videos.
  - Simulation/Virtualization-based: refers to testbeds, simulation platforms, and exercises.
- *Topology*: by this term, we refer to the type of tool used to conduct training. Specifically, we identify:
  - Video
  - Presentations (e.g. PowerPoint)
  - Virtual Reality
  - Augmented Reality
  - PowerPoint
  - Digital Intelligent Assistant
  - A mix of the above
- *Attributes*:
  - *Accountability*: refers to the responsibility of individuals to prevent cybersecurity breaches through knowledge and diligence. This involves rewarding employees who report suspicious activity and making cybersecurity a part of every

employee's performance goals, rather than punishing those who do not comply.

- Fun: refers to a cybersecurity training approach that uses engaging and entertaining content to educate employees about the importance of cybersecurity. Gamification is also used.
- Hands-on: refers to a cybersecurity training approach that actively involves employees in identifying and reporting suspicious activity. Role-playing and testing are also included.
- Interactivity: refers to a cybersecurity training approach that encourages active engagement from employees. This involves storytelling, encouraging employees to ask questions and share experiences and share the material. Role-playing and scenarios, such as phishing attacks, are also used to provide practical experience.
- Just-in-time training: refers to a cybersecurity training approach that provides material to employees as they join the company and when they fail test emails. When employees fail for test emails, they are informed that they failed and directed to specific materials or videos to review and learn from their mistakes.
- Personalization: refers to a cybersecurity training approach that is tailored to the specific needs and concerns of individual employees. This approach seeks to personalize the training to address the specific needs and concerns of each employee, making it more relevant and engaging.
- Reinforcement: refers to a cybersecurity training approach that emphasizes regular assessments and micro-trainings to keep employees informed and engaged. This includes staying up-to-date with new and emerging threats and sending regular email blasts about threats.
- Relevancy: refers to a cybersecurity training approach that provides tailored curricula to individuals based on their specific roles and responsibilities. This includes providing department or application-specific advice that explains the importance of cybersecurity in simple terms that employees can understand.

This approach seeks to make the training more engaging and effective by providing employees with practical tools and knowledge that they can apply in their work.

- Reward: refers to the action of giving out incentives when someone answers a question posed to the group or wins a game or simulation.
- Strengths: strengths of the training program solution
- Weakness: limits identified in the training program solution.

Table 1 - Cybersecurity Training Programs

Ref.	Description	Delivery Method	Topology	Attributes	Strengths	Weakness
(Jin et al., 2018)	A game-based learning method for cybersecurity education using Virtual Reality.	Game-Based; Simulation / Virtualization-based	Virtual Reality	Fun; Relevancy	The content was well memorized due to the high experiential training. Participants enjoyed the training and felt involved.	Suitable only for employees who already have technological skills. Difficult to navigate a large number of procedures and rules.
(Tan et al., 2020)	Adaptive awareness training system which updates its knowledge base. A list of questions is presented to the user by a Digital Intelligent Assistant.	Online and Software Based	Digital intelligent assistant	Interactivity; Personalization; Reinforcement; Relevancy	Always be up-to-date and be able to do micro-training when desired. Interacting with a virtual assistant reduces the shame employees might feel when interacting in class.	It can be tedious, time-consuming, and cognitively demanding to have to answer all these questions frequently.
(Nagarajan et al., 2012)	A first-person interaction game where the user is confronted by an adversary or problem and must take a proper course of	Game-Based	Video	Fun; Interactivity; Personalization;	The users are engaged and motivated. Participants reported good results.	Might be difficult to tailor the game to each organization and users' skills and attitude

	action or else is penalized severely.					
(Nagarajan et al., 2012)	A virtual online environment with provided limited resources. Good choices result in a richer environment and additional resources, bad choices result in diminishing resources.	Simulation/ Virtualization - based	Video	Fun; Interactivity; Personalization; Relevancy; Reward	The users are engaged and motivated. Rewards were a good incentive.	Time and cost-consuming to adapt the simulation environment to different organizational scenarios
(Angaf or et al., 2023)	A scenario-based virtual incident response exercise. Before the exercise users are given procedures and rules to handle cyber incidents.	Conventional Methods; Simulation / Virtualization-based	Presentations; Video	Hands-on; Interactivity	Reported good results in terms of identifying threats and strategies to handle incidents. Users felt engaged and empowered.	Need continuous updates with new threats and vulnerabilities. Focused on specific users and roles.
(Tonkin et al., 2022)	A multiplayer cybersecurity education platform for evaluation and learning. The game offers an entertaining and competitive setting that includes educational elements. It allows	Online and Software Based; Game-Based	Video	Fun, Interactivity, Reward	Improved level of engagement, communication, immersion, flexibility, and interactivity.	Currently, lack of a testing scenario and limited learning content. Hard to use for technologically unskilled users.

	players to participate with random individuals in open rooms or closed/reserved rooms with groups.					
(Jayakrishnan et al., 2022)	A simulated game that replicates a business environment where executives need to make decisions on investments, allocating resources for cybersecurity.	Online and Software Based; Game-Based	Video	Hands-on; Interactivity; Personalization; Relevancy.	Employees seeing a system highly customized to their role were found to be more engaged and interested.	Limited learning content.
(Eze & Hawker, 2022)	A cyber awareness platform prototype that enables users to evaluate their existing knowledge and skills, and then tailor a training program based on evaluation results and their roles.	Online and Software Based	Video	Personalization; Relevancy	The role-sensitive solution was considered beneficial in the training program.	Limited learning content and roles available for assessment.
(Sheng et al., 2007)	A game to train users not to fall for phishing attacks.	Game-Based	Video	Fun; Interactivity; Hands-On	The users were engaged and reported good results.	Might result hard to use for people without basic knowledge of the topic and technology.

## 6 Discussion e Conclusion

On the one hand, the analysis of cybersecurity training programs confirms the lack of a single approach that guides organizations in defining which parameters are useful for implementing effective training. On the other hand, what emerges from the analysis of strengths and weaknesses is how effective training turns out to be in relation to the context variables in which it is found (e.g., level of preparedness of the users, size of the organization, learning objective to be pursued, etc.) (Venables, 2021). Another interesting aspect that emerges from the literature is a generally shared view that emphasizes the importance of moving toward training that uses innovative technologies, yet multiple papers show how organizations are still anchored to traditional training methods even in sectors with high cyber risk (Chowdhury, Nystad, et al., 2022) or in context of Small and Medium Enterprises (Johansson et al., 2022).

Finally, an interesting aspect found in several studies is to integrate training with the completion of questionnaires for self-assessment of cybersecurity behavior. The questionnaires presented in previous relevant studies can be classified according to their characteristics such as the number of items it contains, whether it is based on a theoretical framework, its accessibility to the general public, the year of publication, the topic covered, and the target recipients or audiences. Among Information Security Awareness questionnaires, the most used are: UISAQ = Users' Information Security Awareness Questionnaire (Velki et al., 2014); BCISQ = Behavioral- Cognitive Internet Security Questionnaire (Velki & Strossmayer, 2019); OSBBQ = Online Security Behavior and Beliefs Questionnaire (Schaffer & Debb, 2019); HAIS-Q = Human Aspects of Information Security Questionnaire (Parsons et al., 2014).

Overall, the study underlined how in the context of cybersecurity, organizational learning can play a crucial role in improving an organization's overall security posture. The increasing frequency and sophistication of cyber attacks have made it imperative for organizations to not only invest in technical security solutions but also in training their employees to be more vigilant and proactive in recognizing and responding to potential security threats. By fostering a culture of continuous learning and innovation, organizations can enhance their cybersecurity posture and better protect themselves against emerging threats and vulnerabilities. Research has shown that organizations that prioritize

organizational learning are better equipped to deal with the evolving cybersecurity landscape (Mikalef et al., 2019).

The solutions classified highlight that cybersecurity training programs must provide an active role of the learner and attention to his/her behavioral aspects. Moreover, context-based characteristics are vital to tailor a training program to the specific organizational environment in which the training is needed. Indeed solutions should be designed and implemented in a way that aligns with the organization's culture, values, and strategic objectives. This requires a thorough understanding of the organization's learning needs and preferences, as well as the use of innovative and engaging training methods that promote active learning and knowledge transfer. In this scenario, the use of technology-enhanced learning solutions, such as simulation, gamification, and virtual reality, can further enhance the learning experience, increase engagement and retention rates, and contribute to the processing of information into useful organizational knowledge and behavioral processes following an organizational learning perspective.

### Abstract

Resilience is a widely accepted concept to which scholars and policymakers refer to address the complexity of urban systems. Many frameworks to measure urban resilience already exist. In this paper, the main urban resilience frameworks (i.e., City Resilience Index, Resilience Maturity Model, and the Sendai Framework for Disaster Risk Reduction) are analysed to shed light on the common dimensions they present. Additionally, the relationship between (i) resilience and (ii) sustainability and well-being in the urban context is investigated. To do so, Agenda 2030 for Sustainable Development, scaled at city level, and the Equitable and Sustainable Territorial well-being framework are compared with the urban resilience frameworks. In the urban domain, the concepts of resilience, sustainability and well-being partially overlap. Many dimensions (e.g., health, economic prosperity, environmental protection) are considered in the resilience as well as in sustainability and well-being frameworks. Such dimensions are indeed measured with the same or very

similar metrics. However, an in-depth analysis of dimensions and indicators showed some interesting differences. The paper provides knowledge advancement on the topic of resilience in the urban context and highlights those aspects that policymakers should consider so as to pursue resilience as well as sustainability and well-being goals in the initiatives they implement to face emerging urban challenges.

**Keywords** – Resilience, Urban system, sustainability, measurement

**Paper type** – Academic Research Paper

## 1 Introduction

In recent years, resilience has become a central topic in studies spanning from ecology to psychology (Meerow and Stults, 2016; Zeng et al., 2022). In the urban domain, resilience, i.e. the capacity of an urban system to absorb, resist, transform, change, recover and prepare, in relation to events (such as shocks, stresses, hazards, disasters) that have occurred or may occur (Figueiredo et al., 2018) is one of the concepts to which both scholars and policymakers refer to address the complexity of urban systems (Béné et al., 2014; Meerow et al., 2016). For those reasons, urban resilience has been widely studied by academia and practitioners, as well. A plethora of definitions (Meerow et al., 2016; Nunes et al., 2019a; Nunes et al., 2019b) and several frameworks – e.g., the City Resilient Index (ARUP, 2014) – to guide in the construction and measurement of urban resilience have been developed. The existence of multiple definitions and frameworks may confuse urban decision-makers who need to operationalize and measure the resilience of their city so as to properly plan future initiatives as well as assess and report the effects of the implemented policies.

Some studies point out that resilience has been often examined in association with sustainability, another crucial topic, but “without a precise meaning and as an additional label attached to pre-existing research” (McPhearson, 2014; Zhang et al., 2018). Urban resilience and sustainability are different concepts that partially overlap, so it is relevant to investigate their relationship (Bautista-Puig et al., 2022).

The goal of the paper is twofold, namely (i) clarifying the concept of resilience in the context of cities and (ii) investigating to what extent such a concept overlaps with the one of sustainability. To this aim, three main frameworks to assess and measure resilience of urban systems, namely the City Resilience Index

(ARUP, 2016), the Resilience Maturity Model (Hernantes et al., 2019) and The Sendai Framework for Disaster Risk Reduction (UNDDR, 2015), are analysed. Each framework focuses on specific resilience dimensions, so involving different aspects that should be considered to build a resilient urban system.

The three resilience frameworks are compared to identify the dimensions of urban resilience as well as the performance and metrics to assess it. Then, the identified dimensions, performance, and metrics are compared with those used to assess urban sustainability. To do so, two frameworks – Agenda 2030, a well-known framework for sustainable development (United Nations, 2015), and Equitable and Sustainable Territorial Well-being (Bellantuono et al., 2021), a framework aimed at measuring well-being at local level – are considered. The latter framework is considered as it focuses on well-being, which is a concept very much intertwined with sustainability.

The study is organized as follows: after a Section that focuses on the concept of urban resilience and its theoretical evolution, the extant literature addressing the relationship between the concepts of (i) urban resilience and (ii) urban sustainability and well-being is discussed; then some well-known frameworks to measure urban resilience, sustainability and well-being of urban areas are presented and the methods adopted to make the comparison explained. Finally, results of the study are presented, and future research avenues are drawn.

## **2 Resilience in the urban domain**

Nowadays, academics and practitioners widely acknowledge the three-dimensional conceptualization of resilience in the urban domain (Nunes et al., 2019a) which stems from the conceptual evolution from the engineering and ecological resilience toward the socio-ecological resilience.

In 1970s Holling (1973) adapted the notion of engineering resilience to ecosystems which are dynamic systems with multiple stable states. Holling (1973) describes resilience as the ability of an ecological system to persist and continue functioning after a disturbance. Successively, Holling (1996) broadened the concept of resilience by distinguishing ecological resilience, defined as the ability of an ecosystem to withstand and absorb a temporary disturbance and fully recover its functionalities; ecological resilience refers to the magnitude of absorbed disturbance and implies that multiple states of equilibrium exist. This means that the system can bounce forward to a new state of equilibrium,

accepting that it is not always possible or desirable to return to previous conditions. More recently, the concept of resilience evolved into the socio-ecological resilience, an evolutionary perspective that recognizes that a system is in constant change with or without external disturbance and refers to the ability of the socio-ecological system to change, adapt, and, crucially, transform in response to stresses and strains (Davoudi et al., 2012; Folke, 2006). This evolutionary perspective of resilience stresses the adaptive capacity, self-organization, and transformability that a resilient system should have. The evolutionary resilience perspective seems to be well accepted by institutional organizations with respect to the urban context. For instance, OECD defines urban resilience as “the capacity of cities to absorb, adapt, transform and prepare for shocks and stresses along the economic, social, institutional and environmental dimensions, with the aim of maintaining the functions of a city and improving response to future shocks (Figueiredo et al., 2018)”; in a similar manner, urban resilience is defined as “the capacity of social, economic, and environmental systems to cope with a hazardous event or trend or disturbance, responding or reorganizing in ways that maintain their essential function, identity, and structure, while also maintaining the capacity for adaptation, learning, and transformation” by the Intergovernmental Panel on Climate Change (2014).

The concept of resilience is tending towards a theoretical stabilization, in which ‘social-ecological resilience’ can be understood as the most integrative and relevant resilience conceptualisation in urban domain; however, this theoretical evolution does not imply that the three conceptualizations cannot coexist in urban resilience research. The adoption of one conceptualization does not exclude the others but is rather mutually reinforcing (Nunes et al., 2019b).

The literature has addressed tensions and inconsistencies in the notion of urban resilience and its application in practise (Grafton et al., 2019; Meerow et al., 2016; Moser et al., 2019). From a theoretical standpoint, the malleability of the concept of resilience gives to urban resilience an important function as a “boundary object” to foster collaboration between disciplines and stakeholders. As cities are complex systems that require the expertise of multiple disciplines and stakeholders, the possibility to resort to boundary objects is quite relevant (Brand et al., 2006; Meerow et al., 2019; Sharifi et al., 2017). On the other hand, the ambiguity of the resilience concept makes its operationalization extremely challenging (Olsson et al., 2015; Serbanica et al., 2023). Additionally, although in the urban studies the concept has become a buzzword (Chelleri et al., 2021;

Stumpp, 2013), the confusion and overlap with other similar concepts (as sustainability) undermines the concept's utility and its practical application (Anderies et al., 2013; Zhang et al., 2018).

### **3 Resilience, sustainability and well-being of urban systems: literature overview**

To understand how extant literature addressed the relationship between (i) resilience and (ii) sustainability and well-being in the urban domain, a literature review was conducted. A search query combining the terms "sustainability" and "well-being" with those related to the domain of interest ("urban resilience", "city resilience", "resilient city", "community resilience") was applied to the Title/Abstract/Keyword section of Scopus database (only English documents and journal articles were considered). A total number of 778 studies were retrieved and then screened to eliminate those not relevant to the goal of the review.

Some scholars argue that the concepts of resilience and sustainability are used in interchangeable way when referred to the urban context (Saunders et al., 2015; Stumpp, 2013), particularly in urban policy agendas and frameworks (Chelleri et al., 2021; Elmqvist et al., 2019; Suárez et al., 2016).

In other studies, resilience is considered as a component of or, to some extent, related to sustainability (Davidson et al., 2019; Pirlone et al., 2020; Zeng et al., 2022). A survey conducted by Chelleri et al. (2021) revealed that for both researchers and practitioners was hard to establish a clear distinction between the two concepts; most of them thought that resilience and sustainability have different, but not conflicting goals, and, in particular, resilience is a prerequisite of sustainability. Resilience is indeed considered critical for attaining and achieving sustainability goals in urbanized contexts (Cartalis, 2014; Tainter et al., 2014) and in some cases used to operationalize some aspects of sustainability (Pickett et al., 2014). In this view, urban sustainability is a societal goal aimed to achieve a balance between urban development and long-term protection of the environment, to guarantee an inclusive, democratic, economically equitable development of local areas. It refers to a desirable state characterized by environmental and human well-being as well as intra- and intergenerational equity (Delgado-Ramos et al., 2017). In the urban context, sustainability is an approach to envision the future and defines urban systems' desirable outcome (such as the enhancement of human well-being, social equity or environmental

integrity). Urban resilience is seen as a problem-solving oriented process (Zhang et al., 2018) that concerns the recovery from environmental, societal or economic shocks or chronic challenges (Zeng et al., 2022) by leveraging, among the others, on self-organization capabilities (Rogov et al., 2018; Zhang et al., 2018). This perspective was effectively synthesized by Redman (2014) - who argues that sustainability prioritizes outcomes and resilience prioritizes processes - and Rogov (2018) who states that sustainability sets the objectives whereas resilience is considered a means to achieve these objectives. Such studies also stress the different timescale considered when dealing with resilience and sustainability initiatives. Resilience focuses on short-term characteristics of urban system behaviour and it operates as adaptive cycles initiated by shocks (Rogov et al., 2018). Urban sustainability focuses on long term sustainable development goals (Zhang et al., 2018) and seeks to address the major challenges facing the society with a more long-term perspective (Rogov et al., 2018). Based on this view, Rogov et al. (2018) asserts that urban sustainability, as a long-term goal, is based on systems' resilience that, in the short-term, is revealed within sudden shocks and negative stress factors.

By studying in depth the resilience strategy of cities participating in the 100 Resilient Cities Programme, Serbanica et al. (2023) provided a conceptual model that depicts the relationship between urban sustainability and resilience by identifying some latent challenges or dimensions that are at the intersection of the two concepts (e.g., shifting macro-economic trends, inadequate health system and infrastructure failure) on which policy decision makers should operate to increase both resilience and sustainability. However, in the same study, the scholars also argued that it is possible to distinguish resilience from sustainability based on the type of hazards, shocks or stresses they focus. In particular, according to Serbanica et al. (2023), urban resilience has a strong focus on hazards (disruptive events) and acute shocks (as landslides, earthquakes, drought, cyber-attacks) that may cause serious human, material, economic and environmental losses and impacts; urban sustainability, on the other hand, is associated with long-term, chronic and cumulative stresses, namely climate change (environmental perspective), economic inequality (economic perspective) and lack of cohesion (social perspective). Other studies investigate the differences among the two concepts. For example, redundancy, which is a crucial characteristic of resilient socio-ecological systems (Figueiredo et al., 2018; Zeng et al., 2022), could reduce competitiveness of a city in economic or environmental

terms (Chelleri et al., 2015). Also, whereas sustainability pays considerable attention on balancing economic, environmental and social justice goals, the urban resilience agenda is commonly critiqued for not adequately addressing social equity goals (Fitzgibbons et al., 2019; Muñoz-Erickson et al., 2021; Zeng et al., 2022). Muñoz-Erickson et al. (2021) by surveying researchers, government practitioners and members of civil and business groups in nine cities of America and Latin America found that equity and sustainability are rarely associated with resilience.

Although resilience and sustainability operate on different time scales and are considered, to some extent, different concepts, most scholars agree with the perspective of resilience and sustainability as related concepts. As by 2070, almost 60% of the world population is projected to live in urban areas and be exposed to both chronic and emerging urban challenges (UN Habitat, 2022), frameworks and methodological approaches to face such challenges should integrate both resilience and sustainability (Chelleri et al., 2015; Delgado-Ramos et al., 2017) and urban policy makers should pay equal attention to both urban resilience and sustainability to achieve a rational urban development (Zhang et al., 2018).

In the literature, less attention is devoted to the investigation of the relationship between urban resilience and well-being. McCrea et al., (2014) argue that well-being is a state of the community, whereas resilience is a process; well-being at the community level is defined as 'the satisfaction with the local place of residence taking into account the attachment to it, the social and physical environment, and the services and facilities' (Forjaz et al., 2011) and it refers to a state to evaluate important aspects of a community at a given point in time, whereas the resilience of a urban community is the process to responding and adapting to changes and disasters with the aim of maintaining or enhancing community well-being over the time. Community resilience and well-being are vaguely defined concepts that often overlap as they share some dimensions, e.g., community engagement and cohesion (McCrea et al., 2016). Community well-being is a high relevant but underused concepts to assess the community response to resilience processes and strategies (Gibbs et al., 2015). A conceptual model to explain the relationship between community resilience and wellbeing (McCrea et al., 2014) considers resilience and well-being as distinct constructs and states that they can be related in different ways (for instance, good resilience processes may be triggered by a sense of poor well-being; differently a good

level of community well-being and a sense of community may trigger active resilience processes).

## 4 Materials and Methods

In this Section, we briefly describe three resilience frameworks, namely City Resilience Index, Resilience Maturity Model and Sendai Framework for disaster risk reduction, and two sustainability and well-being frameworks, namely 2030 Agenda for Sustainable Development and Equitable and Sustainable Territorial Well-being.

### 4.1 City Resilience Index

City Resilience Index (CRI), developed by Arup (2014) and supported by The Rockefeller Foundation, has been designed to enable cities to measure and monitor the multiple factors that contribute to their resilience. Particularly, it captures the views of the poor and vulnerable groups as they normally suffer more severely the impacts of disruptions and failures. CRI identifies four fundamental dimensions, namely Health and Well-being, Infrastructure and Ecosystems, Leadership and Strategy, Economy and Society, 12 goals (Table 1) and 52 indicators that contribute to a richer articulation of resilience measurement. Additionally, for each of the 52 indicators, CRI provides 156 metrics (ARUP, 2016) so as to measure different aspects of urban resilience. The full set of CRI metrics is reported in Appendix (Table A1).

Table 1. The City Resilience Index (CRI) – Dimensions and Goals

Health and Wellbeing	
Description	Goal
Relates to people - the health and well-being of people living and working in the city. It considers if a city can meet basic need (food, water and shelter) and to safeguard the health of its population through its normal and emergency healthcare provisions	Minimal human vulnerability: minimising human vulnerability enables individuals and household to achieve a standard of living which goes beyond mere survival. This relates to the extent to which everyone's basic needs (food, water and sanitation, energy, and shelter) are met
	Diverse livelihoods and employment: livelihoods opportunities and support mechanisms (finance, skills training, accrue savings, business support and social welfare) enable citizens to proactively respond to changing conditions in their city without compromising their wellbeing and helping them survive in times of crisis
	Effective safeguards to human health and life: integrated health facilities and services, and responsive emergency services are fundamental to maintain public health and treat chronic and acute health problems

<b>Economy and Society</b>	
Description	Goal
Relates to the organisation of cities - how social and economic systems enable urban populations to live peacefully, and act collectively. It includes the systems that enforce law and order and the environment within a city that creates collective identity and mutual support	Collective identity and mutual support: active community engagement, strong social networks and social integration enable individuals, communities, and the city government to create a city with a strong identity and culture
	Comprehensive security and rule of law: a comprehensive and contextually appropriate approach to law is needed to reduce and prevent crime and corruption in a city. A transparent justice system enables cities to promote citizenship in daily life. Furthermore, well planned, and resourced law enforcement facilitates peaceful recovery reducing crime-related injury, fatality, and stress
	Sustainable economy: A robust economic system is fundamental to sustaining the investment that a city needs and contributes to create contingency funds that are critical to respond to emergencies and unexpected events
<b>Infrastructure and Ecosystems</b>	
Description	Goal
Relates to place - the quality and the robustness of infrastructure and ecosystems that provide critical services, protect, and connect every citizen, particularly under shock or stress situations	Reduced exposure and fragility: working together, both natural and man-made assets help to improve protection against severe conditions, avoiding injury, damage, or loss. A comprehensive understanding of the hazards and risks to which a city is exposed is needed to develop integrated strategies that combine sound environmental stewardship, robust design and maintenance of man-made infrastructure, and enforcement of appropriate building codes and regulations
	Effective provision of critical services: Well-maintained systems are better able to accommodate abnormal demand, withstand unusual pressures and continue functioning specially during times of stress. Well-established management practices enable infrastructure managers to better restore disrupted services
	Reliable mobility and communications: reliable communications and mobility support rapid mass evacuation and widespread communication during emergencies as well as connecting places, people, and services
<b>Leadership and Strategy</b>	
Description	Goal
Leadership and Strategy is underpinned by knowledge. A resilient city learns from the past and takes appropriate action based on evidence which means effective leadership, inclusive governance and evidence-based decision-making are required	Effective leadership and management: leadership is a key ingredient in encouraging individuals and communities to act during challenging times. Trusted individuals, multi-stakeholder consultation, evidence based decision-making and disaster risk reduction activities enable city to respond to shocks and stresses
	Empowered stakeholders: underpinned by information, education, knowledge and provision of early warnings, individuals and communities take appropriate decisions and act better under shocks and stresses
	Integrated development planning: the creation and implementation of integrated plans enable to deal with multidisciplinary issues (climate change, disaster risk reduction or emergency response) as well as ensure alignment of individual projects and programmes

## 4.2 Resilience Maturity Model

Resilience Maturity Model (RMM), developed within the project Smart Mature Resilience For More Resilient cities in Europe (SMR: Smart Mature Resilience Project, 2015), helps cities assessing the current resilience maturity level as well as identifying and prioritizing policies useful to improve in terms of resiliency (Hernantes et al., 2019). RMM identifies four dimensions: Leadership and Governance, Preparedness, Infrastructure and Resources, Cooperation. Each dimension contains subdimensions related to specific aspects of resilience (Table 2). For each of them, the framework provides some indicators to measure the resilience maturity level (Appendix - Table A2). RMM lays out five stages of maturity, namely Starting, Moderate, Advanced, Robust and Vertebrate that cities go through in the resilience building process.

Table 2. Resilience Maturity Model – dimensions. Adapted from: (Resilience Maturity Model Handbook, 2018)

Dimensions	Subdimensions
Leadership and Governance (L)	Municipality, cross-sectorial and multi-governance collaboration (L1) Legislation development and refinement (L2) Learning culture (learning and dissemination) (L3) Resilience action plan development (L4)
Preparedness (P)	Diagnosis and Assessment (P1) Education and Training (P2)
Infrastructure and resources (I)	Reliability of Critical Infrastructures (Cis) and their interdependences (I1) Resources to build up resilience and to response (I2)
Cooperation (C)	Development of partnerships with city stakeholders (C1) Involvement in resilience networks of cities (C2)

## 4.3 Sendai Framework for Disaster Risk Reduction

Sendai Framework for Disaster Risk Reduction 2015-2030 (SFDRR or Sendai Framework) (UNDDR, 2015), developed based on the Hyogo Framework for Action 2005-2015, was adopted at the Third UN World Conference on Disaster Risk Reduction in 2015. It aims to achieve by 2030 the substantial reduction of disasters' risk and losses in lives, livelihoods, and in the economic, physical, social, cultural, and environmental assets of persons, businesses, communities, and countries. Differently from the CRI and RMM frameworks which focus on resilience at city level, the Sendai Framework addresses resilience at national level. The Sendai Framework outlines four priorities for action (Table 3) and seven global targets to reduce disaster risks, losses in terms of human lives as well as

any economic, social, and environmental damages. The global targets (Table 4) may be clustered in two groups: targets from A to D concern specific outcomes, targets from E to G concern inputs or enablers. Each target is supported by one or more indicators (Sendai Framework Indicators, 2015). A total number of 38 indicators is provided to measure the achievement of resilience global targets (Appendix - Table A3).

Table 3. Sendai Framework for Disaster Risk Reduction – Priority for action

Priority	Description
Understanding disaster risk	Disaster risk management needs to be based on an understanding of disaster risk in all its dimensions of vulnerability, capacity, exposure of persons and assets, hazard characteristics and the environment
Strengthening disaster risk governance to manage disaster risk	Strengthening disaster risk governance at the national, regional and global levels for prevention, mitigation, preparedness, response, recovery and rehabilitation is necessary
Investing in disaster reduction for resilience	To enhance dimensions of resilience (e.g., economic, social, health) public and private investment in disaster risk prevention and reduction are essential. Such investments contribute to save lives, prevent, and reduce losses and ensure effective recovery and rehabilitation
Enhancing disaster preparedness for effective response, and build back better in recovery, rehabilitation and reconstruction	Making nations and communities resilient to disasters is fundamental. The constant growth of disaster risk combined with the lessons learned from the past disaster, indicates the need to prepare ahead the recovery, rehabilitation and reconstruction phase as an opportunity to "build back better"

#### **4.4 2030 Agenda for Sustainable Development**

2030 Agenda for Sustainable Development (United Nations, 2015) signed by the governments of the 193 member countries of the United Nations and approved by the UN General Assembly, outlines 17 Sustainable Development Goals framed within a broader action programme consisting of 169 linked targets, to be achieved by 2030. In the path towards sustainability, it is fundamental acknowledging the decisive role played by cities. They centralize the majority of the population and resources to be invested in fighting poverty, inequality and climate change. In 2017 UN Sustainable Development Solutions Network (SDSN) launched the U.S. Cities SDG Index in which Agenda 2030 goals and targets are scaled at the city level. Such a set of indicators was developed to support mayors, other local government leaders and the U.S. federal government to assess and measure the status of sustainable development through the lens of cities and Metropolitan Areas. In 2018, Eni Enrico Mattei Foundation, in collaboration with

UN SDSN network, published the Italia SDGs City Index, a similar set of indicators to be used by majors to assess the sustainability level of Italian cities so as to support policymaking. The Index outlines 46 indicators that cover 16 goals (SDSN, 2020). Table A4 in Appendix reports the full list of indicators. With the same purposes a similar list of indicators was also proposed in 2019 Index and Dashboards Report for European Cities (SDSN, 2019a). The indicators were used to assess European cities' sustainability. The indicators included in the U.S. Cities SDG Index resemble those reported in Agenda 2030; those adopted at the European and Italian level were in some cases modified to take into account the available local official statistics.

#### ***4.5 Equitable and Sustainable Territorial Well-Being***

In 2010, the Italian National Institute of Statistics (ISTAT), together with the National Council for Economics and Labour (CNEL), launched the Equitable and Sustainable Well-being Project to measure the quality of life at the national level (ISTAT, 2010). The framework includes a set of 153 indicators that covers 12 different domains of well-being e.g., Economic Prosperity, Health, Education (Monte et al., 2022). To consider differences at local scale and the territorial distribution of well-being (Bellantuono et al., 2021), in 2018 ISTAT published the Benessere Equo e Sostenibile dei Territori (BESdT, in English: Equitable and Sustainable Territorial Well-being) that provides a set of indicators to assess well-being for Italian provinces and metropolitan cities. The current version of the framework outlines 70 indicators spanning into 11 domains (compared to 12 of the equitable and sustainable well-being at national level) namely: Health, Education and training, Work and reconciliation of living times, Economic and well-being, Social relations, Policy and institutions, Safety, Landscape and cultural heritage, Environment, Innovation, Research and creativity, Quality of services (ISTAT, 2022). BESdT indicators are listed in Table A5 in Appendix.

## **5 Results and Discussion**

To achieve the paper's goal, a comparison between the frameworks described in Section 4 was carried out. Such a comparison was conducted in two stages. First, the three resilience frameworks were compared so as to identify possible common dimensions; the comparison was based on the indicators provided by the three frameworks. As CRI and RMM frameworks consider city as unit of

analysis, while the Sendai Framework addresses resilience at national level, to compare the three frameworks, the indicators provided by the Sendai Frameworks were scaled at urban level. Second, the resilience indicators provided by the three resilience frameworks were compared with those used to assess urban sustainability and well-being. To that aim, Agenda 2030 and BES, both scaled at city level, were considered. As the BESdT framework, as already mentioned, is specifically referred to the Italian territorial context, Italia SDG City Index (rather than the U.S. or European SDG index) was considered.

In this Section, the results of the study are presented and discussed. We discuss the dimensions common to the examined resilience frameworks. Then, overlaps and differences that arise in the comparison with sustainability and well-being frameworks are discussed by examining the indicators and metrics used.

### ***5.1 CRI, RMM and Sendai: common dimensions***

The analysis and comparison of indicators provided by the three resilience frameworks reveal that there are some commonalities between the resilience aspects addressed by the frameworks. Although similar indicators are included in different dimensions in the three frameworks, in many cases, they measure the same aspect of resilience. As shown in Table 5, four dimensions are common to the three frameworks (i.e., Risks identification and Assessment, Shock and disasters Management, Effective Emergency management, Knowledge Sharing and cooperation with other entities); three more dimensions are common to CRI and RMM frameworks (i.e., Services and Critical Infrastructures to address security and legal requirements, Insurance Coverage, and Resilience Plan). All resilience frameworks provide metrics to assess the urban systems' ability to identify and assess potential risks to which may be exposed: the Sendai framework provides more generic indicators (for instance, adoption and implementation of local disaster risk reduction strategies in line with national strategies), whereas CRI and RMM more specifically measure the ability of an urban system to assess risks: for instance, CRI provides metrics measuring the percentage of residential dwellings in high risk areas; both CRI and RMM focus on the measurement of the revision of risk assessment plans, so providing urban systems with some indicators to measure their ability to be prepared to face potential risks. Additionally, the three resilience frameworks include indicators to measure the urban system's ability to manage shock and disasters; however, the approach adopted to measure such a

dimension is different: Sendai focuses on the quantification of disasters' damage in terms of lives, livelihood and economic losses; differently, CRI and RMM look at the protection mechanisms that the urban system should have to be able to recover from a shock or a disaster (for instance, CRI provides metrics to measure the percentage of population which has access to disaster recovery mechanisms or the percentage of city's hospitals with back-up electricity generators); similarly, RMM measures the resources allocated to adopt infrastructures to face shocks. In other words, CRI and RMM address the resilience as ability of the urban system to react and recover from a shock, the Sendai mostly allows urban system to quantify the entity of damage occurred. Another common dimension among the three frameworks regards the emergency management: the Sendai framework only measures the capacity of urban systems to implement a pre-emptive evacuation after an emergency situation; CRI and RMM frameworks assess the capacity of the urban system to be prepared to an emergency situation (e.g., RMM measures the resources deployed to training, CRI measures the budget allocated to emergency planning). The cooperation with international and external networks of organizations are aspects taken into account by RMM and Sendai. Aspects related to knowledge sharing of resilience practices are considered both in RMM and CRI.

In conclusions, CRI and RMM frameworks are more similar: they adopt a common approach to the management of shocks and disasters (as they both assess the ability of urban system to recover from them) and to the emergency management (as they both assess the urban systems' capacity to be prepared to emergency). Additionally, CRI and RMM frameworks present two dimensions (Services and Critical Infrastructures to address security and legal requirements and Insurance coverage) that are addressed in similar manner and for which both frameworks provide very similar metrics.

Table 5. Comparison of CRI, RMM and Sendai Frameworks

Common dimensions	CRI – metric	RMM – indicator	Sendai - Indicator
Services and Critical Infrastructures to address security and legal requirements	Percentage of houses which have passed national safety standards (H&W)	Percentage of CIs that fulfil legal requirements (I1M5)	
	Percentage of city population with authorized electrical service (H&W)		
	Percentage of buildings within the city with planning permission records (I&E)		
Insurance Coverage	Percentage of buildings with insurance cover for high risk hazards relevant to the city (H&W)	Percentage of infrastructures and population with insurances (I2A1, I2A3, I2A4, I2R1,I2T2)	
Risks Identification and Assessment	Percentage of city area for which a comprehensive exposure and vulnerability assessment has been undertaken within the past 5 years (I&E)		
	Number of years since last citywide critical asset assessment (I&E)		Number of countries that have multi-hazard early warning systems (G-1)
	Number of years since the last city-wide review of the adequacy of the city's protective infrastructure assets (I&E)		
	Percentage of residential dwellings within the city that are situated within high risk areas (L&S)	Number of assessments to identify weaknesses (P1S1)	Percentage of local governments that adopt and implement local disaster risk reduction strategies in line with national strategies (E-2)
	The number of times the 5 most significant hazards identified in the city's local risk profile have been assessed by multi-stakeholders in the last 5 years (L&S)		
	Number of years since		

	city hazard maps have been updated (L&S)		
	Number of reviews of city-wide emergency protocols undertaken in the past 5 years (H&W)	Number of revisions of CI risk assessment (I1M4)	Percentage of local governments having a plan to act on early warnings (G-4)
Shock and disasters Management – Damage quantification		Average time for CIs to return to normality (I1M3)	A-1 Number of deaths and missing persons attributed to disasters, per 100,000 population
			A-2 Number of deaths attributed to disasters, per 100,000 population
			A-3 Number of missing persons attributed to disasters, per 100,000 population
			B-1 Number of directly affected people attributed to disasters, per 100,000 population
			B-2 Number of injured or ill people attributed to disasters, per 100,000 population
			B-3 Number of people whose damaged dwellings were attributed to disasters
			B-4 Number of people whose destroyed dwellings were attributed to disasters
			B-5 Number of people whose livelihoods were disrupted or destroyed, attributed to disasters
			C-1 Direct economic loss attributed to disasters in relation to global gross domestic product
			C-2 Direct agricultural loss attributed to disasters
			C-3 Direct economic loss to all other damaged or destroyed productive assets attributed to disasters
			C-4 Direct economic loss in the housing sector attributed to disasters

			C-5 Direct economic loss resulting from damaged or destroyed critical infrastructure attributed to disasters
			C-6 Direct economic loss to cultural heritage damaged or destroyed attributed to disasters
			D-1 Damage to critical infrastructure attributed to disasters
			D-2 Number of destroyed or damaged health facilities attributed to disasters
			D-3 Number of destroyed or damaged educational facilities attributed to disasters
			D-4 Number of other destroyed or damaged critical infrastructure units and facilities attributed to disasters
			D-5 Number of disruptions to basic services attributed to disasters
			D-6 Number of disruptions to educational services attributed to disasters
			D-7 Number of disruptions to health services attributed to disasters
			D-8 Number of disruptions to other basic services attributed to disasters
Shock and Disasters Management – Recovery and protection mechanisms	Number of mechanisms in place to support local, small- and medium sized businesses following a disaster (H&W)	Percentage of businesses/CIs with contingency plans (P1S3)	
	Percentage of population which has access to disaster recovery mechanisms from shocks (H&W)	Resources allocated to adopt extraordinary infrastructures to face shocks (I1S3,	

	I1A1, I1T1)	
Number of days that city fuel supplies could maintain essential household functions (through alternative sources) (H&W)	Resources invested in preventive maintenance activities (I1M2)	
Percentage of population that could be served by city's access to stock of emergency shelters for 72 hours (H&W)	Number of maintenance procedures in each CI sector (I1M2)	
Percentage of population which can be supplied water by alternative methods for 72 hours during disruption (H&W)	Number of redundant systems-infrastructures per CI sector (I1M3)	
Percentage of city's hospitals with back-up electricity generators (I&E)		
Percentage of city's hospitals with back-up water supply to meet its needs for three days (I&E)		
Percentage of emergency responders with arrangements which enable them to communicate in an emergency (satellite phones, airwaves) (I&E)		
Percentage of city government data with secure back-up remote storage (I&E)		
Percentage of government databases protected by a dynamic proactive I.T. security system (I&E)		
De-rated capacity margin: the amount of excess electricity supply above peak demand (expressed as a percentage) (I&E)		
Percentage of infrastructure which relies on operational		

	technology protected by a dynamic proactive I.T. security system (I&E)		
	Percentage of government departments that have tested their own continuity arrangements in the last 2 years (L&S)		
Effective Emergency management	Percentage of hospitals that have carried out disaster preparedness drills in the last year (H&W)	Resources deployed for training exercises (P2S1, P2M1, P2A1, P2A2, P2A4, P2R2, P2T1, P2T2, P2T3)	
	Number of search and rescue trained emergency responders with collapsed structures expertise per 100,000 population (H&W)		
	Number of reviews of city-wide emergency protocols undertaken in the past 5 years (H&W)		
	Percentage of the police force which has undertaken disaster response training in the last 5 years (E&S)	Frequency of training exercises (P2S1, P2M1, P2A1, P2A2, P2R2, P2T1, P2T2, P2T3)	
	Emergency planning budget as a percentage of total city budget (E&S)	Number of trained volunteers (P2S2, P2R1, P2T3)	
	Number of times the city's multi-stakeholder emergency management strategy has been tested in the last 5 years (L&S)		
	Number of times multi-stakeholder emergency responders meet and undertake joint activities (e.g., exercises, risk assessment, plan reviews) per year (L&S)	Effectiveness of training exercises (P2S1, P2S3, P2M1, P2A1, P2A2, P2A4, P2R2, P2T2)	
	Number of times the emergency response centre capability has been tested (and successfully passed) in the last 5 years (for real or scenario) (L&S)	Existence of emergency plans that integrate stakeholders (C1S1, C1M1)	

	Percentage of citizens intended to be evacuated, which were successfully evacuated in the last disaster drill or disaster event in the last 5 years (L&S)		
Resilience Plan	Percentage of population that have made a household or a community resilience plan (L&S)	Resources dedicated to the development of the resilience action plan (L4S1, L4M1, L4A1, L4R1)	
		Number of updates of the resilience action plan (L4R1)	
		Percentage of local government budget spent on resilience building activities (L3S1, L3M1)	
Knowledge Sharing and cooperation with other entities	Number of training and knowledge sharing agreements with international networks (L&S)	Number of cooperation agreements with external governmental bodies and cities (L3T2)	F-1 Total official international support, (official development assistance (ODA) plus other official flows), for national disaster risk reduction actions
		Learning activities executed among stakeholders and with other cities (L3M2, L3T2)	F-2 Total official international support (ODA plus other official flows) for national disaster risk reduction actions provided by multilateral agencies
		Number of best practices shared among stakeholders (L3A1, L3R1, L3T1, L3T2)	F-3 Total official international support (ODA plus other official flows) for national disaster risk reduction actions provided bilaterally
		Effort taken to learn from what other stakeholders do to increase resilience (L3M2, L3A1, L3R1, L3T1, L3T2)	F-4 Total official international support (ODA plus other official flows) for the transfer and exchange of disaster risk reduction-related technology
			F-5 Number of international, regional and bilateral programmes and initiatives for the transfer

			and exchange of science, technology and innovation in disaster risk reduction for developing countries
			F-6 Total official international support (ODA plus other official flows) for disaster risk reduction capacity-building
			F-7 Number of international, regional and bilateral programmes and initiatives for disaster risk reduction-related capacity-building in developing countries

### **5.2 Resilience and Sustainability: similarities and divergences**

The comparison of indicators provided by the three resilience frameworks with those reported in the sustainability and well-being frameworks reveals that resilience and sustainability partially overlap. As shown in Table 6, one dimension is common to all frameworks, i.e., risk identification and assessment. For instance, both Italia SDGs City Index and BESdT provide metrics that measure the population at risks of flooding. However, CRI, RMM and Sendai examine a full range of risks through specific indicators (e.g., percentage of residential dwellings in high-risk areas, number of assessments to identify weaknesses, adoption of risk reduction strategies). The Sendai Framework has only one more indicator in common with Italia SDGs City Index (i.e., number of deaths and missing persons attributed to disasters) and with BESdT (i.e., disruptions of basic services - in the specific case of BESdT, the basic service considered is electricity). However, the approach is different: the Sendai Framework measures disruptions to quantify damage due to disasters, BESdT assesses the quality of services offered at the city level (not necessarily under emergency conditions). RMM presents one more similarity with both the sustainability and well-being frameworks: RMM and BESdT measure the involvement of citizens in education or training activities (BESdT promotes participation in cultural activities, RMM promotes social, cultural, economic and environmental activities). RMM and Italia SDGs City Index measure alignment with national resilience and environmental sustainability standards, respectively.

A stronger overlap between resilience and sustainability emerges when CRI framework is considered. By comparing CRI with Italia SDGs City Index and BESdT, 12 and 21 correspondences are obtained, respectively. All three frameworks adopt perfectly overlapping metrics to measure well-being and health (e.g., life expectancy at birth and infant mortality rate), economy prosperity (e.g., GDP), environment and ecosystem protection (i.e., PM10 concentration, municipal waste production), safety and efficiency of critical services (e.g., the sustainability and well-being framework measure the number of deaths related to road transport, the CRI framework considers the mortality rate related to all type of transports); both CRI and BESdT include the interruption of basic critical services which is specifically addressed by measuring the number or the length of interruptions of the electrical service. Although measured by adopting slightly different metrics, the electoral participation and the level of education of the population are measured in all frameworks. Other aspects addressed by both the resilience and well-being frameworks concern the availability of hospital beds, gender equality at political level, the unemployment rate, the environmental protection rate of urban areas, number of murders committed, and number of charitable organizations.

The considered sustainability and well-being frameworks do not consider the importance of planning regular maintenance procedures for critical infrastructures and more generally do not consider the need for disaster planning and prevention which are assessed by the CRI and RMM frameworks. Resilience frameworks focus on stakeholder engagement, the creation of a sense of community and a culture of resilience, dimensions that are not relevant to sustainability and well-being frameworks. Furthermore, the lack of plans for cooperation with other cities facing similar risks and knowledge sharing, that are indicators considered by RMM, CRI and Sendai Framework, lead to further points of divergence among resilience and sustainability and well-being frameworks. The well-being of a society is also reflected in its way of inhabiting the land and taking care of its cultural heritage. The dimension of creativity is included only in the BESdT framework and is not reflected in any of the other analysed resilience frameworks.

Table 6. Comparison of resilience, sustainability and well-being frameworks

<b>Italia SDSs City Index - indicator</b>	<b>BESdT- indicator</b>	<b>CRI- indicator</b>	<b>RMM - indicator</b>	<b>Sendai - indicator</b>	<b>Synthesis indicator</b>
Economic suffering index (Goal1)		Percentage of population living below national poverty line (H&W)			Poverty
Life expectancy at birth (Goal3)	Life expectancy at birth (Health)	Average life expectancy at birth (years) (H&W)			Life expectancy at birth
Infant mortality rate (Goal3)	Infant mortality rate (Health)	Maternal mortality rate per 100,000 live births (H&W)			Infant mortality
Deaths and injuries in road traffic injuries (Goal 3)	Road accidents mortality rate (15-34 years old) (Health)	Transportation fatalities per 100 000 population (I&E)			Transport-related deaths
	Hospital beds per 10,000 inhabitants (Quality of services)	Hospital beds per 100,000 people (H&W)			Hospital capacity
Population with Isced 3 Middle School License (Goal 4)		Percentage primary education completion rates (L&S)			Completing education
	People with at least upper secondary education level (25-64 years old) (Education and training)	Percentage of adults with higher education as a percentage of total population aged 16-64 (E&S)			Completing education
	Women municipal councillors (Politics and institutions)	Women as a percentage of total elected to city-level office (E&S)			Gender equality

	Irregularities in electric power distribution (Quality of services)	Average length of electrical interruptions (I&E)		D-5 Number of disruptions to basic services attributed to disasters	Basic services interruptions
Average taxable income per capita (Goal 8)	Average disposable income per capita (Economic well-being)	GDP (PPP,\$) per capita (E&S)			Gross domestic product
	Non-participation rate (Work and life balance)	City's unemployment rate (% of working-age population) (H&W)			Unemployment
	Youth's non-participation rate (Work and life balance)	Youth unemployment rate (percentage of youth labour force) (E&S)			Youth unemployment
	Average annual salary of employees (Economic well-being)	Average hourly compensation cost (wage + benefits) for an hour of labour (H&W)			Workers' wages
Mobility offer public transport (Goal 9)	Seat-Km of public transport networks (Quality of services)	Percentage of commuters using a travel mode other than a personal vehicle (as a percentage of total commuters) (I&E)			Public transport efficiency
PM10 (Goal 11)	PM10 Annual average concentration (Environment)	PM10 concentration (I&E)			PM10 concentration

Number of deaths, missing persons and directly affected persons attributed to disasters per 100,000 population (Goal 11)				A-1 Number of deaths and missing persons attributed to disasters, per 100,000 population	Shock and disasters management
Municipal waste production (Goal 12)	Municipal waste generated (Environment)	Waste generation rate per capita (municipal solid waste, kg per capita per year) (I&E)			Municipal waste production
	Separate collection service for municipal waste (Quality of services)	Percentage of the city population with regular solid waste collection (I&E)			Waste collection management
Population exposed to flood risk (Goal 13)	Population at risk of landslides Population at risk of flood (Environment)	Percentage of residential dwellings within the city that are situated within high risk areas (L&S)	Number of assessments to identify weaknesses (P1S1)	E-2 Percentage of local governments that adopt and implement local disaster risk reduction strategies in line with national strategies	Risk identification and Assessment
Ecolabel licenses (Goal 15)			Number of certifications (L2A1, L2R1, L2T1)		Alignment with standards
	Protected natural areas (Environment)	Percentage of city area that has been officially recognised for environmental protection (including shorelines)			Environmental protection

		down to low-tide mark) (E&S)			
Political electoral participation 2018 (Goal 16)	Voter turnout (Regional Councils) (Politics and institutions)	Voter participation in last municipal election (as a percentage of eligible voters) (E&S)			Electoral participation
	Intentional homicide rate (Safety)	Homicides per 100,000, per year (E&S)			Homicides
Broadband access (Goal 17)		Internet users (I&E)			Users with internet connection
	Non-profit organizations (Social relationships)	Number of charities operating in the city per 100,000 population (E&S)			Charitable organizations
	Participation in life-long learning (Education and training)		Number of trained volunteers (P2S2, P2R1, P2T3)		Citizen involvement

## 6 Conclusions

The existence of different definitions and frameworks to measure resilience may confuse urban decision-makers who need to develop policies and plans to increase urban resilience. To clarify the concept of urban resilience, three well-known resilience frameworks (CRI, RMM, and Sendai Framework) were analysed and compared. Some resilience dimensions common to the three frameworks were identified (e.g., Risks identification and assessment, Shock and disasters management, Effective emergency management, Knowledge sharing and cooperation with other entities). We found that while CRI and RMM share a common preventive approach to the management of shocks and disasters, the Sendai framework mainly focuses on the measurement of the entity of damages and losses occurred after a disaster.

The paper also discussed the relationship between (i) resilience and (ii) sustainability and well-being in the urban domain. The comparison, based on the

indicators provided by the three examined urban resilience frameworks and two sustainability and well-being frameworks, namely Italy SDGs City Index and BESdT, highlights that resilience and sustainability are partially overlapping concepts. The considered resilience and sustainability frameworks indeed provide the same indicators to measure aspects such as health, economic prosperity, environmental protection, safety and efficiency of critical services, and very similar indicators to assess some other aspects such as the level of education attained by population or the electoral participation. However, some differences also arise, e.g., the importance of planning and knowledge sharing. The leverage of culture, community sense, and stakeholder engagement, which are relevant dimensions/indicators in resilience frameworks, are of little relevance in sustainability and well-being frameworks.

From a theoretical perspective, the paper provides further insights into the concept of resilience and clarifies the relationship between resilience and sustainability and well-being in the context of cities. From a practical point of view, the results of the analysis can be used by policymakers to assess and monitor the resilience, sustainability and well-being of the urban system as well as define policies able to address such issues.

Despite their relevance, only few frameworks were examined and compared. Further research will include the analysis of other frameworks as well as the examination of resilience and sustainability indicators provided by academic studies. Based on that, the development of a comprehensive set of indicators, including resilience, sustainability, and well-being metrics will be developed.

## Appendix

Table A1. City Resilience Index – Indicators and metrics

CRI - Dimensions	CRI - Goals	CRI - Indicators	CRI - Metric	
Health and wellbeing	Minimal Human Vulnerability	Safe and affordable housing	Number of homeless people per 100,000 population	
			Percentage of houses which have passed national safety standards	
			Percentage of population that could be served by city's access to stock of emergency shelters for 72 hours	
		Adequate affordable energy supply	Average percentage of household income spent on fuel and electricity by the poorest 20 percent of the population	
			Percentage of city population with authorized electrical service	
			Number of days that city fuel supplies could maintain essential household functions	
		Inclusive access to safe drinking water	Percentage of population that has access to safe and reliable water	
			Percentage of population which can be supplied water by alternative methods for 72 hours during disruption	
		Effective sanitation	Percentage of population with access to improved sanitation	
			The number of years since the city's wastewater contingency plan was updated	
		Sufficient affordable food supply	Percentage of malnourished children under five as a percentage of all citizens under five	
			Average distance of the centre of the 20 percent most deprived neighbourhoods (LSOA level and the Index Measure of Deprivation) from a vegetable market or supermarket selling fresh food and vegetables	
			Percentage per capita food reserves within city (including supermarket agreements) for 72 hours (percentage population which could be served)	
		Diverse Livelihood and Employment	Inclusive labour policies	Average hourly compensation cost (wage + benefits) for an hour of labour (US Dollars)
				Percentage of population living below national poverty line
Relevant skills and training	Percentage of people unemployed for more than 6 months who have access to a programme that is intended to improve their employment chances			
	Job security: Probability to become unemployed (the number of people who were unemployed in this year, but were employed last year, divided by the total number of employed in last year, x 100 and expressed as a percentage)			

		Local business development and innovation	Percentage employment change from the last year	
			City's unemployment rate (% of working-age population)	
			Number of new businesses registered within the city in past year, per 100,000 population	
			Percentage of local businesses with female / minority owner	
		Supportive financing mechanisms	Annual number of approved and regulated small business-loans or micro-credit per 100,000 population	
			Percentage value of loans / credit provided to female / minority owned businesses as a percentage of overall loans	
		Diverse protection of livelihoods following a shock	Percentage of buildings with insurance cover for high risk hazards relevant to the city	
			Percentage of population which has access to disaster recovery mechanisms from shocks	
			Number of mechanisms in place to support local, small- and medium sized businesses following a disaster	
		Effective safeguards to human health and life	Robust public health systems	Percentage of children 12-23 months who have received specific vaccines for BCG, measles, and three doses each of DPT and polio vaccine (excluding polio 0 months) per poorest quintile of the population (percentage 12-23 year olds within poorest 20% population)
				Average life expectancy at birth (years)
				Drug-related mortality with drugs as primary cause of death per 100,000 population aged 15-64
	Adequate access to quality health care		Number of physicians (MD/DO degree) working within the city per 100,000 population	
			Maternal mortality rate per 100,000 live births	
			Premature (before age of 70) NCD mortality rate per 100,000 population	
			Number of mental health practitioners per 100,000 population	
	Emergency medical care		Hospital beds per 100,000 people	
	Effective emergency response services		Percentage of hospitals that have carried out disaster preparedness drills in the last year	
			Number of paramedics per 100,000 population	
Number of fire-fighters per 100,000 population				
Number of (operational) police officers per 100,000 population				
Number of search and rescue trained emergency responders with collapsed structures expertise per 100,000 population				
Number of reviews of city-wide emergency protocols undertaken in the past 5 years				

Economy and society	Collective identity and mutual support	Local community support	Percentage children living outside of the care of a responsible adult
			Family benefits public spending as a percentage of total city GDP
			Percentage of people who responded that they know the names of their immediate neighbours
		Cohesive communities	Hate crimes reported per 100,000 population
			Women as a percentage of total elected to city-level office
			Youth unemployment rate (percentage of youth labour force)
		Strong city-wide identity and culture	Percentage of respondents who felt a sense of pride in their neighbourhood
			Number of months throughout the year that have a major, free public festival
		Actively engaged citizens	Voter participation in last municipal election (as a percentage of eligible voters)
			Proportion of corporate charitable giving within community as a percentage of city GDP
			Number of charities operating in the city per 100,000 population
		Comprehensive security and law	Effective systems to deter crime
	Percentage re-offending by youths leaving custody		
	Percentage of women and men who report feeling safe walking alone at night in the city or area where they live		
	Proactive corruption and prevention		Percentage of local major local government contracts and tenders (of more than \$15,500) made public
			Proportion of city residents that agree corruption is somewhat or very common
	Competent policing		Homicide arrest rate: The number of persons arrested for intentional homicide in a given year divided by the number of reported intentional homicides in the same year, x 100 and expressed as a percentage
			Percentage of the police force which has undertaken disaster response training in the last 5 years
	Accessible criminal and civil justice		Percentage difference of criminal or civil punishments imposed by judges for the same type of crime from a total average compared to the defendant's or victim's race, for the two biggest ethnic groups
			Percentage of people taken into police custody who have the option of a lawyer made available to them before questioning
Weeks between a small claims case (less than £10,000 / \$15,500) being submitted to court and			

			hearing (expressed in weeks)
	Sustainable economy	Well-managed public finances	Own-source revenue as a percentage of total revenues
			Debt service ratio: total long-term debt servicing costs including lease payments, temporary financing and other debt charges divided by total own source revenue and expressed as a percentage
			Emergency planning budget as a percentage of total city budget
		Comprehensive business continuity planning	Number of years since city economic asset assessment (public and private)
			Percentage of large businesses (500+ employees) within the city that have developed business continuity plans in accordance with ISO 22301
			Percentage of registered SMEs the city has engaged with regarding business continuity in the last 5 years
		Diverse economic base	Percentage employment per sector by broad industry group
			Average GDP per capita percentage change over last 5 years
			GDP (PPP,\$) per capita
			Percentage of total medium and large businesses (250 employees +) within the city that are a member of the chamber of commerce
		Attractive business environment	Average FDI (foreign direct investment)-attributable jobs over the last 3 years per 100,000 16-64 year olds
			Number of businesses per 100,000 16-64 year olds
			Percentage of adults with higher education as a percentage of total population aged 16-64
		Strong integration with regional and global economies	Value of city exports as a percentage of city GDP
	Average city GDP per capita minus national average GDP per capita expressed as a percentage		
Infrastructure and ecosystems	Reduced exposure and fragility	Comprehensive hazard and exposure mapping	Percentage of city area for which a comprehensive exposure and vulnerability assessment has been undertaken within the past 5 years
			Years since the city's climate change strategic plan was updated
		Appropriate codes, standards and enforcement	Estimated percentage of new buildings completed within the city in the last 5 years that conform to current building codes and standards
			Percentage of buildings within the city with planning permission records
			Number of years since oldest current building code was reviewed
		Effectively managed	Percentage of natural areas within the city that have undergone ecological evaluation for their

		protective ecosystems	protective services
			Percentage green, open space increase or decrease over the past 5 years
			Percentage of city area that has been officially recognised for environmental protection (including shorelines down to low-tide mark)
		Robust protective infrastructure	Number of years since the last city-wide review of the adequacy of the city's protective infrastructure assets
			Number of years the city's stormwater (or other protective) infrastructure has been inspected
			Percentage of annual budget for stormwater infrastructure spent on upgrades
	Effective provision of critical services	Effective stewardship of ecosystems	Number of years since assessment of the city's ecosystem assets / services
			PM10 concentration ( $\mu\text{g}/\text{m}^3$ )
			Percentage change in the number of native species
		Flexible infrastructure	How many years ahead does the city's electricity plan look
			Number of different supply sources providing at least 5 percent of electricity generation capacity
			How many years ahead does the city's water plan look
			Number of different supply sources providing at least 5 percent of water supply capacity
			Average \$ per \$10,000 of total annual expenditure of city sanitation provider(s) spent on strategic, long-term (10 years +) planning activities
			Percentage of annual unsound waste disposal (as a percentage of total disposal)
			Number of different solid waste treatment or disposal plants processing at least 5 percent solid waste generated within the city (Number of sources)
		Retained spare capacity	De-rated capacity margin: the amount of excess electricity supply above peak demand (expressed as a percentage)
			Average annual residential electrical use in kw hours per year per capita
			City electricity supply capacity as a percentage of total demand
			Total water consumption per capita (litres/day)
Percentage of the city's wastewater that has received no treatment			
Percentage of the city population with regular solid waste collection			
Waste generation rate per capita (municipal solid waste, kg per capita per year)			
Diligent	Average length of electrical interruptions (hours)		

		maintenance and continuity	per year per customer)	
			Average annual hours of water service interruptions per household	
			Annual percentage of wastewater system losses (due to storms or malfunction) prior to treatment and/or discharge to the environment	
			Percentage of defined medium- to long-term waste management service contracts agreements (as a percentage of total waste service contracts)	
		Adequate continuity for critical assets and services	Number of years since last citywide critical asset assessment	
			Percentage of city's hospitals with back-up electricity generators	
			Percentage of city's hospitals with back-up water supply to meet its needs for three days	
		Reliable mobility and communications	Diverse and affordable transport networks	Average speed of road journeys from city centre to the city boundary (km per hour)
				Percentage of commuters using a travel mode other than a personal vehicle (as a percentage of total commuters)
	Percentage of journeys undertaken by walking or cycling			
	Number of other cities to which this city has daily connections by bus			
	Effective transport operation and maintenance		Average percentage of the city's transport budget spent on maintenance and upgrade over the past 5 years	
			Transportation fatalities per 100 000 population	
			Number of years since the city evacuation plan was updated	
	Reliable communications technology		Internet users (per 100 people)	
			Number of media types used to alert people in an emergency	
			Percentage of emergency responders with arrangements which enable them to communicate in an emergency	
	Secure technology networks		Percentage of city government data with secure back-up remote storage	
Percentage of government databases protected by a dynamic proactive I.T. security system				
Percentage of infrastructure which relies on operational technology protected by a dynamic proactive I.T. security system				
Leadership and strategy	Effective leadership and management		Appropriate government decision making	Number of training and knowledge sharing agreements with international networks
				Percentage of non-sensitive city government documentation and data sets that are publically available
	Effective co-ordination with	Percentage of major policy / regulatory decisions made within the last year that were the product of		

		other government bodies	city-upwards, downwards (regional, national) government consultation
			Percentage of major policy / regulatory decisions made within the last year that were that are the product of cross-departmental government consultation
		Proactive multi-stakeholder collaboration	Percentage of major projects within the last year which included private sector consultation
			Percentage of city government major policy and plan changes within the past year sent out to public consultation
		Comprehensive hazard monitoring and risk assessment	Number of years since city hazard maps have been updated
			Percentage of local severe weather warnings issued by national metrological agency which are received in a timely fashion by city emergency responders
			The number of times the 5 most significant hazards identified in the city's local risk profile have been assessed by multi-stakeholders in the last 5 years
		Comprehensive government emergency management	Percentage of government departments that have tested their own continuity arrangements in the last 2 years
			Number of times the city's multi-stakeholder emergency management strategy has been tested in the last 5 year
			The number of times the 5 most significant hazards identified in the city's local risk profile have been exercised in the last 5 years. (Add up total and divide by 5)
			Number of times multi-stakeholder emergency responders meet and undertake joint activities (e.g. exercises, risk assessment, plan reviews) per year
			Number of times the emergency response centre capability has been tested (and successfully passed) in the last 5 years (for real or scenario)
	Empowered stakeholders	Adequate education for all	Percentage primary education completion rates
			Adult literacy rate (as a percentage)
		Widespread community awareness and preparedness	Percentage of households that have a smoke alarm
			Percentage of population that have made a household or a community resilience plan
			Percentage of citizens intended to be evacuated, which were successfully evacuated in the last disaster drill or disaster event in the last 5 years
		Effective mechanism for communities to	Percentage of major city plans published in the last year that incorporate consultation with communities

		engage with government	
	Integrated development planning	Comprehensive city monitoring and data management	Percentage of census data available for planning
			Number of years validity of population projections
			Percentage of residential dwellings within the city that are situated within high risk areas
		Consultative planning process	Percentage of current land use and zoning plans that have been subject to a formal consultation process
			Percentage of current land use and zoning plans that have been subject to a formal consultation process with utility providers and transport agencies
			Percentage of current land use and zoning plans that have been subject to a formal consultation process with minority communities affected by the development
		Appropriate land use and zoning	Areal size of informal settlements as a percentage of city are
			Percentage of high risk areas within the city where development is restricted or prohibited under planning guidelines
			Amount spent on transport in the last 5 years as percentage of overall city budget
			Number of years since the city plan was updated
		Robust planning approval process	Percentage of buildings [or new development] constructed within the city in the past 10 years that were approved or otherwise authorised by the relevant city planning authorities
			Percentage of planning applications submitted to the city during the past 5 years on which emergency services agencies have been consulted

Table A2. Resilience Maturity Model - Indicators

Dimensions	Subdimensions	Indicators
Leadership and Governance (L)	Municipality, cross-sectorial and multi-governance collaboration (L1)	Number of cooperation agreements with CITY stakeholders (L1M2)
		Resources dedicated to the development of the resilience action plan (L1S1, L1S2, L1M1, L1M3, L1M4)
		Number of cooperation agreements with external governmental bodies and cities (L1M2, L1A1, L1A2, L1R1, L1T1)
		Number of stakeholder group involved in resilience-building activities about resilience (L1M1, L1A2)
		Number of policies aligned with regional, national and international input (L1M2, L1A1, L1R1, L1T2)
	Legislation development and refinement (L2)	Number of cooperation agreements with external governmental bodies and cities (L2M1)
		Number of certifications (L2A1, L2R1, L2T1)
	Learning culture (learning and	Effort taken to learn from what other stakeholders do to increase resilience (L3M2, L3A1, L3R1, L3T1, L3T2)

	dissemination) (L3)	Number of cooperation agreements with external governmental bodies and cities (L3T2)		
		Percentage of local government budget spent on resilience building activities (L3S1, L3M1)		
		Number of debriefing meetings carried out (L3A1, L3T1, L3T2)		
		Learning activities executed among stakeholders and with other cities (L3M2, L3T2)		
		Percentage of lessons learned implemented per lessons learned identified (L3A1, L3R1, L3T1)		
		Number of best practices shared among stakeholders (L3A1, L3R1, L3T1, L3T2)		
	Resilience action plan development (L4)	Resources dedicated to the development of the resilience action plan (L4S1, L4M1, L4A1, L4R1)		
Preparedness (P)	Diagnosis and Assessment (P1)	Number of analysis of CIs interdependencies (P1M1)		
		Number of assessments to identify weaknesses (P1S1)		
		Number of revisions of CI risk assessment (P1S2, P1A1, P1R1)		
		Number of policies aligned with regional, national and international input (P1T1)		
		Percentage of businesses/CIs with contingency plans (P1S3)		
	Education and Training (P2)	Resources deployed for training exercises (P2S1, P2M1, P2A1, P2A2, P2A4, P2R2, P2T1, P2T2, P2T3)		
		Number of cooperation agreements with external governmental bodies and cities (P2A2, P2R2, P2T1, P2T2)		
		Number of cooperation agreements with CITY stakeholders (P2S1, P2M1, P2A3, P2R1)		
		Number of awareness raising events targeting CITY stakeholders (P2S2, P2S3, P2A3)		
		Frequency of training exercises (P2S1, P2M1, P2A1, P2A2, P2R2, P2T1, P2T2, P2T3)		
		Number of trained volunteers (P2S2, P2R1, P2T3)		
		Effectiveness of training exercises (P2S1, P2S3, P2M1, P2A1, P2A2, P2A4, P2R2, P2T2)		
		Infrastructure and resources (I)	Reliability of Critical Infrastructures (Cis) and their interdependences (I1)	Resources allocated to adopt extraordinary infrastructures to face shocks (I1S3, I1A1, I1T1)
				Resources allocated to improve the reliability of the CI (I1S2, I1M3)
Number of stress tests/audits (I1M5)				
Resources invested in preventive maintenance activities (I1M2)				
Number of cooperation agreements with CITY stakeholders (I1S1)				
Number of revisions of CIs risk assessment (I1M4)				
Number of analysis of CIs interdependencies (I1M1, I1R1)				
Number of maintenance procedures in each CI sector (I1M2)				
Number of redundant systems-infrastructures per CI sector (I1M3)				
Percentage of CIs that fulfil legal requirements (I1M5)				
Average time for CIs to return to normality (I1M3)				
Resources to build up resilience and to response (I2)	Resources dedicated to the development of the resilience action plan (I2M1)			
	Resources allocated to incentivize CITY stakeholders to invest in			

		resilience (I2M2, I2A1, I2A3, I2A4, I2R1, I2T2)
		Percentage of local government budget spent on resilience building activities (I2S2, I2S3, I2A2, I2R2)
		Percentage of resources dedicated to lead EU projects or other joint initiatives (I2T1)
		Percentage of infrastructures and population with insurances (I2A1, I2A3, I2A4, I2R1, I2T2)
		Funding received from EU projects and similar initiatives (I2S1)
Cooperation (C)	Development of partnerships with city stakeholders (C1)	Number of cooperation agreements with CITY stakeholders (C1S1, C1M1, C1A1, C1A2, C1T1)
		Number of debriefing meetings carried out (C1R2, C1T2)
		Number of mechanisms (platforms, websites) to share lessons learned with CITY stakeholders (C1S2, C1M2, C1A4)
		Number of awareness raising events targeting CITY stakeholders (C1A3, C1R2)
		Number of stakeholder group involved in resilience-building activities about resilience (C1A2, C1R1, C1T2)
		Number of best practices shared among stakeholders (C1M2, C1A3, C1R2, C1T2)
	Involvement in resilience networks of cities (C2)	Existence of emergency plans that integrate stakeholders (C1S1, C1M1)
		Number of cooperation agreements with external governmental bodies and cities (C2M1, C2A1, C2A2, C2R1, C2T1, C2T2)
		Number of mechanisms (platforms, websites) to share lessons learned with CITY stakeholders (C2T2)
		Number of policies aligned with regional, national and international input (C2T1, C2T2)

Table A3. Sendai Framework - Indicators

Sendai – Global Target	Indicators
A: Substantially reduce global disaster mortality by 2030, aiming to lower average per 100,000 global mortality between 2020-2030 compared with 2005-2015	A-1 Number of deaths and missing persons attributed to disasters, per 100,000 population
	A-2 Number of deaths attributed to disasters, per 100,000 population
	A-3 Number of missing persons attributed to disasters, per 100,000 population
B: Substantially reduce the number of affected people globally by 2030, aiming to lower the average global figure per 100,000 between 2020-2030 compared with 2005-2015	B-1 Number of directly affected people attributed to disasters, per 100,000 population
	B-2 Number of injured or ill people attributed to disasters, per 100,000 population
	B-3 Number of people whose damaged dwellings were attributed to disasters
	B-4 Number of people whose destroyed dwellings were attributed to disasters
	B-5 Number of people whose livelihoods were disrupted or destroyed, attributed to disasters
C: Reduce direct disaster economic loss in relation to global gross domestic product (GDP) by 2030	C-1 Direct economic loss attributed to disasters in relation to global gross domestic product
	C-2 Direct agricultural loss attributed to disasters

	C-3 Direct economic loss to all other damaged or destroyed productive assets attributed to disasters
	C-4 Direct economic loss in the housing sector attributed to disasters
	C-5 Direct economic loss resulting from damaged or destroyed critical infrastructure attributed to disasters
	C-6 Direct economic loss to cultural heritage damaged or destroyed attributed to disasters
D: Substantially reduce disaster damage to critical infrastructure and disruption of basic services, among them health and educational facilities, including through developing their resilience by 2030	D-1 Damage to critical infrastructure attributed to disasters
	D-2 Number of destroyed or damaged health facilities attributed to disasters
	D-3 Number of destroyed or damaged educational facilities attributed to disasters
	D-4 Number of other destroyed or damaged critical infrastructure units and facilities attributed to disasters
	D-5 Number of disruptions to basic services attributed to disasters
	D-6 Number of disruptions to educational services attributed to disasters
	D-7 Number of disruptions to health services attributed to disasters
	D-8 Number of disruptions to other basic services attributed to disasters
E: Substantially increase the number of countries with national and local disaster risk reduction strategies by 2020	E-1 Number of countries that adopt and implement national disaster risk reduction strategies in line with the Sendai Framework for Disaster Risk Reduction 2015-2030
	E-2 Percentage of local governments that adopt and implement local disaster risk reduction strategies in line with national strategies
F: Substantially enhance international cooperation to developing countries through adequate and sustainable support to complement their national actions for implementation of this framework by 2030	F-1 Total official international support, (official development assistance (ODA) plus other official flows), for national disaster risk reduction actions
	F-2 Total official international support (ODA plus other official flows) for national disaster risk reduction actions provided by multilateral agencies
	F-3 Total official international support (ODA plus other official flows) for national disaster risk reduction actions provided bilaterally
	F-4 Total official international support (ODA plus other official flows) for the transfer and exchange of disaster risk reduction-related technology
	F-5 Number of international, regional and bilateral programmes and initiatives for the transfer and exchange of science, technology and innovation in disaster risk reduction for developing countries
	F-6 Total official international support (ODA plus other official flows) for disaster risk reduction capacity-building
	F-7 Number of international, regional and bilateral programmes and initiatives for disaster risk reduction-related capacity-building in developing countries
	F-8 Number of developing countries supported by international,

	regional and bilateral initiatives to strengthen their disaster risk reduction-related statistical capacity
G. Substantially increase the availability of and access to multi-hazard early warning systems and disaster risk information and assessments to people by 2030.	G-1 Number of countries that have multi-hazard early warning systems
	G-2 Number of countries that have multi-hazard monitoring and forecasting systems
	G-3 Number of people per 100,000 that are covered by early warning information through local governments or through national dissemination mechanisms
	G-4 Percentage of local governments having a plan to act on early warnings
	G-5 Number of countries that have accessible, understandable, usable and relevant disaster risk information and assessment available to the people at the national and local levels
	G-6 Percentage of population exposed to or at risk from disasters protected through pre-emptive evacuation following early warning

Table A4. Italia SDGs City Index

<b>Italia SDGs City Index - target</b>	<b>Indicators</b>
Goal 1. End poverty in all its forms everywhere	Economic suffering index
	Individuals in households with low-work intensity
Goal 2. End hunger, achieve food security and improved nutrition and promote sustainable agriculture	Obesity and severe obesity
	Urban gardens
Goal 3. Ensure healthy lives and promote well-being for all at all ages	Life expectancy at birth
	Life expectancy at 65 years
	Infant mortality rate
	Deaths from suicide and intentional self-injury
	Deaths and injuries in road traffic injuries
Goal 4. Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all	Alphabetical competence level of the students
	Numerical competence level of the students
	Population with Isced 3 Middle School License
	Index of take charge by users of childcare
	Child education services
	Schools with ramp
Goal 5. Achieve gender equality and empower all women and girls	Education level women
	Women enrolled in university courses
	Difference between female and male employment
Goal 6. Ensure availability and sustainable management of water and sanitation for all	Resident population served by urban waste water sewerage system
	Resident population connected to urban waste water treatment plants
	Total water losses
Goal 7. Ensure access to affordable, reliable, sustainable and modern energy for all	Photovoltaic solar panels per square km
	Photovoltaic solar panels per inhabitant
Goal 8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all	Average taxable income per capita
	NEET 15-29 years old
	Early exit from the education and training system

Goal 9. Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation	Mobility offer public transport
Goal 10. Reduce inequality within and among countries	Gini index including imputed rents
	Digital divide from fixed and mobile network
Goal 11. Make cities and human settlements inclusive, safe, resilient and sustainable	Persons residing in dwellings without cabinets
	Cycle paths
	Noise pollution
	Dead, missing and people directly affected by disasters
	PM2,5
	PM10
	Nitrogen dioxide - NO2
Goal 12. Ensure sustainable consumption and production patterns	Separate collection
	Municipal waste production
Goal 13. Take urgent action to combat climate change and its impacts	Population exposed to flood risk
	CO2
Goal 15. Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss	Green urban usable
	Ecolabel licenses
Goal 16. Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels	Political electoral participation 2018
	Average stock of ordinary civil proceedings of first instance
Goal 17. Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development	Social cooperatives
	Broadband access

Table A5. Equitable and Sustainable Territorial well-being (BESdT)- Indicators

BESdT - dimension	BESdT - indicator
Health	Life expectancy at birth
	Avoidable mortality (age 0-74)
	Infant mortality rate
	Road accidents mortality rate (15-34 years old)
	Age-standardised cancer mortality rate (20-64 years old)
	Age-standardised mortality rate for dementia and nervous system diseases (65 years and over)
Education and training	Children who benefited of early childhood services
	Participation in the school system of children aged 4-5
	People with at least upper secondary education level (25-64 years old)
	People having completed tertiary education (ISCED 5, 6, 7 or 8)
	First-time entry rate to university by cohort of upper secondary graduates
	People not in education, employment, or training (NEET)
	Participation in life-long learning
	Inadequate level of numeracy (students in grade 8)
	Inadequate level of literacy (students in grade 8)
Work and life balance	Employment rate (20-64 years old)
	Non-participation rate

	Incidence rate of fatal occupational injuries or injuries leading to permanent disability
	Youth's employment rate (15-29 years old)
	Youth's non-participation rate
	Paid days in the year (employees)
Economic wellbeing	Average disposable income per capita
	Average annual salary of employees
	Average annual per capita amount of pension income
	Pensioners with a low pension income
	Per capita assets
	Bad loan entry rate of bank loans to households
Social relationships	Non-profit organizations
	Schools without physical and structural barriers
Politics and institutions	Voter turnout
	Voter turnout (Regional Councils)
	Women municipal councillors
	Municipal councillors under the age of 40
	Prison density
	Municipalities collection capacity
	Provincial governments and Metropolitan Cities collection capacity
Safety	Intentional homicide rate
	Deadly crimes reported
	Burglaries reported
	Pick-pocketing reported
	Robberies reported
	Road mortality in non-urban roads
Landscape and cultural heritage	Density and importance of museums' heritage
	Spread of rural tourism facilities
	Presence of Historic Parks/Gardens and other Urban Parks recognised of significant public interest
Environment	PM10 Annual average concentration
	PM2.5 Annual average concentration
	Warm Spell Duration Index
	Extreme precipitation events
	Consecutive Dry Days
	Population at risk of landslides
	Population at risk of flood
	Water losses in urban supply system
	Protected natural areas
	Urban green
	Municipal waste generated
	Separate collection of municipal waste
	Electricity from renewable sources
Innovation, research and creativity	Patent propensity
	Municipalities with online services for families
	Brain circulation (Italians, 25-39 years old)
	Employed in local units of cultural enterprises
Quality of services	Irregularities in electric power distribution
	Seat-Km of public transport networks

	Overall Fixed Very High-Capacity Network (VHCN) coverage
	Separate collection service for municipal waste
	Hospital beds in high-care wards
	Hospital patient emigration to a different region
	Medical specialists
	Inpatient and day care hospital beds in public and private accredited hospitals per 10,000 inhabitants

### Abstract

Made in Italy, in its entrepreneurship, constitutes an invaluable cultural and economic heritage for our country and too is worldwide considered as a synonym of art, quality, uniqueness and craftsmanship. In fact, this sector contrasts "knowing how to do well" against mass production, often poor of quality in materials and finishes, as well as certainly lacking an artistic and innovative dimension.

The analysis of the literature highlights that the craftsmanship dimension, in fact, imposes flexibility and adaptability to particular needs, according to a slower pace of production, as well as shorter production lines at the local level, also making use of local craft, skills and traditions, fitting them into regional and national culture and heritage (Murzyn-Kupisz & Hołuj, 2021). In order to avoid making our analysis generic and too vague, it is important to specify that our theoretical background will refer to a specific type of company, i.e. craftsmanship.

Our research objective, in the context just described, will be to observe how these realities are moving towards the rapidly expanding race for sustainability, not only as a new sales opportunity, but also, as a necessary condition to guarantee their survival over time. The call to sustainability, especially at the European level with the transposition of the new European Directive 2022/2464/EU approved in November 2022, will lead to an obligation of sustainable reporting to a larger group of companies (Ottenstein et al., 2021). Made in Italy, typically made up of SMEs, will therefore certainly be directly affected by this new scenario, for which it will be appropriate to take the right measures and understand the new logic.

In addition to the above, based on an empirical analysis carried out on a sample of companies referring to the blown glass sector, we have analyzed quantitative data in order to bring evidence to our study. The blown glass sector, in fact, corresponds to Italian excellence of craftsmanship, and also, to fine art (Bialek, 2022). In this sector, it is also true, that there is evidence of numerous polluting residues, making the issue of sustainability very relevant and crucial (Hamada et al., 2022). Our empirical research, thanks to the data provided by the association "AssoVetro," the National Association of Glass Industrialists adherent to "Confindustria", will therefore propose to analyze how in a group of sample companies sustainability is managed, valued and reported. In accordance with what has been stated, the purpose of our empirical analysis is to answer the question: "How the glass sector has grown in relation to the impact of sustainability?".

**Keywords** – Sustainability, Entrepreneurship, Made in Italy, Craftsmanship, SMEs, Blown Glass Sector

**Paper type** - Academic Research Paper

## 1 Introduction

Thanks to human ability and inspiration, made possible by craftsmanship, the value of a product can increase in terms of quality and uniqueness compared to a non-standardized good (Campana et al., 2016). In modern times, in line with Campana et al. (2016) said, we are witnessing a gradual and steady enhancement of craftsmanship, not only connected with the elaboration of the finished product, but especially, in the process that influences the performance of "artisan" workers, characterized by expertise, creativity, culture, history, tradition and attention to the territory. Not far from the characteristics listed above for producers, we can also find factors related to individual consumer elements. According to Rivaroli et al. (2020), these can be configured in the following list: information and knowledge seeking, local identity, self-identity, humanization and brand personification, and also price perception. Certainly, it is clear that what was previously stated is strongly in contrast with the production logic, followed by the industrial revolution, where the keywords were: speed, standardization and decreasing costs. In this context, industry mainly employed workers to control machines that increase the efficiency of production by replacing humans in repetitive tasks instead of artisan work.

In his famous book Richard Sennett (1998) believes, to avoid being nostalgic for the past, that we need to rediscover the best craftsmanship and produce higher quality products, valuing artisans' autonomy, dialogue with customers and

social responsibility. In our opinion, what Sennett stated twenty-five years ago, today is very relevant and valid at the Italian and international level. The attention that the world is showing on sustainability, in fact, is pushing towards the choice of products that are far from the typical logic of mass production, bringing a regression effect with respect to the logic of "mass-produced" items. It therefore seems fair to say, as we will try to demonstrate in the course of the paper, that craftsmanship and sustainability are two closely related concepts. Some sectors, such as blown glass, certainly constitute a clear and concrete example of this trend.

The challenge of sustainability, however, must therefore be seen on the one hand as a great potential, but at the same time, also as a significant change in today's practice, thus constituting a considerable effort and commitment for companies (Überbacher et al., 2020). In these times, Italy is experiencing a major challenge in transitioning technology to a level where it can get closer to the needs of the customer and to expand the scope of SMEs as well (Matarazzo et al., 2021). This effort could be in our opinion an element strictly connected to having a better vision, and better practice, in supporting and implementing sustainability respecting our craftsmanship dimension.

## **2 Craftsmanship and Sustainability**

The "creative economy", which is growing at the global level, is increasing requires skills typical of craftsmanship, in a trend toward a growing consumer culture that emphasizes authenticity and quality products (Klamer, 2012). As reported by Klamer (2012), Italy provides interesting examples of how associations and institutions responsible for craftsmanship can play an important role in boosting this kind of production. In our opinion, a successful example of what has been stated, turns out to be the blown glass sector, because of his attention and respect for sustainability shown since the 18<sup>th</sup> century.

In the 18th century, conditions were created for the development of a "glass culture" in and around Venice, as well as for the emergence of real entrepreneurs in the glass industry and the emergence of highly specialized production areas (Panciera, 2006). According to Panciera (2006), the glass production network revolved around blown and semi-finished glass from the island of Murano, and the existence of a series of vertically integrated and aligned activities led to a hierarchy of specialization, and also a real industrial culture in the city, that

preserved valuable knowledge that still exists today. The number of workers in the Murano furnaces, which numbered more than 40 at the end of the 18th century, increased significantly, especially among those who produced glass sheets and blown glass. The number of glass workers in Murano increased from about 160 at the end of the 17th century to 284 in 1787. The total number of furnace workers was between 5 and 6,000, accounting for about 40 percent of the island's working male population (Pancierera, 2006).

Today glass is, worldwide, one of the most important materials that plays an important role in both traditional and innovative sectors (Testa et al., 2017). In the innovative sector, glass is used in combination with certain substances for high-tech applications such as space exploration, medical research, optics, and telecommunications. As reported by Testa et al. (2017), the main glass traditional sectors are instead, container glass (which include a range of products used for packaging food, beverages, cosmetics and pharmaceuticals), flat glass (which includes products used in construction, transportation, and solar energy) and continuous fiberglass and glass wool, which are used for insulation, roofing and composite reinforcement.

In Italy, as in the rest of the world, this type of production belongs to large companies that are often part of important international groups that operate according to a mass logic production. On the opposite, the landscape of blown glass maintains to this day an artisanal and artistic connotation, living in small realities composed of artisans and SMEs. This will mean, in the immediate future for this sector, a delicate obligatory adaptation in line with national and European laws, related to sustainability that previously referred exclusively to larger realities that are part of the same sector.

The challenge of sustainability today is an issue that directly affects not only large companies anymore, but also medium-sized and small ones (Martins et al., 2022). Indeed, the new 2022 CSRD directive, which is a continuation of the European Green Deal, aims to greatly expand sustainable reporting requirements for more companies, as well as to improve the quality of the data required. At the plenary session on November 28, 2022, members of the European Parliament adopted the CSRD directive with 525 votes in favor, 60 against, and 28 abstentions. After the European Parliament's position was approved by the Council, the legislative act was adopted. In addition, the new rules are to be implemented by member states within the next 18 months, introducing more detailed reporting requirements on sustainability issues, environmental rights,

social rights, human rights and governance factors. Adoption of this law will bring the number of companies involved from the current 11,600 to 49,000 by 2028, according to a proportionate, cascading involvement plan aimed at encompassing as many players as possible with an effective, efficient reporting system that has the will to overcome a cultural gap in the expression of new needs and potential. The rules will be implemented between 2024 and 2028 and will affect, in a cascade logic, firstly "large enterprises" not yet subject to the Non-Financial Reporting Directive, and subsequently, SMEs and the residual listed companies (Article 5, p. 80 – EU Parliament, 2022).

The sustainable revolution, in fact, can only pass through a cultural revolution that, by leveraging the expectations of the younger generations, leads to a general increase in environmental, social awareness and knowledge sharing system (Arsawan et al., 2022). The call to sustainability, according to the terms of the CSRD just mentioned, will affect smaller realities for the first time, which will have to react with scarcer tools at their disposal (Dinh et al., 2022).

### **3 Empirical Analysis**

#### ***3.1 Methodological approach***

In our opinion, the blown glass sector is in our opinion a congenial case study to represent the state of the art, in the current moment, of the transition to sustainability of SMEs in the context of Made in Italy. Indeed, on the one hand, this sector has been known for more than two centuries for its artistic connotation, but at the same time, also for its significant environmental impact in terms of waste and pollution. In line with the presented framework, our research methodology was focused on the analysis of the sector presented thanks to the valuable sustainability report made "AssoVetro" through "Confindustria". Specifically, from the analysis of the aforementioned sustainability report, our attention was focused on observing a few main variables, such as:

- Research And Development Expenses;
- Turnover Growth;
- Quality Certifications (OHSAS 18001: 2007 ISO 22000: 2018 ISO 14001: 2015 ISO 9001: 2015);
- Environmental Certifications;
- Injuries.

The variables listed were analyzed in the only two sustainability reports provided by "AssoVetro," namely 2016-2018 and 2019-2020.

### **3.2 Sample**

The sample examined, in the reports provided by "AssoVetro" at this date, concerns a group of 19 companies taken into account, respectively: 15 hollow glass manufacturers and 4 flat glass manufacturers. The premise, about the composition of the sample, is crucial because it constitutes the main limitation of this empirical research. In fact, the entities assimilated to the size of the blown glass sector are connected exclusively to the 15 hollow glass manufacturing companies. In concrete terms, although these makeup as much as 78.95% of the sample analyzed by "AssoVetro," the data analyzed in this empirical analysis has not been purified of the remaining 21.05%, i.e., from the 4 flat glass manufacturing companies not connected to the blown glass sector. Talking about small companies, it was impossible to find reliable data purified and referring only to the sample of our interest, forcing us to a scientific compromise. A next step of this research, could be in fact, to find the strategic sustainability information, summarized in the aforementioned list, by implementing an ad hoc interview for each reality, thus increasing the percentage of reliability of the data.

### **3.3 Collected data**

From the reports provided by "AssoVetro," 2016-2018 and 2019-2020 respectively, it was possible to collect the data inherent to our field of interest classified into the five categories shown in Figure 1. By our choice, we decided to weight the number of injuries through the ratio of two variables, namely the frequency index and the severity index, both of which are present in the sustainability reports. The table pictured in Figure 1 also shows the totality of data from all sample companies, collected in the reports for each individual year of the reporting period:

- 2016 to 2018: sample composed of 16 companies;
- 2019 to 2020: sample consisting of 19 companies;

	Sustainability Report 1			Sustainability Report 2	
	2016	2017	2018	2019	2020
Research And Development Expenses	22.480.462,00 €	24.238.303,00 €	26.182.869,00 €	15.970.506,00 €	13.945.782,00 €
Turnover Growth	2.391.784.195,00 €	2.452.781.838,00 €	2.830.507.688,00 €	3.141.871.260,00 €	2.991.866.891,00 €
Quality Certifications	10	11	11	9	11
Environmental Certifications	61	69	79	91	95
Injuries*	10,84	6,974	5,194	6,896	5,2212
*Frequency index x Severity index					

Figure 1

Because of the presence of this significant difference in sample composition between Sustainability Report 1 and Sustainability Report 2, in order to standardize the data collected, we decided to divide the individual data for the companies in the sample year by year. Figure 2, in fact, corresponds to the overview of the average data and performance collected in order to arrive at our statistical conclusions with reference to a model company.

	Sustainability Report 1			Sustainability Report 2	
	2016	2017	2018	2019	2020
Research And Development Expenses	1.405.028,88 €	1.514.893,94 €	1.454.603,83 €	840.552,95 €	733.988,53 €
Turnover Growth	149.486.512,19 €	153.298.864,88 €	157.250.427,11 €	165.361.645,26 €	157.466.678,47 €
Quality Certifications	0,625	0,6875	0,6111111111	0,473684211	0,578947368
Environmental Certifications	3,8125	4,3125	4,388888889	4,789473684	5
Injuries*	0,68	0,435875	0,288555556	0,362947368	0,2748
*Frequency index x Severity index					

Figure 2

Subsequent to the composition of our sample, as explained in the logical step of the previous paragraphs, we compared the data collected in Figure 2 in two-year classes, highlighting in addition, the decreases by highlighting the relevant cells by coloring them. The composition of Figure 3, therefore, corresponds to a statistical comparison of the data in Figure 2 for each individual class of year x and year x+1 starting with the first year available from the sustainability reports of "AssoVetro".

	2016-2017	2017-2018	2018-2019	2019-2020
Research And Development Expenses	8%	-4%	-42%	-13%
Turnover Growth	3%	3%	5%	-5%
Quality Certifications	10%	-11%	-22%	22%
Environmental Certifications	13%	2%	9%	4%
Injuries*	-36%	-34%	26%	-24%
*Frequency index x Severity index				

Figure 3

### **3.4 Results and Discussion**

In light of the data collected, it is possible to make some reflections that can provide evidence to support our initial question: "How has the glass sector grown in relation to the impact of sustainability?". The last column of the table in Figure 3, considering this simple question, gives us the cue to draw some conclusions.

Companies' commitment to proper management of their environmental profiles is not only in compliance with environmental legislation, but is geared toward reducing associated impacts and continuously improving performance, as evidenced by the steady growth in certifications from 2016 to 2020. This logic is evidenced by the increasing adoption of management systems certified to major international standards. The theme of management system certifications covers not only the industry's environmental, energy commitments and performance, but also those related to quality, worker health and safety, with a 22% increase from 2019 to 2020.

Parallel to this, the documents analyzed showed how health and safety protection in the workplace is a top priority for companies in the glass sector, through the observation of accident dynamics as a fundamental requirement of membership. In addition to technical interventions, investments and targeted training, companies flank intensive information and awareness-raising activities for employees of immediate perception - through posters, panels and dedicated signage - which report behavioural and organizational information on prevention. Reporting by all employees of potential unsafe behaviors and situations identified within work environments is also encouraged in order to take timely and preventive action. The documents covered attest to the industry's decades-long commitment to safety, achieved through specific investments aimed at ensuring safe conditions in facilities, training employees to observe safe behaviors, appropriate protective equipment, and appropriate work organization measures. Thanks to this focus, as shown in Figure 3, the trend of accidents has always been declining, with the exception of the two-year period 2018-2019.

The trend in investment in production facilities, over the five-year period 2016-2020, was measured as an increase of plant and machinery. The significant decline recorded in the two-year period 2018-2019 and 2019-2020 can be attributed, on the one hand, to the physiological cyclicity of investments in new plant and machinery - which recorded significant peaks between 2016 and 2018 - and, on the other hand, as a reversal of trend in IT investments not detected in this class.

In the area of investments, in fact, the questionnaire survey by "AssoVetro" investigated that the improvements sustained by companies in IT - including software, licenses and, in general, investments in the digitization of production processes - are clearly growing. In addition to this, a further setback in investment is certainly due to the pandemic crisis that occurred in 2020, which has effectively halted the development of new initiatives.

If the pandemic factor, as stated, has weighed on investment we can say with certainty that it has also affected the turnover to a certain negative extent. The trend for turnover, as can be seen from Figures 3, followed a constant and linear growth until a negative contraction of -5% was recorded in the two-year period 2019-2020. This data, while negative, is nevertheless encouraging and stimulating for the future. Glass companies, in fact, benefit a constantly growing domestic and international market, thanks in part to the efficient import/export network that has allowed these companies to survive in such a complex historical moment.

What we can say, in conclusion of this empirical analysis, is that although with major limitations and elements to be deepened and improved, this empirical analysis has confirmed our initial thesis. Glass companies have always been attentive to sustainability and ethics by respecting: the environment, culture, people and territory. This is the reason that allows companies to establish themselves and grow in a competitive environment, but without sacrificing attention to sustainability and ethics.

#### **4 Conclusions**

Our thesis, in conclusion, is that craftsmanship, precisely because of their propensity for culture and respect for traditions, as well as for the surrounding environment, are certainly an example of excellence also in the pursuit of sustainability. In fact, regardless of their size and their presence on the Italian territory, these realities highlight the attention to sustainability not only as an element of pride, but on the contrary, as a real and proper condition necessary for their production and their company philosophy. Sustainability, therefore, was not a foreign concept to this type of company, which however today will be called upon to report this information, certainly having fewer resources than large companies. This is undoubtedly an excellent starting point, but at the same time, it makes us aware of the future effort that will have to be done to provide the right tools for this transition. So, in conclusion, sustainability could concern the

continuation, and preservation, of craftsmanship in terms of skill, culture and tradition in the future (Fyhn & Søråa, 2017). Indeed, in our opinion, this focus on sustainability and ethics will enable companies in the blown glass industry not only to survive the complex and difficult historical moment, but also, to project themselves into a future of growth and improvement without losing the main characteristics of their business history.

### **Abstract**

Recent environmental changes and socio-economic issues, required companies to adopt sustainability practices in order to safeguard the ecosystem on which insist and, at the same time, guarantying their profitability. In this scenario, the agri-food industry is particularly concerned, as food production and delivery have high impact on environment and society. Companies are investing in a digitization journey, surfing the flow of the transition from the actual technocentric vision of technology to a synergistic one involving social and environmental sustainability. Starting from these assumptions, the aim of this paper is to provide an overview of how the scientific literature explored the relationship between sustainability, Industry 4.0 (I4.0) and the agri-food sector, as well as delving into the role of the I4.0 pillars in driving sustainability moving toward Industry 5.0 (I5.0). A rigorous methodology guided the study toward a double-layers scientometric, performed with Bibliometrix. The sample was identified, using PRISMA methodology, in Scopus and

WoS, leading to a database of 1114 papers and a further 9 sub-datasets, one for each I4.0 pillar. These datasets were analyzed in depth in order to recognize i) the main characteristics of the investigated research field; ii) the main research routes addressed in the investigated research field; iii) the current capability of each I4.0 pillar to drive sustainability in the investigated research field. The results reveal that the topic is recently and internationally debated; there is a strong interest in searching for sustainable solutions that safeguard natural resources with the help of data-driven technologies; among the I4.0 pillars, the simulation is the most recognized pillar in driving agri-food toward sustainability; the main topics addressed are linked to environmental and social domains. The study provides research and practical implications consisting of understanding the field concepts multiplicity, laying groundwork for future researchers, encouraging in the study replication, understanding how pursue sustainability issue, supporting the adoption of technology-based sustainable practices toward I5.0, stimulating in the exploration of new sustainability topics leveraging on technology application.

**Paper type** – Academic Research Paper

## 1 Introduction

In a world characterized by a growing need to environment respect and raw materials preserve, to enhance workplaces ethic practices and to make more efficient cost saving decision-making, companies are constantly faced with the challenge to ensure sustainability practices: economic, social or environmental (Adams, Jeanrenaud, Bessant, Denyer, & Overy, 2016). By virtue also of the regulatory references that are gradually being proposed, companies need of identifying and implementing solutions and strategies consistent with this objective, in order to satisfy a twofold need: guarantee the productivity, and innovate the products, processes and strategies to implement the desirable level of sustainability (Ajwani-Ramchandani et al., 2021; Macassa, Rashid, Rambaree, & Chowdhury, 2022). Among the main recipients of these measures, a strategic player is the agri-food industry which has a high impact on environmental and social ecosystems (Ioris, 2018). Agricultural activities are essential for food production that, by 2050, must double to fulfil the global population demand: is expected that global population will reach about 9.8 billion by 2050 and 11.2 billion by 2100 (Abbate, Centobelli, & Cerchione, 2022). This need could encourage companies to adopt strategies to maximize the production compromising the sustainable use of resources. For example, in the tropical areas

the agricultural expansion is one of the deforestation causes, with consequent loss of timber or biodiversity (Rueda, Garrett, & Lambin, 2017).

In the advanced economies, efficient model production in agriculture are based on the use of pesticides and chemicals which are capable of increasing crop yields but generate significant environmental impacts (Shuqin & Fang, 2018).

Another relevant issue, related to the society lifestyles and wellness in the advanced economies, is the increased food waste which is triggering a domino effect on sustainability and global hungry: at now approximately 33% of all foodstuffs produced globally, corresponding to 930 million tones, is leaving 800 million people hungry (Belaud, Prioux, Vialle, & Sablayrolles, 2019). These evidences attested a global agri-food industry under pressure to provide products that meet higher social and environmental standards.

Reducing the environmental impact, managing social issues, solving supply chain network design problems, tackling the economic pressure, fulfilling the informative needs expressed by conscious consumers and complying with regulations (Latino, Menegoli, Lazoi, & Corallo, 2022) represent some of the main challenges that agri-food companies must face. Companies are investing in a digitization journey to try to solve challenges of this nature (Secundo, Schena, Russo, Schiavone, & Shams, 2022). Empowered by the fourth industrial revolution (I4.0) advances, digital technologies have pervaded different industries, including agri-food industry (Hassoun, Boukid, et al., 2022). I4.0 proposes 9 technological pillars (additive manufacturing, advance robotics, augmented reality, big data analytics, cloud computing, cybersecurity, Internet of things (IoT), simulation and system integration (Narula et al., 2021)) which have been widely studied with focus on the concept of smart farms and smart food factories (Hassoun, Bekhit, et al., 2022). Therefore, in the agri-food sector, these technologies are capable of supporting the knowledge management in the agri-food supply chain (AFSC), bridging the gap between digitalization and sustainability, thus improving the performance (Ranta, Aarikka-Stenroos, & Väisänen, 2021).

Digitalization, driven by the I4.0 paradigm, conceives a societal transformation that use ubiquitous digital technologies to connect ever larger social space, without any specific attention to sustainability. Complementing the existing I4.0 paradigm, the I5.0 paradigm born. The fifth industrial revolution as the mission to transit from the actual technocentric vision of technology to a synergistic vision of technology and social and environmental sustainability. I5.0, in fact, is considered

as one of the driving forces to enrich the green transition with social and economic expectation (Saniuk, Grabowska, & Straka, 2022)

Addressing the current growing focus on I4.0 and sustainability, Abbate et al., (2022) proposed a literature review, content analysis-based, to summarize the research stream which in the last 10 years studied the impact of I4.0 on agri-food sustainability, representing, at the better knowledge of the authors, the only study focused on this specific topic. As declared by the authors, this study has several limits which probably affect the breadth and validity of the results: i) the consideration of only Web of Science (WoS) database; ii) the selection of only articles and reviews published in double-blind peer-reviewed journals; iii) the use of machine learning techniques to perform data collection and screening which are less accurate than systematic literature review procedures. Moreover, considering that the data collection phase in Abbate et al., (2022) study ended the 5<sup>th</sup> February 2021, it is partially capable of exploring how the agri-food digitalization process embraces the sustainability issues moving toward the I5.0, since this paradigm was proposed in October 2021 by Xu et al., (2021).

Whereas the exploitation of the available scientific knowledge could be useful for agri-food companies to increase the decision-making effectiveness during the implementation of technology-based sustainable practices, this research field requires more attention. For example, understanding how each I4.0 pillar can be useful in supporting sustainable development (moving toward I5.0) can be discriminating in the choice of a technology. Leveraging on these assumptions, the purpose of this paper is to explore the role of digital technologies during the implementation of sustainability practices in the agri-food industry, overcoming the limits of the previous literature review. The following research questions (RQs) were posed to achieve the study purpose:

*RQ1–What are the main characteristics of the investigated research field?*

*RQ2–What are the main research routes addressed in the investigated research field?*

*RQ3–What is the current capability of each I4.0 pillar to drive sustainability in the investigated research field?*

Specifically, investigating the first RQ we want to provide the updated picture of the analyzed research topic through the description of its characteristics: i) annual scientific production, ii) most frequently used journals to publish articles on the topic, iii) authors most involved (and collaboration between their countries) and iv) countries that produced the most influential contributions.

Investigating the second RQ we want to create a frame about the main research routes addressed by scholars through the analyses of the: i) most frequently used words and, ii) most prominent thematic clusters.

Finally, investigating the third RQ we want to discover the capability of each I4.0 pillar to drive sustainability in agri-food industry analyzing the use of each pillar in food sustainability.

A rigorous methodology (Section 2) was followed to achieve the purpose of the study. Section 3 highlights the results of the double-layers scientometric, organizing them by the core topic of the RQs. Section 4 discusses the results and reflects theoretical and practical implications. Finally, Section 5 presents the conclusions, limits and follow ups of the study.

## **2 Materials and Methods**

Starting from the proposed RQs, we need to identify bases of knowledge characterized by features useful to provide an answer to each question. Therefore, we realized a double-layers scientometric analysis in which we used search schemes to discover data samples to analyze. In both layers, we used the PRISMA guidelines (Page et al., 2021) for data collection procedure and the Bibliometrix software (Aria & Cuccurullo, 2017) for data analysis (Figure 1). Data collection was realized between December 2022 and January 2023, querying WoS and Scopus, recognized as two of the most relevant scientific databases (Mongeon & Paul-Hus, 2016). All samples were selected considering only the contributions in English language and eliminating duplicates, leading to the 10 final samples described in Figure 1.

Specifically, the first layer of scientometric analysis was designed to obtain, through a single query, a knowledge base useful to identify the main characteristics and the main research routes addressed by the investigated research field. We analyzed this sample using frequency analysis on bibliometric data to provide the updated picture of the analyzed research topic toward the description of its main characteristics (timespan, most relevant sources, production countries, most influential authors and collaboration network). Moreover, applying a quantitative text analysis on contributions' abstract, we detected the most frequent words in the sample. Finally, through a thematic cluster analysis on the abstracts in the sample we discovered the main research routes addressed by the research field.

Therefore, a second layer of scientometric analysis was designed to obtain, the current capability of each I4.0 pillar to drive sustainability in the investigated research field. Here, we used a multi-query approach, proposing 9 different sub-datasets, one for each I4.0 pillar, through which investigate the capability of each I4.0 pillar to drive sustainability.

These 9 sub-samples were analyzed through a quantitative text analysis, based on the identified contributes title and abstract. The aim was to retrieve, for each sub-queries, an overview of the most frequent representative contents, thematic clusters and co-occurrences. About co-occurrences, an analysis of the most frequent binomials in the articles' abstracts was performed. Following their identification, and from the emerging ones, those representing sustainability topics for the agri-food industry were selected.

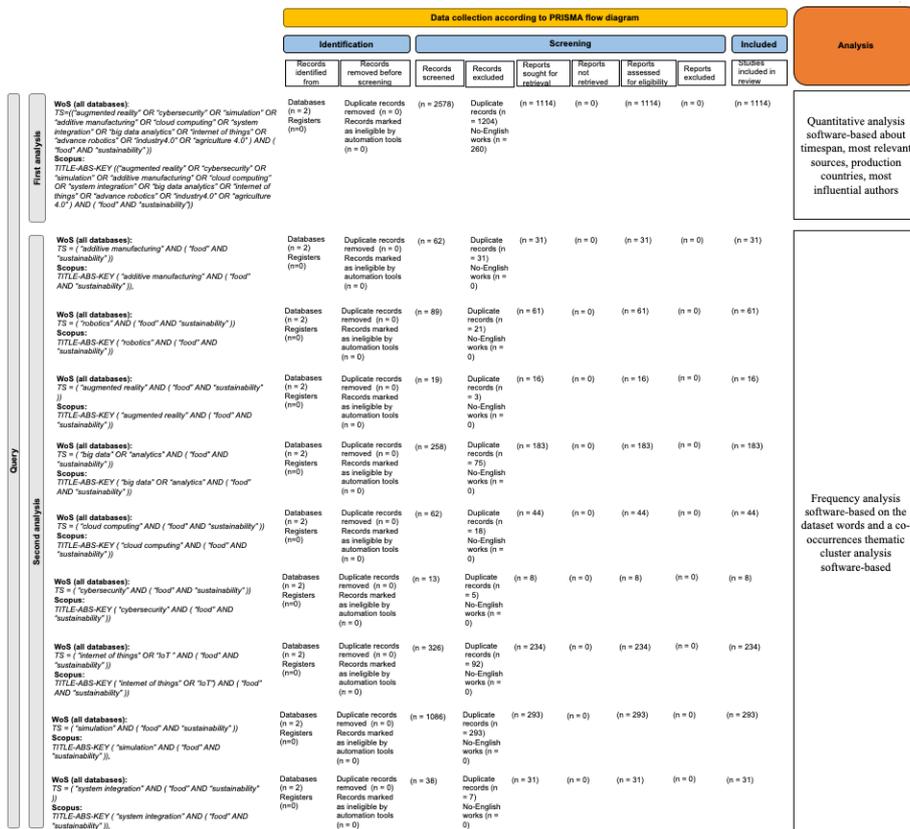

Figure 2: Procedure of data collection, according to PRISMA flow diagram, and data analysis

### 3 Results

This section highlights the results of the double-layers scientometric, organizing them by the core topic of the RQs.

#### 3.1 The main characteristics of I4.0 for sustainable agri-food industry research field

In order to answer to the RQ<sub>1</sub>: *what are the main characteristics of the investigated research field?*, we provided the updated picture of the analyzed research topic toward the description of its main characteristics, described below.

Figure 2 summarizes the annual scientific production. Our results showed that the largest surge of scientific papers on the topic occurred in the years 2020 to 2022, with 547 articles, about half the total sample. By considering the analyzed timespan (1994-2023), the average growth rate of articles is therefore around +43.2%.

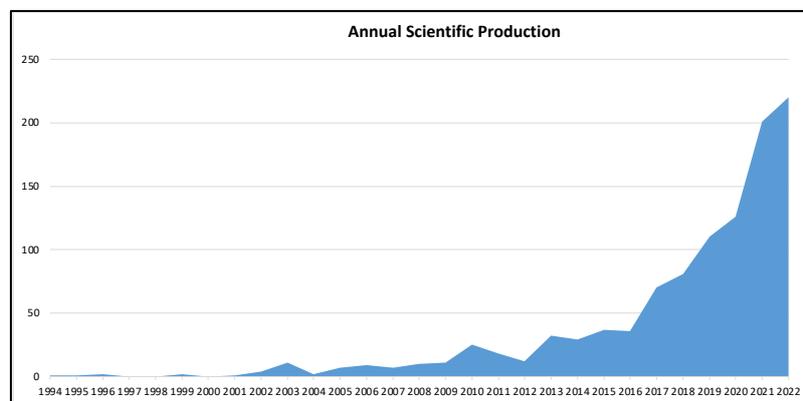

Figure 3: Annual Scientific Production

The journals most interested in the publication of studies focused to analyze the role of I4.0 in sustainability, addressed topics related to the environmental protection and sustainable solutions study to improve environmental resources management, such as Sustainability, Journal of Cleaner Production and Plos One. The aforementioned journals also prove to be those most present in the trend of recent years, with significant increases from the year 2019. Figure 3 shows the list of the most productive authors in the research field and the established collaboration network. Considering authors that published at last 4 studies, we

identified a list of 32 relevant authors guided by Liu Y. with 10 studies. Furthermore, in terms of collaboration world map, the most productive cooperation networks belonged to USA and China; France, Germany, Italy and United Kingdom (UK), as well to India and UK.

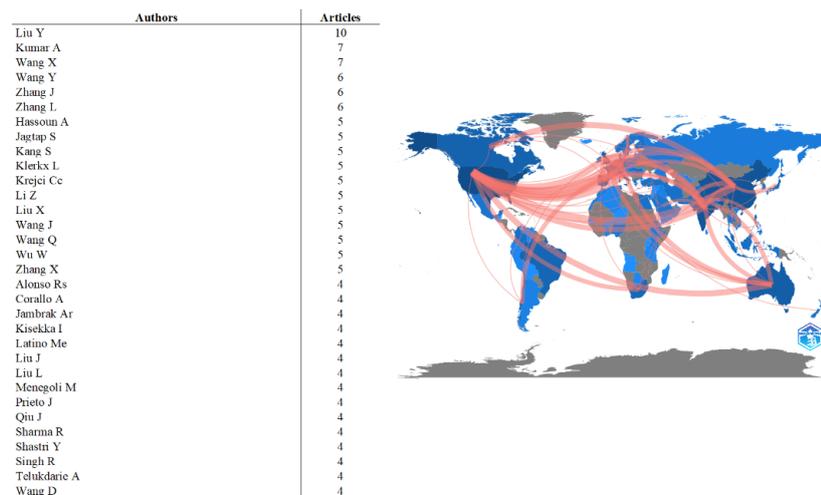

Figure 4: Most productive authors and collaboration network

Analyzing the sample from the geographical viewpoint (Figure 4) the countries more focused on the analyzed research topic are: USA (723), China (366), India (322) Italy (301), Great Britain (297), France (222), Germany (195), Australia (178), Spain (174), Netherlands (135), Brazil (119) and Canada (102).

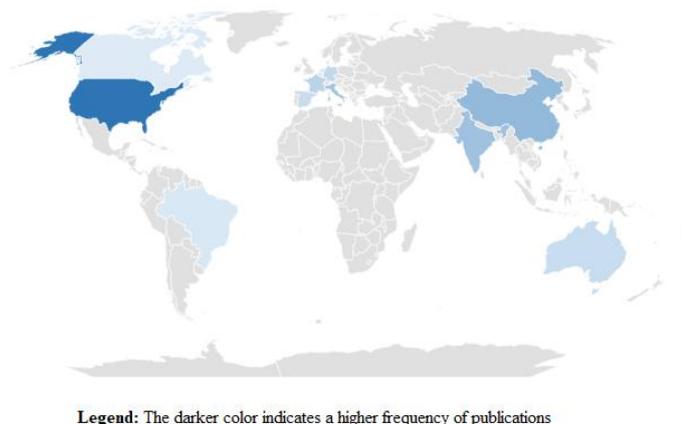

Figure 5: Most productive countries.

impact), and of food supply chain management (with particular attention to the assurance of food safety, security and quality).

### **3.3 The current capability of I4.0 pillars to drive sustainability in agri-food industry**

In order to answer to the RQ<sub>3</sub>: *What is the current capability of each I4.0 pillar to drive sustainability in the investigated research field?*, we investigated the capability of each I4.0 pillar to drive sustainability in agri-food industry. Firstly, we investigated the use of each pillar in food sustainability evaluating the size of the samples obtained by applying the 9 queries in the selected databases, as described in Section 2.

In accordance with the results coming from cluster analysis (see section 3.2), the results show that the technologies belonging to the Simulation pillar are the most used for sustainable purposes in the agri-food field, with a clear prevalence of 56.3% of the sample. This is followed by the IoT (16.6%) and Big Data (13.0%) pillars. The remaining pillars are currently marginally used: Advanced Robotics pillar (4.8%), Cloud Computing (3.1%), Additive Manufacturing (2.2%), System Integration (2.2%), Augmented Reality (1.1%), and Cybersecurity (0.6%).

Moreover, analyzing the most frequent co-occurrences in the abstracts of the 9 I4.0 pillars samples, the results showed that each pillar is related to specific sustainability topics of agri-food industry (Figure 7). Specifically, our analysis revealed that some sustainability topics recur in different pillars, for example: i) climate change is a sustainability topic that agri-food industry address using simulation, advance robotics, IoT and, big data analytics; ii) food security or safety is a sustainability topic that agri-food industry address using simulation, advance robotics, cloud computing, IoT, cloud computing, augmented reality, big data analytics and system integration; iii) food waste and waste management are sustainability topic that agri-food industry address using additive manufacturing, IoT, cloud computing and augmented reality.

Other sustainability topics seemed to be more linked to specific technological pillars. In particular, we found that: i) health promotion is a sustainability topic that agri-food industry address adopting system integration; ii) land use is a sustainability topics that agri-food industry address using simulation technologies and big data analytics; iii) food printing is a sustainability topics that agri-food industry address through additive manufacturing; iv) sustainable agriculture and

circular economy are sustainability topics that agri-food industry address using augmented reality; v) environmental-social-government-themed (esg-themed) megatrend and global megatrend are sustainability topics that agri-food industry address using cybersecurity.

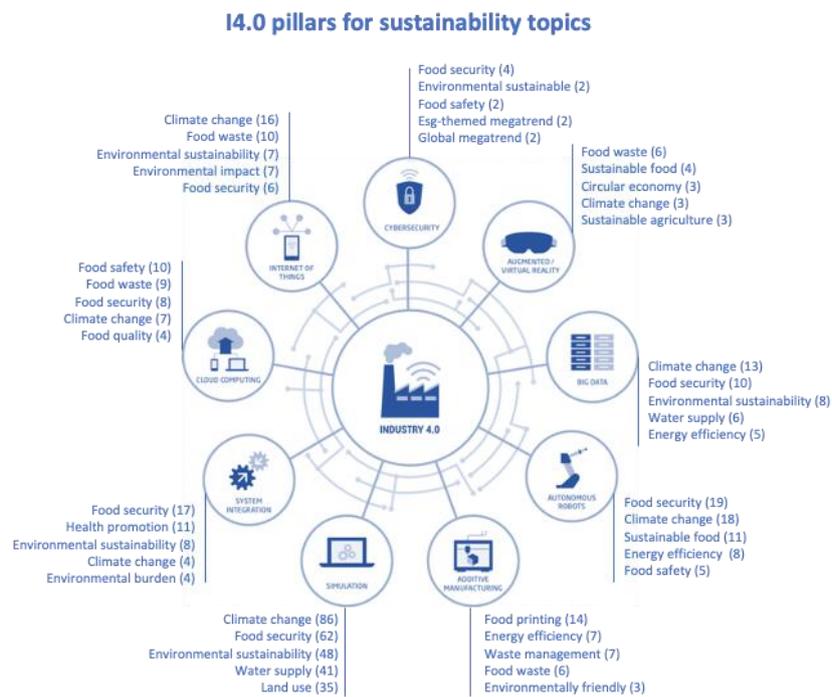

Figure 8: Most frequent bigram occurrences in sub-queries abstracts – sustainability topics (frequency)

Downline these evidences and with the aim of proposing an overall picture of the sustainability topics addressed by agri-food industry using I4.0, the emerging co-occurrence bigrams previously discussed, were reorganized according the relation with the three sustainability dimensions (environmental, social, economic). As Figure 8 shows, the several sustainability topics were grouped in families of topics and listed in order of frequency.

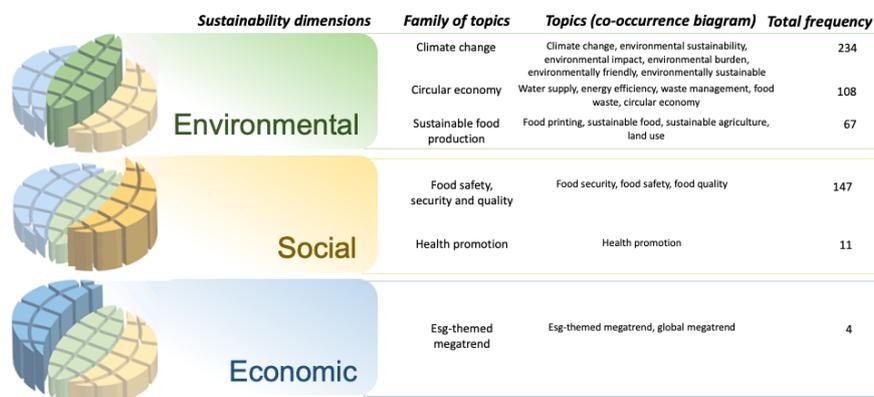

Figure 9 Sustainability dimensions addressed by I4.0

Summarizing, by answering to RQ<sub>3</sub>, a variable capability to drive toward sustainability was attested among the 9 I4.0 pillars. Simulation technology resulted the major protagonist for driving sustainability in agri-food sector with particular reference to the environmental one. Social and economic dimensions of sustainability were driven by one or more I4.0 pillars. Attention is given to the only one family of topics in economic sustainability dimensions: esg-themed megatrend which aims to attest and evaluate the economic impact of environmental-social-government changes in sustainability direction. This family of topics was driven only by cybersecurity pillar.

#### 4 Discussion and Implications

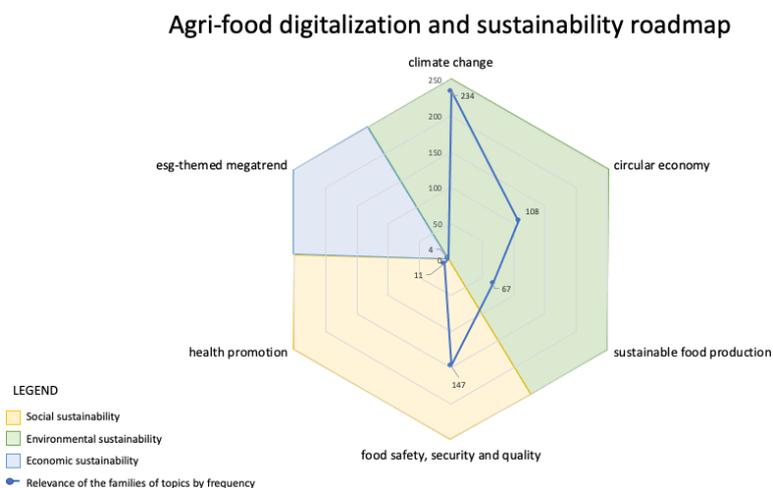

The proposed study overcomes the limits and the evidences released by Abbate et al., (2022), providing a systematic literature review based on an inclusive data collection performed in two databases and in a more recent historic period, allowing us to explore how the agri-food digitalization process embraces the sustainability issues moving toward the 15.0. Specifically, thanks to our insights, we can understand how the scientific literature explored the relationship between sustainability, I4.0 and agri-food and, the role of the I4.0 pillars in driving sustainability. The research field is characterized by an increasing attention by academics in the last 2 years, probably related to the regulations introduced recently for stimulating agri-food companies to adopt sustainable practices such as the European Agenda 2030 (EA2030) or the frameworks for sustainable planet established by USA and China (Egan, Raube, Wouters, & Chaisse, 2023). The

geographical distribution of the literature production on the theme and the authors collaboration networks, confirmed the relevance of the topic worldwide.

About the research routes addressed by the research field, the main words able to describe them surround the environmental sustainability sphere with particular attention to the impact that food technology-based production/agriculture could have on it, especially in the saving of natural resources (i.e., water). Numerous are the initiative that agri-food researchers and companies performed in this sense, just think to the investments in Agriculture 4.0 solutions for energy, water, costs, losses saving (Secundo et al., 2022). This effort in sustainable-oriented innovation development enriches agri-food sector and, as attested by Testa, Nielsen, Vallentin, & Ciccullo, (2022), impacts both on organizational and production systems, leading to a profound organizational transformation and radical systemic change and to an incremental improvement in traditional products and processes. In this sense, our cluster analysis highlighted that AFSC management is evolving toward a more technological approach which use AI, machine learning and data analytics to monitor and predict foods quality and safety. At the same time, food production is shifting toward a more sustainable mood, thanks also to technology involvement (such as IoT, simulation model), putting the attention to the production and distribution practices environmental impact.

About the current capability of I4.0 pillars to drive sustainability in agri-food industry, our results attested that simulation technology is widely employed in agri-food sector to achieve environmental sustainability goals such as, climate change monitoring and prediction, improvement of decision making with particular attention to the resources usage (i.e., energy, water, land). This result is in line with the thesis of Utomo, Onggo, & Eldridge, (2018) which reveals that simulation models have the potential to drive sustainability in agri-food sector. Although the environmental sustainability dimension resulted widely driven by one or more I4.0 pillars, social and economic dimensions are it less. This evidence reveals that the transition towards the fifth industrial revolution is in act. I5.0, in fact, is considered as one of the driving forces to enrich the green transition with social and economic expectation (Saniuk et al., 2022). Leveraging on our results, an agri-food digitalization and sustainability roadmap can be supplied (Figure 8). It is a clear overview about how and how much the I4.0 pillars are driving agri-food sector toward sustainability purposes. Climate change is the main issues addressed by the sector involving 7 out 9 pillars (additive manufacturing and cybersecurity seem not be considered for this purpose may be because more

focalized, respectively, to sustainable food production and food security and safety). The importance of this issue is attested also by the EU which dedicated to climate change a specific SDG claimed it as “urgent”. Circular economy and sustainable production topics complete the environmental sustainability domain gaining the attention of the sector which leverage on the synergistical use of the all 9 pillars. Food safety, security and quality and, health promotion, are the only two social sustainability topics I4.0-driven, recognized in our study. They are core goals in the EA2030 which proposed the objective to achieve food security, improve nutrition, promote sustainable agriculture, and to ensure healthy lives and well-being for all. ESG-themed megatrend is the only economic sustainability topic, and it was driven by only cybersecurity. Being ESG a rating system for assessing environmental, social and governance performance of businesses in an economic way, it is strictly linked to the global megatrends described by the EU (Franco, Nicolle, & Tran, 2021). Demographic and social changes, recourse scarcity, inequalities, volatility, scale and complexity, enterprising dynamics, are the five global megatrends which I5.0 are inheriting from I4.0 improving its humanization and sustainability (Esposito & Tse, 2018).

*Figure 10 Agri-food digitalization families of topics by frequency and sustainability domains*

Research and practical implications emerged. This study is the first to provide a systematic overview and critical appraisal of the ex-tant literature on the role of digital technologies in sustainability practices implementation for agri-food industry. Results could help researchers, academics and practitioners to: i)

understand the research field concepts multiplicity; ii) lay the groundwork for future studies envisaging new research routes; iii) encourage scholars to replicate the study in other industrial sectors.

From a practical implication perspective, the knowledge map created by this study represents for agri-food companies: i) a guide to better understand how to pursue sustainability issues, discovering useful information from the current research routes; ii) a tool to support the adoption of sustainable practices based on technologies toward the implementation of I5.0; iii) a stimulus to explore new sustainability topics by leveraging technology.

## 5 Closing remarks

The study explored the role of digital technologies during the implementation of sustainability practices in the agri-food industry. We provided the updated picture of the analyzed research topic through the description of its characteristics and its main research routes. Finally, we discovered the capability of each I4.0 pillar to drive sustainability in agri-food industry. Despite that the research methodology was carefully defined adopting PRISMA and widely used software, some limits can be debated: the research could be explained using other databases (e.g., Science Direct), analysis (e.g., semantic analysis), descriptive indicators (quantitative or qualitative), parameters (e.g., frequency threshold) and software (e.g., VOSViewer), integrating different results. Future researches can be performed in order to overcome these limits and enrich the ex-tant knowledge.

### Abstract

The New VUCA entrepreneurial environment (Millar et al., 2018) asks new entrepreneurs to quickly respond to the ever-changing needs they are targeting with their business ideas.

Entrepreneurs may answer by adopting a lean startup approach (Ries, 2011; Blank and Dorf, 2012; Blank, 2013) that, according to Wang et al. (2022) suggests entrepreneurs to test their assumptions through business experiments (Bocken and Snihur, 2020). In particular, adopting an experimental approach, action-oriented, nimble, and in some case even low-cost, can help get ideas off the ground quicker than usual. Moreover, these processes may be useful in identifying and engaging the first customers (McDonald and Eisenhardt, 2020) and in tackling those grand challenges for which there are no simple and obvious solutions (Yunus, et al. 2010).

According to Furr and Dyer (2014), theoretical and virtual prototypes may help this approach, helping entrepreneurs to get a minimum viable prototype that later may, eventually, evolve into a full-fledged product. The Fablabs - short form for Fabrication Laboratories - are shared spaces open to the public that offer both tools and services for digital manufacturing (Manzo and Ramella, 2015). These spaces give access to sophisticated technologies, so that their users can explore, learn and, obviously, make new things (Rayna and Striukova, 2021).

The possibility of "sharing technology tools in social spaces" is a distinctive trait of the so-called "maker movement", which is based on the interaction, even internet-based ones (Howard et al., 2014), between subjects who use shared resources (technology, spaces, knowledge) to create artefacts (Browder et al., 2019).

In particular, the technologies and the tools that the startupper and the entrepreneurs may get access to in the Fablab may help them to exploit digital prototypes as a way to reduce the start-up costs, to test and optimise their products in a better and faster way. Furthermore the digital nature of these products may help the would-be entrepreneurs to create an entrepreneurial team that is not limited by the need to be geographically co-located (Capdevila, 2018).

In this work in progress research, we will study a sample of Italian Fablabs, both private ones and university-based ones, to understand how they do participate in helping both the "makers", and the local entrepreneurs, in developing the competencies needed to access to the digital technologies, and to exploit them to implement a Lean Startup Process.

**Paper type** – Academic Research Paper

## 1 Introduction

The trends in the entrepreneurial scenario call emerging businesses to be able to respond more quickly than before to shifting customer requirements. The lean startup approach seems to offer a response to this call due to the fact that it has the potential to speed up the process of getting ideas off the ground and engaging customers. Fabrication Laboratories, more often known as Fablabs, are collaborative workspaces in which the equipment and services necessary for digital manufacturing are available to the public, in line with the "maker movement," which is based on "sharing technology tools in social spaces."

In this research, we propose to investigate the relationship between the production of artefacts and entrepreneurship. Using a qualitative approach, we analyse a sample of the 98 Italian Active Fablabs that are registered on the fablabs.io digital platform and those created by Italian universities as one of their activities in the so-called third mission activities, in order to deepen and investigate the ways in which these spaces facilitate the knowledge transfer and sharing among the actors involved in the makerspace. Using a thematic analysis on a set of interviews with both the "managers" and the "users" of these shared spaces, we will try to understand how these structures can help local area companies, and entrepreneurial ventures as well, to adopt a lean startup approach (Ries, 2011; Blank and Dorf, 2012; Blank, 2013).

The remainder of the paper is organised as follows. In section 2, we develop an initial literature review in order to identify the main themes to investigate in the

empirical part of this ongoing research activity that we end with the proposal of three main research questions that this research project is trying to find an answer to. In section 3, we first present the thematic analysis as the main methodological approach that we are planning to use “make sense” of the complex set of data that we are gathering in the interactions with the sampled Fablabs, and then we report the main information of the data-gathering process that we have developed to answer this research process main questions. In the following section 4, we present the expected results of this ongoing research process, while in the last section, section 5, we provide a initial discussion of the potential implications of the expected results.

## **2 Literature review**

The New VUCA entrepreneurial environment (Millar et al., 2018) asks new entrepreneurs to be able to have a quicker response to the ever-changing needs they are trying to answer with their business idea.

One approach entrepreneurs may adopt to answer our turbulent themes is to adopt a lean startup approach (Ries, 2011; Blank and Dorf, 2012; Blank, 2013) that, according to Wang et al. (2022) suggests entrepreneurs to test their assumptions through business experiments (Bocken and Snihur, 2020). In particular, the authors hold that leveraging an action-oriented, nimble, and in some case even low-cost, experimental approach can help get ideas off the ground quicker than adopting a more traditional one. Moreover, these processes may prove to be useful in identifying and engaging the first customers (McDonald and Eisenhardt, 2020) and in tackling those grand challenges for which there are no simple and obvious solutions (Yunus, et al. 2010).

In any case, experimenters may benefit from both successful and failed attempts, as they may be able to anticipate potential problems and concerns, and the related solutions and, as a consequence, they may be able to get better business models than otherwise (McGrath, 2010). Furthermore, using experiments, startupper may earlier avoid the risks of offering the market a product that is not able to meet the specific needs of a given set of customers (Eisenmann et al., 2011).

According to Furr and Dyer (2014) the benefits of the lean start-up approach may be amplified leveraging both theoretical and virtual prototypes as a way to reach for a minimum viable prototype that later may, eventually, evolve into a

full-fledged product. The Fablabs - short form for Fabrication Laboratories - are shared spaces open to the public that offer both tools and services for digital manufacturing (Manzo and Ramella, 2015). These spaces aim to provide non-specialists with an access to sophisticated technologies, so that they can explore, learn and, obviously, make (Rayna and Striukova, 2021).

The possibility of "sharing technology tools in social spaces" is a distinctive trait of the "maker movement", which is based on the interaction between subjects who use shared resources (technology, spaces, knowledge) to create artefacts (Browder et al., 2019) exploiting the internet as a way to go beyond face-to-face interactions (Howard et al., 2014).

Recent studies highlight the need to explore further the link between the artifact creation and entrepreneurship outcomes, suggesting several possible paths linking the two (Browder et al., 2019). In this regard, beyond the technological standpoint, which regards the fact that the artefact creation process may enable makers to build prototypes or even market-ready items, they identify additional research directions based on social and knowledge dimensions. For instance, they find that interactions that occur in the making spaces may lead to the consolidation of entrepreneurial teams or to the emergence of potential customers.

According to Browder et al. (2019), digitization was at the root of the MIT Center for Bits and Atoms program that spawned the Fablab network as it help to join the digital and the physical worlds as a continuous whole and helping knowledge sharing, sourcing and creation, making easier to learn new skill and fostering creativity.

Taking a resource-based view (Barney, 1991), and its extension in the knowledge-based view, fab-spaces could be seen as providers of resources and competences.

In particular, the technologies and the tools that the startupper and the entrepreneurs may have access to in the Fablab may help them to exploit digital prototypes as a way to reduce the start-up costs, to test and optimize their products in a better and faster way. Furthermore the digital nature of these products may help the would-be entrepreneurs to create an entrepreneurial team that is not limited by the need to be geographically co-located (Capdevila, 2018).

Accordingly, we propose to find the answer to three main questions regarding the support that fablabs may give to help entrepreneurs, and startupper, in adopting the lean startup approach.

*RQ1: How do fablabs offer services, not only the technology-based ones, to the local area entrepreneurs and startupper*

*RQ2: Which competencies are local area entrepreneurs and startupper desiring to get from their participation in fablabs?*

*RQ3: How are fablab related services helping local area entrepreneurs and startupper to adopt a lean-startup approach?*

### **3 Methods**

#### **3.1. Thematic analysis**

Thematic analysis is a prominent qualitative research method that uses in-depth data analysis to identify relevant themes (Khokhar et al., 2020). Thanks to the thematic analysis, it is feasible to provide concise data descriptions and interpretations based on observable trends and patterns in the data (Majumdar, 2019).

Thematic analysis necessitates performing an in-depth analysis of qualitative data, which then has to be sorted and categorised. After that, the process of coding entails compressing the data into smaller, more easily interpretable units that are referred to as codes. These codes are then considered as themes (Khokhar et al., 2020). In order to ensure that theme analysis is applied in an acceptable manner, Braun and Clarke (2006) have suggested a six-step process that is commonly utilised (Majumdar, 2019). These include fundamental phases of the analysis, such as becoming familiar with the data, coding, the development themes, and interpretation. These steps indicate that the researcher read the data several times in order to become comfortable with them, that data pieces are identified and assigned a meaningful code, and that the researcher then builds themes and subthemes by expanding on the codes and their context (de Farias et al., 2021).

The use of thematic analysis is suitable for a wide variety of research contexts because of its versatility and flexibility. Thematic analysis is applicable to both qualitative and mixed-methods research designs, and it enables the generation of novel hypotheses and insights that may be evaluated further in subsequent research using a variety of research methods (Alhojailan & Ibrahim, 2012). It is appropriate for use in both an inductive and a deductive approach, and it is

possible to integrate theory-driven codes with data-driven codes in a mixed research strategy (Fereday & Muir-Cochrane, 2006).

Due to its theoretical openness, its adaptability, and its capability to give rich and full answers to the social phenomena being studied, thematic analysis has become more popular as a tool for conducting qualitative research in the field of social sciences (Majumdar, 2019). In the field of study on entrepreneurship, thematic analysis has been utilised in a number of different studies. For example, Lián (2015) and Ali (2021) use thematic analysis to investigate and classify the relevant literature regarding entrepreneurial goals and sustainable entrepreneurship, respectively. They do this by focusing on the similarities and differences between the various studies. Some researchers use thematic analysis to trace the growth of entrepreneurial research on specific issues, such as cultural entrepreneurship (Burger, 2020). This allows them to discover gaps in the research as well as trends in the field.

### **3.2. Data gathering**

In order to understand how the answers to the social phenomena being studied, we propose to study a sample of the Italian Active Fablabs, looking at both the fablabs that have been listed in the fablabs.io digital platform, and those that have been created by the Italian universities in their "third missions" initiatives.

In particular, in Italy there are slightly more than 100 fablabs. 98 of them are part of the international fab-labs global network that has been created as a way to spread the ideas and the concepts behind the need to share common tools and processes, as a way to create a world-wide distributed network of laboratories for research and invention (i.e. fablabs.io). The main details are reported in the following table 1.

Table 1 - Distribution of Fablabs in the fablabs.io global network

<b>State</b>	<b>Italy</b>	<b>Worldwide</b>
Active	98	1305
Planned	15	208
Corona	0	24
Closed	5	59

In particular the data on fablabs.io, shows that in Italy, in the first months of the 2023 there are 98 active fablabs (7.5% of those active in the world) and 15 more are planned to be opened in the next few months (7.2% of those that have been planned in the whole world in the next few months according those that have been listed on fablabs.io).

Then there are other fablabs that have been created by the Italian universities in their third mission activities or as separate entities (e.g., University of Bolzano has created the BITZ to provide services to the local area entrepreneurs and startupper) or as internal research centres (e.g., University "Gabriele D'Annunzio" - Chieti/Pescara have a research centre in their Architectural Department that offers the services of a Fablab). Furthermore, only 8 of the Italian universities have created a network to group their fab-labs, the U-lab network initially founded by Polifactory (i.e., the fab-lab of the Politecnico di Milano) and the Santa Chiara Lab (i.e., the fab-lab created by the Università di Siena) as a way to create a network of the Italian university-based makerspace in order to make them more effective by sharing their best-practices, and to develop operational synergies, and to co-develop cultural and experimental activities.

#### **4 Expected Results**

The research protocol defined to gather data, prescribes that, for each of the fab-labs, we will have to interview above all those in charge of the fablab operations (i.e., the responsible managers or the director according to the organisation of the specific fablab). This first interview is needed to get a first-hand report of the services that these structures are offering to the local area entrepreneurs and startupper. In particular the interview will investigate not only the main technologies that the fab-lab may offer, such as those related to the additive manufacturing technologies (e.g., FDM, DLP, SLS, 3d printing machines) or more traditional ones (e.g., CNC machines, and laser engravers) but even those more related to the digital technologies such as Arduino, and the other more advanced microcontrollers, and the related programming languages. In particular the interview will highlight, from the fablab point of view, how the makerspace is able to help the local area entrepreneurs, and startupper as well, to leverage the new digital technologies to adopt a lean-startup approach that may effectively leverage digital and physical experiments.

This first set of interviews will help us to find the data to study in order to answer the first RQ and to have the first perspective on the third RQ.

Furthermore, during these interviews we will get the needed information to contact the users of the fablab services in order to hear the other side of the value co-creation: the users. In particular our research will target both local area entrepreneurs, usually the owners of local SMEs that have decided to interact with the fablab to learn how to use one or more specific technologies, and startupper, both as new entrepreneurs and as potential ones. In both cases, the interviews will be driven to understand how the users are interacting with the makerspace, which services they use the most, which competences they were trying to develop and how these new competences should help them in their ventures, and last but not least, which new relationships they have developed through these interactions (in order to understand if, and how, they are using an open-innovation approach). Through these interviews, and the related thematic analysis, we do not only want to find evidence to corroborate the results of the analysis on the first set of interviews, and provide the primary ground to answer RQ2, but we use them to start gathering the data for giving an answer to the third RQ from the user's perspective.

## **5 Discussion and Conclusions**

This research should help to understand how a makerspace may help local area entrepreneurs to get access to an heterogeneous set of resources and competences that may be leveraged to adopt a lean startup approach.

The results should be able to give useful hints to both managers, fablabs, policy makers, and academicians as well.

From the managerial perspective the research tries to provide a guide to highlight some best practices in integrating the different services in order to improve the value co-creation potential of enterprises and startups. At the same time, this information may be used to provide guidance to the fablab organisations to help them to look at what is happening in other Italian regions, to improve their understanding of the local area evolution, and, as a consequence, be more effective in providing needed services according to the specific needs that may develop in their area .

The results are potentially interesting to the policy makers as well. Depending on the results, this research may provide useful information on which

technologies to support in public competence-development programmes not only to help the existing enterprises, that often may be blinded by knowledge myopia (Levinthal & March, 1993), but to help creating a stronger startupper movement.

Finally this research may provide useful information for the academicians as well, not only the Italian university may use the evidence gathered for this paper to decide how, and using which approach, they may start participating in the maker movement, but even to provide new evidence for the real effectiveness of the lean startup approach in the various Italian contexts that may be later used to define new research propositions that may explore how the various competences may be better developed in different contexts.

### **Abstract**

The study aims to assess the potential of artificial intelligence (AI) for improving the customer experience in the banking sector by designing and developing a digital human sustaining the customer care. Digital humans are conversational robots that have transformed traditional human-human interactions into new disruptive machine-human interactions that are more reliable and exceptional, but also fragile. The study analyses Algho, a virtual assistant platform developed by QuestIT company, to automate the banking customer care service, and in particular the loan request. The key aspect of this process was creating and consolidating an effective Knowledge Base, the indispensable basis for a successful performance of the digital human. The research evaluates the performance of the virtual assistant, equipped with a digital human interface, through the creation of an Algho tester that can verify the effectiveness of the knowledge base. The

results show that AI-based technologies can have a positive impact on business processes. The originality of the study lies in the training of a digital human according to business needs with a perspective of creating an optimised customer experience.

**Paper type** – Academic Research Paper

## 1 Introduction

Digital transformation is “a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies” (Vial, 2019), which allows artificial intelligence-based technologies to emerge and be applied to support business activities and processes. Artificial intelligence (AI) supporting the customer experience is revolutionising the way companies interact with consumers (McLean and Osei-Frimpong, 2019). By developing AI technologies strategically, several key touch points can be triggered that could bring significant benefits to companies and the possibility of increasing customer satisfaction. In this context, chatbots emerge that act as a gateway to an immediate and satisfying experience and, by incorporating machine learning functions, learn from their own “mistakes” and user behaviour (Tebekov and Prokhorov, 2021). The advantages of using chatbots are many, the most important of which is the 24/7 availability, i.e. the immediacy of such tools that can offer services at any time, leading the company to improve customer satisfaction and consequently its brand reputation.

The evolution of chatbots is represented by “*Digital Humans*”, which go beyond the obsolete concept of chatbots by embodying humanoid forms to relate with the customer in a more empathetic way (QuestIT, 2023). Digital Humans are conversational robots that represent the empathic evolution of virtual assistants. These tools are of enormous importance not only in the economic sphere but also in the social sphere, as they have transformed traditional human-human interactions into new disruptive machine-human interactions that are more reliable, exceptional but also fragile (Kaczorowska-Spychalska, 2019), in which a crucial part is the creation of trust (Przegalinska et al., 2019). The anthropomorphic nature of the digital human under analysis highlights a number

of psychological consequences that can potentially increase the engagement of the user with which it interacts (Alabed et al., 2022; Go et al., 2019), but can also occur a negative impact as a result of the chatbot disclosure, driven by a subjective human perception against machines, despite the objective competence of AI chatbots (Luo et al., 2019).

Despite the growing interest in the applications of Digital Humans for improving the customer experience, the role of digital technologies in improving the customer service experience through the adoption of digital human tools is still in an infancy phase. With the aim to cover this gap, the purpose of this paper is to assess the strategic potential of artificial intelligence for improving the customer experience (Ameen et al., 2021) in the banking sector. The aim is to design and develop a digital human, as a fintech application tool (Zarifis and Cheng, 2022; Hwang and Kim, 2021), as well as a digital marketing leverage (Paschen et al., 2019). Through the realisation of a virtual assistant trained for the purpose of automating the financing process on a banking platform, the advantages, opportunities and limitations of the research will be analysed. The crucial point in this process is the elaboration of a well-structured Knowledge Base, the indispensable basis for an effective performance of the digital human, which will be verified by the creation of a Knowledge Base tester.

Findings show that integrating AI systems can positively impact business processes.

Hence, the remaining sections of this paper are organised as follows. Section 2 presents an overview of the current literature, section 3 presents the research methodology. Then, section 4 is dedicated to the exposition of the findings, section 5 discusses the results in the light of the existing literature and section 6 concludes the paper by highlighting the implications.

## **2 Literature background**

Artificial intelligence found its roots in 1950, with the publication of the article "Computing machinery and intelligence" written by Alan Turing on this avant-garde topic. It developed concretely from the 1940s onwards, a period in which the term "cybernetics", i.e. the discipline that deals with the study of processes concerning "communication and control in the animal and in the machine" (Wiener, 1948), became widespread.

In order to meet consumers' needs, financial intermediaries can deploy digital technologies that optimise operational processes, especially AI technologies that can speed up credit recovery activities, reduce credit management costs, optimise more complex processes, maximise performance, and enhance touchpoints for customer care services.

### **2.1 AI-enabled tools: Digital Humans**

The main AI technology supporting customer care services is chatbots, 'intelligent agents' (Turing, 1950; Poole and Mackworth, 2010) based on systems aimed at communicating with users using natural language processing (Adam et al., 2020); they are designed to imitate human speech in approximating written text or vocal speech as best as possible to interact with people via a digital interface (Ling et al., 2021; Thomaz et al., 2020). They become the technological reflection of humans leading to "the dehumanisation of what is human and the humanisation of technology in all its manifestations" (Kaczorowska-Spychalska, 2019).

As a result, chatbots are gradually replacing human service agents on websites, social media platforms, and messaging services. According to industry experts, the market for chatbots and related technologies is projected to surpass \$1.34 billion by 2024 (Wiggers, 2018). While some experts argue that chatbots can improve customer service while also reducing costs (De 2018), others fear that they may have a negative impact on firms and customer service (Kaneshige and Hong 2018). Hence, determining the optimal design and implementation of chatbots for customer service purposes remains an open question, as businesses weigh the benefits and drawbacks of these tools in delivering efficient and effective customer service (Crolc et al., 2021).

The shift from chatbot to digital human represents a move towards creating AI systems that can simulate human-like interactions, emotions, and behaviours to a greater extent than current chatbot technology. A digital human goes beyond the scripted responses of a chatbot and can respond more naturally to complex queries and even understand nonverbal communication such as facial expressions, tone of voice, and body language. The development of digital humans involves using advanced algorithms and machine learning techniques, including deep learning and natural language processing, to create more

sophisticated and personalised interactions with users, as well as being equipped with a digital human interface (QuestIT, 2023).

## **2.2 Digital Humans in the banking sector**

The digitalisation of businesses, in which digital technologies are used to change business models and create new revenue opportunities, is transforming the way that service providers and customers interact (Oviatt and Cohen, 2015; Hennig-Thurau et al., 2010; Pousttchi and Dehnert, 2018; Schmidt et al., 2017). As new technologies emerge, it can be assumed that the digitalisation-enabled transformation in services will be even further amplified (Gomber et al., 2018). The financial service sector has already experienced the impact of digitised services such as mobile wallets, payment apps, and automated wealth advisors that have entered the market as replacements for established banking services (Basole and Patel, 2018). To fully realise the potential of digitalisation-enabled service transformation, it is important for those leading the transformation to see its potential from a customer perspective (Kandampully et al., 2021; Lähteenmäki et al., 2022).

The finance industry has been at the forefront of utilising AI technology, including chatbots, and is seeing an increase in the number of financial institutions adopting chatbots to enhance customer service (Adobe, 2019; Sarbabidya and Saha, 2020; Suhel et al., 2020). This has led to progress in research on chatbot technology in the finance industry, with many researchers studying algorithms and systems that reflect the unique characteristics of the industry. Financial firms face challenges in providing customers with the right information due to the complexity of the financial system, resulting in time and labour lost on simple inquiries (Chaitrali et al., 2017). Chatbots have been proposed as a solution to answer frequently asked questions using natural language processing (NLP), providing customers with quick and efficient service (Elcholiqi and Musdholifah, 2020; Rajbabu et al., 2019; Yu et al., 2020). Several banks have embarked on a digital transformation process (Zhang, 2021), and chatbots are widely recognized as a vital and necessary element of this transformation, as well as a sustainable strategy for the development of the banking industry (Forbes, 2021). Chatbots are frequently employed by banks in their marketing efforts, sales activities, and customer relationship management practices (Eren, 2021), enabling them to deliver quick, affordable, and customised services to their customers.

Nguyen et al. (2021) suggest that to keep customers using chatbot services in banking, providers must ensure their chatbots are trustworthy, useful, and meet customer needs. They can do this by focusing on three quality aspects of chatbot services: information quality, service quality, and system quality. Information quality is critical for users' trust and satisfaction, and providers must offer relevant and up-to-date information. Service quality is essential to provide accurate information and prompt responses to users' queries. Personalised services, addressing customers by name, can alleviate uncertainty and build trust. System quality is the most important factor in building users' trust in chatbots, and banks must provide a stable, attractive, and adaptable interface with 24/7 support. Additionally, they must consider systematic risk and users' privacy when developing chatbots, particularly in emerging markets with weak legal protection. Providing high-quality chatbot services can result in many benefits for banks, such as a good reputation and positive image.

Digital Humans are the right tool for banking customer care as they facilitate navigation, provide live insights, are multimodal, predictive, inclusive, and optimise work, automating first-level processes, facilitating the work of operators and reducing costs (QuestIT, 2023).

The study therefore aims to enrich the existing literature with more knowledge on the shift from chatbots to digital humans, by describing the key features of these innovative AI-enabled digital tools. The focus of the work is on the automation of banking customer care, thanks to the Algho platform, to examine the potential impact of digital humans on the customer experience.

### **3 Research methodology**

The study adopts the case study (Yin, 2003) of Algho, a technology produced and developed by QuestIT and a registered trademark of The Digital Box. Algho is a virtual assistant, based on latest-generation 3D technology with human features, with the aim of creating an empathic relationship with the user and thus establishing a new and effective User Experience. *The research question driving this study is: How does the implementation of Digital Human for banking impact the customer experience?*

To address this question, a digital human was created and developed using the Algho Platform in order to automate the financing process on a banking website. Fundamental in this phase is certainly the process of creating and consolidating a

"Knowledge Base" capable of understanding and solving the user's specific problems and earning the user's trust. To evaluate the effectiveness of the virtual assistant, an Algho Knowledge Base tester was created to optimise the performance.

## 4 Findings

The first step in proceeding with this study was to realise the digital human according to business needs. We proceed to choose the name, the voice, the language, the gender. We then proceeded to insert a welcome and welcome back message. The digital human was created and trained completely in Italian, as the bank for which it was developed is Italian.

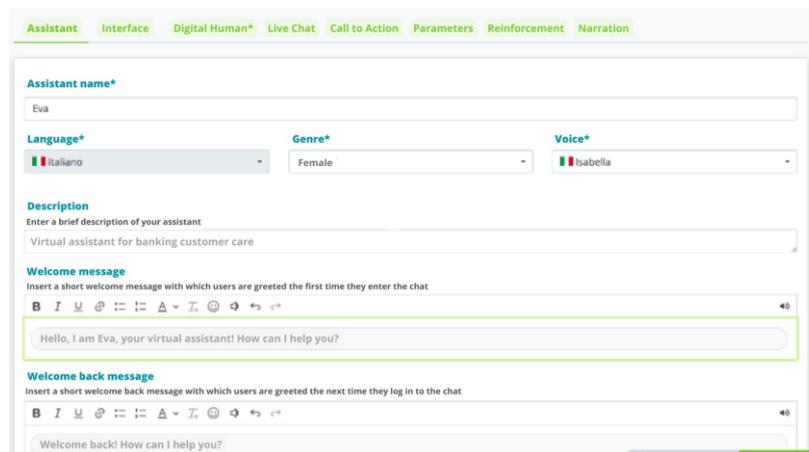

The image shows a web-based configuration interface for creating a digital assistant. At the top, there is a navigation bar with tabs: Assistant, Interface, Digital Human\* (highlighted), Live Chat, Call to Action, Parameters, Reinforcement, and Narration. The main form is titled 'Assistant name\*' and contains several sections: 1. 'Assistant name\*' with a text input field containing 'Eva'. 2. 'Language\*' with a dropdown menu set to 'Italiano'. 3. 'Genre\*' with a dropdown menu set to 'Female'. 4. 'Voice\*' with a dropdown menu set to 'Isabella'. 5. 'Description' with a text area containing 'Virtual assistant for banking customer care'. 6. 'Welcome message' with a text area containing 'Hello, I am Eva, your virtual assistant! How can I help you?'. 7. 'Welcome back message' with a text area containing 'Welcome back! How can I help you?'. Each text area has a rich text editor toolbar above it. The interface is clean and modern, with a light blue and white color scheme.

Figure 12. Creation of the Digital Human

Next, we set the colours of the chat, the company logo and settings related to the speed of the assistant's response. The latter setting allows you to set a slower response type, if you are trying to simulate human interaction, or a faster one.

There is the possibility of setting up the 'Live chat' function, which allows a human operator to enter the chat and replace the assistant in the event that the user, for example, asks to interface with a real person, or in the event that after a pre-set total of questions that the digital human is unable to answer, the automatic call to the human operator starts. By means of the 'Parameters' setting section, one can set the degree of flexibility, confidence and correspondence one wishes to give the virtual assistant. Specifically, the correspondence refers to the degree of importance the digital human attaches to the semantic and syntactic

component in order to provide the most suitable answer to the question received from the user. The "Reinforcement" section allows the user to set various types of learning that the assistant can perform automatically. This function allows the user to rate the digital human's answer positively or negatively, thus making him/her remember whether a particular answer was useful or not in order to help him/her with future questions. The risk, however, is that the answer is voted negatively even if it is correct, for whatever reason or problem not arising from the chatbot.

After setting these technical settings, we entered the phase of creating the knowledge base of the digital human. The platform provides pre-set basic questions for small talks, and to create custom questions, one must formulate the question and enter an appropriate answer that satisfies different variations of the question. Conversational forms can also be added, along with a link function to guide users to relevant pages. Multiple answers can be created for a single question and targeted according to the user's focus. To train the virtual assistant, indirect or direct information can be sought to convert the user into a customer. Trust and a suitable tone of voice must be established to adapt to a broader range of customers, especially in the banking sector. A solid knowledge base must be created to understand and solve the user's specific problems, building trust with the user.

The Knowledge Base Test was the key point to improve the virtual assistant's ability to answer questions correctly. In fact, thanks to this test, which was carried out by entering all the questions in the virtual assistant's Knowledge Base with variants that a user could ask in an excel file uploaded directly to the Algho platform, the latter provided the result as a percentage of this performance. Thus, the Knowledge Base was optimised until a 100% performance result was obtained.

## **5 Discussion**

In our study, we examined the historical evolution of chatbots and how they have now turned into Digital Humans, conversational robots that represent the empathic evolution of virtual assistants. Specifically, we analysed the case study of the Algho platform, which gives the possibility of training a Digital Human to assist users by reshaping the User Experience.

Then, we designed and trained a Digital Human for banking customer service, working on the possibility of optimising banking processes such as a loan request. This process represents a great advantage for the market, giving the possibility of optimising costs and employing human resources in more complex and difficult to predict activities. Several studies indicate that the use of such AI tools offers substantial advantages, especially with regard to interactions with customers, who form more personal bonds with robots than with an AI without a physical embodiment.

A wide range of potential functions and advantages offered by chatbots are the subject of reflections that will certainly be deepened in the coming years, in the face of new interactions with customers that represent an interesting win-win. The customer in fact obtains a constantly evolving 'product' that satisfies his needs, and companies are motivated to optimise it to increase the customer lifetime value (Kaczorowska-Spychalska, 2019).

The provision of accurate, timely, and pertinent information by chatbots can enable users to make prompt and accurate financial decisions. Users are likely to experience increased satisfaction when they perceive chatbots as trustworthy (Gao et al., 2015). Notably, the quality of service is the primary determinant of user satisfaction (Nguyen et al., 2015).

According to Nguyen et al. (2015) customers tend to continue using chatbot services only if they perceive them as reliable and useful and if their needs are met. Therefore, banking service providers should pay close attention to three key quality aspects of chatbot services - information quality, service quality, and system quality - and ensure that users' expectations are met. Understanding customers' expectations is a vital first step for banks to provide timely solutions that satisfy them. Hence, to promote customers' intentions to continue using chatbot services, their expectations must be met or even exceeded. Furthermore, given the significant role of perceived usefulness in the relationship between satisfaction and continuance intention, banks must ensure that their chatbot services are error-free, as service failures can prevent customers from getting what they are looking for, causing dissatisfaction. Banks should also anticipate users' most common questions or requests and program chatbots to perform their tasks efficiently. In addition, interactions between users and chatbots should be efficient and user-friendly (Nguyen et al., 2015).

Endowed with personality and based on self-improvement mechanisms, Digital Humans could become our faithful reflection in the future (Kaczorowska-Spychalska, 2019).

## **6 Conclusion and implications**

Having created and trained the virtual assistant, the enormous potential of such a tool emerged, as not only does it have a simple and intuitive interface, it also allows the digital human to be trained and tested in an iterative manner. This makes it possible to constantly improve its performance in order to offer the user an innovative and immersive customer experience.

The main managerial implications that emerge from our study are first the possibility of automating certain processes currently entrusted to human resources so that certain business activities and processes can be optimised. Second, a growing awareness has emerged with respect to the benefits that these tools can bring, but a low ease of use, so the focus on which there is a need to work is on increasing knowledge of these technologies. In addition, future research, building on the implications of our study, could deepen this topic by analysing the psychological factors underlying human-machine interactions to improve and optimise the customer experience, reducing the current resistance with respect to these technologies and thus increasing the propensity to adopt them.

The ideal evolution of the project we have outlined is represented by the future possibility of placing one's trust in AI tools that, in a completely automated manner, can on the one hand provide all those operational banking services such as applying for a loan, opening an account, or requesting a debit or credit card, and on the other hand also provide all those advisory services that, based on the customer's need and financial situation, can help him or her orientate themselves in the investment choices that are best suited to them.

Underlying possible future developments is an awareness on the part of individuals of how such technologies can improve their customer experience. Furthermore, in an optimal process improvement and optimisation in addition to automating the totality of banking services, a possible future development that would be of incredible importance is the possibility of automating customised advisory services according to customer requests. This process would be the natural evolution of the so-called robo-advisors, i.e. those tools that are aimed at

providing investment solutions in a totally, or almost totally, automated manner; in order to improve the customer experience supported by artificial intelligence tools.

Future research could also analyse and test the reaction and behaviour of users when using such a tool, in order to better understand the role of artificial intelligence on the customer experience.

### **Abstract**

Serendipity – the notion of making unexpected and valuable discoveries – and knowledge arbitrage have played a significant role in the debate about innovation and innovation effectiveness, opening a considerable discussion about the feasibility of R&D investments. The chance to detect serendipitous events and the mechanisms triggering it may attract

the attention of those seeking greater efficiency in research and those aiming to sustain basic research. Depending on the above, our research focuses on the serendipitous events and knowledge arbitrage in the R&D of rare diseases and orphan drugs to detail the market opportunities and the economic value arising from the untargeted discoveries. The Tigem research center in Pozzuoli (Italy) is engaged as a case study to achieve this purpose. Since no previous researches are available about the serendipity in R&D of rare disease, this paper provides new knowledge in a still underexplored field, offering new insights at both theoretical and practical levels.

**Keywords** – Serendipity; R&D; pharmaceutical industry; rare diseases; orphan drugs

**Paper type** – Academic Research Paper

## 1 Introduction

Innovating is always risky, as introducing something new (not existing before) always involves a reasonable chance of failure. Therefore, '*The willingness to commit resources to projects, ideas, or processes whose outcomes are uncertain*' – risk-taking (Covin and Wales, 2012, p. 694) – may reasonably affect the investors' propensity to engage in risky/innovative activities. It is especially true for industries with high research and development (R&D) investments, such as pharmaceutical and biopharmaceutical industries. Both pharmaceutical and biopharmaceutical companies spend massive amounts of money on R&D to discover new drugs. They also face significant uncertainty across the whole value chain, from drug discovery to post-launch pharmacovigilance. After having found a new drug, the companies can exploit the exclusive marketing rights for a period as a reward for their R&D efforts<sup>1</sup>. Unsurprisingly, the allocation of resources in the pharmaceutical and biopharmaceutical industries is usually driven by the expected returns on investments. Thus, the potential market size is crucial in addressing R&D investments in both sectors (Gamba et al., 2019). This evidence finds support in the research results by Dubois et al. (2015) and Acemoglu and Linn (2004), who confirmed a direct relationship between the potential market size and the development of new drugs. Following the above considerations, pharmaceutical and biopharmaceutical companies are reluctant to invest in rare diseases, mainly because of cost and the uncertainty linked to developing orphan drugs (it takes about ten years on average to discover and market a new drug to

---

<sup>1</sup> Once the drug comes off patent, generic drug manufacturers can produce and sell the drug at a significant discount. This circumstance reduces the profits for the company that first invested in the R&D.

treat a rare disease) and the reduced market opportunities, the last ones limited to a small patient population.

Rare diseases affect a few people compared to the general population, and specific issues are raised concerning their rarity. Nguengang Wakap et al. (2020) estimate that the number of people worldwide living with a rare disease is 300 million. Notably, in Europe, a rare disease affects one person per 2000<sup>1</sup>. In 2021, research and development spending in the pharmaceutical industry was about 238 billion U.S. dollars globally<sup>2</sup>, with only 11% of new drugs expenditure addressed to the treatment of rare diseases and orphan drugs<sup>3</sup>. Moreover, Gamba et al. (2019) revealed that while R&D has increased over time for all orphan diseases, the increase has been much more remarkable for the less rare.

This gap opens a considerable debate among academia, institutions, and civil society on triggering private and public investments toward R&D in rare diseases and orphan drugs. Mainly, we sustain the idea that market opportunities may arise from unexpected and beneficial discoveries in R&D, claiming a new evaluation of the profitability of the original investments. Carayannis (2008; 2011; 2011a; 2014; 2014a; 2015; 2016; 2019; 2022) labels these "happy accidents" and considers them derivatives of Strategic Knowledge Serendipity and Arbitrage instances to emphasize the role of an individual's ability to identify, accessing, and integrating the knowledge arising from serendipitous events and employing it to get defensible, sustainable, and financial benefits. The most famous 'happy accident' in the past was the fortuitous detection of penicillin by Alexander Fleming in 1928, but hundreds of unexpected discoveries characterize the history of innovation. Serendipity was prominent in discovering many drugs and medical treatments, including vaccination, insulin to treat diabetes, penicillin, quinine, and Viagra. It was also crucial in many fundamental discoveries, including x-rays, radioactivity, pulsars, and cosmic microwave background radiation, and in finding many valuable products such as Teflon, vulcanized rubber, microwave ovens, and velcro. In 2006, Thomas Ban found that *serendipity was one of the many factors contributing to drug discovery*.

In line with the above considerations, our research focuses on the serendipitous events and knowledge arbitrage in the R&D of rare diseases and

<sup>3</sup> Source: Report: Orphan Drugs in the United States: Rare Disease Innovation and Cost Trends Through 2019. IQVIA Institute for Human Data Science, December 2020

orphan drugs. The final aim is to detect and detail the market opportunities and the economic value of the 'not targeted' discoveries. In so doing, we focus on the research activities held by Tigem. Tigem is a Telethon Foundation research center in Pozzuoli, Italy. It comprises several research groups and over 200 staff members dedicated to understanding the molecular mechanisms behind rare genetic diseases and developing novel treatments. Recently, one of the Tigem research groups identified a novel disease–gene association in the autism spectrum disorder (gaining a new goal in the research of rare diseases) thanks to the genomic surveillance of the acute respiratory syndrome coronavirus 2 (SARS-CoV-2)<sup>1</sup>. Because of its focus on rare diseases and the efforts paid to attract external funds, Tigem should likely generate rich information on the phenomena which aims to explore, justifying its selection in our research (Miles and Huberman, 1994).

Following Shorten and Smith (2017), we designed a mixed method (exploratory sequential) to reach our final goals. Given the complexity and multi-step nature of our research process, in this conference's context, we mainly explain the results arising from the first step of our investigation (qualitative data collection and analysis).

The paper is organized as follows: after reviewing the literature on *Serendipity* and *Knowledge Arbitrage* and their impacts on rare diseases and orphan drugs, the study method and the selected case study are detailed. Thus, the first results are presented and discussed. The paper ends by providing implications, limitations, and directions for the forwarding research steps.

## **2 Serendipity, Knowledge Arbitrage, and discoveries**

In 1754, Horace Walpole introduced the word serendipity to label '*the faculty of making happy and unexpected discoveries by accident*'. As known, Walpole was a prolific inventor of new words. However, it could not imagine that the Oxford Dictionary would have declared 'serendipity' one of the ten most difficult English words to translate (2004), nor that it would become the core of a vast scientific analysis aiming to understand its mechanisms and antecedents (Wareham et al., 2022; Garud et al., 2018; Yaqub, 2018).

---

<sup>1</sup> The Tigem group developed an optimized and cost-effective strategy to monitor SARS-CoV-2 genetic variability without automation.

Several scholars (Wareham et al., 2022; Garud et al., 2018; Yaqub, 2018; Carayannis, 2014, 2008; De Rond, 2014) consider serendipity no longer a pure lucky event nor a random process. In contrast, 'there may be important combinations of factors affecting its occurrence and scope for altering its prevalence' (Yaqub, 2018, p. 175), able to impact, lastly, the effectiveness of the overall un-targeted R&D. Therefore, understanding serendipity, its mechanisms, and antecedents is the first step to look for a new balance in the rationales triggering investments in targeted and un-targeted research.

Serendipitous events arise in basic science, applied research, and technological development activities. Definitions of *serendipity* may be found in several research contexts: information (Agarwal, 2015); science and technology (Anzel, 1994; Merton, 1984); organizational learning and innovation (e Cunha et al., 2010; de Rond, 2014); innovation ecosystems (Carayannis, 2014; 2008); creativity (Austin, 2003); entrepreneurship (Dew, 2009); recommendation systems (Kotkov et al., 2016); and medicine (Scherman and Fetro, 2020).

Serendipity generally means discovering something we are not in quest of (Merton and Barber, 2004).

The most extensive exploration of *serendipity* started in the 40s. At that time, Robert K. Merton began his project to chart serendipity's lexicographical history and sociological semantics. Pursuing his research aims, Merton collected hundreds of examples of serendipitous events and detailed writing notes about the phenomenon. Recently, Yaqub (2018) has reviewed Merton's archives and has been able to classify *serendipity* on the bases of the nature of the inquiry (targeted/non-targeted) and the result of the discovery itself (type of solution discovered: solution to the target problem/solution to an un-targeted problem).

Notably, the authors identified the following:

1. The *Walpolian serendipity*: discovering something which the researcher was not looking for (solution to a different/un-targeted problem)
2. The *Mertonian serendipity*: discovering something which the researcher was looking for through an unexpected path (targeted problem/different path);
3. The *Bushian serendipity*: discovering a not sought-for solution (un-targeted research solves an immediate problem)
4. The *Stephanian serendipity*: discovering something that does not directly solve an instant problem but could solve a problem in the future (un-targeted research solves a problem later)

The above typologies are presented in Table 1. The nature of the inquiry (targeted research vs un-targeted research) and the research outcome (solution to targeted problem vs solution to the un-targeted problem) are reported in the table's headings.

Table 2- Types of serendipity

		NATURE OF THE INQUIRY	
		TARGETED RESEARCH	UNTARGETED RESEARCH
RESEARCH OUTCOME	SOLUTION TO UNTARGETED PROBLEM	Walpolian	Stephanian
	SOLUTION TO TARGETED PROBLEM/UNEXPECTED PATH	Mertonian	Bushian

Source: Yaqub, 2018

In the same vein, Busch (2020) detected three types of serendipity based on the nature of the inquiry (the researcher is already looking for something or not) and the research outcome (expected discovery vs unexpected discovery). Björneborn (2017), and Bogers and Björneborn (2013) distinguished between 'foreground serendipity' (arising from the researcher's direct focus) and 'background serendipity' (arising from a change in the researcher's focus) based on how research interests (preoccupations/foreground interests vs background/latent interests) are prompted.

In general, the researchers recognize the typologies mentioned above only after they have occurred (Wareham et al., 2022; Yaqub, 2018), and, as in the case of Stephanian serendipity, the discovery may find its usefulness and applications only time later, sometimes in different research areas, influencing the investigators' ability to value its effectiveness. In contrast, more helpful information arises by examining the processes and the mechanisms supporting the emergence of serendipitous events. Notably, Yaqub (2018) identified four mechanisms through which 'happy accidents' may arise: according to the scholar, serendipity may be *theory-led*, *observed-led*, *error-born*, and *network-emergent*. These mechanisms suggest as many recommendations to foment serendipity.

Examining the deviation from the theory is the first source of serendipity (*theory-led*). It means detecting incongruences between output and process and predictions and expectations on the other. In sum, if the theory guides the researcher on where to look, it is only by diverging from conventional and

institutionalized knowledge that the observer widens the scope of its potential discoveries (Åkerström, 2013). Observation is the second source of serendipity (*observed-led*). Notably, observation routines (individual characteristics) and instrumentation availability (context characteristics) affect both individuals' discoveries and their ability to perceive serendipity (Wareham et al., 2022; McCay Peet & Toms, 2015). Depending on this, cultivating serendipity requires both individual-level catalysts (ex.: alertness) and enablers (ex.: cognitive flexibility) and organization-level triggers (ex.: social embedding) (Busch, 2022). Sometimes serendipitous events emerge from errors, mistakes, and forgetfulness. One of the most well-known *error-led* serendipity is the discovery of penicillin. In 1928, Alexander Fleming was exploring influenza when one of his petri dishes became spoiled and grew a mold. Fleming noted that the mold grew in a circle in which no bacteria was found. After isolating the mold, Fleming made liquid to fight bacteria. This drug is known as Penicillin (Ban, 2006). Finally, *serendipity* may be *network-emergent*. Almost all recognize the crucial role of collaboration in fostering innovation and cooperation, enabling individuals and organizations to share what they already know and explore new knowledge (Canestrino et al., 2022). In the same vein, serendipity will likely arise thanks to the interactions between and among several people (e Cunha et al., 2010; Meyers, 2007). According to Yaqub (2018), networks support serendipity, '*bringing discoveries to the attention of researchers who can exploit them*' (p. 174). Nevertheless, networks could also bind serendipity because of a 'bandwagon effect' that limits the researcher's ability to combine different and unrelated information (Busch, 2022). Given the serendipity, it is more likely to arise in a diverse research network, within which the interaction between different fields of knowledge and industries is supported. Social networks can support the emergence of fortunate encounters if they increase the amount and/or diversity of interactions (McCay-Peet et al., 2015; McDaniel & Walls, 1997), thus potentially increasing the surfacing and sharing of unexpected ideas. In this vein, research networks are expected to trigger serendipitous events to the extent to which they support the *knowledge arbitrage*.<sup>1</sup>

---

<sup>1</sup> Carayannis (2014) defines knowledge arbitrage as 'the ability to distribute and use specific knowledge for applications other than the intended topic area. More specifically, it refers to the capacity to create, identify, reallocate, and recombine knowledge assets more effectively and efficiently to derive, develop and capture non-appropriable, defensible, sustainable, and scalable pecuniary benefits' (p. 205 – JoKE)

## **2.1 The research model in the framework of rare diseases**

The European Union considers a disease rare when it affects **less than one in 2,000** citizens. Despite this, the number of people affected by a rare disease is numerous. Up to 36 million people in the EU live with a rare disease. There are more than 6000 distinct rare diseases in the EU. Around 80% of rare diseases are of genetic origin, and 70% already start in childhood. Discoveries leading to new treatments and drugs for rare disease represents a unique challenge. The small patient population negatively affects the market's attractiveness to companies and scientists (Douglas et al., 2022).

Moreover, time and costs associated with drug discovery and development discourage pharmaceutical companies from addressing their investments in less profitable markets (Scherman and Fetro, 2020). Several factors (ex.: the small market size, the high cost of research and development, high failure rates, industry's need to recoup high-risk investments, amongst others) increase the cost of producing new drugs. Additionally, the complexity of regulations (from the lead compound identification to the market authorization) contributes to lengthening the time between the research and preclinical and clinical development. This process takes ten to fifteen years and costs several billion dollars. Under such circumstances, the needs faced by rare disease patients risk remaining unmet because of the inability to fix a sustainable price for the healthcare system. In the face of these challenges, we support the idea that detecting, tracking, and supporting the emergence of serendipitous events in the R&D in rare diseases could add economic rationale for both public and private fundings and address a better combination of *mission-oriented* vs *diffusion-oriented* policies. In the context of this research, we aim to answer the following questions:

*RQ1: What and how many serendipitous events do the researchers experience in the R&D of rare diseases? (type of discovery)*

*RQ2: Which mechanism does prevail in the trigger of serendipity in the R&D of rare diseases?*

*RQ3: How does knowledge arbitrage contribute to serendipity?*

Since the nature of inquiry in rare diseases is mainly 'target' (researchers concentrate on a specific disorder to discover a treatment), we focus only on Walpolian and Mertonian serendipity. All the mechanisms conducive to

serendipity (*theory-led*, *observed-led*, *error-born*, and *network-emergent*) were considered in our research framework (see Fig. 1).

### 3 Methodology

This paper represents the first output of multiple-step research aiming to detect the profitability of the serendipitous discoveries arising from R&D in rare diseases. The overall research design follows Shorten and Smith (2017) and is based on an exploratory sequential. In this conference's contest, we mainly explain the first step of our investigation (qualitative data collection and analysis). Sample selection, procedure, and data analysis are detailed in the following subsections.

### **3.1 Sample**

Tigem (Telethon Institute of Genetics and Medicine) was selected as an instrumental casework (Stake, 1994). Tigem is a Telethon Foundation organization founded in 1994 as a leading European research center. It is in Pozzuoli, Italy, with 230 staff members and 17 research groups.

Tigem is a multidisciplinary research institute exploring the mechanisms underlying rare genetic diseases. Its main aim is to discover how anomalous molecular mechanisms produce disease and develop innovative therapies. To achieve its aims, the institute conducts research projects along three main lines: cell biology, medical genomics, and molecular therapy. Tigem is supported by Telethon Foundation, which guides scientists in the processes needed to foster discoveries and turn them into valuable products and therapies. Notably, Telethon Foundation enables research partnerships with academia, industry, and potential investors.

The case study fits all the criteria Miles and Huberman (1994) suggested for the sample selection in qualitative research. Because of its core activity (R&D in rare diseases), Tigem is relevant to the conceptual framework and the research questions addressed by our investigation and will likely generate significant knowledge about the phenomena we wish to explore. Since we focus on the scientists' research activities, our case study allows us to comprehensively describe the serendipitous events and the mechanism leading to accidental discoveries. Finally, the sample plan is feasible regarding the accessibility of the research center and competencies (homogeneity between parties regarding linguistic and communication skills).

### **3.2 Data collection and procedure**

In this study, we employed an instrumental casework selection (Stake, 1994). After collecting information about the activities held at Tigem, we contacted the head of the Molecular Therapy Program (one of the three main research lines in Tigem) to check the availability to participate in our investigation. The research group belonging to the program is currently developing novel therapeutic approaches for mitochondrial-associated disorders. After, confirmation, a first meeting was organized in Tigem Pozzuoli and an in-depth interview was managed to check whether and to what extent the Tigem scientists' activities could address our research goal. As Yin (2009) recommended, a research

protocol—including the interview and procedure guide—was planned before engaging in the research. The interview lasted about 60 minutes, was managed flexibly, and involved the exploration of the two macro-areas of investigation (serendipity and knowledge arbitrage). During data collection, we encouraged the informant to provide concrete examples to describe certain aspects of the Tigem activities and the R&D in rare diseases in more detail. After the interview, a shared research guide was detailed to be delivered (online) to the three main research groups actively working in Tigem.

Based on open-ended questions, the interview guide was developed following Ahmad (2018). Questions mainly focus on the respondents' research experience developed within the Tigem and the role of serendipitous events and knowledge arbitrage in the R&D. Participants were asked to provide examples about the experiences of serendipity and knowledge arbitrage, detailing the mechanisms driving the unexpected discoveries. A copy of the interview guide is available upon request.

After the first screening, face-to-face meetings were scheduled with the scientists who agreed to participate in the research.

The interviews were audio recorded, later transcribed, and checked for accuracy. We adopted a qualitative interpretive approach (Nag & Gioia, 2012; Gioia et al., 2013) to get a compelling account and explanation of what is observed. This approach helped us prevent the loss of information by coding the data corpus (informants' voices) as first-order codes before aggregating them to second-order themes (abstract concepts from the first-order categories) and finally identifying the aggregate dimensions (theoretical themes).

#### **4 Some findings and future research directions**

Given the complex nature of our exploration and the high number of interviews to be scheduled, the investigation is still running at the submission date. Consequently, the proposed findings should be considered provisional in any case.

Notably, the first in-depth interviews were held at the beginning of February 2023. Online survey distribution started on March 2023. Ten scientists agreed to be engaged in our research; thus, forwarding meetings were scheduled in line with each participant's availability.

Regarding the first research question, collected information confirms that serendipity is crucial in advancing research in rare diseases. Remarkably, one respondent reported:

*"unexpected discoveries are crucial in the advancement of knowledge. There is no research without serendipity...every scientist in this institute has experienced a serendipitous event at least once in his carrier...we have many examples".*

The respondents cited Walpolian and Mertonian serendipity, even if collected data are insufficient to determine the frequency of each event within the research process. Nevertheless, detecting the contribution of Walpolian serendipity to untargeted problems (Ex.: fields others from rare diseases) could be helpful in tracking the discoveries, detailing their impacts and profitability. It means providing the potential stakeholders with new information to assess the expected return on their investments (the last being linked to related and unrelated business).

Relevant remarks also refer to both the mechanisms triggering the serendipity and the contribution of knowledge arbitrage (RQ2 and RQ3).

Alessia Indrieri, responsible for the mitochondrial lab, explained:

*"One day, some years ago, I was having a break for a coffee together with my close friend Sabrina Carella. At that time, Sabrina worked within the research group led by Sandro Banfi in Tigem. During our break, Sabrina described how two RNA molecules affect the development of the retina. These two molecules (miR181 and miR181b) also play a role in mitochondrial activities. Thus, we asked ourselves if they could be what I was in search for... I discovered that miR181 and miR181b affect mitochondrial life, from their born to the disposal of those no longer need, and I found that unexpectedly while having a coffee..."*

*"We patented a new molecule, inhibiting miR181 and miR181b. We put the molecule in an inactivated virus to transfer it inside human cells in a safe way. The results of the first experiments to treat the Leber hereditary optic neuropathy and dominant optic atrophy are promising".*

The collected information confirms the relevance of networks in supporting knowledge share among the parties and triggering serendipity. In so doing, it provides suggestions on how collaboration may avoid 'echo chamber' and 'group-thinking'. Moreover, the example opens a more in-depth investigation of knowledge arbitrage and the difficulties in demarking boundaries between

*network-led serendipity mechanisms* and using knowledge from different sources. Since a *network-led* mechanism always implies the engagement of multiple people, knowledge arbitrage should be considered a *condictio sine qua no* to prompt serendipity.

More interesting to get our final goal is tracking the impact of the mentioned discovery on treating more common diseases due to mitochondrial dysfunctions, like Parkinson's. Considering the positive effects of the serendipity in rare diseases on the untarget markets is necessary to get a more truthful and accurate assessment of the potential return on investments of the stakeholders.

## Abstract

Waste management in touristic areas and the hospitality industry is a significant concern, with the problem exacerbated during large events. This research paper aims to explore the main problems of waste management in these sectors and propose the implementation of smart waste bins as a solution. The study includes an in-depth analysis of current waste management practices and the potential benefits and challenges associated with smart waste bins. We examine their effectiveness, cost-efficiency, and potential for integration with existing waste management infrastructure, as well as their potential environmental and social benefits. The results show that smart waste bins, when strategically deployed and integrated into a comprehensive waste management plan, can significantly improve waste management efficiency, reduce environmental impact, and support sustainable tourism and hospitality operations.

**Keywords** - sustainability, waste management, smart waste bins

**Paper type** – Academic Research Paper

## **1 Introduction**

### ***1.1 Background and problem statement***

Waste management has emerged as a critical issue for touristic areas and hospitality industry, with these sectors being significant contributors to the generation of solid waste. The high volume of tourists, coupled with the nature of their activities, leads to the production of large amounts of waste, particularly during peak seasons and events. Proper waste management is essential not only for preserving the environment, but also for maintaining the attractiveness of these destinations and ensuring sustainable tourism and hospitality practices.

The challenges faced by the industry include inefficient waste collection and disposal systems, lack of waste segregation and recycling facilities, environmental pollution, and limited infrastructure and budget allocation for waste management. In response to these challenges, the implementation of innovative solutions, such as smart waste bins, is increasing particular attention. These intelligent systems aim to improve waste management efficiency, reduce environmental impact, and optimize resources.

### ***1.2 Research objectives***

The primary objectives of the research paper are to:

a) Identify and analyze the main problems of waste management in touristic areas and hospitality industry. b) Investigate the potential of smart waste bins as a solution for waste management during large events in these specific fields. c) Evaluate the advantages, challenges, and limitations of smart waste bins. d) Provide recommendations for the successful implementation of smart waste bins in touristic areas and hospitality industry.

### ***1.3 Research scope and limitations***

This study focuses on the application of smart waste bins as a waste management solution for touristic areas and hospitality industry, particularly during large events. The paper reviews the existing literature and case studies to understand the potential of smart waste bins and their role in addressing the identified waste management problems. The research is limited by the scarce availability of data on the implementation of smart waste bins in these specific

sectors and the potential bias in case study selection. Additionally, the findings of this study may not be universally applicable, as waste management challenges and solutions may vary depending on the local context and available resources.

## **2 Literature Review**

### ***2.1 Waste management evolution***

The history of waste management dates back to ancient civilizations, where waste was typically disposed of in open pits or dumped into rivers or other bodies of water (Fytilis, N., & Poulakakis, N. (2017)). However, the development of cities and industrialization in the 18th century led to increased amounts of waste, and the need for more sophisticated waste management practices (Graham-Rowe, E. (2011)).

From 1750 to the mid-20th century, waste was primarily collected by hand and transported to disposal sites such as open dumps or landfills. The first modern landfill was established in 1937 in the United States, which marked a significant milestone in waste management (Yang, S. (2019)). In the 20th century, advances in technology led to the development of more efficient waste management practices, such as incineration and recycling. Incineration became popular in the 1950s and 1960s as a way to reduce the volume of waste, and it is still used today in some areas. Recycling also became more widespread in the latter half of the 20th century, and continues to be an important part of waste management (Tsai, Y. C., & Kang, Y. T. (2018)).

The development of the internet and digital technology in the late 20th century and early 21st century led to the emergence of smart waste management systems (Medina, M., & Bovea, M. D. (2013)). These systems use technology such as sensors, cameras, and artificial intelligence (AI) algorithms to optimize waste collection, sorting, and processing.

Artificial intelligence (AI) can play a significant role in improving waste management in smart cities (Sahoo, S., Ghosh, S. K., & Das, S. (2021)). By using advanced analytics and machine learning techniques, AI can help identify patterns and trends in waste generation and disposal, and provide valuable insights to city planners and waste management authorities (Gholami, R., Nabavi, S. M. B., & Esmaeili, M. (2019)). AI has, in fact, the potential to transform waste management

in smart cities by optimizing the collection, transportation, and disposal of waste (Kothari, R., & Tariq, F. (2020)).

## ***2.2 Waste management in touristic areas and hospitality industry***

Touristic areas and hospitality industry face unique waste management challenges due to the seasonal and event-driven nature of their activities (Mensah, 2006). Waste generation tends to increase significantly during peak seasons and large events, which can strain existing waste management infrastructure (Khan et al., 2016). Moreover, the diverse range of waste materials generated in these sectors, including food, packaging, and hazardous waste, poses additional challenges for effective waste segregation and recycling (Sharples, 2014).

The consequences of inadequate waste management in these sectors are manifold, including negative environmental impacts, damage to the local ecosystem, and decreased tourist satisfaction (Dodds et al., 2010). Sustainable waste management practices have, therefore, become increasingly important for preserving the environment and maintaining the long-term attractiveness of touristic areas and hospitality industry (Gössling et al., 2015).

## ***2.3 Smart waste bins and their role in waste management***

Smart waste bins are an emerging waste management solution that integrates Internet of Things (IoT) technology to optimize waste collection and disposal processes (Al-Masri et al., 2020). These bins are equipped with sensors that monitor waste levels, enabling real-time data collection and communication with waste management systems (Matta et al., 2018). By providing real-time data on waste levels, smart waste bins can help optimize waste collection schedules, reduce waste transportation costs, and improve overall waste management efficiency (Zorpas et al., 2020).

Additionally, smart waste bins can support waste segregation and recycling by providing separate compartments for different waste materials and offering visual and auditory cues to users for proper waste disposal (Bing et al., 2016). By promoting recycling and more efficient waste management practices, smart waste bins can contribute to environmental sustainability and reduce the negative impacts of waste in touristic areas and hospitality industry (de Lange et al., 2019).

## **2.4 Environmental impact of waste in touristic areas and hospitality industry**

Waste generated in touristic areas and hospitality industry has significant environmental implications, including land and water pollution, greenhouse gas emissions, and depletion of natural resources (Cohen et al., 2014). In particular, improper disposal and management of waste can lead to soil and water contamination, posing risks to local ecosystems and human health (Andrades & Dimanche, 2017).

Furthermore, waste generation contributes to climate change through the release of greenhouse gases during waste decomposition and incineration processes (Bogner et al., 2007). As a result, sustainable waste management practices, such as the implementation of smart waste bins, are essential for mitigating the environmental impacts of waste in these sectors and supporting global efforts to combat climate change (Brouwer et al., 2017).

## **3 Methodology**

This study employs a mixed-methods research design, which combines both qualitative and quantitative approaches to address the research questions. Our approach allows for a comprehensive understanding of the effectiveness of smart waste bins in addressing waste management challenges in touristic areas and hospitality industry during large events. The coming sections will focus on the methodology employed in this research paper, consisting of three primary components: data collection, data analysis, and evaluation criteria.

### **3.1 Data collection**

1. In view of the mixed-method approach underlying the methodology of our study, data have been acquired from various sources: academic articles, reports, and books. A comprehensive literature review has been conducted to gather information on the waste management challenges in touristic areas and hospitality industry, environmental and social impacts of improper waste management, and the concept and technology of smart waste bins.
2. Case studies: two case studies have been selected to examine the implementation of smart waste bins in a touristic area and in the hospitality industry, during a large event. These case studies will

provide real-world examples of the application of smart waste bins and their effectiveness in addressing waste management challenges.

3. Government documents, industry reports, and news articles: these sources have been used to gather information on waste management policies, regulations, and practices in the study areas, as well as the costs and benefits of implementing smart waste bins.
4. Interviews and surveys: key stakeholders, such as waste management authorities, event organizers, and hospitality industry representatives, have been interviewed to gather insights into the challenges faced in waste management during large events and the implementation of smart waste bins. Surveys have also been conducted among event attendees and local residents to gather their perspectives on the effectiveness and benefits of smart waste bins.

### **3.2 Data analysis**

The data analysis process involved a qualitative assessment of the collected literature to identify and categorize the main problems of waste management in touristic areas and hospitality industry. Further analysis focused on the potential application of smart waste bins as a solution to these problems, considering their advantages, challenges, and limitations. The assessment also includes a review of case studies where smart waste bins have been successfully implemented during large events. This analysis aims to provide insights into the feasibility and potential impact of smart waste bins in addressing waste management issues in the studied sectors.

### **3.3 Evaluation criteria**

To evaluate the effectiveness of smart waste bins as a waste management solution for touristic areas and hospitality industry, the following criterias were considered:

- a) Waste management efficiency: The ability of smart waste bins to optimize waste collection, transportation, and disposal processes, thereby improving overall waste management efficiency.
- b) Waste segregation and recycling: The potential of smart waste bins to promote waste segregation and recycling, contributing to waste reduction and resource recovery.
- c) Environmental impact:

The extent to which smart waste bins can mitigate the negative environmental effects of waste generated in touristic areas and hospitality industry. d) Cost and resource optimization: The potential of smart waste bins to reduce waste management costs and optimize the allocation of resources, such as labor and equipment. e) Implementation challenges: The identification and assessment of potential barriers to the successful implementation of smart waste bins in the studied sectors, including technological, financial, and logistical challenges.

The evaluation of these criteria, based on the data analysis, will inform the recommendations and conclusions of this research paper.

#### **4 Main Problems of Waste Management in Touristic Areas and Hospitality Industry**

Touristic areas and hospitality industry often struggle with **inefficient waste collection and disposal systems**, resulting in waste accumulation and improper disposal (Mensah, 2006). Inefficient systems can stem from a lack of proper planning and coordination among stakeholders, outdated waste management infrastructure, and inadequate investment in waste management technologies (Khan et al., 2016). **Tourist influx** during peak seasons and large events leads to a significant increase in waste generation, putting additional pressure on waste management systems (Sharpley, 2014). The temporary nature of some events complicates waste management, as event organizers may not prioritize sustainable waste practices or invest in long-term solutions (Dodds et al., 2010). **Waste segregation and recycling are often limited** in touristic areas and hospitality industry due to a lack of awareness among tourists and employees, insufficient recycling facilities, and inadequate policies and incentives to encourage recycling (Gössling et al., 2015). As a result, valuable resources are lost, and the environmental impact of waste is exacerbated (Cohen et al., 2014). Improper waste management in touristic areas and hospitality industry can lead to severe **environmental pollution**, including land and water contamination (Andrades & Dimanche, 2017). The pollution not only harms local ecosystems, but also poses risks to human health and is negatively affecting the attractiveness of tourist destinations (Brouwer et al., 2017). In many touristic areas and hospitality industry, **waste management infrastructure** is inadequate due to limited financial resources and competing priorities (Matta et al., 2018). Budget constraints can hinder the development and maintenance of waste management

facilities, leading to suboptimal waste management practices and increased environmental impacts (Zorpas et al., 2020). Furthermore, a lack of coordination among stakeholders, including local authorities, businesses, and event organizers, leads to an exacerbation of all these challenges (de Lange et al., 2019).

## **5 Implementation of Smart Waste Bins**

### ***5.1 Overview of smart waste bins***

Smart waste bins are innovative waste management solutions that leverage Internet of Things (IoT) technology to optimize waste collection, transportation, and disposal processes (Al-Masri et al., 2020). Equipped with sensors that monitor waste levels, smart waste bins provide real-time data on waste levels, enabling efficient waste collection scheduling and route planning (Matta et al., 2018).

### ***5.2 Advantages of smart waste bins***

Smart waste bins allow for real-time monitoring of waste levels, which helps optimize waste collection schedules and reduce waste transportation costs (Zorpas et al., 2020). This data-driven approach can also assist in identifying waste generation trends, allowing event organizers and local authorities to plan and allocate resources more effectively.

Smart waste bins can facilitate waste segregation and recycling by providing separate compartments for different waste materials and offering visual and auditory cues to users for proper waste disposal (Bing et al., 2016). By promoting recycling, smart waste bins contribute to waste reduction, resource recovery, and environmental sustainability.

The real-time data provided by smart waste bins enables waste collection services to focus on bins that are full or nearing capacity, thus preventing overflows and reducing the frequency of unnecessary collections (Matta et al., 2018). This efficiency can result in lower fuel consumption and reduced greenhouse gas emissions from waste transportation vehicles. By streamlining waste collection processes and promoting recycling, smart waste bins can help reduce waste management costs and optimize the use of resources such as labor and equipment (Zorpas et al., 2020).

### **5.3 Challenges and limitations of smart waste bins**

The implementation of smart waste bins requires a significant initial investment in IoT technology, sensors, and related infrastructure (Al-Masri et al., 2020). Additionally, the maintenance of smart waste bins can be more costly than traditional bins due to the complexity of the technology. Integrating smart waste bins into existing waste management systems can be challenging, as it may require significant adjustments to waste collection routes, schedules, and procedures (Matta et al., 2018). The collection of real-time data by smart waste bins raises privacy and data security concerns, as improper handling of this information could potentially compromise users' privacy (de Lange et al., 2019).

### **5.4 Case studies**

To demonstrate the effectiveness of smart waste bins in addressing waste management challenges in touristic areas and hospitality industry during large events, we present two case studies.

*Case study 1: Implementation of smart waste bins in a touristic area*

Location: A popular beach destination

Problem: During peak tourist season, the beach area faced issues such as overflowing waste bins, littering, and inadequate recycling, leading to environmental pollution and negative visitor experiences.

Solution: The local municipality implemented a network of smart waste bins along the beachfront and nearby commercial areas. The smart waste bins were equipped with sensors for real-time monitoring, separate compartments for waste segregation, and interactive elements to encourage proper waste disposal.

Results: After implementing smart waste bins, the following improvements were observed:

1. More efficient waste collection: The real-time monitoring data allowed the municipality to optimize waste collection schedules and routes, reducing fuel consumption and labor costs.
2. Increased recycling rates: The waste segregation features of the smart waste bins resulted in higher recycling rates and reduced waste sent to landfills.

3. Improved visitor experience: The cleaner beach environment and interactive elements of the smart waste bins contributed to a more positive visitor experience.

*Case study 2:* Deployment of smart waste bins during a large event in hospitality industry

Location: A music festival at a hotel resort

Problem: The large influx of attendees led to a significant increase in waste generation, creating waste management challenges such as overflowing bins, littering, and inadequate recycling.

Solution: The event organizers deployed a network of smart waste bins throughout the festival grounds. These bins featured real-time monitoring, waste segregation capabilities, and interactive elements to encourage proper waste disposal.

Results: The implementation of smart waste bins during the music festival led to the following outcomes:

1. Optimized waste collection: The real-time monitoring data enabled event organizers to efficiently schedule waste collection, reducing overflowing bins and associated littering.
2. Enhanced recycling efforts: The waste segregation features of the smart waste bins facilitated recycling and improved waste diversion rates.
3. Positive attendee experience: The cleaner festival environment and engaging features of the smart waste bins contributed to a more enjoyable experience for attendees.

These case studies demonstrate that the implementation of smart waste bins in touristic areas and during large events in hospitality industry can effectively address waste management challenges by optimizing waste collection, promoting recycling, and improving the overall visitor experience.

## **6 Discussion**

### ***6.1 Evaluating the feasibility of smart waste bins for touristic areas and hospitality industry***

The feasibility of implementing smart waste bins in touristic areas and hospitality industry depends on various factors, such as the availability of financial resources, technological infrastructure, and stakeholder collaboration. While the

initial investment and maintenance costs can be significant, the potential benefits, including improved waste management efficiency, waste reduction, and environmental sustainability, can outweigh these expenses in the long run (Zorpas et al., 2020).

Successful integration of smart waste bins into existing waste management systems requires careful planning and collaboration among local authorities, businesses, and event organizers. This collaboration can help address potential challenges, such as adjusting waste collection schedules, routes, and procedures, while also ensuring that smart waste bins are used to their full potential (Matta et al., 2018).

### ***6.2 Potential impact on waste management efficiency and environmental sustainability***

When strategically deployed and integrated into a comprehensive waste management plan, smart waste bins can significantly improve waste management efficiency in touristic areas and hospitality industry. Real-time monitoring and data collection allow for better waste collection planning, reducing transportation costs, and preventing waste overflows (Al-Masri et al., 2020).

Moreover, by promoting waste segregation and recycling, smart waste bins can contribute to waste reduction and resource recovery, reducing the environmental impact of waste generated in these sectors (Bing et al., 2016). This can, in turn, help preserve local ecosystems, maintain the attractiveness of tourist destinations, and support sustainable tourism and hospitality operations.

### ***6.3 Recommendations for successful implementation***

To maximize the potential benefits of smart waste bins in touristic areas and hospitality industry, the following recommendations should be considered:

a) Develop a comprehensive waste management plan that incorporates smart waste bins as part of an integrated solution, addressing the unique challenges faced by touristic areas and hospitality industry. b) Establish public-private partnerships and collaborate with stakeholders, including local authorities, businesses, and event organizers, to secure funding, share expertise, and facilitate the implementation of smart waste bins. c) Invest in public awareness campaigns to educate tourists, event attendees, and employees about proper waste disposal,

recycling, and the use of smart waste bins. d) Address privacy and data security concerns by implementing robust data protection measures and ensuring transparency in data handling practices. e) Continuously monitor and evaluate the performance of smart waste bins to identify areas for improvement and ensure their long-term effectiveness in addressing waste management challenges.

By considering these recommendations, touristic areas and hospitality industry can successfully implement smart waste bins and benefit from their potential in improving waste management efficiency and promoting environmental sustainability.

## **7 Conclusion**

Waste management in touristic areas and hospitality industry presents unique challenges, including inefficient waste collection and disposal systems, high waste generation during peak seasons and events, limited waste segregation and recycling, and environmental pollution. Addressing these challenges is crucial for maintaining the attractiveness of tourist destinations, preserving local ecosystems, and ensuring sustainable tourism and hospitality practices.

Smart waste bins offer a promising solution for improving waste management efficiency, promoting waste segregation and recycling, and mitigating the environmental impact of waste generated in these sectors. By leveraging IoT technology and real-time data, smart waste bins can optimize waste collection and transportation, reduce waste management costs, and contribute to environmental sustainability.

However, the successful implementation of smart waste bins in touristic areas and hospitality industry requires a comprehensive waste management plan, stakeholder collaboration, and public awareness campaigns. Additionally, addressing privacy and data security concerns is essential to ensure the responsible use of this technology.

In conclusion, while smart waste bins present a viable solution for addressing waste management challenges in touristic areas and hospitality industry, their successful implementation depends on careful planning, resource allocation, and collaboration among all stakeholders. By adopting a strategic and integrated approach, these sectors can harness the potential of smart waste bins to support sustainable waste management practices and contribute to a more environmentally responsible tourism and hospitality industry.

## **Appendices**

### ***Appendix A: Technical Specifications of Smart Waste Bins***

This appendix provides an overview of the technical specifications and features commonly found in smart waste bins:

1. **Sensors:** Various types of sensors can be used in smart waste bins, including ultrasonic, infrared, and weight-based sensors, to measure the fill levels of the bins.
2. **Communication systems:** Smart waste bins typically use wireless communication technologies such as IoT, GPS, or cellular networks to transmit data to a central control system.
3. **Waste compartments:** Some smart waste bins have separate compartments for different types of waste, such as organic, recyclable, and non-recyclable materials, to facilitate waste segregation and recycling.
4. **Waste compactors:** Some models of smart waste bins feature built-in waste compactors that compress the waste, increasing the overall capacity of the bin and reducing the frequency of waste collection.

5. Interactive elements: Smart waste bins may incorporate touchscreens, audiovisual feedback, or other interactive elements to engage users and encourage proper waste disposal behavior.
6. Power sources: Smart waste bins can be powered by various sources, including the electrical grid, solar panels, or batteries.

### ***Appendix B: List of Case Studies and Sources***

This appendix provides a list of case studies and sources used in this research paper:

1. Case study 1: Implementation of smart waste bins in a touristic area  
Source: [Reference to the relevant academic article, report, or news article]
2. Case study 2: Deployment of smart waste bins during a large event in hospitality industry  
Source: [Reference to the relevant academic article, report, or news article]

### ***Appendix C: Interview and Survey Questions***

This appendix includes sample interview and survey questions that can be used to gather insights from key stakeholders and the public:

3. How do you perceive the current waste management practices in touristic areas or during large events in hospitality industry?
4. What are the main challenges you face in managing waste during large events or in touristic areas?
5. Have you had any experience with smart waste bins? If so, how effective were they in addressing waste management challenges?
6. What benefits or drawbacks do you see in implementing smart waste bins in touristic areas or during large events in hospitality industry?
7. As a visitor or event attendee, how important is the cleanliness of the location, and how does it affect your overall experience?
8. How likely are you to engage with smart waste bins and follow proper waste disposal practices if they were available in touristic areas or during large events?

### Abstract

Large Scale Research Infrastructures are rising in the competitive and globalized research environment, since they offer to external researchers-users, inputs and services for cutting-edge, large scale research. Such researches would not be possible with normal infrastructures and budgets of single Universities and Research institutions. However, despite the strategic relevance acknowledged to LSRI by the nascent literature and by national policymakers, there is a lack of comprehensive frameworks capturing both strategic dimensions and inherent options a LSRI may have. Given the infancy of this topic, and the empirical nature of the literature to date, a holistic framework on LSRI would increase the sense of existing studies and provide the ground for future advancement. This paper aims to bridge this gap, by identifying strategic *dimensions* and relative options, a Large Scale Research Infrastructure can assume.

The research is carried out adopting a mixed research methodology merging a literature review with a survey conducted on a sample of 11 LSRI; they provided the dataset for the parametrization of a *Morphological Matrix*.

The research led to the identification of the strategic *dimensions* and the *solutions* (i.e. the spectrum of strategic *options*) defining the LSRI's morphology. These findings represent, on another side, the starting point for a future and hopeful Morphological Analysis of LSRI.

This paper originally proposes the dataset needed to develop a morphological analysis of Large Scale Research Infrastructures.

**Paper type** – Academic Research Paper

## 1 Introduction

In a global and hypercompetitive geo-political context, national research strategies are becoming focal for the competitiveness of economic and industrial systems. Pushed by innovative managerial paradigms and supported by new technologies, the strategies of research are outlining emerging and rising models able to trade off large scale and lower budget, thus securing quality and impact of research. In this scenario, Large Scale Research Infrastructure is catalysing attention from both policymakers and Management scholars.

LSRI are pivotal for several governments today, as confirmed by the share of research investments allocated by advanced countries (Florio and Sirtori, 2016; South Africa Ministry of Science and Technology, 2016). LSRI is one strategic objective of the European Commission, to promote international cooperation and integration, as well as to provide tools dedicated to the development of open science and to improve the performance of academic research (Fabre *et al.*, 2021).

Nonetheless, LSRI literature is lagging and lacking of strategic management understanding.

This paper aims to bridge this gap, analysing a fuzzy and embryonal topic, largely empirical according to current literature, by proposing a taxonomy and a characterization of LSRI.

To come to an effective and insightful framing of existing research, we develop a General Morphological Analysis (GMA) (Zec and Matthes, 2018; Zwicky, 1967, 1969). The research question underpinning this study is then: what are dimensions and inherent positions a LSRI has? The answer to this question allows

to frame the field of existence of LSRI, and provide the basis for a characterization. We attempt to answer this question by crossing a critical literature review on LSRI and a survey conducted on a sample of 12 LSRI.

The paper is structured as follows. In the first section, the dual approach to making science (*Big vs. Small*) is discussed, and the relevance of *research infrastructures* is highlighted with regard to Big science. The second section deepens the strategies of Science, discussing the *platformization* as a relevant and effective way to face risks, results and investments in the current global and competitive political scenario. The third section, then, put under the lenses the LSRI a specific model of research platform, who is finding the rising interest of policymakers and strategic management scholars. In section four the LSRI are analysed and common dimensions of analysis are detected; the full range of options any LSRI can have is also explored. It reports the parametrization of the *Zwicky space* resulting from the literature analysis. Finally, section five discusses the findings, the limitations and the future developments of the research.

## **2 Conceptual Background**

### **2.1 Science, Research and Research Infrastructures**

Science is advancing at higher pace and volume as never seen before. As witnessed by scientific publications - any scientific or engineering article published in the fields of physics, biology, chemistry, mathematics, clinical medicine, biomedical research, engineering and technology, earth and space sciences - research has increased regularly over the past 20 years, reaching the count of 2.5 mln. in 2018 (WorldBank, 2018). Just to stress the expanding stage of research, both geographically and numerically, the number of publications per year has doubled in only 15 years, from 2003 to 2018 (WorldBank, 2018).

The huge growth of science in a more competitive and constrained environment is awaking reflections on the efficiency and effectiveness of the research models: how to cope with the need of larger researches and smaller budgets?

If we look at the past, disruptive theoretical findings were obtained with almost no infrastructures, while incremental theoretical improvements achieved with large research teams and infrastructures (Wu *et al.*, 2019). Let us consider Einstein's results (1905): six researches of great impact in three different fields of

physics in few days, alone. Besides, in a few weeks he demonstrated the existence of atoms, theorized the existence of photons and the wave-particle dualism. He also demonstrated the equivalence between energy and matter, showing the (likely) most relevant research result of modern science:  $E = mc^2$ .

This case highlights the nature of *Small Science* (i.e. small research teams, almost no research infrastructures, driven by creativity, disruptive discoveries), opposed to that of *Big Science* (i.e. large, interorganizational research teams, large scale research infrastructures, driven by methodological and instrumental rigour, incremental discoveries).

Big Science produces results that are much cited but, in general, not very innovative (Wu *et al.*, 2019) and with lower societal, direct impact. As per (Kuhn, 1962) Big Science just do 'normal science'.

The scientific discoveries that require a "change of glasses" and even the abandonment of established paradigms are correlated with small research teams and infrastructures (Wu *et al.*, 2019). However, no Small science could have proved the Higgs boson, or sent a probe to the far side of the moon, considering the large scale of teams, infrastructures and funds. Both Small and Big Science are necessary and reinforcing. In addition, the more research obtains results, the more the relationship between Small Science and Big Science is closely interrelated. Today, in a global and competitive scenario, large research teams and infrastructures would support adequately any research.

*Research infrastructure* subtends both the physical and the virtual dimension of the research assets, whose importance is rising in recent years, due to the digital technologies. They are creating an unprecedented change and shaping the research process. The relevance of such changes are interesting both theoretically and practically, with regard to National research strategies and for the Local Development.

The role of Research Infrastructures (RI) is recently under the lenses of Management scholars, and of Universities and policymakers, since the higher, global research challenges require larger research infrastructures able to provide researchers with innovative technology and then produce competitive research. However, the ways to best exploit the RIs are underexplored to date.

A fundamental role in the scientific research process is played by the *research infrastructure*, the set of major equipment, instruments, services, knowledge-related facilities (e.g. collections, archives or scientific data infrastructures) databases, the researchers use (Toom and Miller, 2017). So they are facilities,

resources and related services (ESFRI, 2020). Due to technological innovation (e.g. artificial intelligence, computing, big data, social media, and others) infrastructure is gaining strategic relevance in research. The results they obtain, and the capacity to foster innovation, depend largely by the quality (e.g. reliability, innovativeness), the scale, the scope, the governance, the surrounding ecosystem, the RI has.

The national strategies in research are also addressing the infrastructure as a dimension able to support cross-institutional and cross-national networks, to contribute to the science advancement.

*Infrastructure* is different from *facility*. The use of Facilities (instruments, collections, data banks, laboratories) is commonplace as an indispensable support, but only in some cases these facilities are built and managed to provide service to external users (not belonging or funded by the owner institution or even coming from other countries). Many Facilities (sometimes also very expensive) are built, funded and managed mainly for the specific use of their owners (institutions, universities, industry). They have only marginal use for external researchers but their impact is relatively limited in terms of outreach and international visibility, on the contrary a RI is mainly designed, built and managed for external users/researchers (then those belonging to the owner).

Actually, Universities within their third-mission activities (Laredo, 2007; Vesperi and Gagnidze, 2019) put at disposal of both internal and external demand (e.g. private companies, public institutions, and other research centres) their research infrastructures, with regard to those located in Laboratories (Linzone *et al.*, 2020). The use and the funding for that is regulated by contracts.

Research infrastructures can be both physical and electronic (e-infrastructures) (Toom and Miller, 2017). On a different perspective RIs are used as inputs to, or as underlying foundations for, scholarly research phases: conceptualization/funding, data collection, experimentation/analysis, publication, dissemination/out-reach, impact assessment (da Silva Neto and Chiarini, 2023). RIs include data sets, software packages, computational models, observational platforms, and computing facilities (Mayernik *et al.*, 2017)

The *European Strategy Forum on Research Infrastructures* highlights that RIs are used to conduct top-level research in their respective fields and covers major scientific equipment; knowledge-based resources such as collections, archives or structures for scientific information; enabling Information and Communications Technology-based infrastructures such as Grid, computing, software and

communication, or any other entity of a unique nature essential to achieve excellence in research (ESFRI, 2020).

Many research facilities are available to industry entrepreneurs, engineers, other researchers, and research institutions to carry out researches or technology developments (Toom and Miller, 2017).

Research facilities can be observatories, laboratories (including rooms and machines, devices, gears, mechanisms, etc.). While e-Infrastructures can be research databases including open data infrastructures and digital archives, research networks, software and service infrastructures (platforms of supercomputing facilities, research analysis software platforms for processing and analyzing data) (Toom and Miller, 2017).

## **2.2 The Platformization of research and the LSRI**

The extraordinarily fast scientific development of the vaccine for COVID-19 pandemic in about one year and a half, given that historically it takes about 17 years for research to translate from bench to bedside, is principally due to research infrastructures (Zakaria *et al.*, 2021). Unlike the traditional sequential development of research activities, multiple strands of activities were undertaken contemporary and supported by underlying research infrastructures (RI) or "platforms" (Zakaria *et al.*, 2021).

Economic hardships and strategic emergence of research infrastructures, pressure governments to review and scrutinize research allocation. Pioneer studies and researches support the importance of RI investment and aware against short-termism in resource allocation.

Thus, the concept of research infrastructure is rising in Strategic Management studies, since it can become the convenient dimension in which to allocate the *platform* model.

In today's networked age, strategic benefits are increasingly generated over platforms, which allow various actors to engage with one another (Fehrer *et al.*, 2018). Platform paradigm is influencing and shaping research as many other domains. An increasing number of mature incumbent organizations, like Universities or National Research Institutes, are in environments in which they need either to operate as a platform provider or integrate into a business ecosystem governed by platforms (Altman, 2015).

The platform concept is emerging as an effective organizational model able to integrate a variety of (research) actors, around a basic and strategic asset, like the LSRI. It is not new with regard to scientific research. The *platformization of science* is running over any dimension and across many phases of research, up to the whole research life cycle (da Silva Neto and Chiarini, 2023).

(Mirowski, 2018) provided a "landscape of science platforms", crossing phases of scientific activities (getting started; preparatory; research protocols; writeup; publication; and post-publication) with users (normal scientist; funders; competing scientist; spectator scientist; outsider citizens; and, kibitzer), illustrating with some representative platforms.

Moreover, specific categories of research platforms have consolidated themselves as infrastructures, while certain scientific infrastructures have been platformed (da Silva Neto and Chiarini, 2023). The intertwine of the concepts *platform* and *infrastructure* is strategic and capable of great exploitation in a competitive scenario rewarding global, cutting-edge research.

The complex contributions played by different parts of the research system may be better described by progressing the current research evaluation model from one characterized by a "pipeline" to one better described as a "platform".

The concept of platform is coherent to analyse the large scale research infrastructures, in a scientific landscape that requires larger researches and higher efficiency at the same time.

Platform outputs are than families of research outcomes, sharing a common infrastructural base.

(Plantin *et al.*, 2018) explored the "landscape of science platforms", crossing phases of scientific activities (getting started; preparatory; research protocols; writeup; publication; and post-publication) with users (normal scientist; funders; competing scientist; spectator scientist; outsider citizens; and, kibitzer), illustrating with some representative platforms.

### **2.3 Large Scale Research Infrastructure. A Strategic Management review**

Big Science is driven by the scale, economic and/or structural, of research infrastructures (such as large particle accelerators, space research, the Human Genome Project).

LSRIs are enablers of research in almost all scientific domains and represent an increasingly large share of research investment. RI is an organisational structure

dedicated to facilitate or conduct research, provide scientific equipment, data or services for use in basic or applied research (OECD, 2019). LSRI are long-term enterprises, often operating for several decades. Research infrastructures (RI) are facilities, resources, systems, and services needed by scientific communities to carry out large-scale research in cutting-edge fields (Fabre *et al.*, 2021). The European MERIL project defines RI as a “facility or (virtual) platform that provides the scientific community with resources and services to conduct research in their respective fields. These research infrastructures can be single-sited, distributed or virtual (e-infrastructure), and can be part of a national or international network of facilities, or of interconnected scientific instrument networks” (Beckers, Jägerhorn, & Höllrigl, 2012). Examples of RI are astronomical observatories, particle accelerators, synchrotrons, lasers, and intensive computing resources, as well as data production and management tools. These infrastructures are used by researchers from all disciplines, in astronomy, biology, physics, chemistry, human and social sciences, earth sciences, etc., who have access to high-performance equipment in a high-level scientific environment.

*“Over the past decades, Large Scale Research Infrastructures (LSRIs) have come to play a central role in providing scientist-users access to highly specialised scientific instrumentation and experimental conditions. Collaborations between (permanent) instrument scientists and users are at the core of these organisations, yet knowledge about the nature of such collaborations and their development over time is surprisingly scarce” (D’ippolito and Rüling, 2019).*

LSRIs are large-scale research facilities that require large investments and complex engineering and networking efforts; these infrastructures are usually primarily funded by national governments, shared by communities of scientists, and most often involve scientists permanently based at these facilities as well as external scientist-users (D’ippolito and Rüling, 2019).

LSRIs are large scientific instrumentation, facility, and equipment clusters that require large investments and complex engineering and networking efforts; they are usually recipients of funding by national or supranational bodies and shared by communities of scientists (D’ippolito and Rüling, 2019; Qiao *et al.*, 2016).

A useful model elaborated by the (South Africa Ministry of Science and Technology, 2016) distinguishes the research infrastructures into: small equipment, departmental equipment, medium-sized infrastructures, and LSRI. Roughly, they require from 0.5 mln € of investment up to 500 mln €. The range of

scientific equipment and infrastructure considered for the research infrastructure roadmap. SARIR focuses on RIs used for the whole scientific community in South Africa or, in some cases, with the participation of South Africa in other international RI. Some equipment in education or research institution departments may be included when it constitutes a component of a distributed RI and is coordinated with other infrastructures available in other nodes of the network to offer a global service to the scientific community. For reasons of comparison, Figure 1 also depicts the span of infrastructures

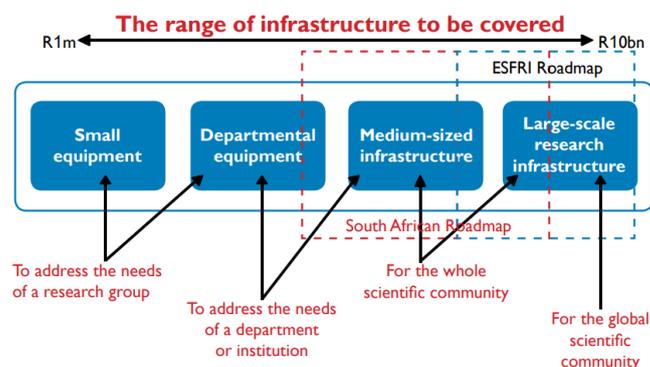

Fig. 1 - Objectives and financial scale (in RSA's rand) of Research infrastructures (South Africa Ministry of Science and Technology, 2016)

Most of the LSRI are large experimental platforms, including, for example, synchrotron radiation sources, neutron sources, or advanced laser facilities, which serve both fundamental and applied research in a wide range of scientific disciplines (Qiao *et al.*, 2016).

The purpose of *experimental platforms* consists primarily in providing scientist-users access to highly specialised scientific instrumentation and experimental conditions beyond the reach of most university organisations. In areas such as neutron scattering, synchrotron radiation, and free electron lasers facilities, experimental platforms require intense collaboration between permanent scientists and external users, which is essential to produce science (Hackett *et al.*, 2004; Hallonsten, 2016), and facilities need to be highly specialised while remaining attractive to broad scientific communities (Heidler and Hallonsten, 2015).

LSRIs are suitable in the current global and competitive scenario that require international research teams, cutting-edge research results. Scientific collaborations have always spanned organisational borders, but today globalization imposes it; the complex challenges posed by the society to science, make research questions too broad to be tackled by a single laboratory and require cross-discipline and cross-border cooperation.

Despite their value LSRI comes up as a challenge for Policy Makers and Universities, since the evaluation of financial and economic returns of LSRI investment is hard to account because of the many non-financial returns, over those strictly monetary (Novikova, 2022).

Uncertainty on the definition of the actual value, and of the returns of a LSRI investment affect decisions and strategies of research. Besides, LSRI projects are partly public and private, thus making inadequate both Cost Benefit Analysis and Financial Investments as evaluation approaches. This poses an interesting challenge to management scholarship regarding the public-private partnership (Beisheim *et al.*, 2014; El-Gohary *et al.*, 2006; Elia *et al.*, 2017) model suited to participate and fund the LSRI.

Given the large economic investments and the multidimensional types of returns, LSRI poses some relevant questions to Management. LSRI is a way of doing research based on large groups and/or large research infrastructures. This means that the result must be reasonably certain, otherwise, great resources are wasted (or, at least, they are thought to be wasted). Also, the results and returns have various forms both financial and not, difficult to account.

Financial efficiency is the rate of return of LSRI as 'investment', while economic efficiency is the return performance including the all the other various forms of return (e.g. social, environmental, scientific) (Novikova, 2022).

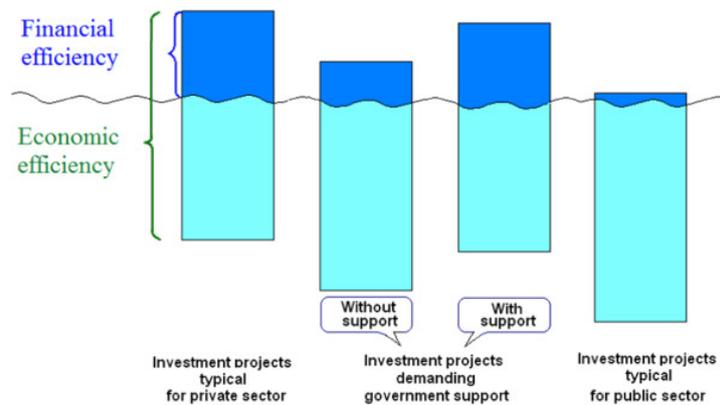

Fig. 2 – Financial and Economic efficiency of RIs, depending on the type of owner (Novikova, 2022)

Projects of the third group cannot attract ordinary private investors without any special support. Due to GS, financial efficiency increases to a level acceptable to private participants. Thus, government intervention solves the gap in financial and economic efficiency. The government uses the whole system of support tools, including various tax advantages and exemptions, tax expenditures, subventions, government guarantees, budget loans with lower interest rates, investments in equity, infrastructure facilities construction and other types of Public-Private Partnership contracts (Delmon, 2017). Thus, the government and the development institution play an essential role for specific participants, which can influence financial efficiency and bring it into line with the economic efficiency of this project.

RIs have a societal value and their impacts are not limited to fostering scientific knowledge for the benefit of scientists; they also impact their environment socially and economically (OECD, 2019). Their conception, construction and operation can involve and require unique technological developments, data management systems and highly-skilled staff. RIs offer opportunities for innovation and market development, can attract investments and contribute broadly to socio-economic development. In some cases, they can constitute a focal point for the development of an innovation ecosystem.

RIs are **largely funded** by public resources and their socio-economic impact is difficult to assess using conventional methodologies. Besides, RIs are extremely diverse, and can have a very broad range of direct and indirect impacts, which vary along the life cycle of the RI.

At the very least, information and communication technologies and data management services will be a fundamental part of every type of research infrastructure, but the construction phase of a new RI could also require the development and testing of new materials, the robotic manipulation of scientific instruments in hazard environments, or the deployment of a distributed network of specialised sensors in a wide range of RIs (South Africa Ministry of Science and Technology, 2016).

Linked with the economic effects of a LSRI, is the issue about the dimensions (Florio & Sirtori, 2016; D'Ippolito & Roling, 2019). Experts identify technological effects (Griniece, Reid, & Angelis, 2015; Reference, 2019; Reid, 2021), as well as knowledge spillovers (Ramadani, Abazi-Alili, Dana, Rexhepi, & Ibraimi, 2017; Tsyplakova, 2010; Li, 2002) among the most significant specific effects of LSRI projects (Prettner & Werner, 2016; Saler & Martin, 2001). Their study was carried out in the last century as part of a study of diffusion of innovations and related spinoffs (Llerna, Matt, & Trenti, 2011), indirect and external effects (Llerna et al, 2011; Lucking, Bloom, & Van Reen, 2018). Nevertheless, for LSRI there are serious obstacles to success, since their most important results are not taken into account in the traditional methods of financial evaluation.

Literature highlights the '**social practice**' of RI's, as a core enabler. and Drawing from this, we proceed from an understanding of research infrastructures as deeply relational and adaptive systems where the material and social aspects are in permanent interplay. They are embedded in the social practice of research and influenced by environmental factors (Fecher *et al.*, 2021).

To date, many policies tend to focus on getting the technical aspect of research infrastructures off the ground, such as the development of major scientific equipment, sets of archival or scientific data, or communication and computing networks (Fecher *et al.*, 2021). Nonetheless, scholars in this field largely agree that only when a technical service is embedded in practice, when it becomes 'invisible' (Star and Ruhleder 1996; Bowker and Star 1999), can it be considered part of an infrastructure. In this understanding, infrastructures are much more than the technical assemblage of things; only when these are part of practice, can they be considered part of the infrastructure (Fecher *et al.*, 2021).

The nuances and complexity of a "platform" model, where utilization of expertise and facilities, delivery of team science, and fostering of innovation translates into benefits for the population, is not typically addressed through any of the tools and methods mentioned in the literature (Zakaria *et al.*, 2021)

Large Scale RI are long-term infrastructural investments, that makes existent evaluation research impact assessments unrealistic due to the timescales of current methods, too short (Zakaria *et al.*, 2021). Traditional criteria for assessing the impact of LSRI are not fit for purpose.

Thus RI finds a challenge with regard to evaluation of the impacts: if the use of linear or logic models (and their derivatives) is agreed for research projects and programmes, they are less applicable to LSRI as they provide the platform from which the projects and programmes are delivered.

All in all LSRI are rising for the advanced of scientific research (ESFRI, 2010); in particular they are central in research, education and innovation through their key role in advancing and dissemination of knowledge and technology (Beck and Charitos, 2021; Marcon and Ribeiro, 2021). They also contribute increase efficiency in the science-making. In particular, since science making is increasingly multidisciplinary, LSRI help researchers to integrate and give answer for very complex scientific and social problems.

#### **2.4 A Taxonomy of LSRI**

Research infrastructures are facilities, resources, systems, and services needed by scientific communities to carry out large-scale research in cutting-edge fields (Fabre *et al.*, 2021). The European MERIL project defines RI as a “facility or (virtual) platform that provides the scientific community with resources and services to conduct research in their respective fields. These research infrastructures can be single-sited, distributed or an e-infrastructure, and can be part of a national or international network of facilities, or of interconnected scientific instrument networks” (Beckers, Jägerhorn, & Höllrigl, 2012).

Typical RIs are astronomical observatories, particle accelerators, synchrotrons, lasers, and intensive computing resources, as well as data production and management tools. These infrastructures are used by researchers from all disciplines, in astronomy, biology, physics, chemistry, human and social sciences, earth sciences, etc., who thus have access to high-performance equipment in a high-level scientific environment.

By reviewing current literature, the following key dimensions can be identified.

1. **Location** (ESFRI, 2020; South Africa Ministry of Science and Technology, 2016) firstly identify the *location*.

- a. **Single-sited** global facilities are unique, geographically localised facilities where governance is fundamentally international in character. The Large Hadron Collider at CERN and the International Thermonuclear Experimental Reactor are current examples.
  - b. Globally **distributed** research infrastructures constitute national or institutional nodes, which are part of a global network, and where governance is fundamentally international in character. For example, LifeWatch, the e-Science European Infrastructure for Biodiversity and Ecosystem Research, can only function through a globally coordinated set of nodes; Argo, a system for observing temperature, salinity, and currents in the Earth's oceans, and the Global.
  - c. E-infrastructure
  - d. National facilities of global interest are national facilities with unique capabilities that attract wide interest from researchers outside of the host nation. Antarctic or ocean drilling facilities are typical examples. The MeerKAT radio telescope in South Africa could be another example, since it will remain a globally important South African research instrument for several years prior to its amalgamation with the SKA. Existing RIs with the potential for wide international utilisation (for instance, facilities that leverage geographical advantages or exhibit unique opportunities for advanced research) may fall in this category. (South Africa Ministry of Science and Technology, 2016)
  - e. Mobile
2. **Function** (Qiao *et al.*, 2016) dissect RIs into the following three types according to their functions:
    - a. dedicated research infrastructure
    - b. public experimental platform
    - c. public infrastructure
  3. **Scientific effect** (Qiao *et al.*, 2016)
    - a. science and technology advancement
    - b. capability cultivation
    - c. networking

- d. clustering
- e. knowledge spillover
- 4. Scientific domain (South Africa Ministry of Science and Technology, 2016):
  - a. Humans and society;
  - b. Health, biological and food security;
  - c. Earth and environment;
  - d. Materials and manufacturing;
  - e. Energy.
- 5. Types of RI may (Mayernik *et al.*, 2017):
  - a. Telescope
  - b. Particle accelerator
  - c. Synchrotron
  - d. Laser
  - e. Intensive computing
  - f. Imaging
  - g. Biobanking
  - h. Big Data/ Data Mining
  - i. Other

### 3 Research Methodology

The aim of this paper is to develop a taxonomy of LSRI by the mean of a General Morphological Analysis (GMA) (Ritchey, 2018; Zwicky, 1967, 1969). GMA consists in the analysis by decomposition of a problem, through iterative cycles, to create a shared morphological model (Ritchey, 2018; Zec and Matthes, 2018). The problem is decomposed into key *parameters*, then possible *values* for each parameter are generated. The parameters and associated values define the *formal solution space* and are represented in the so-called *Zwicky Box* (i.e. a morphological field or *morphospace*) (Zec and Matthes, 2018). All the solutions to the initial problem can, then, be generated by combining the different partial solutions. In practice, many configurations are not viable for various reasons (e.g. logical or physical constraints).

This way the GMA will allow to dissect the parameters and values of LSRI, and provide the basis for a comprehensive characterization.

business model element value proposition (vp)		This business model element covers all issues, which create value for the stakeholders of the business model.		
<i>design fields</i>		<i>design options</i>		
segmentation	none	segment	niche	atomic segmentation
characterization of the offer	product	hybrid product	service	
level of individualization	standardized	standardized customized	fully customized	
kind of the (main) customer benefit	functional	economic	social	emotional
level of customer integration	none	partial integration	full integration	

Fig. 3 - Example of the Morphospace applied to 'Business model elements' (Seidenstricker et al., 2014)

To take viability into account and reduce the combinatorial explosion, GMA software features pairwise *cross-consistency assessment* of parameter values for the semi-automated synthesis and interactive visualizations of the solution space (Ritchey, 2018). Dedicated software are then useful to provide such analysis.

### 3.1 Survey

To integrate the data emerged from the literature review we carried out a survey including a sample of selected LSRI. The survey allowed to contextually triangulate, corroborate or refine the literature data, through an iterative process of definition and refinement of the *values* and *dimensions* of LSRI.

Tab. 1 – Surveyed LSRI

LSRI name	Location (Country)	Topic	Web Address
Elettra Sincrotrone Trieste	Trieste (Italy)	Synchrotrons and Fels	<a href="https://www.elettra.eu/it/index.html">https://www.elettra.eu/it/index.html</a>

## 4 Results

By combining qualitative data coming from both types of sources, literature and LSRI's websites, we were able to organize a Morphological Matrix for LSRI's.

Dimensions	Characteristics										
LOCATION	Single Sited			Distributed			E-Infrastructure			Mobile	
FUNCTION	Dedicated				Public experimental platform				Public infrastructure		
EFFECT	Science and technology advancement		Capability cultivation		Networking effect			Clustering		Knowledge spillover	
DOMAIN	Humans and society		Health, biological and food security			Earth and environment			Materials and manufacturing		Energy
SECTOR	Food	Sea	Health	Society	Culture	Environment	Energy	Science	Engineering	Digital	
TYPE	Telescope	Particle accelerator	Synchrotron	Laser	Intensive computing	Imaging	Biobanking	Big Data/ Data Mining	Other		
SCOPE	National				International				Global		
INVESTMENT	Private		PPP without Support			PPP with Support			Public		
REVENUE	Companies		Industrial Users	Consumer/Citizen Association	Industry R&D Dep.	Control Agencies	Public Labs	Private Labs			

Fig. 4- Large Scale Research Infrastructure. Morphological Matrix

## 5 Conclusions

Despite the strategic role of LSRI for future research policies, literature on LSRI is in an embryonal state. Some studies address the issue regarding the evaluation of the investment (Novikova, 2022), some other the definitorial aspects (Fabre *et al.*, 2021), other the strategic aspects (South Africa Ministry of Science and Technology, 2016; Toom and Miller, 2017) however from a political standpoint.

With this research we attempted to focus strategic management elements of LSRI, by developing a unitary framework able to tie together the key dimensions and values of LSRI. To this aim we identified the General Morphological Analysis (Zwicky, 1967, 1969) as a powerful model, and combining a literature review and a survey on a sample of LSRI we come to a tentative *Morphological space*. This result is limited by the consistency and representativeness of the sample, by the literature review, which is not structured and does not rely on a solid base given the infancy of the literature stream.

This paper's results, however, provide the basis and the direction for a full application and analysis of the GMA for LSRI, that will fulfil an open question for both scholarship and policymakers.

### **Abstract**

The objective of this article is to present the analysis of a case study regarding a small-medium enterprise Italian-owned company in the start-up phase, which produces consumer goods such as playful learning products for 0-24 months children. The Company is unlisted and is fully held by a family-controlled group. It meets the basic requirements of a 'Made in Italy' brand and its products are manufactured using production processes that reflect the concept of sustainability. The term 'sustainability' of a company refers to an organisation's concrete commitment to promoting a business model that not only enables the company's long-term profitability, but is also attentive to the environment, social welfare and long-term governance. The research is conducted through a qualitative method and intends to analyse implemented processes and results of the case study, obtained interviewing Company's management. In particular, the research focuses on

commercial, financial, and social strategies. The Company was founded in 2020 and, after establishing itself in the Italian market, it started a process of internationalisation, promoting itself as a 'Made in Italy' company.

**Keywords** – Entrepreneurship, Sustainability, Made in Italy.

## 1 Introduction

The evolution of Italian industrial organisation since the 1990s coincides with the formation of a further phase of Italian capitalism involving an increase in company size (Colli, 2005). It should be emphasised that most of the firms do not grow internally, but mainly externally (Tattara, 2006), moving from a simple to a more complex legal structure: corporate groups. This is linked to the considerable fixed costs required to use new technologies.

In those years, the development of medium-sized enterprises have place. These business have not only production but also logistical, commercial and financial competences, and work as the links between the final purchaser and the numerous small production units at certain stages of the process. Some of them achieve niche positions in the made-in-Italy sector and are able to invest in innovations to remain competitive, making in-house expertise increasingly exclusive and unique (Martucci and Rinaldi, 2012). They establish relationships with specialised suppliers by integrating the sector upstream, mainly within the same local production system or with other Italian entities, rarely with foreign companies (Gagliardi, 2006). Many companies, especially those that target foreign markets and have managed to improve their marketing networks, have established themselves among medium-high-end customers who appreciate the details and high quality of the product.

In light of the above, the transition from small to medium-sized enterprises improves the production efficiency of the entire system and increases its competitiveness when it is able to combine polyarchic and hierarchical systems (Arrighetti and Traù, 2007). In addition, product innovation stems from the demand for good characteristics and enables the company to improve profitability. Enterprises are induced to innovate not only by the pressing demand and the structure of the market in which they operate, but also by the skills they possess, which are the intangible elements to obtain positive effects from the

adoption of an innovation (Antonelli, 2001). Many companies that manage to arrive at the development of high technical, process and intellectual capabilities developed for the specific production of certain products in some markets manage to apply them in production chains that are completely different from the main product.

As known, firms are an open and interactive systems (Bertini, 1990) that continuously exchange with the outside, maintaining a network of connections with other players in the economic and social world. Indeed, company is the target and object of expectations and demands, the hub of a complex network of material, informational, and financial flows that flow both inside and outside, and it often serves as a point of convergence for goals and expectations that are at odds with one another (Martini, 2009).

Having this in mind, this paper intends to analyse a case study belonging to the Made in Italy sector, trying to point out possible improvements that the Company should pursue.

## **2 Research Methodology**

Through a qualitative analysis, this research intends to answer the research question, using the case study method. We are aware that the results provided by a single case study may not be representative of the entire universe, but at the same time this research strategy is preferred for complex and deeply rooted contexts (Audet and d'Amboise, 2001; Lee, 1999; Yin, 1992). Focusing on a single case study enhances richness and contextualisation (Dieleman and Widjaja, 2019): as Mitchell states in his famous 1984 paper "the search for a 'typical' case for analytical exposition is probably less fruitful than the search for an 'eloquent' case, in which the particular circumstances surrounding a case serve to suddenly make previously obscure theoretical relationships evident".

A single case such as the one presented in this paper adds a concrete contribution to the previous literature from a real business perspective. Our case study refers to a small Company born within a solid and well-established all-Italian multi-business group, based in Rome, which intends to apply the exclusive skills operating in other sectors to a new business model. The management's intention is to compete in a market area currently not covered by an adequate product offering. These products are marketed through an exclusive, specially created brand and are developed for the benefit of young children and their

parents. The Company is in the start-up phase and launched sales in May 2022, after two years of pre-activity.

We conducted several semi-structured interviews (primary data) with the Head of Finance department. In conducting the interview, we followed the snowball method (Morgan, 2008), which proved to be appropriate for our analysis because it allowed to obtain a substantial amount of information. Thanks to the interview process, we understood managerial thinking and purpose, the challenges that management faced and is facing. The interviews were conducted in March 2023 and lasted an average of one hour. All of them were audio-recorded and then transcribed. In the following, the outcome of the interview is reported.<sup>1</sup>

### **2.1 What is the business model and value proposition?**

The idea that started this business and on which the business is articulated is that of producing toys useful for the correct growth and cognitive development of the child in the first 24 months of life, in an interaction with the parents. The toys produced are based on Montessori learning theories and in fact all products are settled and approved in consultation with the foundation.

The need to be satisfy is: "how can be improved child's cognitive development as he or she grows up?". The creation of a 'set' of play experiences, accompanied by a 'guide for parents', which teaches kids how to use the individual games contained in the box, is geared towards meeting this need. Such a guide requires the parent to actively participate in play with the child, so that this activity influences the quality of the child's growth. The necessary implication of the product (currently only the boxed product in its various variants is on sale) is that the parent must play with the child and that the child, consequently, does not play alone. The set of toys sold within the box, in fact, does not allow for autonomous play on the part of the child, but requires parent-child interaction.

### **2.2 What products are marketed and how are they eco-friendly?**

Currently, the Company only produces and sells a box containing a set of toys, without the possibility of marketing the individual components.

---

<sup>1</sup> Due to confidentiality reasons, the name of the Company is omitted.

New prototypes are being developed to create another 10 new product lines that are different from each other, but always with the aim of educating children between 0-24 months.

The box currently on sale is pre-packaged and made of cardboard, is not additionally wrapped in plastic, and is 'self-shipped' when the order is placed: in fact, it is simply printed with the recipient's name, applied in the warehouse and sent by courier. It contains toys suitable for the infant's period and learning. Each box covers 2 months of the child's life, for a total of 12 boxes.

There are no sales outlets where the products can be purchased because it is sold just via e-commerce. The choice of packaging and production of the toys is as environmentally friendly as possible. The toys inside the box are in no way subjected to chemical and harmful treatments as they will come into contact with children. The toys and the box itself are also 100% recyclable.

### ***2.3 How can be described these products?***

As an instance, the first box, the one from 0 to 2 months, provides the first 'transition object', helps exercise the eye muscles, and encourages the transition from the supine to the tummy-down position. The first two months of life are a time of important development of the eyes, touch, recognition of voices and faces of loved ones. To encourage baby's first discoveries, inside the box are toys inspired by the Montessori philosophy and featuring black and white contrasts to stimulate sight, which can be used together to build a bond of trust and love.

### ***2.4 What sales channels do you use and what products are currently marketed?***

Sales take place exclusively through a dedicated online channel. As already mentioned, for the time being only the boxes and not the individual games that make them up can be purchased according to one of the following offers:

1. single box;
2. three boxes (6 months of games): at an interval of 2 months, a new box is sent, different from the previous one, with different games in line with the child's age and learning;
3. six boxes (12 months of games, extended version of the previous one);

4. subscription: you subscribe and are sent a box every 2 months, until you withdraw from the contract.

Currently 70% of the turnover is generated by the sale of the single box.

There is also the possibility of satisfying a potential customer who discovers the brand and is intrigued by it, but is still undecided. To capture this 'customer slice', the product is sent for a 15-day free trial at the end of which the customer can decide whether to buy it or return it (only 10% of customers return the product after trying it, 90% agree to keep it and pay for it).

### ***2.5 How can the product be discovered?***

The Company has two proprietary digital channels that are implemented through two downloadable applications on smartphones. The purpose of these applications is to provide general and specific information to parents or prospective parents through registration and free updates (Attract and Keeping). The information conveyed by the apps is always based on Montessori principles and has been validated and implemented by a well-known hospital complex specialising in child research.

Once registered free of charge, the user of the applications obtains constantly updated information of a general nature. This information is not directly related to the company's activities, but has a high scientific value, as it comes from an international body specialising in babies and provides advice for pregnant women and parents-to-be. On the other hand, while this information is being consulted free of charge, advertising banners for products offered by the company appear continuously and, if interested, link to the relevant e-commerce page.

### ***2.6 How were the initial costs of setting up the company distributed?***

The initial investment required a high outlay of several tens of millions of euros, which were needed for:

- personnel, which involved the creation of the transverse functions of Marketing, Finance, Business Development, with about 40 employees;
- external suppliers, freelancers who developed the product design. Currently, marketed products and prototypes are developed by various external professionals working in different areas, such as specialised designers and development psychologists;

- external manufacturing, entrusted to the leading international toy manufacturer;
- purchase of digital platforms to dialogue and maintain contact points with customers for e-commerce sales.

### **3 Discussion**

At present, the Company is encountering difficulties in pursuing its economic viability of its business, since the level of sales volumes of the product currently on the market is lower than expected and does not allow to cover the costs. Therefore, the management, and in particular the strategic function, is currently interested in proposing improvement actions. Corporate strategy, in fact, is defined as a management activity and is dedicated to seeking economic balance in internal operational processes and in relations with the environment in which the company operates. The objective of strategic management can be defined as the definition of the fundamental characteristics of an organisation's interaction pattern with the environment, both in a political and operational context (Normann, 1987).

The implementation of this involves the development of an organisational and material framework that can best support this process. Ideas, choices and actions that directly aim at defining, creating or modifying the organisational framework of the Company's internal and external operational and competitive conditions are part of strategic management.

The processes of investment, innovation and learning are linked to the way resources and competitiveness accumulate over time, settle and stratify on the basis of an organisation's structural support system. Strategic ideas, choices and operations can have a favourable impact on the trend lines of the production mix.

The organisational framework of operational and competitive conditions comprises a set of 'factual situations' (Bertini, 1995) that, specifically, define the operational effects of enterprises and categorise their activities both internally and externally in terms of their interactions with the environment. The particular circumstances that make an individual enterprise unique, unpredictable and distinct from others even if it operates in the same competitive and environmental environment are represented by the combination of internal and external factors (Eminente, 1986).

The strategic management process operates precisely under conditions of information uncertainty. In fact, the management issues addressed by strategy concern a series of highly complex, multifaceted and interconnected business situations, both internal and external. The structural imprint determines the characteristics of strategic management to the extent that strategy determines the internal structural structure of the company and its structural relationship with the environment and change. Innovation is actually the foundation of strategy.

As a result of the interview process, some critical points were highlighted that, if analysed and implemented, could help the cost-efficiency process, because according to Bertini (1990), management is defined as the continuous integration of ideas, decisions and actions in a systematic logic. The system of business ideas is transformed into an operational system through the decision-making process. The fundamentals of business economics are to be found in this 'conversion process', in which the human system, i.e. the part relating to economics, is posed as a challenge (Ferrero, 1968).

In our opinion, these critical points are the following:

- the rigid sales channel, as it is exclusively online without the presence of the product in shops or distribution chains. This point represents a strong limitation to distribution and product knowledge, since the customer buys exclusively through a channel dedicated to new parents and does not get there through even casual acquaintance that takes place in a shop and does not have a direct interaction with a physical consultant who can show him directly and concretely the potential of the product. This on the one hand negatively affects the 'sales force' and market penetration, but on the other hand it is a positive factor in terms of localisation, as not only is it concentrated in certain physical locations, but it allows any potential customer interested in purchasing the product to be covered;

- the high cost of both the individual product and the subscription to the entire package makes the product difficult to appeal to less affluent families, who are potentially those with the most children and who should therefore theoretically constitute the most solid consumer base. This interpretation makes the product the prerogative of a small circle of potential buyers, who have to grasp the product's strong potential but also have the financial possibilities to buy it;

- the high initial start-up costs due to the remuneration of foundations, institutions and professionals for the design of the product. The design and realisation with environmentally friendly materials entailed a high initial outlay

due to the fact that specific professionals and manufacturers with specialised skills were called in and required a high initial investment, which can only be recouped with the widespread diffusion of the product. In addition, the still limited production does not yet allow for the possibility of creating economies of scale in the acquisition of finished products from their manufacturers and suppliers; - the product, due to its intrinsic characteristics, is more appreciated by a 'high culture' clientele, or in any case an attentive one. As it is presented, the product is more niche than mass consumption and is difficult to place in large-scale distribution; moreover, it is little known, as is the brand under which it is marketed.

#### **4 Conclusions**

In addition to what has been discussed in the previous paragraph and the analysis and emergence of what are some of the major, and not complete, criticalities that do not allow for initial success in economic terms, it should be added that the commercialisation of the product began relatively recently and therefore, as Giannessi (1969) writes, the transformation of a company's system of ideas into an operating system is a progressive process in which the time factor plays a significant role. We are talking about a system of operational and competitive business conditions that can be shaped and changed over time through a process of accumulation, sedimentation and stratification. The factual situations that have been assessed are not susceptible to sudden and drastic changes (Mazzola, 1993). Rather, they are structural characteristics, the purpose of which is to improve future business performance over time.

The structural characteristic must be viewed from a broader perspective and must not be used to describe the material and organisational system of the company, which only involves internal factors. On the contrary, the system of operational and competitive conditions also includes external factors, which refer to non-contingent situations and can be thought of in terms of how an organisation interacts with its environment (Bertini, 1995; Coda 1989). Insofar as these conditions are 'structural' for the achievement of future economic and business flows that have the characteristics of 'final' results (as they are already consistent with the economic expectations of investors), the system of operating and competitive conditions that has been created as a result of the management performed represents an 'intermediate' result (Galeotti and Garzella, 2013).

Most strategic decisions must be made using an approximate and incomplete information background, despite the considerable analysis efforts made by the company. Today, most organisational information systems focus on strategic analysis. Only on rare occasions is it possible to have a complete cognitive quadrilateral due to the time and cost of information and without considering the fact that, in any case, much strategic information is future-oriented and therefore uncertain and only hypothetical. Therefore, despite all rationalisation efforts, the people entrusted with corporate governance continue to have a significant impact on strategic management decisions. The creation, consolidation and modification of a structural system of operational and competitive conditions constitutes the formation of a system of ideas. These conditions continue, to the company's advantage or disadvantage, even after the conclusion of the transactions that generated them, confirming future economic trends.

### **Abstract**

Start-ups are becoming increasingly important in driving economic growth, job creation, and wealth generation. Their success depends not only on innovative products and services but also on the ability of attracting, retaining, and developing talented employees. The enthusiasm, involvement, and effort of founders and early employees greatly impact the success of start-ups. Unfortunately, the high degree of uncertainty, the intense work and multiple roles of employees may lead to several issues like burnout risk and difficulty balancing work and private life.

Although existing research has produced several contributions on , the quality of working life for start-up employees and entrepreneurs, the knowledge generated in the field appears fragmented and the findings are sometimes ambiguous. The reason for this

fragmentation can be traced back to the lack of reference frameworks that clarify the most used concepts, thus providing a shared language.

Therefore, human resource wellbeing is a research theme that deserves to be further investigated. This study aims to provide a first attempt to consolidate the state-of-art of scholarly research in human resources wellbeing in innovative startups. To this aim, we carried out a systematic literature review by analyzing a set of 41 papers in order to find what are the relevant topics in the investigated research domain. This activity was performed using MySLR software. In particular, we characterized the three relevant topics in the investigated research domain, namely job satisfaction, wages and career development opportunities; work-life balance and psychological wellbeing; women's condition and gender related issues.

Overall, the value of research is to provide a framework for analyzing the phenomenon of human resources wellbeing in innovative startups that can be used as a reference model for envisaging new research directions both entrepreneurship, human resources and innovation management fields of study.

**Nature of proposed paper** - Academic Research Paper

## 1 Introduction

In recent years, innovative start-ups have emerged as key drivers of economic growth, job creation and wealth generation. These companies are often characterized by their agility, flexibility, and willingness to take risks in pursuit of breakthrough innovations and sustainable business models (Corvello et al. 2023). Innovative start-ups are often at the forefront of technological advancements and are often seen as vehicles for social change, as they can address societal challenges and create value for communities.

However, the success of these start-ups depends not only on their ability to develop innovative products and services, but also on their ability to attract, retain, and develop talented employees (Harlin and Berglund, 2021). Among the reasons for the success of many start-ups is the enthusiasm and commitment of the founders and early employees (Margherita and Verrill, 2021). The literature highlights the importance of the enthusiasm, involvement and effort produced by these people (Andries and Czarnitzki, 2014). For this reason, human resources (HR) wellbeing is a critical factor in the success of start-ups, as it can impact employee motivation, engagement, and productivity (Wiklund et al., 2019).

Start-up culture is often associated with a high degree of uncertainty and intense work. In particular, in the early stages of a start-up, there is often a great

deal of uncertainty surrounding the viability of the business model, the market demand for the product or service, and the availability of funding. This uncertainty can create a sense of urgency among start-up employees, who may feel that they need to work long hours and take on multiple roles in order to ensure the success of the company (Mukul and Saini, 2021).

While the intensity of start-up culture can be motivating for some employees, the pace of intense work and uncertainty about results can put staff and entrepreneurs under pressure with negative effects on their well-being. In fact, in uncertain working contexts, cases of burnout are not rare and entrepreneurial work makes it difficult to balance work activity with private life. Employees in start-ups may feel pressure to constantly iterate and improve their products or services, which can result in long hours and high levels of stress. In addition, start-up employees may feel that they need to constantly stay up-to-date with the latest industry trends and developments in order to remain competitive. This can take a toll on the well-being of startup employees (Omrane et al. 2018).

Start-up entrepreneurs need to be mindful of the impact that their culture and work environment can have on employee wellbeing, and take steps to promote work-life balance and employee satisfaction. This can include offering flexible work arrangements, providing opportunities for professional development and growth, and creating a supportive and collaborative work environment. By prioritizing employee wellbeing, start-ups can create a sustainable culture that promotes innovation and growth, while also valuing the health and happiness of their employees.

Despite its importance, the quality of working life of start-up employees and entrepreneurs is a topic that has not yet been investigated in the literature. How theories and models of employee satisfaction theories can be applied to this specific domain is not entirely clear. Therefore, an effort is needed to understand which are the fundamental problems and the most useful theoretical constructs. Because of the lack of such a synthesis, obtaining an overview of this fragmented domain can be difficult. To our best knowledge, this is the first systematic review article to specifically address the theme of HR wellbeing in innovative startups, aiming to provide a comprehensive/integrated analysis exploring the topics, trends, methods/variables, and constructs used in prior studies.

To achieve this goal, we analyzed papers by means of a text-mining approach, namely latent Dirichlet allocation (LDA). By analyzing the papers clustered into

these topics, we provide an integrated view of this knowledge domain and identify research limitations and gaps.

## 2 Methodology

We conducted a Systematic Literature Review (SLR) to provide an overview of scientific literature on the topic of HR wellbeing in innovative startups. In line with the SLR principles provided by Tranfield, Denyer, and Smart (2003), the research protocol we adopted consists of three main steps: paper location and selection, paper analysis, and results presentation/analysis. These three steps have been carried out with the support of MySLR software platform (Ammirato et al. 2022), which is a semi-automated tool supporting researchers in performing SLRs. Figure 1 shows the research workflow adopted in this research.

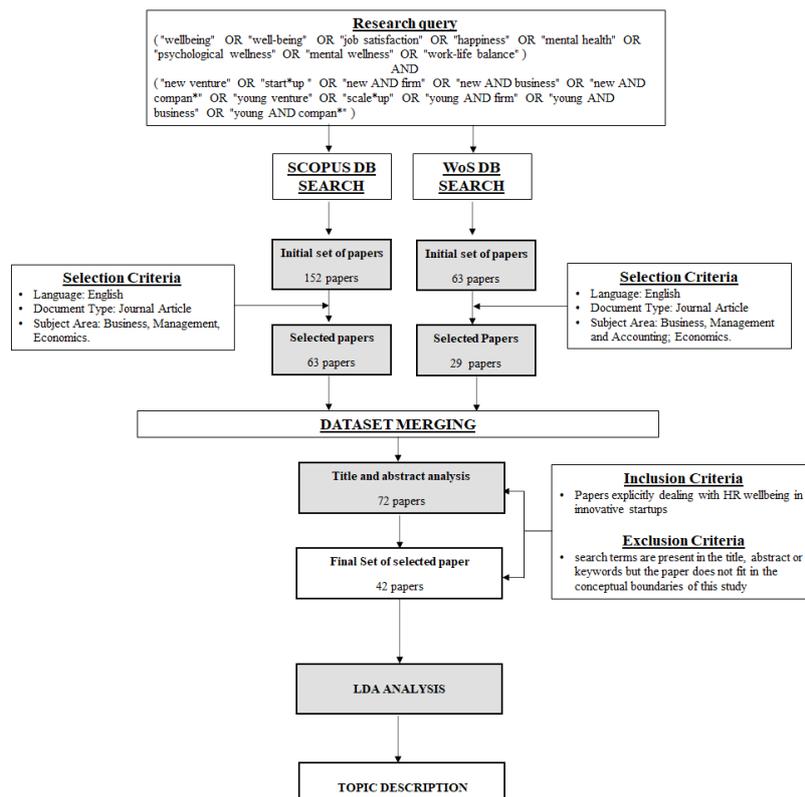

Figure 1. The research workflow

*Papers location and selection.* We defined two sets of keywords to identify the core literature that take into account the concepts HR wellbeing and innovative startups, respectively. The search string was designed to yield papers containing at least one term from each set in the title, abstract, and keywords.

WoS and Scopus have been selected as scientific databases were to perform our search and locate papers. These databases are considered as the most important and comprehensive databases in managerial studies (Bhimani et al., 2019). The search has been performed at the end of March 2023. We initially found 152 papers from Scopus and 63 from WoS. Selection criteria for papers to be analyzed included the following conditions: the papers were written in English, published in scientific journals, and indexed within the Business, Management, and Economics field of study (Felicetti et al., 2023). At the end of this step, we found 63 papers from Scopus and 29 papers from WoS.

Results from these two scientific databases have been merged, resulting in 72 unique papers. We manually analyzed the title and the abstract of each article, in order to verify if it falls within the scope of our study (Christofi et al., 2021). This allowed us to exclude papers that do not fit in the conceptual boundaries of this study, despite search terms are present in the title, abstract or keywords. The final set consists of 41 papers.

*Paper analysis.* We utilized a text-mining approach based on latent Dirichlet allocation (LDA) to reveal the research topics in the context of legal and regulatory innovation. The LDA technique gives as output  $k$  sets of relevant keywords (where each set represents a topic) and the document-term matrix, i.e. a matrix describing how much each paper is devoted to a specific topic (i.e. topic proportion). Following Blei (2012), we selected  $k$ , i.e. the number of topics to be extracted, by evaluating multiple LDA results with  $k$  ranging from 2 to 20. We chose  $k$  and the LDA algorithm to guarantee a sufficiently high value of topic coherence (Chen & Liu, 2014) and, at the same time, a simple interpretation of the results for a human reader. The most meaningful set of topics was achieved with  $k = 3$ .

*Results synthesis* Four topics have been identified through the LDA procedure,

In Figure 2, the intertopic distance map, a visualization of the topics in a two-dimensional space, is provided. The area of these topic circles is proportional to the number of words that belong to each topic across the dictionary. The map would seem to suggest a high degree of polarization of the terms on the individual topics. Figure 3 shows the  $t$ -distributed stochastic neighbour

embedding (t-SNE) map, i.e. a statistical method for visualizing high-dimensional data by giving each datapoint a location in a two dimensional map. The map seems suggesting that the papers that are assigned to a topic have little to do with the other topics.

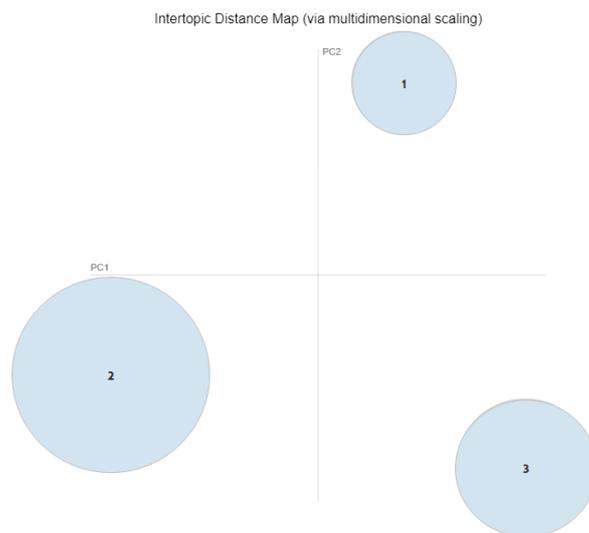

Fig 2. The intertopic distance map with three topics

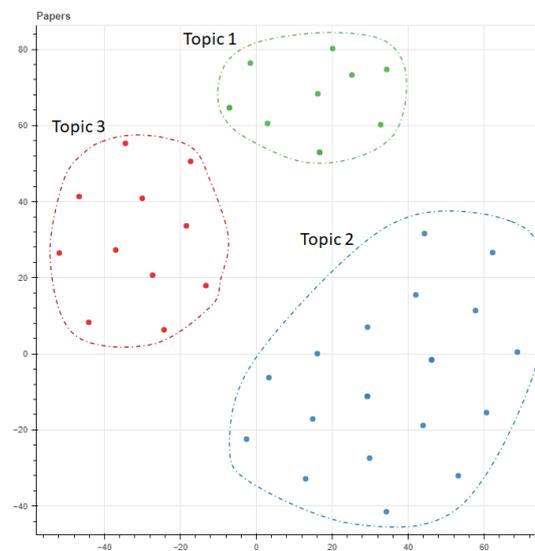

Fig 3. The t-distributed stochastic neighbour embedding (t-SNE) map with three topics.

Each topic identified through the LDA procedure is related to a different perspective. In Figure 4, a set of 10 relevant keywords associated to each topic is presented.

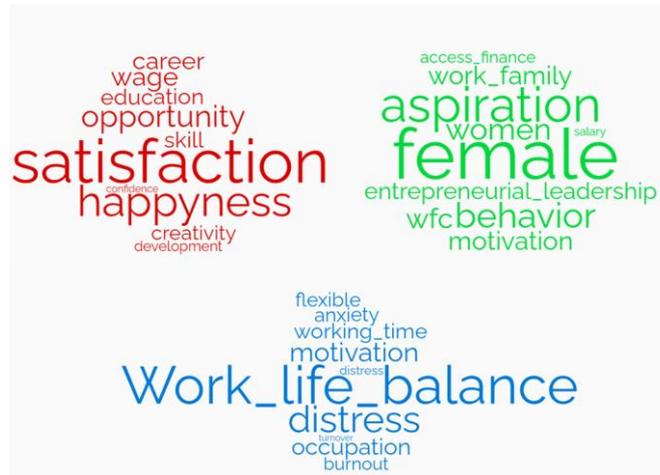

Fig 4. Word-cloud of relevant keywords for each topic.

This allowed as to name the three topics as follows:

- Topic 1: job satisfaction, wages and career development opportunities
- Topic 2: work-life balance and psychological wellbeing (mental health of individuals involved in innovative startups, including stress, anxiety, depression, burnout)
- Topic 3: Women's condition and gender related issues.

### 3 Discussion

In this section, a description of the three topics detected through the LDA procedure is provided. In particular, the description is developed on the base of papers' main concepts proposed.

*Topic 1: job satisfaction, wages and career development opportunities.* Job satisfaction, is a critical factors in the well-being of human resources in innovative startups.

Job satisfaction in startups is a multifaceted concept that involves various factors such as salary, opportunities for advancement, colleagues, management, and the nature of the work itself (Yang et al., 2019). While compensation, benefits, and job security are important factors that shape employee satisfaction, other

factors such as opportunities for growth, progress, and career advancement also play a significant role (Jeong and Choi, 2017). Additionally, intrinsic rewards such as recognition, praise, and flexible working arrangements could also contribute to job satisfaction (Georgellis and Yusuf, 2016).

As a complex construct, job satisfaction is influenced by various factors, such as the work environment (Kanchana and Jayathilaka, 2023), job characteristics (Maaravi et al., 2021), and organizational culture (Muttaqin et al., 2020).

Startups that provide employees with autonomy, meaningful work, less routinary activities and opportunities for personal and professional growth are more likely to have satisfied employees (Maaravi et al., 2021). Also startup entrepreneurs tend to experience greater life satisfaction due to their ability to work independently, have greater flexibility, and utilize their skills more effectively (Naudé et al., 2014; Binder and Coad, 2013). This is based on the assumption that having greater autonomy in their work life leads to positive emotions and a sense of fulfilment from running their own business (Teixeira and Vasque, 2020).

Startups often face financial constraints, and offering competitive wages may be challenging. They often suffer from the inability to provide competitive salaries as per industry standards (Mukul and Saini, 2021). This can make challenging for startups to attract and retain highly skilled individuals. Hence, startups search for new and creative ways to remain competitive, such as offering alternative compensation considerations and strategies, e.g. benefits, equity compensation and stock options (Freeman and Angel, 2007). Chang et al. (2015) found a positive effect of non-executive employee stock options on their long-term commitment, preventing myopic behaviours, with a substantial impact on innovation output. Of course, Startups that provide employees with fair and competitive wages are more likely to have satisfied and motivated workers (Sorenson et al., 2021). Startups offering competitive wages have been found to attract and retain high-quality employees (Kim, 2018).

Career development opportunities are also essential for employee well-being. Several studies have shown that employees who perceive that they have opportunities for career development are more satisfied with their jobs and are more committed to their organizations (Fackler et al., 2019). Startups that provide employees with opportunities for career growth and development are more likely to have satisfied employees (Jia-Jun and Hua-Ming, 2022). Therefore, innovative startups should provide employees with opportunities for career growth and development to foster employee well-being.

*Topic 2: work-life balance and psychological wellbeing*

The concept of work-life balance has become increasingly important in recent years, particularly in the context of innovative startups. Innovative startups are known for their fast-paced, high-pressure work environments, which can make it difficult for employees and founders to manage their professional and personal lives. This can have a significant impact on their wellbeing, both in the short and long term (Rashmi and Kataria, 2021).

Thilagavathy and Geetha (2021) identified three level of factors impacting on work-life balance, namely, individual, organizational and societal factors. Innovative startups have the opportunity to create a culture that values work-life balance and supports employees in achieving it. This can include offering flexible work arrangements, providing resources for mental and physical health, and promoting a culture of work-life balance (Thilagavathy and Geetha, 2021).

While working for a startup can be exciting and offer opportunities for growth, it can also be stressful. The psychological wellbeing of individuals involved in innovative startups has received increasing attention, as the high-pressure environment can result in stress, anxiety, depression, and burnout (Katrodia, 2020). Research indicates that startup founders experience higher levels of stress compared to employees in traditional organizations (Nambisan and Baron, 2021). This is attributed to factors such as the need to raise capital, deal with uncertainties, and manage a rapidly growing team (Wincent and Örtqvist, 2009)

High levels of stress, in turn, have been found to have a wide range of negative effects on employees and startups entrepreneurs, including their ability to make judicious decisions and actions and more broadly, on their performance on a wide range of tasks (Rangrez et al., 2022). Entrepreneurs' passion for their startup can lead to chronic stress, which can have negative effects on their physical and mental health. It is crucial educating entrepreneurs to work through the stresses of entrepreneurship more effectively, leveraging on self-awareness and resilience in managing stress (Cotter and Stetson, 2020).

Employees in innovative startups are also at risk of experiencing burnout due to long working hours, high job demands, and the pressure to meet performance targets (Wiklund et al., 2019). This is particularly evident in necessity-based startups (Kautonen and Palmkroos, 2010). Nikolova (2019) provided causal evidence of the consequences of switching to self-employment from unemployment (necessity-based) and to self-employment from regular employment (opportunity-based). Specifically, the author found that necessity

entrepreneurs does not experience substantial improvements opportunity entrepreneurs experience benefit in mental health. Kollmann et al. (2019) examined how daily stressors affect entrepreneurs' insomnia and their ability to detach from work during non-work hours, with a significant impact on their wellbeing and performance.

Some startups entrepreneurs are involved in *hybrid entrepreneurship activities*, i.e. they are simultaneously working in wage employment settings while also attempting to launch their own new ventures (Folta et al., 2010). Hybrid entrepreneurs face significant time constraints, requiring availability for extended work overtime (Kim et al., 2022). This condition of dual work-venture role engagement often leads to negative psychological pressures and increasing dissatisfaction (Carr et al., 2022).

The workplace must be a source of happiness for employees. Unhappy employees in a workplace tend to increase employee turnover, absenteeism, low productivity, and time wasted deadlines (Kanchana and Jayathilaka, 2023).

*Topic 3: Women's condition and gender.* The challenges and opportunities associated with employee wellbeing in innovative start-ups are closely tied to issues of gender, career aspirations, emotional wellbeing, work-life balance, and motivation. Women may face unique challenges in balancing work and family responsibilities, which can impact their career aspirations and motivation (Aggrawal et al., 2022)

Issues Gender and equity-related issues in innovative startups are an important aspect to consider, as research indicates that there is a significant gender gap in the startup ecosystem (Berger and Kuckertz, 2016). Female founders and employees often face unique challenges, such as gender discrimination and bias, which can impact their wellbeing and career development. Gender discrimination in access to funding is a significant issue for women entrepreneurs in startups.

Research on gender and equity in innovative startups has mainly focused on the underrepresentation of women in the sector (Brush et al., 2019). Studies show that women-led startups receive a disproportionately low amount of venture capital funding, with only 2.3% of VC funding going to women-led startups (Bittner and Lau, 2021). Similar results are provided by Demartini (2018). Her study highlights that female businesses raise, on average, a lower amount of financial resources in comparison to men. This underrepresentation can be attributed to factors such as gender stereotypes, lack of access to resources and networks, and unconscious bias among investors (Ewens & Townsend, 2020).

Moreover, the underrepresentation of women in innovative startups is due to the fact that technological-related activities have traditionally been a "male domain" (Demartini, 2018).

In terms of wellbeing, studies have shown that female startup founders experience higher levels of stress compared to their male counterparts (Chadwick and Raver, 2019).

Work-family conflict is a relevant issue in gender studies on startups wellbeing. Time management played a crucial role in the lives of each of the women as they coordinated various roles: business owner, wife, mother, carer. A key motivation for engaging in venturing is the desire to balance familial responsibilities with running their own business and, thus, fulfil an ambition to be their own boss. Women in startup companies experience what Kamberidou calls *multitasking whirlpool*, i.e. the "experience of being pulled in all directions: juggling professional, social, family and domestic obligations while pursuing individual or creative goals and needs" (Kamberidou, 2020, p.4). Increased flexibility was expected to help them to realize that ambition. Entrepreneurship offers a partial answer to both a desire for greater flexibility and control over personal time and the need to take control over personal and professional ambitions (McGowan et al., 2012).

Innovative startups can promote gender and equity by providing a supportive work environment that encourages diversity and inclusion. Additionally, providing individuals with opportunities for personal and professional development can help to build resilience and coping skills, which can improve gender and equity related issues (Yang et al., 2020)

#### **4 Conclusions**

We carried out a systematic literature review on human resources wellbeing in innovative startups. This article aims to lay the foundations for the extension of organizational theories on employee well-being to the case of start-ups.

This research allowed us to identify multiple dimensions of wellbeing in the context of innovative startups. By identifying three distinct but interrelated topics, this study highlights the complexity of human resources wellbeing in this context and the need for a multifaceted approach to addressing it.

The study provides insights for entrepreneurs and managers of innovative startups on how to promote employee wellbeing, as the importance of

addressing mental health issues in the context of innovative startups, prioritize the implementation of mental health support programs and create a supportive culture that values employee wellbeing.

As far as the authors are aware, this is the first article that systematically addresses the issue. The results are of interest to innovation and entrepreneurship scholars, who will find in the article indications for better understanding the motivational and behavioral dynamics of people in start-ups. The same holds for human resource management scholars, who will find indications for extending their domain theories to this interesting field. Finally, our results are useful to entrepreneurs and employees of new businesses, because they can draw lessons relating to the management of people and interpersonal relationships, and for policy-makers, interested in the success of start-ups but also in the well-being of employees in a sector that employs an ever growing number of people.

### **Abstract**

Knowledge of the Environmental, social, and governance (ESG) factors is the subject of increasing interest in national and international institutions. Within the banking sector, there is a growing awareness of the need to integrate the non-financial information arising to ESG factors knowledge, into strategies, processes, and financial instruments to generate

long-term value. ESG are increasingly considered as a new factor influencing risk in bank's lending activity, and this is the perspective of our paper. Adopting a bank-centered perspective, the main aim of the paper is to investigate, employing a Data Envelopment Analysis (DEA)-based approach whether including ESG factors in the creditworthiness assessment of borrowers increases the firms' efficiency, thus mitigating bank risk taking. The research has been carried out on a sample of European listed firms in the energy sector, which is under increasing pressure from society due to its huge environmental footprint and social importance. Our findings do not provide evidence of the overall significance of ESG factors in affecting firm efficiency. Nevertheless, we provide evidence that high/low ESG scores do not affect firm efficiency, but at moderate level, ESG scores improve the corporate efficiency. The findings contribute (and provide suggestions) for regulators, credit risk managers, and academics.

## 1 Introduction

Knowledge of non-financial information, related to the concept of sustainability, has become crucial in the banking context. Nowadays, it is no longer enough to look at financial data alone to evaluate a company, as for all global companies, compliance with values related to sustainability has become a must. Traditional accounting methods that exclusively considered the financial results of corporate operations do not match the needs of organizational stakeholders in today's global business environment (Gurol & Lagasio, 2022). The request for non-financial information (NFI) has led businesses to disclose it in sustainability reports (SRs)/non-financial reports (NFRs) to address the greater stakeholder demands in environmental, social and governance (ESG) issues (Degan, 2002), even if methodologies for sustainability reporting are not consolidated yet (Patara & Dhalla, 2022). ESGs reflect sustainability practices and are able to report a firm's progress in implementing the SDGs (Khaled et al., 2021). Only recently have banks attached increasing importance to CSR and sustainability reporting, also including stakeholder engagement and ESG disclosure (Bătae et al., 2021; Venturelli et al., 2018). Among the reasons, we can quote the need to recover the reputation compromised by a series of scandals that revealed the social and environmental impact of banks (Venturelli et al., 2018); the 2008 financial crisis, which increased the need for trust as well as accountability and transparency between banks and their stakeholders (Lentner et

al., 2015); the willingness of banks to develop their brand identity and to differentiate themselves from competitors by investing in CSR (Forgione & Migliardo, 2020); an expected superior financial performance for banks involved in CSR activities (Shen et al., 2016). The changed scenario has not only prompted financial intermediaries to analyze and manage relations with various stakeholders more carefully, but also attracted increasing attention from banks to CSR and the adoption of social reporting. The need to improve the reputation and fiduciary relationship with stakeholders was the primary reason for convincing credit institutions to use social reporting tools aimed at communicating their commitments and the overall impact of their ESG activities on the community and to manage their reputational risk (Galletta et al., 2022; Dell'Atti et al., 2017). Knowledge of companies' ESG commitment is extremely important for banks as banks have a fundamental impact on the overall economy, performing the function of transferring funds, and the sensitivity of bank managements regarding sustainability can reflect this in their lending decisions, so highlighting an indirect environmental impact (Gurol & Lagasio, 2022). ESGs, beyond being viewed as a new virtuous approach to business, probably profitable in the near future, could be analyzed in terms of risk. Integrating ESG factors into credit risk assessment is the most novel challenge for the financial industry (Brogi, 2020) and also an opportunity to create sustainable lending (Brogi et al., 2022). In some cases, ESG disclosure contributes to decrease corporate financial irregularity risks (Yuan et al., 2022). This is a timely issue, as regulators and investors increasingly require banks to channel loans to "sustainable" borrowers and ultimately foster sustainable growth. From a regulatory perspective, the new European Banking Authority (EBA) guidelines (EBA, 2020) have set out a series of principles for credit institutions to follow in managing and controlling credit risk which not only focus on the financial and capital structure of firms but also on environmental, social and management factors and qualitative and prospective information. The integration of environmental sustainability criteria in investment decisions and in support of the development of sustainable finance is required for different banking business models. While the banking system is aware of the strategic importance of ESG issues, their practical introduction into lending processes is still extremely heterogeneous and fragmented. This is clearly an issue that needs to be addressed, since credit institutions have time to adapt by 30 June 2024 (Galletta et al., 2022). This paper focuses attention on the bank's lending decision, aiming to investigate whether including ESG factors in the

creditworthiness assessment of borrowers increases the efficiency of firms, thus mitigating the bank risk taking. To the best of our knowledge, in the extant literature there is only one other attempt to explicitly integrate ESG factor in the creditworthiness assessment. In detail, the article of Brogi et al. (2022), adopting a bank perspective, found that ESG scores are strongly and very significantly associated with a reduction in firm credit risk. Differently from Brogi et al. (2022), in our paper, we use a DEA-based approach to take into consideration the non-linearity concerns related to a (supposed) identified non-linear association in the literature between ESG and firm performance/firm risk (Rouine et al., 2022; Barth et al., 2022; Bruna et al., 2022). The contributions of our paper are manifold. Our results might contribute in terms of policy by developing a new perspective of the whole credit risk management process, which includes knowledge of ESG factors. Policy makers should thus reflect on the role of ESG in the regulatory framework and in the prudential treatment of sustainable lending. Our findings are interesting for practitioners, as they are in line with the EBA guidelines (EBA, 2020) requiring banks to deepen the knowledge of factors related to sustainability in their lending decision. Moreover, they can also help credit risk managers to reflect on the role of ESG awareness in credit risk assessment in periods of crises (Demers et al., 2021) and on the opportunity to adopt a sustainable lending policy to achieve competitive advantage. Lending to sustainable firms is less risky, more advantageous from a competitive point of view and presumably produces less risk weighted assets when computing banks' capital requirements (Brogi et al., 2022). Finally, from the academic research perspective, we contribute to the literature on ESG and credit risk assessment by adding knowledge to the research on the association between ESG and borrower's credit risk, which is still a topic without univocal consensus, and in a sector, the financial sector, that is nowadays an under-investigated topic in the literature.

The paper is organized as follows: Section 1 introduces the topic; Section 2 presents the literature review; Section 3 illustrates the data set used; while Section 4 describes the methodology employed; Section 5 presents and illustrates the empirical results; finally, Section 6 concludes the paper.

## **2 Literature review**

Theoretically speaking, at least two established theories can be used to support a link between bank risk-taking on the one hand and ESG on the other. The

*stakeholder theory* (Freeman, 1984) suggests that a shift from shareholder-focused to stakeholder-focused governance would balance the interests of investing and non-investing stakeholders in banks thereby containing excessive risk-taking by management and protecting bank value. ESG-based governance should therefore be associated negatively with bank risk-taking (Di Tommaso and Thornton, 2020). In contrast, under the *overinvestment hypothesis*, ESG leads a firm to divert scarce resources from the maximization of shareholders' wealth, which squeezes out investment, thereby reducing bank value; it therefore predicts a negative impact of ESG on bank performance (Drago et al., 2019). The "stakeholder" versus "overinvestment" debate raises a crucial question, investigating the impact of ESG in reducing (increasing) organizational risk (organizational accounting or market performance).

Empirical studies could be divided into two groups: (a) the studies that analyse the impact of the three pillars of ESG on firm performance; (b) the studies that analyse the impact of the three pillars of ESG on firm risk, in turn articulated into (1) studies focused on all sectors and (2) studies focused on the banking sector. Empirical findings of both strands are mixed. In the first strand, Friede et al. (2015) in their meta-analysis on 2200 studies, found that roughly 90% of studies show a non-negative ESG-Corporate Financial Performance relation, and the large majority of studies reports positive findings. Bruna et al. (2022), provided evidence for a positive and significant impact of ESG performance on financial performance, within a non-linear relationship. Landi and Sciarelli (2019) investigating the FTSE MIB Italian listed companies for 2007-2015 did not find statistical evidence on the abnormal returns of sample companies. Demers et al. (2021) provided evidence that ESG were not significant in affecting stock returns in COVID crisis. As regard the COVID-19, El Khoury et al. (2022) argue that it was an extreme event where the effect of ESG sharply manifests. They found that ESG is beneficial during COVID-19, but the reward appears to be closely tied up to specific aspects of ESG, income level, and firm-specific variables.

As well, Fonger-Laronde et al. (2020) found evidence that ESG investments do not safeguard from financial losses during a severe market downturn. Dimson et al. (2020) and Alda (2021) argued that the ESG factors do not affect the financial performance of mutual funds, whilst Plagge and Grim (2020) underlined that the significant return and risk differences of ESG funds appear to be mainly driven by fund-specific criteria rather than by a homogeneous ESG factor. Some other studies underlined possible differences between firms with high or low ESG

ratings (Pacelli et al., 2022). Cerqueti et al. (2021), measuring the impact of portfolio liquidation in a stress scenario on funds with different ESG ratings, found that the relative market value loss of the High ESG ranked funds is lower than the loss experienced by the Low ESG ranked counterparts in a lower-volatility period, but they do not find differences in high-volatility period of one class over another. Steen et al. (2020), analysing the Morningstar's ESG ratings and the performance of Norway mutual funds, did not find evidence of rating level effects, but dividing the sample into ESG quintiles, they found significant higher returns for the top ESG quintiles. Zhou et al. (2022) analyzing Chinese listed companies from 2014 to 2019 found evidence that the improvement of ESG performance can enhance the market value of the company through the mediating effect of the financial performance. Xie et al. (2019), examining the effect of ESG on firm efficiency provided evidence that ESG disclosure has a positive association with corporate efficiency at the moderate disclosure level, rather than at the high or low disclosure level. Pacelli et al. (2022), examining the link between the risk-return performance and the ESG score of different sectoral portfolios entirely composed of ESG assets, found that the average return is positive but the performance is still heterogeneous among the different sectors, implying that an ESG score cannot yet be considered an additional and uniformly valid ex ante criterion in selecting assets for portfolio managers. As for financial companies, Ahmed et al. (2018), investigating 30 private commercial banks operating in Bangladesh, found that banks pioneering in incorporating ESG factors in lending decisions are compensated through better financial performance. Di Tommaso and Thornton (2020), examining European banks, find that ESG scores are strongly associated with a reduction in the market value. Azmi et al. (2021) provided evidence of a non-linear inverted U-shaped relationship between ESG and bank performance, mainly driven by the environmental pillar.

In the second strand, Barth et al. (2022), investigating the association between ESG ratings and the credit default swap (CDS) for European and US firms from 2007 to 2019 found evidence that higher ESG ratings mitigate credit risks according to a nonlinear association. Rouine et al. (2022), investigating S&P500 listed companies between 2002 and 2017, provided evidence of a nonlinear and wholly negative relationship between ESG and firm total risk, also showing that the mitigating impact of ESG on corporate risk appears more marked beyond a defined score of ESG, suggesting a "threshold effect" induced both by organizational learning and responsible regulations. As for financial companies,

Drago et al. (2019), examining the changes in ESG rating announcement on CDS spreads of European firms, found evidence that better CSR ratings, in terms of both the overall score and the scores for the three main ESG pillars lead to lower CDS spreads, even if an ESG upgrade leads to an immediate and significant decrease whilst an ESG rating downgrade does not have a significant immediate impact on CDS spreads. Di Tommaso and Thornton (2020), examining European banks, found that ESG scores are strongly associated with a reduction in risk-taking. Neitzert and Petras (2021), conducting their research on worldwide banks from 2002 to 2018 provided evidence of the risk-reducing benefit of CSR engagement proxied by the ESG score (driven by environmental pillar). Landi et al. (2022) explored the relationship between companies' ESG assessments and their risk (systematic and volatility) exposures for a sample of 222 large-cap companies belonging to the S&P 500 stock market index for 2014-2018, finding that ESG assessment tends to increase firms risk exposure, and the uncertainty among investors. Galletta and Mazzù (2022), estimating a dynamic panel data model of worldwide listed banks from 2011 to 2020, found evidence that banks with fewer ESG controversies (proxy for bank compliance towards ESG issues) take less risk and Aouadi and Marsat (2018) found that, when interacted with the corporate social performance (CSP) score, ESG controversies to be positively and significantly associated with firm value. Brogi et al. (2022) found that ESG scores are strongly and very significantly associated with a reduction in firm credit risk.

Given the existence of different theories able to explain the impact of ESG on firm performance/risk and given the mixed evidence of the ESG/performance association both in financial and non-financial sectors, we believe that the issue deserves a deeper analysis. In details, our main research question is whether bank managers, in taking their lending decisions should complement their credit risk management models with ESG scores. In other words, how ESG factors can be introduced into the credit decisioning process with the aim of identifying credit opportunities that enable more sustainable future businesses? Should ESG scores be included as relevant factors in bank lending decisions? While ESG may be considered an important part of a firm assessment, they should not completely replace or be seen as interchangeable with traditional financial indicators. Successive sections deal with the sample and data selection and the methodology employed to carry out our research.

### 3 Methodology

Lending is one of the main types of banking operations, as a source of high profit, and in response to an increasing demand from business entities of lending volumes. The provision of bank loans is a fairly risky activity, and most of the risks associated with it are objectively inherent to the lending process. In-depth analysis of financial indicators of a firm allows the bank to obtain the necessary information on credit risk, giving an indication on whether borrowers will be able to repay the credit. For the bank, the purpose of a credit risk assessment is to make a decision whether to lend or not with the aim of maximizing the profit of the credit portfolio and hence to increase the number of loans. The essence of this credit portfolio optimization problem is then to select borrowers from a set of firms asking for credit, according to one or more decisional criteria.

We need to consider, in particular, two distinct dimensions: 1. the ability of the bank manager to increase the value of the loan portfolio; and 2. the ability of the bank manager to maximize the profitability, and hence, the number of loans. Value could be measured by market value indicators such as Tobin's Q (e.g., Bolton, 2013), financial values such as revenues and EBITDA, asset values such as value of total assets and the book value of capital (e.g., Abuzayed et al., 2009). Having obtained these characteristics, we decided to employ the Data envelopment analysis (DEA), consistently with Xie et al. (2019). Using DEA allows us to estimate corporate efficiency by considering several input and output factors. Several methodologies are used in empirical papers to investigate the relation between ESG and firm performance/credit risk, going from static to dynamic panel regressions (Zhou et al., 2022) to machine learning techniques and ordered logistic regression (De Lucia et al., 2020). Many articles have underlined the existence of a non-linear association between ESG scores and firm performance/risk (Barth et al., 2022; Bruna et al., 2022; Rouine et al., 2022; Azmi et al., 2021). Given a supposed nonlinear relationship on the basis of the literature between corporate efficiency and ESG scores, we employed data envelopment analysis (DEA, for short), a non-parametric approach usually used to evaluate the efficiency and inefficiency of a group of companies, called decision-making units (DMUs, for short). DEA can be also used as an early warning index for determining firm credit risk (Iazzolino et al. 2013; Bruni et al., 2014). In this approach, the efficiency measure is derived from the optimal solution of a mathematical model where multiple Input-Output variables are considered for each company.

Traditionally, DEA has some shortcomings when applied to portfolio selection, which is in fact usually performed into two separate steps. In this first step DEA is applied to obtain an assessment of the performance of each company, and then, is a second step, an asset allocation optimization model is applied. To overcome this drawback, we present a novel model (reported in the Appendix), of general applicability, providing an integrated framework for loan portfolio selection which takes into account all the characteristics of the decision problem faced by the banks. The mathematical model that we used, through a two-stage application, allowed us to derive meaningful information on the impact of ESG factors, both on business performance in terms of efficiency and on the investment decisions of financial institutions. This is accomplished by means of weighted sum of two different objective functions into a simultaneous DEA model (Khodaparasti et al. 2015).

Additionally, the model explicitly accounts for the risk connected to the issuance of bank loans, which is intrinsically tied to the lending process. In our model, risk is associated with possible losses of a bank for a specific credit portfolio, in the event of the borrower defaulting on his obligations. In particular, the risk is defined through a constraint which takes into account as the product of the Probability of Default and the 20 percent of total corporate debt. In the model, through this constraint we limit the expected portfolio loss at a value equal to 5 millions of euros

#### **4 Sample and data source**

We decided to address our research question in an environmentally sensitive sector—namely the energy industry—where firms are exposed to higher social pressures and public concern. Consistently with Manes-Rossi and Nicolò (2022) and Adamkaite et al. (2022), we believe that is interesting to research under a sustainable angle as it is under stronger pressure and risk of losing its legitimacy. Notwithstanding the energy industry is among the industries with the most significant environmental impacts, extant sustainability accounting research is scarce in the energy industry (e.g., oil & gas, electricity, renewable energy, consumable fuels). According to the International Energy Agency, energy-related carbon dioxide (CO<sub>2</sub>) emissions are the majority of global greenhouse gas (GHG) emissions, while oil and gas are the largest sources of fuel combustion emissions and are responsible for approximately 53% of global energy-related CO<sub>2</sub>

emissions. Sustainability has long been a critical consideration for firms operating in the energy industry. Adherence to health, safety, and environmental regulations and increasing contributions to the societies in which they operate form the core of existing sustainability strategies, which enhance these firms' ability to create long-term value. These firms now have goals of achieving cost-efficient and environmentally-friendly operations. Particularly among the younger generation, the environmental impact of energy activities has led to an unfavorable perception of the industry. In addition to focusing on reputation management, firms in energy industries have other incentives to prioritize sustainability. Among them are compliance with a growing list of environmental regulations, pressure from shareholders and staff, and a desire to do what is suitable for the planet's future (Kaupke and zu Knyphausen-Aufseß, 2022). In detail, we focused our research on European energy sector listed companies. The extensive regulatory process the EU has begun to institutionalize ESG disclosure inside corporate reporting procedures served as the driving force behind the decision to concentrate on Europe (Baumüller and Sopp, 2022; Manes-Rossi and Nicol, 2022). The EU released Directive 95/2014 on October 22, 2014, as a component of the CSR strategy for 2011–2014. This directive established a "reporting cut-off point" between the European region and the other geographical contexts by imposing specific nonfinancial disclosure requirements on all public interest entities with more than 500 employees (EU, 2014). More recently, a proposal for a Corporate Sustainability Reporting Directive (EU Commission, 2021) was launched to expand the scope and reporting requirements of Directive 95/2014 and the new CSRD has been published in November 2022. At the same time, specific sustainability reporting standards have been under development by the European Financial Reporting Advisory Group (EFRAG) to increase the comparability and reliability of non-financial reports (Agostini et al., 2022). In particular, we investigate the relationship between ESG factors and financial performance, focusing on sustainability sensitive sector, namely the energy industry, where firms are exposed to higher social pressures and public concern. The data provided by these organizations can be considered reliable as they provide an independent evaluation and follow a rigorous process. We are conscious that the disagreement between ESG ratings is far larger than between credit ratings (Buallay, 2019) and that ESG ratings evaluated by different providers are not homogeneous (Berg et al., 2020). This could create confusion for investors (Halbritter and Dorfleitner, 2015) and scarce

comparability of information (Pacelli et al., 2022), mainly due to a divergence of measurement (Berg et al., 2022). In detail, the financial and sustainability data, i.e. ESG scores, will be collected from Refinitiv Eikon ASSET 4, a database widely used in the financial industry (Pacelli et al (2022); Demers et al. (2021); Landi et al. (2022). Refinitiv ESG, a significant provider of ESG ratings, is regarded as one of the meticulous and reliable providers of ESG data (Berg et al., 2021). In 2017, Thomson Reuters made significant changes in Asset4's rating process and rebranded Asset4 as 'Thomson Reuters Environmental, Social and Governance (ESG) scores. Although Asset4's methodology partially changed in 2017, its overall structure remains intact. This CSR database constructs its ratings at four levels: at the first level, there are a large number of data points; at the second level, the data points are combined into indicators; at the third level, these indicators are synthesised into different categories (e.g., 18 categories in 2014) and at the fourth level, the various categories are composed of few pillars. Before 2017, Asset4 comprised four pillars: (1) environmental pillar, (2) social pillar, (3) corporate governance pillar and (4) economic pillar. In 2017, the economic pillar was removed, leaving three pillars (the environmental pillar, social pillar and corporate governance pillar). A new pillar was introduced, namely, ESG Controversy, which comprises 23 controversy indicators. After 2017, the overall rating (i.e., ESG Score) is the equal weighted average of indicators of the environmental pillar, social pillar and corporate governance pillar (De Villiers et al., 2022). The Refinitiv ESG scores seem to be particularly suitable for our purpose thanks to their high informative power and widespread application in the financial industry. The data are shown in Table 1.

In our sample, we chose to concentrate on 2020 since Refinitiv restated their data in April 2020 in a way that made it historically more highly linked with returns (Berg et al., 2021). The final sample, constituted by energy European listed companies with all financial and ESG data available on Refinitiv, is made up of 50 companies. We have considered 50 DMUs, two input variables (Total Assets and

Total Equity), three output variables (EBITDA, Revenues and ESG scores). The credit exposure has been considered as 20% of the total debt of the company.

All the variables identified in the previous section have been extracted from Refinitiv Eikon ASSET 4.

## 5 Empirical results and discussion

In this section, the results and discussion are described. Various experiments were carried out in order to test the correlation between ESG and financial reliability, intended as either ratings or default probability. In particular, our results do not show the existence of a relationship between ESG scores and financial reliability. The correlation coefficient between efficiency values, calculated taking into account ESG scores, and credit ratings and PD, is around values very close to zero (0.0026 and 0.0725). This is in line with recent studies on the impact between ESG activities and corporate performance, which emphasize that an investment strategy linked to ESG factors does not significantly affect the profitability or value of the company in the energy sector (Adamkaite et al., 2022) or even found negative association between ESG performance and corporate financial performance in the oil and gas industry (Kaupke and zu Knyphausen-Aufseß, 2022). More generally, this trend line is also confirmed on other sectors, indeed Atan et al. (2018) conducting a panel study on Malaysian companies, not belonging to the energy sector, found no significant relationship between individual and combined factors of ESG and firm profitability (i.e., ROE) as well as firm value (i.e., Tobin's Q). Even in the utilities sector, the study by Veltri et al. (2023) does not find a significant relationship between ESGs and financial performance.

Table 2 shows the correlation coefficients, together with the ESG value for each DMU, and the efficiency results with and without ESG. As we can observe, for those companies with high ESG scores (ESG score > 80), the efficiency score remains the same whether ESG factors are considered, or they are excluded from the efficiency evaluation. Furthermore, on 10 companies in the sample with higher ESG scores and low efficiency, 8 of them are characterized by having higher debts than their peers, despite having similar equity values. This is expressive of an unbalanced financial structure, which could have been caused by an overinvestment in ESG, consistently with the overinvestment theory (Azmi et al., 2021; Di Tommaso and Thornton, 2020). For those companies with high ESG

scores (ESG score > 80) and good financial efficiency score, the combined efficiency score remains the same whatever the ESG factors are considered or are excluded from the efficiency score.

Table 2 – Efficiency scores with and without ESG

As it can be seen from Table 3, the model selects 10 out of 50 companies, which saturate the budget risk of the bank. They represent those companies for which the impact of the ESG score significantly improves the efficiency value calculated by taking into account only financial variables.

Among these 10 companies, 4 maintain high efficiency scores both with and without ESG, meaning that if a company is already financially efficient, the ESG does not impact on the overall efficiency. In addition, we can notice that the ESG score of the six remaining selected companies does not have a very high value, instead they record a moderate ESG value.

Our results do not provide evidence of a strong significance of ESG factors in affecting firms efficiency. In detail, our results, consistently with the findings of Xie et al. (2019), show that high/low ESG scores do not affect the company efficiency, which is the same with or without ESG scores; instead at a moderate level (going from 44.44 to 77.21, table 2), ESG scores improve the corporate efficiency. In other words, ESG factors have a positive effect on firm corporate efficiency only at medium level. In a similar vein, other studies highlighted a weak link between ESG and corporate performance/risk (Di Tommaso and Thornton, 2020). Theoretically speaking, our results are in line with the overinvestment theory, according to which ESG may have detracted from companies' value by diverting scarce resources out of investment. Also, they are also consistent with the *window dressing theory* (Palazzo and Richter, 2005), according to which investors may be

"deceived" by communication about a company's pursuit of ESG criteria that, in reality, is very different from what is communicated. This leads investors to perceive ESG companies as riskier (Landi et al., 2022).

## **6 Conclusions**

Within the banking sector, there is a growing awareness of the need to integrate ESG dimensions into strategies, processes, and financial instruments to generate long-term value, which is strongly influenced by non-financial factors, such as reputation, and stakeholder engagement, and customer value (Zumente et al., 2021). Financial institutions have recently started taking steps to cut back on funding for projects that hurt the environment after realizing how their lending and investing activities impact the condition of the world. By recognizing ESG principles and incorporating them into their strategies, banks can contribute to the development of a sustainable financial system. Our research intends to investigate whether the focus on ESG issues, embedded in loan management, has an impact on bank risk. In addressing this research question, we answer a call for a specific future direction identified by a recent bibliometric analysis of ESG performance in the banking industry (Galletta et al., 2022), namely "How will the ESG criteria enter the creditworthiness assessment process?". To the best of our knowledge, only the study of Brogi et al. (2022) posed our same research question, that is, if including ESG factors in the creditworthiness risk assessment mitigates the lending risk for the bank. Differently from theirs, we focus on a specific sector, as recent research provided evidence that it is not possible to assess a unique intensity and direction of the relationship between ESG and the firm performance/risk for all sectors (Pacelli et al., 2022). More specifically, we decided to focus on an environmental sensitive industry: the energy sector (i.e., oil and gas companies), as companies belonging to this industry are subjected to intense social and environmental scrutiny because of the nature of their activities (Galletta and Mazzù, 2022). In particular, focusing on the energy sector from a banking creditworthiness point of view seems important, as lending to extractive industries, such as oil, gas and mining, has always entailed significant operational, credit and political risks. Now climate change is exacerbating these risks – while adding reputational risk to the mix as banks face greater scrutiny of the environmental impact of their lending operations (BCBS, 2021).

Our results do not provide evidence of a strong significance of ESG factors in affecting firms' efficiency. Also, other empirical studies provided evidence of a weak link between ESG scores in energy sector and returns (Pacelli et al., 2022; Yoon et al., 2018). Our results, providing evidence that moderate ESG performance improves the overall firm performance, can incentivize firms management to increase ESG engagement (at least until a threshold point). In addition to the benefits for the firm, this incentive can lead to significant positive externalities to the environment in which the firm is embedded. As for the limits of our research, a first issue may be related to a sample selection bias because we only selected large listed firms operating in the Energy sector. We focus on large listed firms to rely on a high number of observations, as to the best of our knowledge, there is no accessible data warehouse containing ESG data. Further research can be conducted in other industrial settings, such as the SME environment. Another limit is related to the subjectivity of the variables selected to measure the firm performance, even if this has not to be considered as a big limitation considering that the DEA methodology is a "non-parametric" technique. Future research could be devoted to testing the robustness of our results by using different input and output measures and different budget risk levels for the constraint. Furthermore, given the consideration that ESG scores vary greatly from one rating agency to another (Widyawati, 2020), future research could compare different ESG scoring methods by using a data provider other than Refinitiv and could also conduct further analyses to identify the dominant sub-factor in the relation of ESG on financial performance/financial risk analyzing separately the impact of the three pillars of ESG (Giese et al., 2021; Xie et al., 2019). In addition, future research could consider changing the methodology employed to investigate the hypothesized association or to analyze the association from a point of view different from bank managers such as financial analyst (Luo and Wu, 2022), portfolio managers (Pacelli et al., 2022) rated firms (Clementino and Perkins (2021), investors (Kiesel and Lucke, 2019). In this paper, we used ESG data from Refinitiv, a key ESG rating provider and an influential one; nevertheless, given the concerns related to the widespread corporate practice of 'greenwashing', that is, the well-known phenomenon of disseminating information that is false or incomplete about environmental, social and governance factors (Pacelli et al., 2022), to increase the reliability of information, a future research direction could include ESG controversies in the model, as ESG controversies are not controlled by firms and, hence, represent an effective indicator to express the market

perception of firms real compliance with ESG criteria (Galletta and Mazzù, 2022). Another future research could be to analyze whether considering ESG as an additional criterion in selecting firms to fund is conditional on board of directors' characteristics (Di Tommaso and Thornton, 2020; Burke, 2022). We believe that the introduction in the credit risk assessment of ESG factors is an extremely important issue to investigate, as policy makers and regulators are posing the sustainable lending objective high in their agenda, and our results, adding new knowledge on the issue of the integration of ESG factors in the creditworthiness analysis of borrowers, offer suggestions regarding the inclusion of the ESG issue as a potential credit risk mitigation factor in the eyes of credit managers, investors and regulators. As for the policy implications, the consideration that the weak link between ESG scores and firm performance could be linked to an increasing amount of extra non-univocal financial information on the markets, such as sustainability reports or ESG ratings, poses a fundamental issue in terms of regulation. New and effective regulations for ESG reporting and metrics are needed to guarantee reliability to stakeholders, enabling the exploitation of this additional information without the social and greenwashing phenomena. Policy actions have to aim at making non-financial communications more transparent for investors and at providing companies with generalized and unambiguous indications for reporting on ESGs (La Torre et al. 2021).

As for the research implications, considering that ESG issues have not yet been studied sufficiently from a risk perspective, future research could focus on designing a new risk management framework for tackling ESG risks. Furthermore, future research could investigate the association between ESG merit and systemic risk (Bax et al., 2022).

### Abstract

Digital transformation is revolutionizing the healthcare industry, and the use of digital technologies is generating large amounts of data that can be used to support the healthcare decision-making process. The use of data leads to several improvements in healthcare, such as treatment selection or diagnosis process. The utilization of healthcare services is one of the prominent topics in healthcare, but it is still in its infancy in the digital transformation literature. This study aims to investigate the use of big data analytics to improve the utilization of healthcare services, specifically the Italian national cancer screening programs, through a two-step methodology. First, we investigate the relationship between patient characteristics and the utilization of the healthcare services

under consideration. In the second step, the collected data are used to build a data-driven model to identify patients who are more likely not to use healthcare services based on their characteristics. This study contributes to the existing literature on digital transformation in healthcare by proposing a data-driven model to improve healthcare service utilization. While we contribute to the practitioner perspective by proposing a real-world data-driven methodology that overcomes the disadvantages of the most common methods to identify patients that will not utilise healthcare services (i.e., survey-based methods).

## 1 Introduction

Digital transformation is shaping the future of organizations in many industries (Hanelt et al., 2021). Gong and Ribiere (2021) defined it as “a fundamental change process enabled by digital technologies that aim to bring radical improvement and innovation to an entity (e.g., an organization, a business network, an industry, or society) to create value for its stakeholders by strategically leveraging its key resources and capabilities”. The adoption and proper use of digital technologies have many positive impacts on organizations (Gaglio et al., 2022). These range from improved productivity and efficiency, through the automation of activities, to the creation of new business opportunities (Hanelt et al., 2021; Kraus, Jones, et al., 2021). Moreover, the adoption and use of digital technologies are opening up new ways to further improve the performance of organizations. In this regard, digital technologies generate a large amount of data that can be exploited to extract insightful information to support decisions in different domains (Aceto et al., 2020; Chen et al., 2012). One important trend of digital transformation is the increasing use of big data analytics to analyze large amounts of data and generate these insights (Ashaari et al., 2021; Wang et al., 2018). The major beneficiaries of this breakthrough are those industries characterized by highly complex decision-making processes with uncertain outcomes, certainly including the healthcare industry. The healthcare industry is characterized by highly complex and uncertain decisions, whose outcome is influenced by multiple and different variables and issues, such as the complexity of the patient’s disease and the involvement of various actors in the decision-making process, e.g., physicians, families, and patients (Han et al., 2019; Kraus, Schiavone, et al., 2021). As such, the

healthcare industry can gain great advantages from digital transformation and in particular through the use and exploitation of big data. In the academic literature, the use of big data analytics in healthcare has been widely investigated for delivering personalized care, supporting the diagnosis or treatment selection, identifying patients at risk of developing a disease and improving the use of resources (Galetsi & Katsaliaki, 2020; Kraus, Schiavone, et al., 2021). Despite the growing literature on the use of big data analytics to support decision-making in healthcare, it is clear that it has not yet reached its full potential and there is still room for further investigation (Galetsi & Katsaliaki, 2020). In this regard, the potentiality of big data analytics for improving the utilization of healthcare services is a promising topic (Dal Mas et al., 2023; Hu et al., 2021; LaVeist et al., 2009) and at the same time, it seems to be overlooked by the literature about digital transformation in healthcare. Underutilization of healthcare services refers to the unwillingness to use a healthcare service that has the potential to improve the patient's quantity and quality of life (Elshaug et al., 2017). The underutilization of healthcare services can be due to contingency factors, such as financial barriers, and the patient's characteristics, such as lack of knowledge, lack of awareness, and risk attitude (Glasziou et al.; 2017).

A pivotal example of the underutilization of healthcare services regards the screening programs aimed at preventing and detecting diseases at an early stage. Data on the screening programmes for breast, cervical, and colorectal cancer provided by the Italian national healthcare system (NHS) in the 2019 campaigns show that only 60.7%, 39.1%, and 41.6% respectively, of the target population, access to these services (ONS, 2020). Since the screening programs are free of charge for all the citizens who are in the at-risk age group, the patients' characteristics can be considered as a main explanatory factor of the underutilization of these healthcare services.

Therefore, healthcare policymakers need to take into account these characteristics to understand how a patient will act with respect to using a healthcare service and to develop strategies to lead the patient's behaviour towards optimal choices. However, acquiring information about these characteristics is a big challenge. In fact, it requires interviewing individuals through questionnaires, which makes this information difficult to be exploited as the process would be costly and time-consuming (Houston et al., 2021; Regmi et al., 2016). In this regard, digital transformation can support healthcare

policymakers by enabling the extraction of information about the patients' characteristics in real-time without any relevant additional costs.

Despite this topic seems promising to support healthcare policymakers, to the best of the authors' knowledge, the use of data to improve the utilization of healthcare services seems overlooked by academic literature. Pursued by this research gap, this study investigates how big data analytics could support policymakers in optimising the utilization of healthcare services. Consequently, this study seeks to answer the following research question:

*How can big data analytics support healthcare policymakers in increasing the utilization of healthcare services?*

Aiming to answer the research question we developed a methodology consisting of two steps. In the first step the relationship between patients' characteristics and utilization of healthcare services has been deeply investigated in the academic literature, and a survey has been developed and administered. In the second step, the data collected in the first step are used to build a big data analytics model to classify patient characteristics that lead to underutilization of healthcare resources. The remainder of this paper is structured as follows: section 2 describes the theoretical background. Section 3 presents the research design and the methodology. Section 4 presents the results, and section 5 discusses the results before concluding with limitations and future research avenues.

## **2 Theoretical background**

### ***2.1 Digital transformation and big data analytics in healthcare***

One of the main beneficiaries of digital transformation is the healthcare industry (Baudier et al., 2022; Kraus, Schiavone, et al., 2021). Technology concepts such as big data, the Internet of Things and cloud processing are driving this sector towards 'Healthcare 4.0' (Aceto et al., 2020). Wearable and portable devices, telemedicine and electronic health records are some of the most widely used technologies in healthcare (Marques & Ferreira, 2020). Digital technologies are characterized by their ability to generate and collect large amounts of data (i.e. big data) (Dal Mas et al., 2023; Kraus, Schiavone, et al., 2021). The availability of these data provides an opportunity to extract information and, if used correctly, provide decision support (Basile et al., 2023; Weerasinghe et al., 2022). The information is extracted through big data analytics (BDA). BDA refers to

technologies, processes, and methods that evaluate large amounts of data to help an organisation make more informed, critical decisions (Wang et al., 2018). Big data can come in different formats, for example, images or X-rays, structured datasets, and medical records, and to eventually get data analytics there are several algorithms and techniques to extract meaningful information (Chen et al., 2012; Dicuonzo et al., 2022; McAfee et al., 2012). Big data analytics can have an impact on several domains of healthcare. Disease surveillance is one of the domains addressed by the big data analytics literature. For example, BDA can be used to ensure a rapid reaction to disease outbreaks, for instance, to identify the need for new vaccines (Abdel-Basset et al., 2021; Baudier et al., 2022). Another prominent topic is the use of BDA in disease management. In this regard, BDA can support the physicians' decisions to identify patients at risk, and for diagnosis and treatment selection (Bukhari et al., 2021; Chi et al., 2022; Eletter et al., 2021). Moreover, the use of BDA has also proven successful in improving healthcare processes in terms of organizational performance by assessing resource efficiency, tracking workload, and reducing human error (Augustin et al., 2022; Demir, 2014; K. Zhu et al., 2015). Considering the utilization of healthcare services, the academic literature focused mainly on how to ensure basic healthcare services and the continuity of care by using data collected through telemedicine and wearable technologies (Cannavacciuolo et al., 2022; Khodadad-Saryazdi, 2021; Wu et al., 2016). Telemedicine allows patients to communicate with healthcare professionals remotely via videoconferencing or other digital platforms, while wearable and portable devices enable remote tools to monitor patient health data. However, the current focus seems to be on overcoming issues such as the inaccessibility of services by delivering services remotely through the use of digital technologies, rather than using big data analytics to increase the use of healthcare services (e.g., screening and prevention programmes). To the best of our knowledge, no work has proven whether the use of BDA to support healthcare policymakers' decision-making process can lead to an increase in the utilization of healthcare services. This paper aims at contributing to the academic literature about the use of big data analytics in healthcare by filling this gap.

## ***2.2 Utilization of healthcare services and risk attitude***

The main causes of underutilization of healthcare services can be outlined in inadequate access, healthcare system failures, physicians' decisions and

competencies in delivering care, and patient's behaviour (Glasziou et al., 2017). These aspects have been widely studied in the literature (Elshaug et al., 2017; Saini et al., 2017; Titaley et al., 2010). Among others, the patients' risk attitude (RA) is considered a key determinant of the decision-making process and a leading cause of patients' behaviour in healthcare (Lutter et al., 2019; Zhu et al., 2020). RA can be defined as the individual's characteristic that explains the willingness of people to prefer decisions with lower or higher risk, depending on whether they are risk-averse or risk-seeking, respectively (Weber, 2010). According to the scientific literature, RA may also change over time, for instance, as people ages, they may become more risk-averse (Massin et al., 2018; Prosser et al., 2002; Rosen et al., 2003). In this context, the information about an individual's RA could support the healthcare professionals' decision-making. For example, physicians could use the patients' RA to identify patients that need to be encouraged in treatment adherence (Zhu et al., 2020). Moreover, it is possible to inform healthcare policymakers to properly design vaccine campaigns considering patients' RA since risk-averse patients tend to avoid vaccination (Diza et al., 2022). In accordance with these results, Lutter et al. (2019) found that "risk-seeking" patients have lower odds of attending medical check-ups. The most used methods to measure RA are questionnaire-based: lotteries, assessment of hypothetical or actual behaviour and self-reports based on situational questions and rating scales (Lutter et al., 2019; Weber, 2010). These methods have several limitations including the administration and answer time, patients may not be interested in filling them out also due to their attributes (including RA), and finally considering the changing nature of RA in individuals the answer to a questionnaire may no longer be valid a short time later. In this paper, following the academic literature, we maintain that RA is a relevant patient characteristic that can inform healthcare policymakers about healthcare utilization. However, current measurement methods do not enable easy measurement of risk attitude and therefore its use. Despite the availability of data (e.g., electronic health records) and the spreading of big data analytics, academic literature did not explore the potential of big data analytics in improving the utilization of healthcare services through the use of patient characteristics (i.e., risk attitude).

### **3 Methodology**

In this research project, we investigated whether the use of information about the patient's risk attitude obtained through the use of big data analytics could support the healthcare policymakers' decision-making in increasing the utilization of healthcare services, and the research methodology is based on the Design Science Research Methodology (DSRM) (Peffer et al., 2007), since this methodology supports researchers in addressing both practice-driven and research-driven goals (Hevner et al., 2004). Moreover, this methodology support researchers to implement "artefacts" based on digital technologies to support healthcare decision-makers, e.g. to support physicians in treatment selection (Basile et al., 2021) and for disease assessment and monitoring (Casal-Guisande et al., 2020). The process of the DSRM consists of six steps (Peffer et al., 2007). The first step is devoted to the identification and definition of the problem. The second step includes the definition of the research's goals. The third step provides the design and development of the artefact. The fourth step is focused to demonstrate how the model can solve the problem identified in the first step. The last steps are the evaluation of the proposed solution and the communication of the objectives and performance reached by the proposed artefact.

#### ***3.1 Identification of the problem***

In the current era, technological and medical advancement is driving an increase in average life expectancy. The ageing of the world's population is increasing and it is bringing out more and more diseases related to genetics and lifestyles (WHO, 2022). In this context, cancer is the second leading cause of death, accounting for roughly 10 million deaths in 2020 (Ferlay et al., 2020), consequently, it represents a significant social and economic burden in all countries, reflecting premature mortality, morbidity and high healthcare expenditures. As the cost of cancer care increases, attempts to prevent and detect cancer at an early stage through screening programmes become more and more relevant (Abati et al., 2020; Xi & Xu, 2021). Despite their relevance, the screening programs are underutilized healthcare services (Baird, 2022; Nuche-Berenguer & Sakellariou, 2019). The underutilization can be determined by financial issues, lack of awareness and patients' behavioral characteristics (Glasziou et al., 2017). In this research project, we considered the screening programme for breast, cervical and colorectal cancer provided by the Italian national healthcare system (NHS) for

three reasons. Firstly, the Italian NHS provides these healthcare services free of charge for all the citizens who are in the at-risk age group (i.e., women that are 50-69 for breast cancer, women that are 25-64 for cervical cancer and women and men that are 50-69 for colorectal cancer), as a result in the Italian case the financial barrier to access healthcare services can be excluded from the causes of underutilization (ONS, 2020). Secondly, the Italian NHS has for many years been committed to campaigns to raise awareness of the importance of screening, so it is reasonable to assume that the lack of awareness among its citizens has diminished over the years. Third, despite the efforts of the Italian NHS, the utilization of these services is still low and has considerable room for improvement (ONS, 2020). Therefore, the case of the Italian NHS can provide the proper context to investigate whether the use of big data analytics to identify patients at risk of not participating in screening programs due to their behavioural characteristics (i.e., risk attitude) can support the policymakers' decision-making process leading to an improvement of the healthcare utilization.

### ***3.2 Definition of the objectives***

This study aims to investigate the use of big data analytics to improve the utilization of healthcare services, specifically the utilization of screening programmes in Italy. Therefore, firstly this study investigates the utilization of breast, cervical and colorectal cancer screening programmes and the role of patients' risk attitude in the use of these services. Secondly, we investigate the potential of big data analytics in informing policymakers and healthcare policymakers about the patient's risk attitude in order to enable data-driven decision-making to improve the utilization of healthcare services.

### ***3.3 Design and development of the artefact***

Aiming to answer the research question and achieve the research project's goal we designed and tested a decision support model following two steps. In the first step, we developed and administered a survey to investigate the relationship between patient characteristics and utilization of the healthcare services under consideration. In the second stage through a process of big data analytics, a model will be defined to predict the risk attitude of patients with respect to their

characteristics collected in the first step. This paper presents the results of the investigation of patient characteristics and utilization of healthcare services.

### **3.4 Demonstration**

The information collected through the survey will be used to build a model that compares the performance of screening programs in terms of costs and time savings in three scenarios: the real scenario (baseline), the scenario in which healthcare policymakers use the risk attitude information from the questionnaire (first scenario) and the scenario in which they use the risk attitude information extracted through the model. The demonstration of the effectiveness of the model will be carried out by means of Monte Carlo simulations under the three reference scenarios.

### **3.5 Evaluation and Communication**

The evaluation will be carried out by analysing the results of the proposed model in the three scenarios in terms of utilization of healthcare services utilization and costs. As for communication, the model will be implemented to be used in a real case. To this aim, a pilot project in a hospital would be carried out.

## **4 Results**

To collect information about patients and investigate the relationship between patients' risk attitude and screening programme utilization we developed a survey consisting of three sections. In the first section, the questions aim to assess the risk attitude of respondents through a self-assessment question and the DOSPERT scale (Blais and Weber, 2006). We selected these assessment methodologies because they are considered among the most reliable for the assessment of respondents' risk attitudes (Lutter et al., 2019). In particular, we considered only the health and general domains of the DOSPERT scale since the academic literature highlights the need to measure risk attitudes in the area where the decision-makers have to make the decision (Rosen et al., 2003; Weber, 2010). Considering the DOSPERT scale, the survey developed in this research project investigates the patient's risk attitude in two domains. The first is the general domain in which the respondents were asked general questions about their willingness to take risks in the situation as the betting of their salary in

different scenarios. The second is the health domain, where the respondents were asked to indicate their preference in engaging in risky activities for their health such as not carrying a helmet on a motorcycle or not using sunscreen when they are sunbathing. In the second section, the survey aims to collect respondents' personal information that are at the same time available in hospital electronic health records and which, according to the scientific literature, are related to risk attitudes. For instance, we collected data about their age, gender, height and general health status. Finally, in the third section, we investigated the current use of healthcare services and in particular of cancer screening programs under investigation. Table 1 shows the sections and questions of the survey.

Table 1 The survey

Section	Item	References		
<b>Risk Attitude</b>	In general, in the different domains of your daily life, where do you situate yourself between 0 and 7, where 0 means "not at all willing to take risks" and 7 means "fully prepared to take risks"?	Lutter et al., 2019		
	Admitting that your tastes are different from those of a friend.	DOSPERT (Blais and Weber, 2006)		
	Betting a day's income at the horse races.			
	Drinking heavily at a social function.			
	Disagreeing with an authority figure on a major issue.			
	Betting a day's income at a high-stakes poker game.			
	Betting a day's income on the outcome of a sporting event			
	Engaging in unprotected sex.			
	Driving a car without wearing a seat belt.			
	Riding a motorcycle without a helmet.			
	Sunbathing without sunscreen.			
	Walking home alone at night in an unsafe area of town.			
	<b>Respondents' Characteristics</b>		What is your age?	(Arrieta et al., 2017; Dohmen et al., 2011; Lutter et al., 2019; Massin et al., 2018; Prosser et al., 2002; Rosen et al., 2003; Weber, 2010; J. Zhu et al., 2020)
			What is your gender?	
How tall are you?				
How much do you weigh?				
What is your city of residence?				
Are you married?				
Are you divorced?				
Are you widowed?				
Do you have children?				
How many children do you have?				
How old is your youngest child?				
What is your educational qualification?				

	Are you a smoker?	
	What is your occupation?	
	How would you define your general health status?	
	Has one or more of the following diagnosed chronic conditions: [ALS (Lou Gehrig's disease); Alzheimer's disease or other dementias; Arthritis; Asthma; Cancer; Chronic obstructive pulmonary disease (COPD); Crohn's disease, ulcerative colitis or another inflammatory bowel disease; Cystic fibrosis; Diabetes; Eating disorders; Cardiovascular disease; Obesity; Osteoporosis]	
	Have you ever had surgery?	
	How long ago did you have the most recent surgery?	
	Are you taking any drug therapy (excluding dietary supplements)?	
<b>Healthcare services utilization</b>	When you had your last visit	Lutter et al., 2019; Dohmen et al., 2011
	When did you have your last checkup?	
	Have you ever participated in a screening program?	
	Have you ever participated in a breast cancer screening program?	
	Have you ever participated in a cervical cancer screening program?	
	Have you ever participated in a colorectal cancer screening program?	

## 5 Conclusion

Digital transformation is reshaping the activities in several industries, and healthcare is considered one of the most beneficiaries. The use of digital technologies produces several data that can be exploited to support the decision-making process in healthcare. In this regard, the underutilization of healthcare services is one of the most discussed topics in healthcare, and the academic literature point out several causes of underutilization. The patients' behaviour decision-making is considered one of the main causes and it can be caused by patients' characteristics (i.e., risk attitude). However, the use of data for the identification of patients who will not use healthcare services is an under-investigated topic in the literature on data-driven digital transformation. Therefore, this study examines the potential of data-driven decision-making in improving the utilization of healthcare services, and in particular, the Italian national cancer screening program, through a two-step methodology. In the first step, we investigated the relationship between risk attitude and patients' personal

information through a literature review and consequently, we developed a survey which was administered to potential users of the screening programme. While the second step concerns the development and testing of a data-driven model to identify patients who will not participate in the screening programme. This paper shows the results of the first step, by describing the survey developed. In this regard, the academic literature points out that there are several methods to measure the individual's risk attitude, but the self-assessment and the assessment of hypothetical or actual behaviour (i.e., DOSPERT scale) are considered the most reliable (Lutter et al., 2019; Massin et al., 2018). Moreover, we identified the patients' information that are related to the risk attitude according to the academic literature. The results presented in this paper contribute to both theory and practice. From a theoretical perspective, this paper contributes to the extant literature about data-driven decision-making in healthcare by proposing the use of big data analytics to improve the utilization of healthcare services. While we contribute to the practitioners' perspective by proposing a data-driven methodology to exploit the information about patients' risk attitudes that overcomes the disadvantages of the most common measurement methodologies that are survey-based. Despite the relevance and potential of this topic, researchers and practitioners must consider that patients' data privacy is of paramount importance. In the current years, artificial intelligence (AI) and machine learning open up several opportunities for automated decision-making that at the same time raised relevant concerns about the use of these tools. Therefore, it is crucial to develop ethical guidelines and regulations that ensure the responsible use of AI and machine learning in healthcare, protecting patients' privacy while harnessing the benefits of these technologies. Additionally, educating healthcare professionals and patients about the implications of AI and machine learning in healthcare can foster a better understanding of these tools' potential and limitations. Though, in this paper, we did not propose a model for automated decision-making but only data-driven tools to support healthcare policymakers' decision-making. Thus, since we maintain a human direct intervention in the decision-making process the issues related to automated decision-making are not a primary concern of this study. Despite this, in accordance with Art. 22 of the General Data Protection Regulation (GDPR) (art. 22 GDPR, 2018), the proposed model could only be used for patients who have authorized healthcare organizations to use their personal information.

### **Abstract**

This paper is intended as a contribution to the ongoing conceptual development of the role of organizations in fostering innovation, and in promoting, at the same time, sustainability. In particular, Sustainability-oriented innovation (SOI) involves making intentional changes to an organization's philosophy and values, in terms of "openness", which consider commercial viability, while simultaneously improving environmental and/or social performance. However, although it is evident how essential it is to ensure a SOI within organizations, little attention has been paid to bridging between open innovation (OI) and sustainability, with particular references to the key drivers enabling such valuable processes within organizations. Starting from these considerations, the main purpose of

this paper is to contribute to the recent debate on the new intersection between innovation and sustainability within organizations. The paper, focusing on Enel case study and through a website content analysis, sheds light on the drivers related to the concept of "open innovability". The study offers several useful implications for both researchers and professionals operating in the sustainable innovation field, highlighting how OI could support the organization in the creation and transmission of sustainability solutions and objectives.

**Keywords** – open innovation, sustainability, sustainability-oriented innovation, content analysis.

**Paper type** – Academic Research Paper

## 1 Introduction

As a result of globalization, technological complexity, increased competition and resource scarcity, organizations have had to adopt a more open, cooperative approach to building their competitive advantage (Barrett et al., 2021). The concept of Open Innovation (OI) has thus enjoyed increasing popularity in the recent scientific literature (Zhang et al., 2023).

However, its potential carried toward developing strategies and policies to solve complex sustainability issues has yet to be fully exploited (Kimpimäki et al., 2022).

Specifically, the literature on OI concerns knowledge transfer between the organization and third parties to support innovation activities (Chesbrough, 2003, 2006). On the other hand, the literature on sustainability suggests that companies should integrate mechanisms to serve the specific purpose of creating and realizing social and environmental value in addition to economic returns (González-Ramos et al., 2023).

In this direction, Sustainability-oriented innovation (SOI) (Adams et al., 2016; Rauter et al., 2017, 2019; Roszkowska-Menkes, 2018; Bogers et al., 2020; Melane-Lavado and Alvarez-Herranz, 2020; Gyamfi and Sein, 2021) involves making intentional changes to an organization's philosophy and values, which improve environmental and/or social performance while simultaneously considering commercial viability. The OI mindset (Engelsberger et al., 2022), conceptualised as a set of values, attitudes, and beliefs that capture an individual's openness towards knowledge sourcing and sharing inside and outside organisational boundaries, is critical for organisations engaging in OI practices. However,

although it is evident how essential it is to ensure a SOI within organizations, little attention has been paid to bridging between OI and sustainability, with particular references to the key drivers enabling such valuable processes within organizations.

Starting from these considerations, the main purpose of this paper is to contribute to the recent debate on the new intersection between innovation and sustainability within organizations. In particular, the work aims to identify important issues in supporting innovation processes and in creating better conditions to properly reach sustainability conditions. In particular, the study's originality lies in the attempt to bring out the conditions under which OI can lead to sustainability.

To meet this aim, this study is based on a qualitative investigation approach that follows the website content analysis (Hasim et al., 2018) of a valuable Italian multinational energy company and a leading global integrated operator in the electricity and gas sectors, shedding light on the drivers related to the concept of "open innovability". As a consequence, the study proposes new ideas regarding SOI, investigating how the proactiveness of some OI processes affects organizations' SOI.

The paper is structured as follows: Section 2 focuses on a literature review on OI and SOI. Section 3 illustrates the methodology used for the study. Section 4 provides the results and the discussion of the analysis. Finally, section 5 sets out conclusions, implications, limitations of the study, and future research agenda.

## **2 Literature review**

### ***2.1 Open Innovation***

In a turbulent, hypercompetitive, and difficult to predict environment, such as the one we have been experiencing for years now, organizations have to face complex challenges in terms of coherent adaptation to the context in which they are embedded (Barrett et al., 2021). New paradigms, such as that of OI (Chesbrough, 2003, 2020; Chesbrough and Appleyard, 2007; Elmquist et al., 2009), could support organizations in the necessary change and improvement of their business models and practices and in the definition of successful strategic paths (Zhu et al., 2019). OI refers to "a distributed innovation process based on purposively managed knowledge flows across organizational boundaries, using

pecuniary and non-pecuniary mechanisms in line with the organization's business model." (Chesbrough and Bogers, 2014, p. 17), thus describing how firms innovate by interacting with other organizations.

Specifically, Chesbrough (2003), in defining for the first time OI, stated that "valuable ideas can come from inside or outside the company and can go to market from inside to outside the company as well" (Chesbrough, 2003, p. 43; Chesbrough and Bogers, 2014), referring to the collaboration between the organization and third parties in the development of innovative products and services and in the sharing of risks and benefits of research, construction, implementation, and commercialization of new ideas (Chesbrough, 2003, 2006; Gatzweiler et al., 2017). This transition from a closed innovation to an OI paradigm - through inbound, outbound, and coupled processes (Gassmann et al., 2010) - could allow for mutual benefits; on the one hand, the organization can increase profitability through the pursuit of differentiation strategies, and the reduction of time-to-market, and, on the other hand, the external subjects involved can broaden their perspectives and seize new growth opportunities (Enkel et al., 2009).

Furthermore, closely connected to the concept of OI is the phenomenon of platformization - platforms as intermediaries for organizing processes of value creation and OI (Gawer and Cusumano, 2002, 2008; Gaver, 2014; Parker et al., 2016; Hagiū and Altman, 2017) - which has contributed to foster an increasingly interconnected environment, creating a system of relationships and collaborations between the organization and the outside that allows to exchange and/or share knowledge and skills in order to develop innovation and to solve OI challenges (Abbate et al., 2019, 2021).

The platforms, through the so-called "network effects" (Boudreau and Jeppesen, 2015), represent the genesis of real organizational ecosystem, a space created for co-evolution and strategic cooperation between parties, maximizing the capacity for knowledge exploration and exploitation (Dahlander and Gann, 2010; Huizingh, 2011).

## **2.2 Sustainability-Oriented Innovation**

Recent developments in the sustainability domain, in the broader scope of the wider "triple bottom line" of economic prosperity, environmental protection, and social equity (Elkington, 1998, 2013) and in line with the Sustainable Development

Goals (SDGs) (Sadiq et al., 2023), suggest that companies should be open to mechanisms that can improve their innovation activities and capabilities, fully understanding how these practices connect to corporate strategy and socio-ecological system needs (González-Ramos et al., 2023). Some scholars have emphasized putting sustainability at the core of an organization's value creation activities (Ennals, 2010) and thus processes (Huber, 2008), reorganization of an organization's routines and structures (Rennings et al., 2006), and products and services (Hart, 1997; Maxwell and Van der Vorst, 2003; Albloushi et al., 2023). Consequently, innovation is perceived to play a key role in the area of corporate sustainability (Hart and Milstein, 2003; Zhou et al., 2020; Bahta, et al., 2021; de Oliveira et al., 2023) and SOI activities are increasingly acknowledged (Hockerts and Wüstenhagen, 2010; Hansen and Grosse-Dunker, 2012; Adams et al., 2016).

As Klewitz and Hansen (2014) have argued, "SOI describes a 'direction', which to follow requires the deliberate management of economic, social, and ecological aspects so that they become integrated into the design of new products, processes, and organizational structures" (p.57).

In particular, SOI (Adams et al., 2016; Rauter et al., 2017, 2019; Roszkowska-Menkes, 2018; Bogers et al., 2020; Melane-Lavado and Alvarez-Herranz, 2020; Gyamfi and Sein, 2021) envisages -through operational optimization, organizational transformation and systems building- merging OI practices with the sustainability concept (Arcese et al., 2015; Allal-Chérif et al., 2023), thus creating more sustainable production methods, market structures, and consumption patterns (Schaltegger and Wagner, 2011).

If an OI mindset was already critical for organizations engaging in OI practices (Engelsberger et al., 2022), it becomes even more central in SOI domain (Little et al., 2023).

Therefore, SOI practices require openness (van Oostrom and Fernandez-Esquinas, 2017), positive attitudes towards knowledge sharing and sourcing (von Briel and Recker, 2017), creativity (De Brentani, 2001), risk and failure tolerance (Mortara et al., 2010), as well as integrative complexity (Tadmor and Tetlock, 2006), on the part of the individuals involved, while respecting the organizational constraints and aligning with organization's business model (Ahn et al., 2017; Bogers et al., 2018; Rangus and Černe, 2019).

In this direction, OI and sustainability intertwine, developing a broader ecosystem (Du et al., 2014), so as to allow the exploitation and leverage of

complementary expertise and formulate a holistic solution that could have a long-lasting impact (Costa and Matias, 2020; Zhang et al., 2023).

### **3 Methodology**

With the aim to contribute to the recent debate on the intersection between innovation and sustainability within organizations, this work performed the website analysis to gather information concerning the conditions under which OI can lead to sustainability. In the last 20 years, although relevant organizational information is usually communicated to stakeholders via annual reports, brochures, and newsletters, because of the increasingly widespread and pervasive use of Information and Communication Technologies (ICTs) and common acceptance of the internet as an 'organizational' tool for communication (Stevens et al., 2000), the website has been generally recognized as an organizational digital space useful to post relevant information (Adams and Frost, 2006). The increasing impact of digitalization has led to the richness of information on websites, also considered a useful tool for communicating organizational responsibilities. Zuo et al. (2012), in a study of 50 international contractors, found that almost 80% of the companies revealed their sustainability policies through their websites. In general, websites are often used to publicize information relating to organizational matters (Cober et al., 2003), sustainability practices (Da Giau et al., 2016;), as well information about innovative business processes (Wei, 2012). Therefore, this study follows a web content analysis as a legitimate research tool for indagating organizations' SOI, looking for the drivers closely related to OI and sustainability.

The content analysis explores the correlation between texts and possible themes or concepts (Jose and Lee, 2007) and it is most appropriate and well-accepted in social and environmental research (Nejati et al., 2011).

The case selected for this study is Enel, an Italian multinational manufacturer and distributor of electricity and gas. This company has been selected due to its huge impact on the global business landscape: in 2018, Enel has been recognized as the second largest power company in the world by revenue after the State Grid Corporation of China (IISole24ore, 2022) and, during the 2021, it was the 73rd largest company in the world by revenue, with €88 billion (PowerTechnology, 2019). In particular, this sector has been selected, besides the strong environmental impact, because the literature highlighted the relevance of the

electricity and gas companies' websites for sharing information relating to sustainability practices (Insch, 2008). In particular, considering the strong relevance related to the research topic, we have selected and analysed Enel's website related to Open Innovability ® (<https://openinnovability.enel.com>), looking for the drivers of the latter.

The website has been manually reviewed. In particular, this technique was carried out by utilizing publicly available data, including any additional accessible relevant documents attached to the website. The analysis of the website considered the contents posted within the specific timeframe of 1 June to 1 December 2022, and it was conducted by typing specific words (Sustainability, Environment, Green, Innovation, Innovability) – the most commonly used descriptors on websites by organizations showing commitment to innovation and sustainability (Hasim et al., 2018) - to find target themes and key drivers related to the SOI.

In particular, as depicted in Figure 1, the flowchart for the content analysis of the selected website has been defined (Hasim et al., 2018). The detailed procedure was as follows:

1. The information was read numerous times, and relevant data sets were identified. These data sets were copied and pasted to the tables in a document. A detailed reading was carried out, and initial thoughts on SOI were noted in the specific column;
2. The relevant data were read again, and the initial notes were transformed into final themes and drivers that were significant and relevant to the research aim and objectives. Any unsuitable and unclear initial notes were excluded;
3. The data were read again for refinement of the themes into definite headings based on common practices and drivers related to SOI. For the purpose of this research, only the most common themes relevant to the research objectives were identified and chosen.

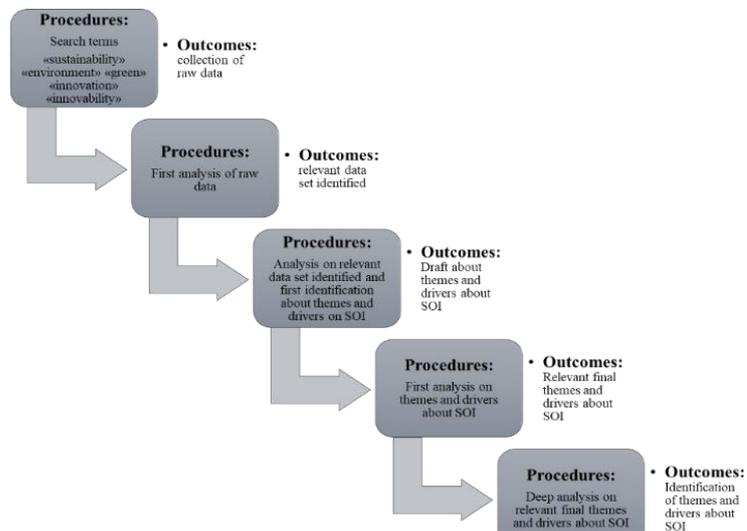

Figure 1 - Flowchart for content analysis on the website

#### 4 Results and discussion

Enel Open Innovability<sup>®</sup> can be described according to its definition, main activities, value proposition, methodology, partnership and collaboration, technological priorities, and relation to sustainable development goals (Table 1).

Table 1 - Enel Open Innovability<sup>®</sup>: definition and characteristics

Enel Open Innovability <sup>®</sup>	
<b>Definition</b>	Enel Open Innovability <sup>®</sup> team, connected to the Enel group, is aimed to seek new business opportunities and is connected to the local ecosystem to identify the brightest solutions.
<b>Activities</b>	The activities are aimed to connect both digitally and physically with the ecosystem to build new solutions that address the world's most pressing and complex challenges.
<b>Value proposition</b>	The value proposition is based on leading energy transition through open collaboration with start-ups, SMEs, large companies, academics, internal and external experts, and investors.
<b>Methodology</b>	The methodology is based on the connection between OI and sustainability, which consists of crowdsourcing the best talent, ideas, and technologies to scale them up into disruptive business models.
<b>Partnership and collaboration</b>	The partners are: <ul style="list-style-type: none"> <li>• Crowdsourcing partners (e.g. Wazoku, Agorize, Innovitalia, Desall);</li> <li>• Start-up ecosystem (e.g. Greentown Labs, Ecosummit, InnoEnergy, InnovUp);</li> <li>• Universities (e.g. Bocconi University, Venice International</li> </ul>

	University, Polytechnic University of Turin, Columbia Climate School); <ul style="list-style-type: none"> <li>• Corporate &amp; international institutions (e.g. 3M, Novamont, Microsoft, Cisco, Intesa San Paolo Innovation Center);</li> <li>• Sustainability related actors (e.g. Human Foundation, Ashoka, Liter of Light).</li> </ul>
<b>Technological priorities</b>	The technological priorities regard: <ul style="list-style-type: none"> <li>• Energy storage;</li> <li>• Renewable technologies;</li> <li>• Smart grids;</li> <li>• Electric mobility;</li> <li>• Smart cities;</li> <li>• Smart home;</li> <li>• Smart industry;</li> <li>• Predictive maintenance;</li> <li>• Digitalization;</li> <li>• Autonomous world;</li> <li>• Safety;</li> <li>• Financial services.</li> </ul>
<b>Relation to SDGs</b>	Enel's aims and scope are related to the following SDGs: <ul style="list-style-type: none"> <li>• SDG 13: Climate action;</li> <li>• SDG 7: Affordable and clean energy;</li> <li>• SDG 9: Industry, innovation, and infrastructure;</li> <li>• SDG 11: Sustainable cities and communities.</li> </ul>

Source: Authors' elaboration from [openinnovability.enel.com](http://openinnovability.enel.com)

Following the analysis, a set of 4 key drivers related to the SOI was identified to represent initiatives of OI towards sustainability. These drivers – Digital platform for crowdsourcing (through owned content and content from third parties), Physical Hubs & Labs, Projects in line with the SDGs, and Dissemination (enabling technologies) - were compiled based on the website's information. The identified drivers, as shown in Table 2, bring out the importance of innovation ecosystem concept as a catalyst for sustainability (Granstrand and Holgersson, 2020).

Table 2 depicts the key drivers emerged, descriptions, and examples of related initiatives.

The first driver is related to the huge potentiality of the digital platform for crowdsourcing, in terms of predisposition (and the possibility of a proposal) of innovative sustainability-oriented challenges. Indeed, Enel, through such initiatives based on great flexibility and ability to adapt to different development timelines for various technologies, has taken part in more than 500 collaborations over the past 6 years. These collaborations are characterized by timelines and investments according to the specific time and resources needed depending on the technology and the needs of the start-up. Furthermore, Open Innovability ®

is able to attract people around the world to come together and share innovative ideas about how the solution of complex problems related to the energy sector. Crowdsourcing platform Open Innovability® has been able to reach a community of 500 thousand "active solvers" from more than 100 countries, who have proposed more than 7 thousand solutions.

On the other side, Open Innovability® has developed innovative hubs and labs to bring together researchers, creators, and innovators to nurture ideas into industry-changing products and services as well as create a direct contact with specific geographic areas.

Open Innovability® is committed to several projects related to the SDGs, focusing not only to the environmental sustainability challenges – through the research regarding innovative technologies – but also by addressing social sustainability questions through entrepreneurial and building cognitive/relational intercultural capabilities courses.

Finally, in order to thrive the sustainable innovation, Open Innovability® is actively committed to the dissemination of success stories with the aim to enhance the visibility, comprehension, and implementation of SOI initiatives, highlighting the importance of the use of key digital technologies, such as Artificial Intelligence (AI), Internet of Things (IoT), and robotics, in a sustainability management context (Schöggl et al., 2023).

Table 2 – Enel’s key drivers related to the SOI

SOI’s Key drivers	Description	Examples
<p><b>Digital platform for crowdsourcing</b></p>	<p><b>1) Owned content (Inducement prize contests)</b> Open Innovability® is committed to the launch of sustainability challenges in order to find innovative solutions worldwide by setting a reward in euros or funding activities.</p> <p><b>2) Content from third parties</b> Open Innovability® leverages a digital platform for crowdsourcing where small businesses and entrepreneurs can request a collective creation process to solve their</p>	<ul style="list-style-type: none"> <li>• <i>The PITCHH challenges – Open Innovation opportunities</i>: promotes collaboration between big corporations, SMEs and startups, technology centers, and other for increasing the competitiveness of European industry (reward: up to 10,000 euros)</li> <li>• <i>Sustainable Synergies: Interconnected Systems for Positive Impact</i> aims to promote the operational and commercial roll-out of services addressing interconnected systems for positive impact (funding up to 200,000 euros)</li> <li>• <a href="https://openinnovability.enel.com">Openinnovability.enel.com</a>: platform open to third parties to propose</li> </ul>

	complex problems.	their challenges
<b>Physical Hubs &amp; Labs</b>	Open Innovability® develops innovative hubs and labs intended as physical space that brings together researchers, creators, and innovators to nurture ideas into industry-changing products and services. The new technological solutions and business models are scaled up internationally, making full use of Enel's global network.	<ul style="list-style-type: none"> <li>• Bari (Italy): Lab focused on low voltage smart grid and sensors</li> <li>• Barcelona (Spain): Living Lab focused on the network digital twin technologies and HV/MV grid technologies</li> </ul>
<b>Projects in line with the SDGs</b>	Open Innovability® is committed to several projects within the scopes of Sustainable Development Goals, such as: <ul style="list-style-type: none"> <li>• Net-Zero ambition</li> <li>• Electrification</li> <li>• People</li> <li>• Environment</li> <li>• Growth accelerators</li> <li>• Pillars</li> </ul>	<ul style="list-style-type: none"> <li>• Futur-E Teruel: seeks to breathe new life into thermal power plants</li> <li>• "Programa de recambio": aims to replace wood-burning stoves with electric air-conditioning systems</li> <li>• WIRED Connecting intercultural skills: an awareness building course on cognitive/relational dynamics from intercultural perspective</li> <li>• Supplier program: aims to support the growth path of companies</li> </ul>
<b>Dissemination (enabling technologies)</b>	Open Innovability® is committed to the dissemination of success stories that demonstrate how an action, intervention, or process triggered innovation in reference to sustainable development.	<ul style="list-style-type: none"> <li>• Enel and Myst AI – Optimizing energy forecast.</li> <li>• Enel and Alesea: IoT technology for supply chain optimization</li> <li>• Aeronex &amp; Enel Green Power advance wind energy thanks to robotics</li> </ul>

## 5 Final implications and conclusion

The findings highlighted the potential related to the concept of "Open Innovability", consisting of crowdsourcing the best talent, ideas, and technologies to scale them up into disruptive as well sustainable business models. In order to reach this goal, the ecosystem is crucial to, from one hand, attract new ideas and talent with different skills or thoughts from all over the world, and, from another hand, offer access to a global network and resources in order to thrive the sustainable innovation progress and improve the portfolio of products and services. The open collaboration with start-ups, SMEs, large companies,

academics, internal and external experts, and investors, makes possible to identify the brightest innovative solutions and drive sustainable development. This is in line with the literature which has previously emphasised that SOI practices require openness (van Oostrom and Fernandez-Esquinas, 2017), positive attitudes towards knowledge sharing and sourcing (von Briel and Recker, 2017), and creativity (De Brentani, 2001).

OI and sustainability intertwine, fostering and being in turn fuelled by a network of multi-layer relationships through which relevant knowledge and creativity flow through a framework of sustained shared value (Du et al, 2014), thus allowing to achieve long-term competitive advantage (Costa and Matias, 2020; Zhang et al., 2023).

In particular, SOI is related to the use of digital platforms as an effective way to "outsource work to the crowd" (Howe, 2006), in order to crowdsource thoughts, ideas and solutions of innovative sustainability-oriented challenges, which should be characterized by great flexibility in terms of funding policies and timeline according to the specific technology and needs of innovators. In addition, the results highlight that the adequate combination of physical and digital environments can attract people from all around the world as well as create connections in the territory with the aim to share innovative ideas and find different solutions related to several sectors. Moreover, SOI includes several projects related to the SDGs, showing organizational commitment to sustainable progress, and emphasizes the key role of major enabling technologies of digital transformation in successful SOI initiatives, pointing to relevant synergies and spillover effects (Schöggel et al., 2023).

The implications of the paper are both theoretical and practical.

From a theoretical point of view, the study contributes to the existing literature on SOI, particularly in the sector of energy, identifying key drivers - Digital platform for crowdsourcing (through owned content and content from third parties), Physical Hubs & Labs, Projects in line with the SDGs, and Dissemination (enabling technologies) - which allow representing OI initiatives towards sustainability.

Furthermore, this analysis may provide practitioners and policymakers with how OI could support organizations in creating and conveying sustainability objectives. Specifically, it is expected that the SOI practices need to be nurtured by policies in order to enhance OI-based ecosystems (Granstrand and Holgersson, 2020).

With reference to managerial implications, the evidence provided by this case study allows us the emerging considerations of an analysis perspective that looks at organizational “openness” as a critical success factor for both innovation and sustainability solutions. Indeed, the implementation of SOI practices is based on the activation and involvement of the relational component in the innovation process.

Specifically, the three main macro-activities of the innovation process -input, throughput, and output (Vermeulen et al., 2003) – should be connected to each other by moments of feedback and cooperation, coming from third parties, who with their contribution offer important suggestions not only to define increasingly successful products and services, but new inputs to trigger the SOI practices, thus representing an important channel for obtaining facilitated access to resources, such as information, technologies, and new knowledge (Du et al, 2014).

Finally, it is possible to highlight the main limitation of the paper, in particular, related to the methodological approach adopted. In fact, the focus on website content analysis of a single case study certainly provided a holistic account but of a specific, unique, and bounded system (Denzin and Lincoln, 2008).

Therefore, future research intends to include several cases to further investigate organizations’ SOI practices (Stake, 2013). The contents analysed could thus be more reliable, giving greater rigor to the study of the observed phenomenon (Gustafsson, 2017).

Furthermore, it could be considered to conduct in-depth interviews to explore the point of view of the organization's managers and representatives, in order to provide much more detailed information on the topic (Boyce and Neale, 2006).

### Abstract

Knowledge workers are central actors for organizational performance and also widely in societies. Specifically, they are central sources, producers and orchestrators of knowledge, in which work creativity plays an important role. The goal of this paper is to shed light on determinants of knowledge worker creativity. We investigate resilience and self-efficacy as predictors of knowledge worker creativity by suggesting that effect of resilience is both direct and indirect, that is self-efficacy works as a partial mediator between knowledge worker resilience and creativity. We collected data from 419 knowledge workers in Finland to test the research model. The model was tested using partial least squares structural equation modelling (PLS-SEM). The findings supported our hypotheses. This study contributes to research on knowledge worker creativity and individual resilience in organizations.

**Keywords** – Resilience, Self-efficacy, Creativity, Knowledge worker

## 1 Introduction

Knowledge workers (KWs) are central actors for organizational performance and wider (Edgar et al., 2015; Seth & Lee, 2017). In organizations, the KWs are both processors of knowledge and organizers of their work, as they perform autonomous, complex and knowledge-based tasks (Davenport et al., 2002; Jacobs, 2017; Kelloway & Barling, 2000), such as constant problem solving and knowledge creation. In addition, knowledge work as a profession (Kelloway and Barling, 2000) can be seen as a creative work, as knowledge workers use their knowledge and competences to construct their work in unique (creative) ways (Anand et al., 2002; Södergren, 2002), that is, knowledge work is based on KW's personal dispositions and knowledge.

While much of research have investigated employee creativity (e.g., Tierney and Farmer, 2002; Amabile, 1983; Liu et al., 2016) in organizations, KW creativity has received less attention. The theory of individual creativity (Amabile, 1983; Csikszentmihalyi, 1996; Liu et al., 2016) and social cognitive theory (SCT) (Bandura, 1989) suggest that an individual's behaviour is influenced by intra-individual psychological factors as well as contextual factors. Of the individual factors, motivations (Liu et al., 2016) and creative self-efficacy (Tierney et al., 2002) are most studied determinants of creativity. However, in knowledge work, the motivational aspects, such as high autonomy, need for self-realization and competence, are essentially inherent in the characteristic of knowledge work, and therefore there is need to shed light on other than motivational factors of KW creativity. In this regard, individual's personal resources (excluding creative self-efficacy, which is studied as a motivational factor (Liu et al. 2016) have received less scholarly attention, although their role is central for creativity in a work that essentially involves high degree of autonomy (enabling determinant of creativity).

In this study we investigate resilience and general self-efficacy (GSE) as determinants of KW creativity. In contexts other than knowledge work, we find that resilient individuals are open to novelty, able to improvise in situations of uncertainty and change (e.g., Youssef & Luthans, 2007), and they are also able to turn negative emotional experiences into positive ones (Youssef & Luthans, 2007; Fredrickson, 2011). As creativity, that is, ability to generate novel ideas requires to accept the ambiguities and uncertainties of such a creative process (Csikszentmihalyi, 1996), the concept of resilience is an appropriate research target to shed light on intra-individual antecedents of creativity. In addition,

resilience is one component of the concept of personal resources (Luthans et al., 2007) and psychological capital (Luthans & Youssef, 2007). It is found to contribute to individuals' work engagement (Hodges, 2010), work performance (Luthans et al., 2007; Luthans et al., 2005), organizational effectiveness (Bustinza et al., 2019), well-being at work (Luthans & Youssef, 2007), satisfaction in work (Badran & Youssef-Morgan, 2015), career (Lyons et al., 2015), and openness to change (Malik & Garg, 2017; Wanberg & Banas, 2000). As a personal resource, resilience refers to an individual's capacity to master their personal growth (Bakker & Demerouti, 2014; Xanthopoulou et al., 2009) and to adapt to or master their environment (Hobfoll et al., 2003), a capacity that is crucial in complex and challenging knowledge work (Sonnenfeld, 2002). We therefore ask: *What is the relationship between knowledge worker creativity and resilience?*

To address the above research gaps, we conducted a quantitative study with the data collected from organizational knowledge workers (N=419) by using partial least squares analysis (SEM PLS; Ringle et al., 2015) and related procedures.

## **2 Theoretical frameworks**

We build on research on individual creativity (Amabile, 1983, Liu et al., 2016, Shalley, Gilson and Blum, 2009), personal resources (Luthans et al., 2007) and psychological capital (Luthans, 2002; Luthans & Youssef, 2004).

### *Knowledge worker Creativity*

Creativity is an individual's ability to generate novel ideas (Amabile, 1983) and to pursue novelty in a variety of situations, problems, and contexts (Csikszentmihalyi, 1992, 1996; Tierney, et al., 1999). In motivation theories, creativity reflects an individual's highest psychological needs, self-realisation, and personal fulfilment (Deci and Ryan, 1985; Maslow, 1987). Scholars acknowledge that creativity is central in knowledge work (Alvesson, 2004; Starbuck, 1992) and knowledge-intensive careers (Anand et al., 2002; Sodergren, 2002). In fact, knowledge work can be seen as creative work in the sense that it consists of constant problem solving, orchestration of knowledge, and knowledge creation, that is, producing novelty for performance (Davenport et al., 2002; Dul et al., 2011). Further, knowledge work as a profession (Kelloway & Barling, 2000) or career requires creativity, as it is based on individual's knowledge and is constructed in original (creative) ways (Anand et al., 2002; Södergren, 2002), that

is, it is based on individuals' personal dispositions, knowledge and life aspirations. For knowledge workers, creativity is an important source of personal satisfaction as it constitutes the satisfaction of self-realisation and meaningfulness of work (Martela & Pessi, 2019).

#### *Knowledge worker resilience*

Scholars have investigated individual resilience as adaptive coping (Sinclair and Wallston, 2004), personal resource (Luthans et al., 2007) and psychological capital (Luthans, 2002; Luthans & Youssef, 2004). Sinclair and Wallston (2004) suggest that resilient coping behaviour refers to an individual's ability to employ their cognitive skills in a flexible and effective ways for active problem solving despite adverse circumstances. The resilient coping involves reliance on one's dispositional resources and it is likely to foster positive adaptation in the face of adversity. Further, Sinclair and Wallston, (2004) claim that individual's coping experiences develop their dispositional traits, such as self-efficacy, and thereby an individual's willingness to engage actively to various adverse situations, such as complex problem solving, increases (Kumpfer, 1999). Thus, individuals with resilient coping are willing to engage in creative and adaptive problem solving and wide variety of adverse situations (Sinclair and Wallston, 2004).

#### *General self-efficacy*

In contrast to the domain specific creative self-efficacy (Tierney and Farmer, 2002), general self-efficacy (GSE) refers to an individual's confidence to perform successfully across a variety of different situations (Eden, 1988; Judge, Erez aet al, 1998; Chen, Gully and Eden, 2001). Thus, GSE is seen as a motivational trait (Chen et al., 2001), which develops over one's life span with accumulated experiences of success and failures across various task domains (Chen et. al., 2001). Thus, GSE can act as an effective shield against adverse events and circumstances (Chen et al., 2001, Eden, 1988). As a part of personal resources, GSE also corresponds with intrinsic motivation to pursue goals (Bakker & Demerouti, 2008).

To sum, knowledge workers' creativity refers to their discretionary behaviour, need for self-realisation, and desire to satisfy personal psychological needs and life aspirations. Knowledge worker resilience refers to their persistence to cope with adversity to satisfy these psychological needs and life aspirations as well as the adversity caused by creativity itself, whereas self-efficacy refers to their belief and competence to perform in a wide variety of circumstances.

### *Hypotheses development*

Given the positive work-related outcomes to which resilience is found to contribute (Hodges, 2010; Luthans et al., 2007; Luthans et al., 2005; Luthans & Youssef, 2007; Badran & Youssef-Morgan, 2015; Malik & Garg, 2017; Wanberg & Banas, 2000), we suggest that resilience contributes to knowledge workers' creativity. Sonnenfeld (2000) suggested that resilience is important in mastering adversities in creative careers. In addition, as a kind of cognitive flexibility and tolerance of paradoxes, resilience can be associated with creativity (Csikszentmihalyi, 1996; Meneely & Portillo, 2005). Specifically, pursuing novel ideas is challenging because it demands tolerance to accept uncertainty and ambiguity resulting from the generative dance between creating and constantly shaping ideas and situations, which call for high levels of resilience (Masten & Powell, 2003). Sinclair and Wallston (2004) also found that resilience is positively linked with coping behaviours in problem solving. Indeed, generation of novel ideas can be frustrating and cause feelings of inadequacy, especially, when ideas do not emerge and flow. Thus, knowledge workers with high levels of resilience are likely to demonstrate higher levels of creativity, because they accept and are able live under circumstances of uncertainty and ambiguity. We therefore posit the following hypothesis:

*H1: Knowledge workers' resilience is positively related to their creativity.*

Resilience refers to individual's positive adaptation while facing and overcoming adversities (Luthans et al., 2000) and it is found to foster individuals' work performance (Luthans et al., 2005) and change orientation (Hobfoll, 1989; Wanberg & Banas, 2000).

In addition to specific adverse situations, resilience is associated with day-to-day adversities (e.g. Davydov et al., 2010). It is especially crucial in mastering the balance between one's creative dispositions and environment (Sonnenfeld, 2002). Wagnild (2009) found that highly resilient individuals use resilience as an adaptable mechanism to handle adversity and they thus recover more quickly from setbacks.

Sinclair and Wallston, (2004) suggest that individual's prior coping experiences enhance their dispositional traits of self-efficacy, which in turn increases their willingness to engage in various adverse and ambiguous situations. Thus, GSE develops over life span and along with experiences, in which an individual's resilience plays central role. Specifically, highly resilient individuals likely engage

in variety of situation and develop their self-efficacy through these experiences. We therefore posit the following hypothesis:

*H2: Knowledge worker's resilience is positively related to their GSE*

In creativity research creative self-efficacy, that is, individual's confidence to perform in situation that demand creativity is associated with individual creativity (Tierney et al., 2002). Similarly, we suggest that GSE, individual's confidence to perform successfully in variety of emerging situations, has an influence on knowledge worker creativity. Specifically, given that knowledge work is complex and constant orchestration of knowledge in various circumstances, we claim that GSE is important determinant for knowledge worker creativity. We therefore posit the following hypothesis:

*H3: GSE is positively related to KW creativity*

### **3 Methodology**

#### **3.1 Sample and measures**

##### *3.1.1 Sample*

We obtained data from Finnish higher educated organizational knowledge workers, who are members of the trade union of the Academic Engineers and Architects in Finland (TEK), through a web-based questionnaire in March–May 2016. The respondents are university graduates, who work as experts or in leading positions in the field of technology and architecture. Thus, they are knowledge workers (e.g. Atkins, 1999; Rüdiger & McVerry, 2007). We distributed 4,940 questionnaires, receiving 423 responses (response rate of 8.6 %) resulting in the effective sample of 419 responses.

The descriptive statistics were as follows: Of the respondents (N=419), 27.0 per cent (N=113) were female while 73.0 per cent (N=306) were male. A total of 2.9 per cent (12) were students, 3.1 per cent (N=13) had a Bachelor's degree, 78.8 per cent had a Master's degree (N=330), and 15.3 per cent had a Doctorate (N=64). In terms of age, the share of the respondents was as follows: 13.4 per cent (N=56) were 29 or under; 20.3 per cent (N=85) were aged 30–39; 26.0 per cent (N=109) were aged 40–49; 21.5 per cent (N=90) were aged 50–59; and 18.9 per cent (N=79) were 60 years of age or older.

### 3.1.2 Measures

We used validated and reliable scales and multi-item measures for the constructs based on a seven-point Likert scale (1 = *strongly disagree*, 7 = *strongly agree*). *Creativity* was measured using a six-item scale adapted from Tierney, Farmer, and Graen (1999). The respondents self-rated their creativity because, as knowledge workers, they are capable of evaluating their own creative behaviour (Conway & Lance, 2010; Shalley et al., 2009). For *resilience*, we used the validated and reliable Brief Resilient Coping Scale (BRCS) (Sinclair & Wallston, 2004). *General self-efficacy* (GSE) was measured with the scale by Chen et al. (2001).

Finally, we controlled for gender as a dummy variable (0 = female, 1 = male) and education to rule out their influence on resilience, creativity, and GSE. We used five categories in assessing the respondents' ages (1 = 29 years or younger; 2 = 30–39 years of age; 3 = 40–49 years of age; 4 = 50–59 years of age; 5 = 60 years or older) and four categories in assessing their education level (1 = student, 2 = Bachelor's degree, 3 = Master's degree, 4 = Doctorate).

### 3.2 Measurement model

The PLS method was used for the analyses (PLS; version 3.2.7 of SmartPLS; see Ringle et al., 2015) and IBM SPSS Statistics 24 software for the analyses. To assess the model's predictive accuracy ( $R^2$ ) and the significance of the structural paths, we employed the PLS bootstrapping procedure. We first assessed the internal consistency and discriminant validity of the scales, as described in the following.

#### 3.2.1 Measurement model validation

For measurement validation, we assessed both internal consistency and discriminant validity, both of which indicated that the model had good validity and reliability for the operationalisation of the concepts under interest.

Regarding internal consistency, the construct reliability (CR) and convergent validity of all constructs demonstrated high internal consistency. All constructs (Table 2) had a CR value (0.807–0.908) above the 0.7 threshold determined by Bagozzi and Yi (1988), and all the average variance extracted (AVE) values (0.516–0.601) exceeded the 0.5 cut-off determined by Fornell and Larcker (1981). Likewise, the loadings of all the items were high enough and statistically significant, which means that they all related to their specific constructs.

Table 1: Construct statistics and correlations

Construct	Mean	SD	Creativity	Resilience	Self-efficacy
Creativity	5.0238	.9224	<b>0.776</b>		
Resilience	4.9600	.94922	0.478**	<b>0.718</b>	
Self-efficacy	5.8353	.69468	0.460**	0.437**	<b>0.766</b>

NOTE: \*\*Correlation is significant at the 0.01 level (two-tailed)  
The square roots of the AVEs are displayed in the diagonal

Discriminant validity indicates the extent to which any one construct differs from the others. While assessing discriminant validity, the square root of each construct's AVE value should be greater than the variance shared between constructs in the model (Fornell & Larcker, 1981). As shown in Table 1, all the measures demonstrated validity and reliability in operationalising the study variables. In addition, significant correlations were observed between the independent variable and the dependent variable, suggesting a link between the constructs.

Overall, the above-mentioned tests showed that the model had good validity and reliability for the constructs of interest

### 3.3 Results

As expected, the findings show support for our hypotheses (Figure 1): Hypothesis 1, the path from resilience to creativity was statistically significant ( $B=0.365$ ,  $p < 0.000$ ). Hypothesis 2, the path from resilience to GSE was statistically significant ( $B=0.472$ ,  $p < 0.000$ ). Hypothesis 3, the path from GSE to creativity was statistically significant ( $B=0.266$ ,  $p < 0.000$ ). The results shows that knowledge worker resilience is related to their creativity both directly and indirectly via GSE. Thus, GSE acts as a partial mediator in the relationship between knowledge worker resilience and creativity

The control variables of Age ( $B=0.253$ ), Education ( $B=0.150$ ) and Gender ( $B=0.159$ ) were significant for creativity.

In addition, Age ( $B=0.126$ ) was significant for resilience, whereas Education ( $B=0.164$ ) was significant for GSE. The finding that education positively related to knowledge workers GSE implies that GSE develops along with one's life span through experiences (Shelton, 1990; Chen et al, 2001). The  $R^2$  0.470 for creativity implies that the model could explain 47,0 per cent of the variance in knowledge worker creativity.

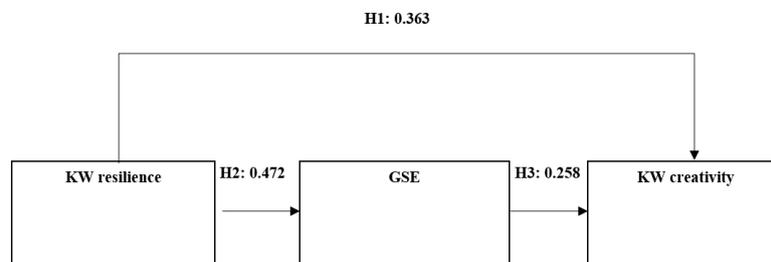

Figure 1: The research model and significant paths (control variables are omitted for clarity reasons)

## 4 Conclusions

Our findings show that both resilience and general self-efficacy are positively related to knowledge worker creativity. While prior research has investigated both resilience and creativity separately, there is less research that links these concepts in work contexts which require a continuous display of creativity, such as knowledge work. Thus, there is a clear need to investigate resilience in relation to knowledge worker creativity. We contribute to research on knowledge worker creativity (Dul et al., 2019) and individual creativity in organizations (Amabile, 1983). While earlier research investigated motivation mechanism of employee creativity (e.g., Liu et al., 2011; Amabile, 1983) in organizations, our study sheds light on employee creativity in knowledge work, that is in an occupation that inherently involves creativity (Starbuck, 1992) and in which individuals need for autonomy and self-realization as well as motivation for creativity are high. In terms of organizational resilience, our research on the relationship between individual's resilience and knowledge worker creativity can also contribute to research on organizational resilience, which is understood as a multi-level phenomenon (Borg et al., 2022; Hartmann et al., 2019).

### **Abstract**

A firm can improve its innovation processes by accessing useful external knowledge, profiting from the Open Innovation outside-in process.

However, to benefit from the flow of knowledge from the firm's outside boundary, the firm's Absorptive Capacity - the ability to correctly acquire, assimilate, transform, and exploit external knowledge according to the innovation needs – plays a pivotal role. So, firms must equip themselves with relevant tools to support all Absorptive Capacity activities.

Despite digital technologies seem to be very promising tools, currently, their supportive role in firms' Absorptive Capacity activities is understudied, hence generating a literature gap related to a very rising topic.

This work aims to contribute to filling this gap by proposing a structured literature review of academic research papers from the Scopus database.

The main results of this research are three: i. the recognition of the most studied digital tools in supporting Absorptive Capacity activities; ii. the explanation of how the identified digital tools support Absorptive Capacity activities; iii. the impact of using digital tools for supporting Absorptive Capacity activities on firm performance.

Contributions are both theoretical and practical.

Theoretically, this work is a first step in linking Open Innovation, Absorptive Capacity, and Information and Communication Technologies theories, often studied separately. In addition, the proposed literature review highlights new possible topics to be researched to improve the scientific knowledge about the phenomenon under investigation.

Practically, the results of this work lead firms' innovation managers to select the most appropriate digital tools to support Absorptive Capacity activities to enhance firms' performance.

## 1 Introduction

According to the Open Innovation (OI) outside-in process, a firm that cannot improve its innovation processes by using only its internal abilities can look outside the firm boundaries to access useful external knowledge (Mina et al., 2014).

However, more is needed for a firm to take advantage of a growing level of openness. Indeed, to benefit from the external flow of knowledge, firms have to rightly acquire, assimilate, transform, and exploit the external knowledge according to the innovation needs (Lazzarotti et al., 2015). In other words, firms must have an adequate level of Absorptive Capacity (ACAP) that consists of the ability to 1) find, evaluate, acquire, and collect valuable knowledge from external sources for their business (Acquisition Capacity) (Bae et al., 2020); 2) absorb, analyse, and interpret the acquired knowledge according to their innovation processes (Assimilation Capacity) (Fosfuri and Tribo, 2008); 3) modifying their internal routines to ease the assimilated knowledge use (Transformation Capacity) (Camisón and Forés, 2010); and 4) using the transformed knowledge for improving their existing products and services and creating new ones (Exploitation Capacity) (Jiménez-Barrionuevo et al., 2011). Acquisition and

Assimilation Capacities build the firm's Potential ACAP, while Transformation and Exploitation Capacities build the firm's Realised ACAP (Zahra and George, 2002).

Realised ACAP follows Potential ACAP; thus, to obtain an overall high level of ACAP, firms must achieve the objectives of each ACAP dimensions (Vega-Jurado et al., 2008), equipping themselves with the most appropriate tools for their execution.

Digital technologies and specifically those Information and Communications Technology (ICT) tools which are part of the digital infrastructure (Nambisan, 2017) – such as intranet and extranet, audio-video technologies, social media, crowdsourcing platforms, artificial intelligence, blockchain and all others that allow users to create, store and exchange information – can support firms in improving their ACAP level.

The link between digital tools and ACAP is a rising topic in the current literature. However, most contributions focus on the relationship between firms' technological investments and ACAP or a (generic) ICT adoption and ACAP.

For instance, Dong and Yang (2015) consider the firms' ICT investments as an internal moderator of the ACAP, while, more recently, Cuevas-Vargas et al. (2022) highlight the positive effect of ICT adoption on firm ACAP level, and Molina-Morales et al. (2018) investigate the impact of the rate of adoption of disruptive technologies on Potential and Realised ACAP.

Although the debate about the potential use of digital tools is ongoing and lively for the firms' need to manage ever-larger amounts of data and acquire and use them quickly, there is a gap related to identifying how single technologies support the ACAP processes within firms.

This work aims to fill this gap, by answering the following research questions:

*RQ1. What are the most studied digital technologies for supporting firms' ACAP activities?*

*RQ2. How do they support the specific dimensions of ACAP?*

*RQ3. What is the impact of digital technologies for supporting ACAP on the firm's performance?*

Specifically, to deal with the above questions, we consider five technologies clusters: Idea, Innovation and Knowledge Management Tools; Collaboration platforms; Data analytic and visualisation tools; Social Media and Online Community; and Enabling technologies.

The paper is organised into five sections. After the introduction, in the second section, the methodology is illustrated. The third section is dedicated to the paper selection phase, while the fourth section consists of the descriptive and content analysis phase. The conclusions and implications of the work are illustrated in the last section.

## **2 Research methodology**

This paper proposes a systematic review of the articles about the most studied digital technologies for supporting firms' ACAP activities, overviewing primary studies and using explicit and reproducible methods (Greenhalgh, 1997).

According to Cerchione and Esposito (2016), we organised the systematic literature review in two main phases:

1. Papers selection
2. Descriptive and content analysis of the selected papers.

Phase 1 is divided into two steps: the material comprehensive search and the selection of papers to be analysed in detail. The first step includes identifying keywords, carrying out the search query, choosing the database source of the documents, and reviewing the selected database using the search query. The second step includes formulating the inclusion/exclusion criteria for selecting the papers.

Phase 2 is divided into two steps: the descriptive analysis and the content analysis. The descriptive analysis aims to aggregate the papers according to different perspectives to give an overall overview of the selected documents. At the same time, the content analysis aims to highlight the literature state-of-the-art about a specific topic.

## **3 Phase of papers selection**

### ***3.1 Material comprehensive search***

The chosen source to select papers for the literature review was Scopus, an Elsevier's abstract and citation database working since 2004, ensuring a high level of rigorousness.

The set of the selected keywords, linked by the boolean logic functions to construct the search query, was: ("Information and Communication Technolog\*"

OR "ICT" OR "digital tool\*") OR ("Social network site\*" OR "Social media") OR ("Opensource software\*" OR "Open Innovation Platform\*") OR ("Crowdsourcing platform\*") OR ("Call4ideas platform\*") OR ("Artificial Intelligence"), ("Online Communit\*") OR ("Intranet") OR ("Data mining technique\*") OR ("Discussion forum\*") OR ("Shared database\*") OR ("Document repositor\*") OR ("Workflow's software\*") AND ("Absorptive Capacity" OR "ACAP" OR "external knowledge acquisition" OR "external knowledge assimilation" OR "external knowledge transformation" OR "external knowledge exploitation").

The subject areas considered for the search were "Business, Management and Accounting", "Social Sciences", "Computer Science", "Economics, Econometrics and Finance", "Engineering", and "Decision Sciences", - while - the temporal window was from 1997 until 2023.

Finally, we considered only articles from English-language journals.

The initial hits found in Scopus were 105.

### ***3.2 Selection of papers***

We used two criteria for including/excluding the research documents. The first criterion is the selection of papers whose abstracts talk about digital technologies used for supporting ACAP activities. So, the abstracts of all 105 articles were read by the principal researcher and, in some cases of uncertainty, also by the other researchers. The second criterion concerns the papers' main body. In this case, the researchers fully read the articles to identify sections about digital technologies supporting ACAP activities.

Applying these criteria, the papers selected for the phase of descriptive analysis were 56.

## **4 Phase of descriptive and content analysis**

### ***4.1 Descriptive analysis***

In this section, we presented a summary overview of the 56 selected documents according to the following six perspectives:

#### 4.1.1 Papers over time

Figure 1 shows the distribution over time of the papers; most of the articles belong to the more recent years. In particular, 2022 is the year with more contributions (16 articles), followed by 2021 (7 articles) and 2020 (6 articles). Only a few articles belong to less recent years. This perspective highlights that papers that link digital technologies and ACAP are growing currently.

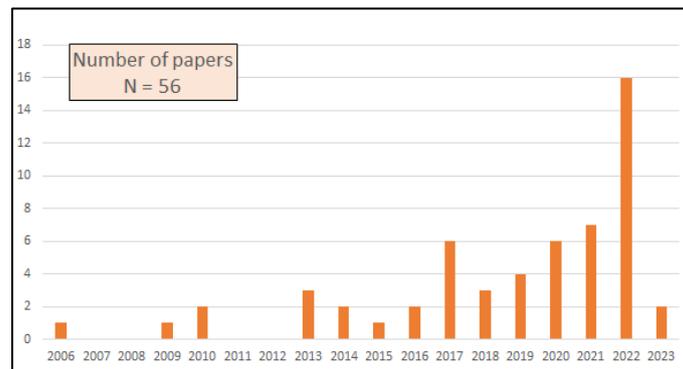

Figure 1 – Papers distribution over time

#### 4.1.2 Papers by Countries

This perspective summarises the articles by the Country where they are developed. The two countries with more contributions are the United States and China – 13 and 10 papers, respectively. Australia contributes with 7 articles, India with 5, and European Countries (e.g., United Kingdom, Italy, France) have more than 20 (figure 2). So, the topic of this literature review is more studied in Countries with solid industrialised activity.

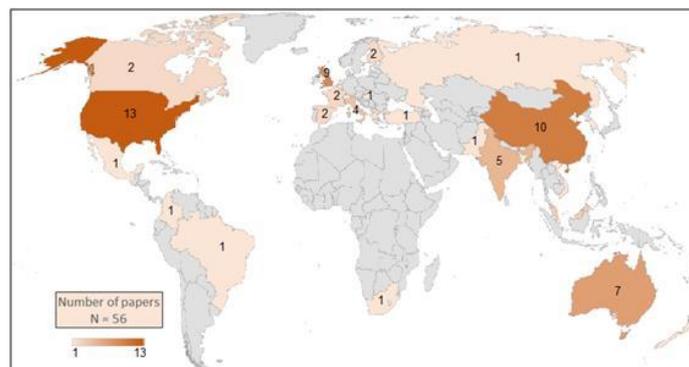

Figure 2 – Papers distribution by Countries

#### 4.1.3 Papers by subject area

According to the chosen subject area (table 1), the selected articles are distributed as shown in figure 3. The most contributions (36) belong to Business, Management and Accounting Area, followed by Computer Science area contributions (21). The selected articles covered both technical and social areas. Indeed, this review matters range from the ICT field to organisational dynamics capabilities (ACAP).

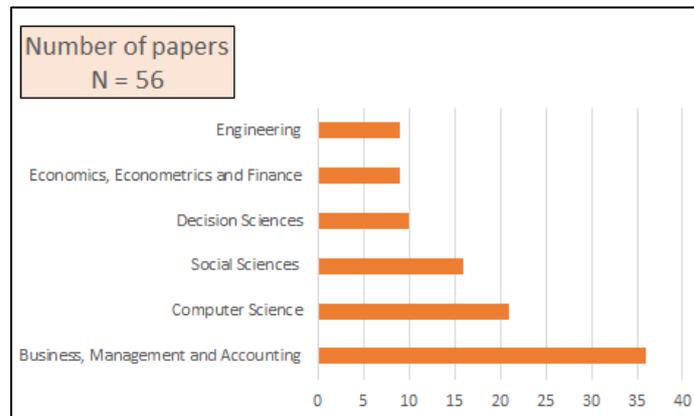

Figure 3 – Papers by subject area

#### 4.1.4 Papers by methodology

This perspective analyses the distribution of the paper according to the methodology used (Figure 4). Most of the contributions are quantitative studies (38, of which 28 are surveys), followed by qualitative research 7 (3 single case studies and 4 multiple case studies), while hybrid works – quantitative and qualitative – are 4. Finally, 7 articles are theoretical research. The low occurrence of case study analysis highlights a substantial literature gap related to the qualitative aspects of ACAP improvement using digital tools in firms' context.

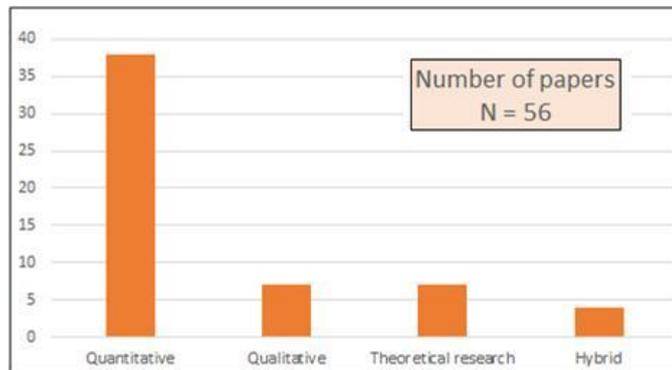

Figure 4 – Papers by methodology

#### 4.1.5 Papers by digital technologies (clusters)

As mentioned in the introduction, we divided digital technologies supporting firms' ACAP activities into 5 clusters. This perspective frames the contributions according to the technology's clusters (figure 5). Many articles present multiple technologies that belong to different clusters.

The cluster "Social-media and Online Communities" is the largest one, gathering 35 papers, followed by the cluster "Data Analytic and Visualization Tools" with 27 papers, while 21 articles belong to the "Idea, Innovation, and Knowledge Management Tools" cluster. The latest clusters are "Enabling technologies" and "Collaboration platforms", with 9 and 8 contributions, respectively. A deeper analysis of how the clusters support firms' ACAP activities is part of the later content analysis.

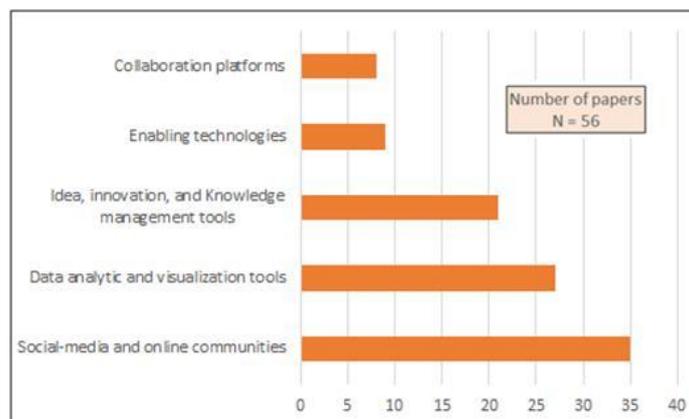

Figure 5 – Papers by digital technologies (clusters)

#### 4.1.6 Papers by ACAP dimensions

The last perspective of the descriptive analysis is related to the number of articles by ACAP dimensions (figure 6). The Acquisition Capacity is the most studied, with, 49 articles. The Assimilation Capacity collects 30 contributions, Transformation Capacity 18, and Exploitation Capacity 21. So, currently, the literature is more focused on Potential ACAP, generating a knowledge gap about digital tools needed to support Realised ACAP activities within firms.

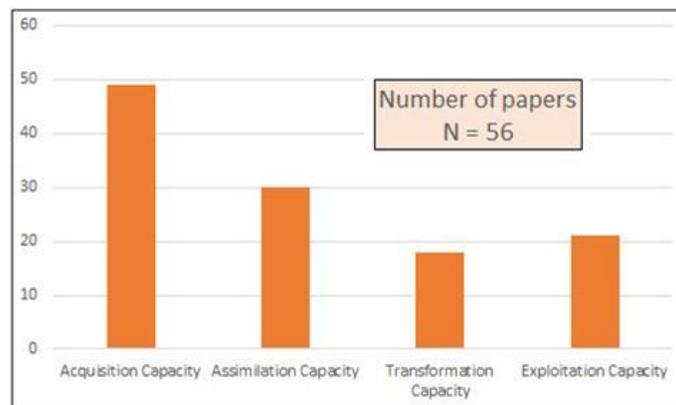

Figure 6 – Papers by ACAP dimensions

## 4.2 Content analysis and results

This section aims to give a detailed analysis of the 56 papers, analysing some issues covered by the literature about the relationship between ACAP and ICT in the firms' context. The identified content-perspective is that of the topic area: digital tools used to support firms' ACAP activities and their impact on firms' performance.

According to the topic area, five areas were identified.

### 4.2.1 Idea, Innovation and Knowledge Management Tools and ACAP dimensions

This area concerns the digital tools belonging to the Idea, Innovation and Knowledge Management Software (Technologies cluster 1) and ACAP dimensions.

The Idea, Innovation and Knowledge Management Tools allow for collecting, organising and prioritising idea from internal and external sources (Igartua et al., 2010), capturing, sharing and leveraging knowledge and expertise across the organisations (Wu and Hu, 2018; Moos et al., 2013), connecting potential partners

and collaborators fostering the innovation process. Examples of technologies in this area include Traditional ICT (e.g., the standard office applications), Intranet, Crowdsourcing platforms, Customer Relationship Management technologies, Enterprise Resource Planning Systems, and Blockchain Technology.

In Cluster 1 studied technologies are predominantly concerning the Acquisition and Assimilation dimensions of ACAP. For instance, Daniel and Huang (2019) and Marsh et al. (2017) discuss traditional ICT to support Acquisition and Assimilation capacity, *facilitating the external knowledge flow from firms' suppliers ... and clients within the firms' boundary*.

According to Cassol et al. (2021), Verbeke et al. (2013), and Gururajan and Fink (2010), the Intranet, as *a network between individuals and groups for transmitting and storing (external) knowledge*, is used to support firms' Acquisition and Assimilation capabilities activities. Vukatana et al. (2022) recently highlighted using the Intranet to channel knowledge flow and support ACAP.

Liu et al. (2017) introduce the role of Crowdsourcing Platforms in knowledge acquisition activities, and Blohm et al. (2013) claim that this kind of technology, *tapping into the collective intelligence of the broad-based community of Internet users*, can help firms in improving all the ACAP dimensions.

In Nguyen et al. (2022), Customer Relationship Management technologies have a role in supporting Acquisition capacity, *increasing the efficiency of knowledge acquisition by providing firm-specific guidelines and easing transfers*. Araujo (2006) gives importance to Group Agenda Enforcement and Software that helps groups establish norms, routines, and procedures on how to use the technology features in supporting Acquisition and Assimilation capabilities, *guiding and coordinating groups' activities in interaction with each other ... aggregating, evaluating, sharing, or structuring information*.

Instead, the link between the technologies belonging to cluster 1 and Transformation and Exploitation dimensions is often marginally studied. For instance, Cao et al. (2020) talk about the Transactive Memory System (tools that allow group members to share responsibility for encoding, storing, and retrieving information from different knowledge fields) as a tool to support ACAP dimensions *locating and integrating knowledge*, while Wook Seo et al. (2013) highlight the very positive influence of the Ubiquitous Decision Support System (tools able to identify the geographic location of the decision makers for allowing them the access to mobile networks to acquire information and make transactions) on ACAP activities.

Baker and Yusof (2017) highlight the role of the Enterprise Resource Planning System (such as the collaborative workflow systems) in improving Transformation and Exploitation capabilities, *supporting cross-functional business processes and enforcing a high degree of task interdependence and generating information about the processes by which an organisation performs its work* using external knowledge also.

Lastly, in a more recent work, Rajaguru et al. (2023) introduce the supportive role of Blockchain Technology for ACAP activities related to supply chain information and data integration; indeed, according to Chatterjee et al. (2022), *with the help of advanced cryptography, blockchain functions as a distributed open-service database.*

The content analysis of this area shows that Potential ACAP is more studied than Realised ACAP as concerns technologies belonging to cluster 1; hence, it emerges a first research gap, i.e. the need to further investigate the supporting role of cluster 1 technologies to ACAP. Furthermore, most articles analysed in this area build on quantitative methodologies to investigate the hypothesized relationship between cluster 1 technologies and ACAP dimensions. So, a second research gap appears: it is about "how" cluster 1 technologies support ACAP dimensions. To address this gap new qualitative studies on this topic are required.

#### *4.2.2 Collaboration platforms and ACAP dimensions*

The topic of this area is the relationship between Collaboration platforms (Technologies cluster 2) and ACAP dimensions.

According to Piller and West (2014), Collaboration platforms allow teams to share information and collaborate on projects in real time. Open Innovation platforms, Computer-assisted networks, Electronic Message Recording, and Crowdsourcing Platforms are examples of technologies that belong to this cluster.

Most of the contributions analysed to carry out information about this area concern the Acquisition and Assimilation dimensions of ACAP. In their quantitative work, Wang and Qi (2022) discuss the role of Open Innovation and Collaborative Platforms in supporting firms' Acquisition and Assimilation capabilities, *advantaging the firms' network connections linking the internal knowledge level and the external network location, and breaking down the barriers between users' internal knowledge and external interaction.*

However, albeit indirectly, Bag et al. (2023) also highlights the supportive role of that platforms for using external knowledge in supply chain activities, implying their support in firms' Transformation and Exploitation capabilities.

Huang et al. (2018) talk about Digital Platforms as technologies *that facilitate the creation, diffusion, and sharing of knowledge among communities*, improving the Acquisition capacity *enabling the rapid diffusion of best practices, strengthening customer relationships, gathering inputs and feedback for new product and service developments, reduce support costs, and incubate user-driven innovations*.

In the only one qualitative work of this area, Carayannis et al. (2006) claim that Computer Assisted Networks are *innovative networks able to interconnect various actors and create new opportunities for efficient interaction and cooperation regarding information dissemination and knowledge sharing, growing capacity to access knowledge (Acquisition capacity) through relationships*.

Arujo (2006) insert Electronic Message Recording among technologies allowing *members of global virtual teams to communicate across time and distance*, improving the Acquisition capacity.

Finally, the considerations related to how Crowdsourcing Platforms - also belonging to this technologies cluster – support the acquisition activities from external sources are the same shown in the previous area.

The concept analysis related to this technologies cluster supporting ACAP dimensions shows a profound lack in the literature about works related to how Collaborative platforms support Realised ACAP. In addition, the predominant quantitative view on this topic does not allow us to gain the qualitative aspects of the phenomenon.

#### *4.2.3 Data analytic and visualization tools and ACAP dimensions*

This area analyses how Data analytic and visualization tools (Technologies cluster 3) support ACAP dimensions.

Data analytics and visualization tools include all technologies allowing organizations to analyze and interpret extensive and different amounts of data and to identify trends and patterns (Arias-Perez et al., 2021; Lukic, 2014). This cluster is populated by technologies such as Big Data Analytic tools, Artificial Intelligence, Data Warehouses, On-line Analytical Processing and Data Mining, and Machine Learning tools.

In the papers belonging to this area, all ACAP dimensions are equally studied in relation to the support cluster 3 technologies give them, even if the quantitative methodology still prevails over the qualitative one.

The works of Bag et al. (2023) and Daniel and Huang (2019) introduce Big Data analytic tools as technologies supporting knowledge-based activities in terms of acquisition, assimilation, transformation and exploitation of new information. On the same view, Blohm et al. (2013) talk about the utility of that tools to correctly interpret *enormous volume and variety of big data acquired via Internet-based platforms* and how firms' CIOs and other organizational leaders can develop an *effective absorptive capacity to enable them to generate knowledge and value from that data*.

Artificial Intelligence (AI) is another technology investigated in relation to its support to ACAP; Bencsik (2021) links AI and Acquisition and Exploitation firms' capabilities. Specifically, in his work he highlights that the role of AI in knowledge acquisition activities is *to process enormous statistical data sets based on given parameters* while that in knowledge exploitation is *to provide the using of the acquired knowledge for machines for task completion, and to unleash knowledge so that it can get to humans, to the improvement of the decision-making process*.

Liu et al. (2020) add that AI can improve ACAP promoting *technological innovation through accelerating knowledge creation and technology spillover*. Specifically, they recognize the AI-based industrial robots' capabilities *to transform acquired information into knowledge and take justified subsequent actions* improving Transformation and Exploitation firms' capacity.

In their recent papers, Pessot et al. (2022), Schintler and McNeely (2022), and Li et al. (2022) also highlight the supportive role of AI for all ACAP dimensions by the automatic external knowledge extraction and using the acquired and transformed knowledge in the firms' industrial processes.

Chatterjee et al. (2022), in supporting Acquisition capacity, add to AI the Quantum Computing technology. This modern cutting-edge technology *possesses algorithms that can accelerate the tasks done by machine learning favoring a quick and accurate acquisition of particular data cannot be searched by ordinary technology*.

According to the literature, also others digital tools belonging to cluster 3 support firms' ACAP activities. For instance, Ahankoob et al. (2021) introduce the role of Building Information Modeling (BIM) tools in supporting ACAP activities. Specifically, they show that *the transparency function of BIM functional attributes is*

*significantly correlated with Acquisition and Transformation dimensions of ACAP.* Indeed, organizations are more likely to acquire and transform knowledge using a more transparent way of consistent, disclosure, and reliable information as BIM allows.

Adamides and Karacapilidis (2020) work is focused on different technologies supporting different ACAP dimensions. Argumentative knowledge construction support tools hold up knowledge-related Acquisition, Assimilation, and Exploitation activities, *offering alternative visualization schemas that help stakeholders control the impact of voluminous and complex data, while also accommodating the outcomes of external web services, thus augmenting individual and collective sense-makings*; Data Warehouses, On-line Analytical Processing, and Data Mining tools support Transformation and Exploitation dimensions *playing a prominent role in the development of current and future Decision Support Systems (..) integrating (aggregate) and managing (store/retrieve) in a single repository all the relevant data, metrics, and objectives*; Natural language processing text analysis tools, Machine Learning, and Computational Linguistics tools help in Acquisition and Assimilation activities *extracting relevant information from the huge amounts of human communication over the Internet or other (offline) sources.*

Finally, Araju (2009) talks about Electronic Discussion tools, Devices to store a complete record of group interaction, and Analytical Tools to evaluate the information in a more objective fashion as technologies *able to support knowledge-related activities in globally distributed teams* quickly, helping in the knowledge acquisition and assimilation by firms.

Although this area has a good analysis level about all ACAP dimensions, there still is, as also shown for the previous areas, the need to deal with the topic through a more qualitative view.

#### *4.2.4 Social Media and Online Community and ACAP dimensions*

This area analyses the role of the Social-Media and Online Community (Technologies cluster 4) in supporting ACAP dimensions.

Social media, Discussion Forums, and Online Communities are the technologies that belong to this cluster, providing platforms for companies to engage with customers, partners and other stakeholders and gather insights and feedback (Scotto et al., 2017).

The descriptive analysis has shown that cluster 4 is the most studied in the literature concerning ACAP activities.

In this area, the Acquisition and Assimilation dimensions of ACAP are the most studied. However, the many literature contributions concerning the relationship between social media and ACAP gives us some examples in which Transformation and Exploitation dimensions are also treated.

The recent works of Pham and Duong (2022), Xie et al. (2022), and Ho and Amin (2022) are just some examples of papers about the relationship between social media using and ACAP dimensions improving.

Cepeda-Carrion et al. (2022) demonstrate how family firms using social media to stay connected *with their customers and stakeholders are probably more oriented to develop open innovation practices and absorption capacity tasks*. Specifically, social-media-based interactions facilitate *knowledge transfer and in improving an organisation's absorptive capacity because social-media-based interactions structural linkage between a firm and its customers drives the capture, transfer, assimilation, and application of customer knowledge*. So, social media tools *impact each of the three abilities that make up a firm's absorptive capacity: the ability to identify the potential new product ideas (Acquisition capacity), assimilate new insights (Assimilation capacity), and apply new improvements to the existing offerings (Exploitation capacity)*.

Peltola and Makinen (2014) discuss a positive relationship between using social media tools and acquiring and Assimilation capabilities.

Cao and Ali (2018) highlight the facilitator role of social media (such as blogs, wikis, and social networking sites) in *knowledge acquisition and application from diverse knowledge resources located within and outside the organisation that enhance ACAP in both aspects of identification and utilisation of knowledge*.

On the same view, Wieneke and Lehrer (2016) talk about social media (such as Facebook and Twitter) as the source from which organisations can acquire relevant data (Acquisition capacity), as the tool for the organisations' employees *to redefine the underlying questions and hypotheses for data analysis at frequent intervals based on their experiences (Assimilation capacity)* and to *scrutinise their processes and routines regularly in order to constantly develop new ideas for customer insight generation (Transformation capacity)* and *exploitation and adapt to changes in the environment (Exploitation capacity)*.

In their extensive analysis, Schlagwein and Hu (2017) highlight that *using social media platforms effectively increases an organisation's ACAP*. Regarding the

Acquisition and Assimilation capabilities, *social media can support exploratory learning, which is how organisations acquire and understand external knowledge, allowing users to access data and information quickly.* Regarding the Transformation and Exploitation capabilities, *social media also enhance transformative learning interpreting knowledge and support the family firm's ability for exploitative learning, allowing new business applications or business processes to be created more effectively.*

Besides social media, Gururajan and Fink (2010) consider the role of discussion forums in external knowledge acquisition and assimilation by firms. In addition, Kumi and Sabherwal (2018) and Hung et al. (2018) agree to identify Online Communities as tools to support Acquisition capacity.

The output of this area analysis shows that the literature debate needs more research about social media supporting role in Realised ACAP activities and qualitative studies.

#### 4.2.5 Enabling technologies and ACAP dimensions

This area concerns the relationship between Enabling Technologies (Technologies cluster 5) and ACAP dimensions.

All the tools needed to enable the technologies of the other clusters in supporting ACAP activities belong to this cluster. The Internet of Things (IoT), Cloud-based platforms, the Internet, and Extranet are examples of technologies of this cluster.

Because of the enabling role of these technologies in supporting tools belonging to all technology clusters, in this case, the selected articles concern all the ACAP dimensions equally.

Rajaguru et al. (2023) and Pessot et al. (2022) highlight the role of IoT as an enabler of technologies fitting to collect and monitor data from firm external sources (Acquisition capacity) and to connect all production machines and devices for using acquiring external knowledge (Exploitation capacity). Chatterjee et al. (2022) talk about IoT as a technology that helps the firm *to effectively recognize and assimilate any congenial external opportunity which is in consonance with absorptive capacity* (precisely, Acquisition and Assimilation capabilities).

Vukatana et al. (2022) describe Computer-based Systems as crucial enablers for technologies - such as data warehouses, search engines, data modelling and visualization, information management, and knowledge management tools – in

transferring and assimilating information making external knowledge explicit. In Pessot et al. (2022), Cloud-based Platforms ensure secure and protected data sharing, supporting technologies in knowledge acquiring and help in the integration of solutions in which *information is collected from customers through social media and in more accurate forecasts and better service levels thanks to analysis on data collected from websites, social media and platforms*. Ratten (2016) talk about Cloud Computing as *a service innovation in the ability of an organization to utilize and internalize knowledge management processes*, which is valuable for supporting knowledge Transformation and Exploitation activities.

Finally, in less recent works, some authors illustrate the role of the Internet and Extranet in knowledge Acquisition and Assimilation activities supporting remote communication and data sharing (Gururajan and Fink, 2010; Carayannis et al., 2006).

This area's concept analysis shows the need for more qualitative studies in which the enabling role of these technologies is duly treated.

#### 4.2.6 Digital tools, ACAP and Performance

The last area of the Content analysis concerns the relationship between ACAP dimensions, supported by digital tools, and firms' performance improvement.

Only 14 of the 56 selected articles discuss the performance implications of the firms' ACAP activities using technologies, and all 14 papers discuss industrial performance.

Specifically, the most studied are the performance improvements due to using social media to support ACAP activities.

Cepeda-Carrion et al. (2022) and Scuotto et al. (2017) highlight how, using social media, family firms can improve non-financial performance, becoming more innovative and competitive. Ali et al. (2020) claim that *when social media is embraced by an organization for innovation, potential and realized absorptive capacity emerge, which leads to enhanced team innovation performance*.

Ammirato et al. (2019) link social media use for ACAP activities with increased knowledge worker productivity, while Cao et al. (2018) discuss the influence of social media on ACAP and the resulting increase in Team Creative Performance. Peltola and Makinen (2014) discuss how social media for ACAP activities enhances ideas development. Wang (2013) demonstrate that the more firms use social media to acquire and assimilate knowledge, the higher their learning performance is, while Ortega-Gutierrez (2022) highlight that social media use

allows firms to have access to customers and market information, fueling ACAP dimensions and then improving the collaboration with value partners and gathering new ideas allowing firms to be more service-dominant oriented.

According to Bencsik (2021), using AI for ACAP activities helps firms' creativity and productivity growth, and Liu et al. (2020) add that *AI affects technological innovation in four angles: knowledge creation, knowledge spillover, learning ability, and investment in R&D and talents.*

Lastly, Baker and Yusof (2017) and Cuevas-Vargas et al. (2022) discuss the relationship between the ICT tools used for ACAP activities and firms' learning performance.

The content analysis of this area highlights that studying the effects of ACAP activities supported by digital tools on performance is still to be deepened. Specifically, no work studies the effect of this relationship (ACAP dimensions and supportive technologies) on the firm eco-fin performance.

## **5 Conclusions and implications**

This review aims to fill the literature gap related to the supportive role of digital technologies in firms' ACAP activities. Indeed, to our best knowledge, it is the first time that research has dealt with this information void.

Following the methodology shown in Cerchione and Esposito (2016), we propose a descriptive and content analysis of the papers selected from the Scopus database.

On the one hand, the descriptive analysis proposes a summary view of the articles and, in particular, highlights that the topic of this research has been investigated in High Industrialised Countries (USA, China, India, and the European Big Four Countries) through quantitative rather than qualitative studies in the Business, Management, and Accounting area predominantly, with a greater focus on Social Media and Online Community tools in supporting Potential rather than Realised ACAP activities.

Specifically, through the descriptive analysis, we can answer RQ1, proposing the papers by digital technologies (clusters) (figure 5) and identifying the most used technologies clusters for supporting firms' ACAP activities.

On the other hand, content analysis proposes a deep investigation of the papers' contents. It highlights how Idea, Innovation and Management tools (cluster 1), Collaborative Platform (cluster 2), Social Media and Online Community

(cluster 4) support Potential rather than Realised ACAP activities and how Data Analytics and Visualisation Tools (cluster 3) and Enabling technologies (cluster 4) equally support both Potential and Realised ACAP activities.

Specifically, through the content analysis, we can answer RQ2, illustrating how technologies belonging to the clusters support the specific dimensions of ACAP. Indeed, in section 4.2, we illustrated the information about the above relationship contained in the selected papers for each cluster.

However, the presence of primarily quantitative articles made the content analysis not simple; indeed, the use of quantitative methodologies, albeit finding a statistical relevance of the use of the technologies on the ACAP activities, provides explicit information about "how" questions rarely.

In addition, an area of content analysis is dedicated to the impact of the technologies used to support ACAP activities on the firm's performance; it highlights that only industrial performances are currently investigated (RQ3).

The contributions of this literature review are both theoretical and practical.

Theoretically, this study represents a crucial first step in the link among the literature of the Open Innovation, Absorptive Capacity, and ICT fields, analysing, for the first time, the current state of the art about the studied topic and highlighting gaps needed to be filled with new research. Indeed, future works should seize the qualitative aspects of the relationship between digital tools and the ACAP dimensions to explain better how technologies can support firms in ACAP activities. In contrast, quantitative studies about the supportive role of technologies on Realised ACAP activities and the impact of the relationship between technologies use and ACAP on firms' performance (both industrial and eco-fin) are required.

Practically, this research can be helpful to firms' innovation managers, or anyone involved in firms' innovation and R&D activities, to identify the most appropriate technologies to be adopted for improving their ACAP activities (both Potential and Realised) and then their performance (albeit limited to the industrial ones).

### **Abstract**

A shift toward more sustainable production and consumption patterns is crucial. The fashion industry is responsible for negative environmental and social impacts along the value chain. Thereby, the fashion industry is one of the priority areas of intervention in the sustainability agenda.

Recently, the literature has devoted much space to the analysis of sustainable fashion consumption. Some literature reviews on sustainable fashion have been published recently. However, these focused on a specific consumption stage. Multiple alternatives to make, use, and dispose of fashion products sustainably are available among all consumption stages and an analysis of the determinants of consumer behavior for each option is missing so far. Such knowledge would be useful for a deeper understanding of sustainable consumption in the fashion industry, to define a holistic picture of the reasons that favor or discourage the adoption of sustainable behaviors for each phase of consumption.

This study aims to fill this gap by systematically reviewing the literature related to sustainable consumer behavior in the fashion industry. A product life cycle approach is adopted by analyzing consumers' perceptions and the influencing factors of consumer

behavior towards the sustainable options existing for each stage (i.e., production, use, and disposal). Specifically, these sustainable options can belong to the phase of garment choice (i.e., before consumer usage), the garment usage (i.e., during consumer usage), and when the consumer ceases to use the garment (i.e., after consumer usage). The research string used to collect articles was created by mixing keywords related to three main domains: consumer behavior, sustainability, and the fashion industry. The research string was launched on Scopus and Web of Science databases on 31st December 2022. After a series of screening following exclusion criteria, a final sample of 216 articles was included in the review.

Results show many factors driving or hindering sustainable consumer behavior. The main barriers to sustainable consumption are high price, skepticism, stereotypes, lack of knowledge, availability, and efforts to access product/service. Furthermore, consumers' environmental concerns and awareness seem to play a secondary role in the decision process. Conversely, high-quality, comfort, and style of garments, together with new emerging technologies and services, can positively contribute to sustainable consumption. Social media can help shift toward sustainable consumption practices, favoring the spread of sustainable knowledge and awareness among consumers. A future research agenda and several implications for managers are provided.

**Keywords** – Sustainable fashion, Consumer behavior, Product life cycle, Sustainable consumption, Systematic literature review.

## 1 Introduction

Clothes are able to satisfy several human needs such as warmth and protection, and to express one's own identity (Niinimäki, 2010; O'cass, 2000). The global fashion market is enormous and several companies operate in this industry to supply the human clothing demands. The fashion market is growing driven by mass production with a consequent increase in clothing use and disposal (McKinsey and Global Fashion Agenda, 2020). Further, unsustainable consumption patterns, such as fast fashion, are widespread (Dissanayake and Sinha, 2015). The clothing industry presents environmental impacts in each consumption stage (Pedersen and Andersen, 2015), accounts for 10% of global greenhouse gas emissions (European Commission, 2022), and is globally responsible for 40 million tonnes of textile waste a year (McKinsey, 2022). Thereby, the fashion industry belongs to the priority intervention area in the sustainability agenda.

Consumers have a critical role in the shift toward sustainable consumption patterns by adopting sustainable product choices, as well as sustainable use and
